MDA-MB-231GEMR cells were 5.06 times more resistant to GEM than parental MDA-MB-231 cells according to fold resistant calculation. qPCR showed significantly reduced expression of hENT1 (0.5 ± 0.1) in MDA-MB-231GEMR cells. The IC₅₀ values for ABT-737 and NVP-BEZ235 were $9.923\mu\text{M}$ and $0.345\mu\text{M}$, respectively. Treatment with the combination of NVP-BEZ235 and ABT-737 significantly inhibited cell growth and migration in MDA-MB-231GEMR cells, while cell cycle analysis revealed a notable SubG0 arrest, with a significant increase compared to the negative controls in resistant cells. Gene expression analysis revealed increased levels of Caspase-3 and decreased level of Bcl-2, and Mcl-1 expression compared to control, indicating the activation of apoptotic mechanisms. Consistent with expectations, the expression of PI3K and mTOR was reduced following treatment. Additionally, the increased expression of hENT1 suggests a potential reversal of resistance.

Conclusion

Our results suggest that the combination of ABT-737 and NVP-BEZ235 is a promising therapeutic strategy for overcoming Gemcitabine resistance in TNBC. This combinational approach enhances apoptosis and inhibits cell proliferation and migration by targeting both the PI3K/mTOR pathway and Bcl-2 family proteins. Further studies are needed to assess the potential of this strategy for GEM-resistant TNBC.

Targeted Delivery of NVPBEZ235 conjugated to gold nanoparticles for Overcoming Gemcitabine Resistance in Triple-Negative Breast Cancer

S. Ayvaz¹, E. Akgün², G. Yeşilay², Z. Bolat²

¹Molecular Biology and Genetics Department, Hamidiye Institute of Health Sciences, University of Health Sciences, Turkey

²University of Health Sciences, Molecular Biology and Genetics, Istanbul, Turkey

Introduction

Triple-negative breast cancer (TNBC) is a highly aggressive subtype of breast cancer characterized by the lack of expression of HER2, estrogen and progesterone receptor (1). Due to limited targeted therapies and frequent development of chemoresistance, effective treatments remain a significant clinical challenge (2). Gemcitabine, a cytotoxic antimetabolite commonly used in chemotherapy, often develops resistance over time, decreasing the therapeutic efficacy (3). PI3K/AKT/mTOR pathway plays an important role in cell survival, growth, proliferation and motility. NVP-BEZ235, a dual PI3K and mTOR kinase inhibitor, decreases the proliferation of chemotherapy-resistant cancer cells (4). Phase II clinical trials of NVP-BEZ235 show anti-tumor efficacy in solid tumors however, side effects were also observed. Thus, employing targeted nanoparticle-based drug delivery systems may help overcome this obstacle. In this study, we aimed to overcome gemcitabine resistance in TNBC cell line (MDA-MB-231GEM) by delivering NVP-BEZ235 drug conjugated to targeted gold nanoparticle (t/BEZ@NP) developed in our laboratory.

Material and method

MDA-MB-231GEM was developed through incremental exposure to gemcitabine over a year. The resistance factor and the doubling time were analyzed to confirm the newly developed drug resistant cell line. Cytotoxic effect of t/BEZ@NP were evaluated via resazurin assay, while colony formation and wound healing assays were used to asses the growth and migration inhibition, respectively. Cell cycle and apoptotic assay were used to analyze the cell cycle arrest and apoptotic cell death induction.

Result and discussion

MDA-MB-231GEM cell line was successfully established with a fold resistance value of 116,04. t/BEZ@NP significantly reduced cell viability in MDA-MB-231GEM cells, with an IC₅₀ of 8.3 nM , compared to free NVP-BEZ235 (IC₅₀ = 10403 nM) at 48h. Colony formation assays demonstrated a reduction in both colony number and size following t/BEZ@NP treatment. Wound

healing assays showed impaired migration, with the lowest closure rate observed in the t/BEZ@NP group. Flow cytometry analysis indicated an increase in the SubG0 phase and a reduction in S phase progression, highlighting the antiproliferative and pro-apoptotic effects of t/BEZ@NP.

Conclusion

The combination of dual PI3K/mTOR inhibition with nanoparticle-based targeted therapy effectively overcame gemcitabine resistance in TNBC. t/BEZ@NP significantly enhanced cytotoxicity, suppressed proliferation, and impaired migration. This approach may offer a new avenue for improving treatment outcomes in patients with aggressive, drug-resistant breast cancer subtypes. *This project is funded by TUBITAK (122S737).*

EACR25-0229

Bacterial modulation of 5-FU chemoresistance in head and neck cancer

L. Mai¹, K. Fenix¹, S. Vreugde¹

¹*The Basil Hetzel Institute, Department of Surgery-Otolaryngology Head and Neck Surgery, University of Adelaide, and the Basil Hetzel Institute for Translational Health Research, Central Adelaide Local Health Network, Adelaide, Adelaide, Australia*

Introduction

Head and neck cancer (HNC), the seventh most diagnosed cancer globally, primarily consists of squamous cell carcinomas (SCCs) that arise in the pharynx, larynx, and oral or nasal cavities. Chemotherapy is commonly used, but chemoresistance, a multifactorial process, often leads to poor outcomes. Changes in cancer cells affect their ability to absorb or metabolize drugs, and emerging evidence suggests that microbiome dysbiosis may influence cancer treatment efficacy and toxicity. In HNC, variations in chemotherapy responses have been linked to oral microbiome dysbiosis, indicating that tumor-associated bacteria may play a pivotal role in chemoresistance.

Material and method

Bacterial isolates were collected from the oral cavity and tumor samples of 39 patients. Complete bacterial genomes were sequenced using long-read (Nanopore) and short-read (Illumina) technologies. To evaluate 5-fluorouracil (5-FU) resistance, minimum inhibitory concentration (MIC) assays were performed using a high range of 5-FU (16–500 µg/ml). Mass-spectrometry was used to detect the presence of Pre-TA operon. Supernatants from 5-FU-resistant Streptococcus isolates were exposed to HNC cells to assess the potential for bacteria-induced 5-FU resistance in cancer cells.

Result and discussion

A total of 427 bacterial isolates were identified from the oral cavity and tumor samples. *Streptococcus* spp. was the most abundant genus, comprising 174 isolates. The MIC assay revealed that 36.2% of *Streptococcus* isolates could tolerate high doses of 5-FU (64 µg/ml). Resistance was not limited to a specific *Streptococcus* species, highlighting the diversity of resistance mechanisms across different isolates. Surprisingly, resistance was not attributed to the Pre-TA operon, which is commonly involved in 5-FU metabolism in other bacterial species.

This suggests that alternative, currently unknown genetic mechanisms may be contributing to the survival of these isolates under 5-FU stress. Eventually, exposure of SCC-1 and SCC-47 cells to the supernatants of 5-FU-resistant *Streptococcus* isolates demonstrated that certain bacterial strains could confer resistance to 5-FU in the HNC cells. This suggests that bacteria through secreted metabolites or other factors, may play a significant role in modulating cancer cell sensitivity to chemotherapy.

Conclusion

This study reveals the significant contribution of tumor-associated bacteria in the development of HNC chemotherapy resistance, particularly in relation to 5-FU. The findings suggest that bacteria may influence chemotherapy outcomes through direct interaction with cancer cells or by secreting factors that alter drug sensitivity. Identifying the molecular mechanisms and genetic components underlying these interactions will be crucial for developing novel therapeutic strategies to overcome chemoresistance and improve clinical outcomes for HNC patients.

EACR25-0247

Investigating AMBRA1's role as a prognostic biomarker of resistance for melanoma therapies

C. Tsavou¹, L. Di Leo¹, S. Traynor², P. Berico³, E. Hernando³, P. Wierenfeldt Staun⁴, H. Ditzel^{2,5}, D. De Zio^{1,2}

¹*Danish Cancer Institute, Melanoma Research Team, Copenhagen, Denmark*

³*New York University Grossman School of Medicine, Department of Pathology, New York, United States*

⁴*Odense University Hospital, Department of Pathology, Odense, Denmark*

⁵*Odense University Hospital, Department of Oncology, Odense, Denmark*

Introduction

Targeted therapies (TT) and immunotherapies (IT) have revolutionized the treatment of metastatic melanoma, but low response rate and resistance remain a challenge. To overcome resistance, these therapies are usually combined or administered consecutively. Identifying biomarkers of resistance is crucial with significant implications for therapy selection. Recently, we found that the loss of Autophagy and Beclin 1 Regulator 1 (AMBRA1), a melanoma suppressor gene, activates the Focal Adhesion Kinase 1 (FAK1) pathway to drive TT resistance and can serve as a predictive biomarker for TT response.

Material and method

In this study, we used the Yale University Murine Melanoma 1.1 (Yumm1.1) cells to generate v-raf murine sarcoma viral oncogene homolog B1 inhibitors (BRAFi)-resistant cells. Ambra1 levels and Fak1 activation were assessed via western blot. BRAFi-resistant cells were extensively characterized through cellular assays and gene-expression profiling. Also, a syngeneic mouse model of melanoma was employed to evaluate the growth

of BRAFi-resistant Yumm1.1 tumors. The composition of the tumor immune microenvironment (TIME) in BRAFi-resistant Yumm1.1 tumors was assessed via flow cytometry.

Result and discussion

We identified that chronic exposure to BRAFi in murine Yumm1.1 melanoma cells resulted in a significant drop of Ambra1 expression compared to the sensitive line, similar to the drop observed upon acquisition of TT resistance in melanoma patients and human melanoma cells. Notably, Ambra1-Low-BRAFi-resistant Yumm1.1 cells exhibited high levels of phosphorylated FAK-Y397 (pFAK-Y397), when compared to the Ambra1-High-sensitive cell line. RNAseq analysis revealed a significant upregulation of cytokine receptor activity and interferon gamma signaling pathway, similar to the one observed in non-responder patients to TT and IT. In vivo, Ambra1-Low-BRAFi-resistant tumors exhibited accelerated growth compared to the Ambra1-High-sensitive tumors and were enriched in immunosuppressive immune populations. Additionally, we identified nuclear translocation of Fak1 and its downstream effector Yes-associated protein 1 (Yap) in both Ambra1-Low-BRAFi-resistant cells and tumors, potentially contributing to immune evasion via Programmed Cell Death Ligand 1 (PD-L1) upregulation.

Conclusion

Further studies are needed to investigate if AMBRA1-FAK1 axis is activated upon TT and IT resistance and if AMBRA1 can be used as prognostic marker of resistance for melanoma therapies.

EACR25-0257

Integrative Omics Insights into Metabolic Adaptations of TRAIL-Resistant

Glioblastoma

D. Inci¹, A. Cingoz¹

¹Bezmialem Vakif

University, Beykoz Institute of Life Sciences and Biotechnology (BILSAB), Istanbul, Turkey

Introduction

Glioblastoma (GBM) is the most common and aggressive primary brain tumor in adults, characterized by poor prognosis and high therapeutic resistance. This resistance, driven by tumor heterogeneity and the brain's complex anatomy, limits treatment success. Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) selectively induces apoptosis in cancer cells, making it a promising therapy. However, GBM cells often exhibit innate or acquired resistance to TRAIL. Our previous studies generated TRAIL-resistant GBM models and identified the major apoptotic and intracellular alterations compared to their sensitive counterparts. Notably, emerging evidence suggests a strong link between metabolic reprogramming and therapy resistance in GBM. A better understanding of these resistance mechanisms could pave the way for improved therapeutic strategies.

Material and method

LC-MS-based untargeted metabolomics was performed to identify metabolite changes in TRAIL-resistant and sensitive A172 cells by analyzing the global metabolome. Gene expression profiling was conducted using RNA

sequencing, and these data were integrated with metabolomics data for a comprehensive analysis. Bioinformatics analysis was performed using R software, MetaboAnalyst, GSEA, and CytoScape pipelines to holistically evaluate the resistance mechanism.

Result and discussion

Integrating RNA sequencing and metabolomics provides a deeper understanding of TRAIL resistance in GBM by linking gene expression changes to metabolic alterations. Joint pathway and enrichment analyses showed significant changes in glycerophospholipid metabolism, glycolysis, oxidative phosphorylation (OXPHOS), and drug metabolism pathways in resistant cells. Integrated omics analysis demonstrated a positive correlation between OXPHOS-related metabolites and resistance, highlighting the potential role of mitochondrial metabolism in therapy resistance. These findings suggest that alterations in energy metabolism, membrane components, and drug metabolism contribute to TRAIL resistance.

Conclusion

Our findings highlight the role of metabolic adaptations in TRAIL resistance, revealing potential therapeutic targets for glioblastoma. Functional assays will further investigate the impact of key metabolic pathways on therapy resistance. Targeting these pathways may lead to novel strategies to overcome resistance and improve treatment outcomes.

EACR25-0278

In Silico Identification of Common Pre-existing Resistance Mechanisms to EGFR Inhibitors in Colorectal Cancer

S. Martín Revuelta¹, C. Fernández-Lozano¹,

J. Liñares-Blanco¹

¹Universidade da Coruña, Department of Computer Science and Information Technologies, A Coruña, Spain

Introduction

Despite the genetic, transcriptomic, and epigenetic heterogeneity of cancers, resistance to therapy often arises through convergent mechanisms, suggesting that tumors rely on shared survival strategies regardless of drug selection or patient-specific factors. We hypothesized that common pre-existing phenotypic states across different tumors contribute to resistance against multiple drugs. To test this hypothesis, we developed an in silico strategy to associate transcriptomic programs with the mechanisms of action (MoA) of drugs. Specifically, we applied this approach to elucidate resistance mechanisms to epidermal growth factor receptor inhibitors (EGFRi) – a key treatment in colorectal cancer (CRC) whose efficacy is frequently limited by resistance.

Material and method

We analyzed transcriptomic profiles from 43 CRC cell lines from the Cancer Cell Line Encyclopedia (CCLE) and their drug response data for seven EGFRi from the Genomics of Drug Sensitivity in Cancer (GDSC) database. Moreover, we employed an external cohort (GSE162104) to validate our approach, as it involves cetuximab, an EGFRi absent in the GDSC. We applied Non-Negative Matrix Factorization (NMF) to decompose the transcriptomic profiles into 15 latent factors. A drug

enrichment score was then developed to identify latent variables associated with EGFRi sensitivity and resistance.

Result and discussion

The 15 latent factors successfully reconstructed the original matrix with an error of 4.84%. Using the drug enrichment score, we found that 3 out of the 15 latent factors were significantly associated with the EGFRi MoA: Factor 1 [ES = -0.755, p-value = 0.002], Factor 2 [ES = 0.756, p-value = 0.002], and Factor 12 [ES = 0.676, p-value = 0.020]. Functional analysis revealed that two of these factors were enriched in estrogen signaling pathways, while one was linked to immune response regulation. External validation confirmed that 22 out of the 230 differentially expressed genes associated with cetuximab resistance were also present among the top 500 genes contributing to factor construction. This suggests that certain resistance mechanisms are directly related to the drug's mechanism of action, independently of drug-specific factors.

Conclusion

Our findings indicate that, despite heterogeneity, different tumors can develop shared resistance mechanisms. Through the combined use of NMF and the drug enrichment score, our approach enables the identification of latent factors associated with EGFRi resistance, providing a framework to explore drug response mechanisms across different therapeutic contexts.

²*Imperial College London, Physics, London, United Kingdom*

³*The Francis Crick Institute, Developmental Dynamics, London, United Kingdom*

⁴*The Francis Crick Institute, Bioinformatics & Biostatistics, London, United Kingdom*

⁵*McGill University, Medicine, Montreal, Canada*

Introduction

Heterogeneity between cancer cells undermines the efficacy of therapies, with both genetic and non-genetic mechanisms generating diversity in cancer cell states. Delineating the mechanisms underpinning heterogeneity in cell state will reveal new strategies for improving the efficacy of cancer therapies. The PI3K/Akt/mTOR signalling pathway promotes cell and tissue growth, with several pharmacological inhibitors in clinical use. Although inhibition of either PI3K or Akt provides benefit in certain clinical contexts, durable responses are rare with reactivation of mTOR and S6 kinase frequently observed.

Material and method

We leverage complementary experimental approaches, including a modified Luria-Delbrück assay, to address

TNBC resistance to AKT inhibition in organoid models. We combine live imaging of AKT activity, glucose metabolism, and organoid growth with molecular approaches including DNA barcoding, RNA sequencing, and metabolomics.

Result and discussion

Linking heterogeneity in cell state to dynamic changes cell signalling, cell metabolism, and ultimately cell fate is challenging. I have found that targeting AKT isoforms leads to a heterogeneous growth inhibition in organoid models of triple negative breast cancer (TNBC). This identifies a subset of TNBC organoids that exhibit a signature positive for Krt14 and p63, similar to basal cells in the normal breast, that resist a bottleneck selection pressure imposed by Akt kinase inhibition. The resistant cell state is reversible and can be driven by ΔNp63α overexpression.

Conclusion

These analyses indicate that resistance to AKT inhibition in TNBC exploits a repertoire of cell states and switching mechanisms inherent to the biology of the breast.

Acquisition of resistance to targeted therapies in lung cancer: mechanistic basis and suppressive strategies

J. Guimarães¹, S. Junqueira-Neto², M. Fernandes², C. Resende², A. Vilarinho², J. Pinheiro³, C. Souto-Moura⁴, S. Melo², J. Costa², J. Machado²

¹*i3S, Intercellular Communication and Cancer, Porto, Portugal*

²*i3S, Intercellular Communication and Cancer, Porto, Portugal*

³*i3S, Ipatimup Diagnostics, Porto, Portugal*

⁴*FMUP, Departamento de Patologia, Porto, Portugal*

Introduction

Targeted cancer therapies efficiently reduce tumor growth and progression. However, the development of resistance unavoidably occurs, representing a major cause of cancer-related deaths. Despite being the triggering event, we have demonstrated that the resistance mutation is present only in a fraction of relapsing tumor cells, evidencing that the resistance phenotype can be transferred among cancer cells. This challenges the prevailing view of resistance development based solely on cell division and selection of mutated cells.

Material and method

We used the human H1975 EGFRp.L858R/EGFRp.T790M Erlotinib-resistant and HCC827 EGFRp.delE746-A750 Erlotinib-sensitive lung cancer cell lines both in vitro and in a co-inoculation immunodeficient C57BL/6[-/-]; Il2rg[-/-] mouse model to study the transcriptomic, proteomic and epigenetic profile of therapy sensitive cells before and after development of resistance. This approach aimed to evaluate the impact of the stimulus from the resistant cell line on the acquisition of resistance in sensitive cells and investigate the stability of the acquired phenotypic resistance.

Result and discussion

We showed that supplementation with conditioned medium from therapy-resistant cells, as well as dual

inoculation of sensitive and resistant cells in our mouse model, leads to a faster and more stable resistance phenotype. In addition, the acquisition of resistance triggers a change in the transcriptional landscape, characterized by the enrichment of the endocytosis pathway, specifically through Caveolin-1 overexpression, which we further validated in human samples. Downstream pathway analysis has identified PI3K as a potential effector of resistance, whose inhibition can restore sensitivity to therapy as well as novel evidence regarding the role of AKT and ERK in cell survival and resistance to therapy. The methylation array analysis revealed that the therapy-resistant phenotype acquired appears to be accompanied by an epithelial-to-mesenchymal transition (EMT) through known mediators such as STK26.

Conclusion

These findings suggest that resistance can arise through alternative mechanisms, potentially influenced by interactions between cancer cells and underscore the complexity of resistance mechanisms, highlighting the potential of targeting intercellular communication to overcome resistance in lung cancer therapy.

EACR25-0379

BET inhibitor Birabresib synergizes with PARP inhibitor Talazoparib in urothelial cancer cell lines and patient-derived organoids

J. Schmitz¹, V. Solanki², T. Mahmoudi², T. Zuiverloon², M. Hoffmann¹, G. Niegisch¹

¹*Medical Faculty and University Hospital, Heinrich-Heine-University Duesseldorf, Department of Urology, Duesseldorf, Germany*

²*Erasmus MC Cancer Institute, Department of Urology, Rotterdam, Netherlands*

Introduction

Patients with urothelial carcinoma (UC) often develop resistance to standard treatment. PARP inhibitors (PARPi) are an effective therapeutic option in cancers with BRCA1/2 mutations (BRCAne), which are rare in UC. We have previously shown that bromodomain and extra-terminal motif inhibitors (BETi) can induce a pharmaceutical BRCAne phenotype in UC cells (UCCs). In this study, we investigated the synergistic effects of a combination therapy with BETi Birabresib (Bira) and PARPi Talazoparib (Tala) in UCCs and their cisplatin-resistant sublines (LTTs) as well as patient-derived organoids (PDOs).

Material and method

T24 and J82 as well as their LTTs and benign HBLAK cells were used for dose response curve analyses after 72 hours of treatment. The Combenefit tool was used to analyse synergism of combination treatment. Reduced dosages were applied to assess effects on DNA damage repair, clonogenicity, cell cycle and apoptosis. Synergistic effects were validated on Cisplatin-sensitive and resistant PDOs.

Result and discussion

IC50 of UCCs for Bira and Tala were all in a low μM range. LTTs were more sensitive to Bira than their parental cell lines. While benign HBLAK cells and UCCs

had similar IC50 for Tala (IC50 T24: 0.2 μM; T24LTT & J82LTT: 0.4 μM; J82: 0.6 μM; HBLAK: 0.3 μM), J82 proved to be more resistant to Bira (IC50 J82: 20.0 μM; T24: 0.3 μM; HBLAK: 0.2 μM). Combined treatment of Bira and Tala resulted in a strong synergism in all UCCs, allowing a dose reduction for further analyses (0.5x IC50 Bira; 0.5x IC50 Tala). Combined treatment caused DNA damage, while impairing repair by homologous recombination. Cell cycle arrest in G2/M and apoptosis were induced, while long-term proliferation capacity was strongly reduced by the combination. Dose response analyses on Cisplatin-sensitive and resistant PDOs revealed similar IC50 values for Bira compared to UCCs (IC50 Azh6T: 1.4 μM; P106T: 0.9 μM), while showing resistance to PARPi (IC50 > 50 μM). However, when combining Bira and Tala on PDOs synergistic effects were again achieved with reduced dosages.

Conclusion

Combined treatment with Birabresib and Talazoparib had strong synergistic effects on all investigated models – UCCs, LTTs and PDOs - enabling a dose reduction. Synergistic response was also observed in models resistant to mono-treatment. Thus, we suggest combined treatment of Birabresib and Talazoparib as a new highly potent treatment option for all UC patients, irrespective of previous Cisplatin-based chemotherapy.

EACR25-0384

Overcoming paclitaxel resistance in ovarian cancer cells using DN200434, an inverse agonist of Estrogen-related receptor gamma (ERRγ)

R. Goel¹, D. Gulwani¹, P. Upadhyay¹, T. Debraj Singh¹

¹*AIIMS, Medical Oncology, New Delhi, India*

Introduction

Ovarian cancer remains a significant contributor to female mortality rates associated with gynecological malignancies. The development of resistance to paclitaxel (PTX), a frontline chemotherapeutic agent, poses a major hurdle in effectively managing this disease. Recent research has identified the nuclear receptor Estrogen-related receptor γ (ERRγ) as a key player in cancer progression, metastasis, and chemotherapy resistance. Notably, ERRγ is found to be upregulated in ovarian cancer, correlating with decreased patient survival rates. In this study, we investigated the efficacy of DN200434, an inverse agonist of ERRγ, in mitigating cancer cell proliferation and overcoming PTX resistance in SKOV-3.

Material and method

Parental SKOV-3 cells were subjected to incrementally increasing PTX concentrations over a period of 3 months to establish PTX-resistant SKOV-3 subline, SKOV-3-PTXR. The effect of DN200434 and PTX on SKOV3 and SKOV-3-PTXR cell proliferation was examined by CCK-8 assay. Apoptosis induced by DN200434 was evaluated in these cell lines using FACS-based Annexin-PI staining. The ability of DN200434 to reverse PTX resistance in SKOV-3-PTXR cells was investigated through CCK-8 assays. Cell cycle arrest and apoptosis resulting from combination treatment were analyzed using FACS-based PI and Annexin-PI staining,

respectively. An agarose-based 3-D spheroid model of SKOV-3-PTXR was employed to further validate DN200434's sensitization effect.

Result and discussion

SKOV-3-PTXR was successfully developed using a stepwise dose escalation approach with a resistance index of 50. The resistance remained stable after 6 months of cryopreservation. Further, both the cell lines exhibited dose-dependent growth inhibition and apoptosis induction when treated with DN200434. Moreover, combining DN200434 with PTX significantly enhanced cell cytotoxicity (50–55%) compared to treatments with DN200434 (20–25%) or PTX (10–12%) in SKOV-3-PTXR. Flow cytometry analysis revealed that DN200434 resensitized SKOV-3-PTXR towards paclitaxel via augmentation of PTX-associated metaphase arrest and apoptosis ability. Intriguingly, the phenomenon of resistance reversal is corroborated in 3-D agarose-based spheroid model.

Conclusion

The present study elucidates the potential of DN200434, a selective inverse agonist of ERR γ , as a potent therapeutic agent in ovarian cancer, demonstrating dose-dependent apoptosis induction. Moreover, the study establishes the role of the inverse agonist in overcoming paclitaxel (PTX) resistance, a significant challenge in ovarian cancer treatment. The observed resistance reversal by DN200434 is attributed to increased cell cycle arrest and apoptosis when combined with PTX. The sensitization effect of DN200434 in combination with PTX is corroborated in a spheroid model. These findings support the combination of PTX and DN200434 as a viable strategy for managing PTX-resistant ovarian cancer.

EACR25-0456

A newly discovered mTOR-STAT3 pathway regulates calcium release and calcium-mediated apoptosis at the ER in Triple Negative Breast Cancer

D. Viavattene¹, S. Paternani², L. Avalle¹, A. Marchetti¹, A. Savino¹, L. Conti¹, E. Calautti¹, F. Raimondi³, P. Pinton², V. Poli¹

¹*University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy*

²*University of Ferrara, Department of Medical Sciences, Ferrara, Italy*

³*Scuola Normale Superiore, Department of Molecular and Translational Medicine, Pisa, Italy*

Introduction

STAT3 is a pleiotropic transcription factor often constitutively activated in tumors including breast cancer. STAT3 canonical transcriptional activity is mediated by Y705 (Y-P) phosphorylation; in contrast, phosphorylation on S727 (S-P) orchestrates transcription-independent activities in distinct cellular compartments. Among them, we have recently described the ability of S-P STAT3 to localize to the ER and Mitochondrial Associated Membranes to control ER Ca²⁺ release and Ca²⁺-mediated apoptosis in STAT3-dependent Triple Negative Breast Cancer (TNBC) cells, by triggering the

proteasomal degradation of the Ca²⁺ channel IP3R3. Accordingly, STAT3 and IP3R3 protein levels are inversely correlated in the highly aggressive basal-like breast tumors, where STAT3 is often constitutively activated.

Material and method

To elucidate the mechanisms regulating STAT3 S-P at the ER, using Cytoscape we generated a network of human putative ER-STAT3 interactors based on the Search Tool for the Retrieval of Interacting Genes/Proteins (STRING) database, selected according to their ER gene ontology (GO) function. The only two serine kinases identified among the top ten putative ER-STAT3 interactors were mTOR and Akt1. The analysis of the TCGA TNBC RNAseq database showed that STAT3 mRNA expression levels positively correlated with those of mTOR but not Akt1.

Result and discussion

We confirmed STAT3-mTOR ER co-localization by immunofluorescence, and their interaction by co-immunoprecipitation from purified ER fractions and Proximity Ligation Assay (PLA) in human TNBC cells. Pan-mTOR inhibition by Torin-1 – but not mTOR Complex 1 inhibition via Rapamycin – could prevent both IP3R3 degradation and Ca²⁺-mediated apoptosis, mimicking the effects of STAT3 silencing. Accordingly, Torin-1 abolished STAT3 S-P within the ER, increasing intracellular Ca²⁺ concentration.

Conclusion

These data demonstrate for the first time that STAT3 Serine phosphorylation can be regulated in the specific cellular compartment where its functions are exerted, in this case occurring at the ER downstream of mTOR. In turn this specific regulation can lead to enhance apoptosis resistance via IP3R3 degradation. Preliminary data indicate that STAT3-mTOR might directly interact, since they can still co-immunoprecipitate in the absence of either mTORC1 or mTORC2 upon RAPTOR and RICTOR ablation, respectively. Accordingly, AlphaFold 3 modelling of an mTOR-STAT3-IP3R3 ternary complex indicates that STAT3 interacts with the Armadillo region of mTOR via its coiled-coil domain. The assessment of mTOR, STAT3, and IP3R3 protein levels in patient-derived tumor samples is in progress. Dissecting these molecular details, in addition to contributing to characterize the multiple non-canonical mechanisms of STAT3 action, may reveal novel therapeutic targets to disrupt apoptotic resistance in STAT3-dependent TNBC cells.

EACR25-0505

Activation of the Integrated Stress Response to overcome multidrug resistance in cancer therapy

J. Mota-Pino¹, L. Sanchez-Burgos¹, M. Anton¹, B. Navarro-Gonzalez¹, M. Murga¹, M. Häggblad², D. Hühn², O. Fernandez-Capetillo^{1,3}

¹*Centro Nacional de Investigaciones Oncologicas (CNIO), Genomic Instability Group, Madrid, Spain*

²*Science for Life Laboratory, Karolinska Institute, Medical Biochemistry and Biophysics, Stockholm, Sweden*

³Medical Biochemistry and Biophysics, Stockholm, Sweden

Introduction

Resistance to therapy is estimated to contribute to treatment failure in up to 90% of metastatic cancer patients and remains a fundamental challenge in cancer. In this regard, we recently found that several kinase inhibitors were able to kill multidrug-resistant cancer cells, through a mechanism independent of their proposed targets. Instead, these compounds killed cells showing multidrug resistance (MDR) by activating the so-called Integrated Stress Response (ISR) (Sanchez-Burgos et al., EMBO Mol Med, 2022). Other reports also converge on similar observations in that: (a) activation of the ISR can overcome MDR in cancer and (b) several drugs activate the ISR by an unknown mechanism.

Material and method

To systematically address the potential of drugs to activate the ISR, we conducted both chemical and CRISPR/Cas9 genome-wide genetic screens using a fluorescent reporter of CHOP, a pro-apoptotic factor that is expressed upon activation of the ISR.

Result and discussion

Chemical screens have allowed us to obtain a panoramic view of how drugs activate the ISR and to identify some surprising inducers of the response: benzimidazole derivatives. We subsequently tested these compounds in both *in vitro* and *in vivo* models of drug resistance, yielding very promising results. As mentioned above, in addition to chemical screens, we have also performed genome-wide CRISPR/Cas9 knockout screens to evaluate which targets, when depleted, lead to a more vigorous activation of the ISR. The idea here is to identify the best targets for which an inhibitor would be an efficacious ISR activator. The screen, also based on our CHOP reporter model, has led us to identify several promising hits, including some chaperones which we are currently investigating.

Conclusion

In summary, our work aims to provide a general overview of the genes and drugs that modify the ISR, and to use this information to develop novel strategies to overcome multidrug resistance in cancer therapy.

EACR25-0566

Evaluate the potential sensitization effect and underlying mechanism of tyrosine kinase inhibitor on cisplatin resistance oral squamous cell carcinoma

Y. Chen¹, T. Liao¹, Y. Chang², H. Tu¹, F. Hsu³

¹National Yang Ming Chiao Tung University, Department of Dentistry, Taipei, Taiwan

²Taipei Medical University-Shuang Ho Hospital Ministry of Health and Welfare, Department of Medical Imaging, New Taipei, Taiwan

³National Central University, Department of Life Science, Taoyuan, Taiwan

Introduction

Oral squamous cell carcinoma (OSCC) is a common cancer, with cisplatin as the main chemotherapy drug. However, resistance often develops, linked to HIF-1 α activation. This pathway increases VEGF and BCL-2

levels, promoting angiogenesis and anti-apoptosis.

Targeting the HIF-1 α /VEGF/BCL-2 axis may improve treatment. Tyrosine kinase inhibitors (TKIs), such as lenvatinib, block key signaling pathways, including VEGF and BCL-2, to inhibit tumor growth and metastasis. However, their potential to enhance OSCC sensitivity to cisplatin remains unclear.

Material and method

In our study, MOC1 cells were cultured under hypoxic conditions (1% O₂) in a specialized medium containing growth factors and nutrients, successfully establishing cisplatin-resistant OSCC cell lines. The MTT assay was used to assess whether cisplatin and TKIs induced cytotoxicity in these resistant cells. Flow cytometry was then performed to determine whether the combination of TKIs and cisplatin enhanced both extrinsic and intrinsic apoptotic pathways. Additionally, transwell invasion and migration assays were conducted to evaluate whether TKIs combined with cisplatin increased the inhibitory effects on cisplatin-resistant OSCC cells. Finally, Western blotting was performed to investigate the molecular mechanisms underlying cisplatin resistance following TKI and cisplatin combination treatment.

Result and discussion

Our study established cisplatin-resistant OSCC cells under hypoxic conditions and found that cisplatin alone had limited cytotoxicity. Nevertheless, combining TKIs with cisplatin restored cisplatin sensitivity. Flow cytometry confirmed that TKIs enhanced cisplatin-mediated apoptotic pathways. Additionally, transwell assays showed significant inhibition of invasion and migration after combining TKIs with cisplatin. Finally, we showed that TKIs and cisplatin effectively suppressed angiogenesis and disrupted the anti-apoptotic mechanisms mediated by the HIF-1 α /VEGF/BCL-2 axis.

Conclusion

In conclusion, our results suggest that combined treatment with TKIs and cisplatin can enhance the response of OSCC cells under hypoxic conditions. Additionally, TKIs restored the sensitivity of OSCC to cisplatin through the HIF-1 α /VEGF/BCL-2 pathway.

EACR25-0574

Study of long non-coding RNAs in resistance to KRAS G12C inhibitors in lung cancers

T. Papazyan¹, A. Matvere², R. Pedeux², T. Derrien³, E. Pons Tostivint^{4,1}, D. Fradin¹

¹CRCI2NA, Team 1 ITMI, Nantes, France

⁴CHU Nantes, Medical Oncology, Nantes, France

Introduction

Lung cancer is the leading cause of cancer-related mortality worldwide. KRAS mutations occur in 30% of lung adenocarcinomas, with half of these being of the KRAS G12C subtype. The development of covalent inhibitors targeting this variant, such as adagrasib, is a recent clinical breakthrough. However, despite promising phase I/II clinical trial results, only 40% of patients initially respond to these treatments and most of them will develop resistance. Current research on resistance mechanisms is limited and predominantly focuses on

genetic factors while non-genetic mechanisms, including those involving long non-coding RNAs (lncRNAs), remain largely unexplored. Our objective is to investigate the role of lncRNAs in resistance to KRAS G12C inhibitors in non-small cell lung cancer (NSCLC).

Material and method

Using the ADCA72 cell line derived from a KRAS G12C-mutated patient, we generated both adagrasib-sensitive and -resistant cells. Then, we conducted two complementary assays to identify candidates lncRNAs involved in resistance. Firstly, long-read nanopore sequencing was used to discriminate differentially expressed lncRNAs between adagrasib-sensitive and -resistant cells. Secondly, a genome wide lncRNA CRISPR activator screen was performed in ADCA72-sensitive cells to find which lncRNAs confer a survival advantage.

Result and discussion

Long-read sequencing analyses identified a specific subset of lncRNAs associated with resistance, including LINP1. Further experiments showed that LINP1 is mainly expressed in the nucleus of resistant cell suggesting that they could remodel chromatin and gene expression. LINP1 has been described to facilitate DNA damage repair via NHEJ pathway, therefore decreasing sensitivity to chemotherapy and radiotherapy. CRISPR screen analysis pinpointed previously uncharacterized lncRNAs, such as Linc01018, which we are studying in a functional way. Finally, cross-referencing of results revealed that some candidates were associated with resistance and survival advantage under adagrasib treatment using both nanopore technology and the CRISPR screen. Again, we are currently investigating their localization and functions.

Conclusion

Our study highlights the importance of lncRNAs in resistance mechanisms to KRAS G12C inhibitors in NSCLC. It suggests that non-genetic mechanisms involving lncRNAs contribute to the development of resistance. Further functional research into these lncRNAs could provide new therapeutic targets and strategies.

Targeting the Non-Homologous End-Joining Pathway Sensitizes MDM2-Amplified Liposarcoma to Doxorubicin-Induced Senescence in a p53-dependent Manner

T. Jalving¹, C. Dufau¹, J. Simon Nieto¹, D. D'empaire Altimari¹, W. van Houdt², D. Peepen¹

¹Netherlands Cancer Institute, Molecular Oncology & Immunology, Amsterdam, Netherlands

²Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands

Introduction

Dedifferentiated liposarcoma (DDLPS) is a rare cancer defined by amplification of MDM2 and CDK4.

Conventional chemotherapy (doxorubicin) and targeted inhibition of MDM2 and CDK4 show sporadic responses, but most tumors display (intrinsic) resistance. We used

an unbiased approach to identify therapeutic strategies sensitizing to these current DDLPS therapies.

Material and method

Three parallel genome-wide CRISPR-Cas9 knockout screens were conducted in DDLPS cells to sensitize to palbociclib (CDK4 inhibitor), nutlin-3a (MDM2 inhibitor) or doxorubicin. Top screen hits were validated and characterized in both *in vitro* and *in vivo* models, while clinical data were leveraged to confirm molecular findings on a larger scale.

Result and discussion

We found pathways related to G1/S transition (CDK2, CKS1B, E2F3 and CCNE1) and Non-Homologous End-Joining (NHEJ; TDP2, PRKDC and XRCC4) to sensitize to palbociclib and doxorubicin respectively. Following validation of both pathways, we focused on mechanistic characterization of doxorubicin sensitization by genetic perturbation of TDP2 or pharmacological inhibition of PRKDC using pepotib. Synergy was achieved by prolonged administration of low-dose doxorubicin *in vitro* and *in vivo*, driven by increased cell cycle arrest and senescence. Senescent cells were triggered to undergo into apoptosis by subsequent senolytic therapy. Surprisingly, despite the amplification of MDM2, senescence was dependent on p53. Leveraging TCGA and DepMap data, we confirm potential p53 activity in DDLPS.

Conclusion

These findings provide a rationale for targeting the NHEJ pathway to enhance the efficacy of doxorubicin in an MDM2-amplified cancer, highlighting a potential therapeutic strategy that exploits p53-dependent cell cycle arrest and senescence for improved treatment outcomes. Furthermore, we provide, to our knowledge, the first evidence of maintained p53 activity in untreated MDM2 amplified DDLPS.

EACR25-0598

Regulation of FOXK2 by AKT in breast cancer cells: Serine 398 as a novel potential phosphorylation site

L. Carneiro¹, G. De Gregoriis², J. Nunes¹, B. Mendonça¹, R. Maia³, R. Carvalho⁴, M. Carvalho^{2,5}, A. Sharrocks⁶, G. Nestal de Moraes¹

⁶University of Manchester, Faculty of Biology, Medicine and Health, Manchester, United Kingdom

Introduction

FOXK2 is a transcription factor which mediates drug sensitivity in breast cancer. Conversely, drug-resistant cells exhibit constitutively high FOXK2 protein levels

which seems to be inactive, suggesting that FOXK2 may be regulated by post-translational modifications. In silico analysis have found the AKT kinase as the main putative regulator of FOXK2. Therefore, the aim of our study is to evaluate whether FOXK2 is regulated by AKT-mediated phosphorylation and its impact on breast cancer chemoresistance.

Material and method

MCF-7 (chemosensitive) and MDA-MB-231 (chemoresistant) cells were used as models. FLAG-FOXK2 mutants were generated by site-directed mutagenesis using the overlap extension approach. Gene knockdown and overexpression were performed by transient transfections. MK-2206 was used for AKT pharmacological inhibition. Immunoprecipitation (IP) assays were performed using beads conjugated to specific antibodies. The NE-PER kit was used for subcellular fractionation. RNA levels were examined by real-time PCR and protein levels, by Western Blotting. The MTT and clonogenic assays were performed to assess cell viability and drug-induced cytotoxicity.

Result and discussion

AKT inhibition reduced exogenous and endogenous FOXK2 protein levels, with no such modulation in FOXK2 mRNA levels. Similarly to phosphorylated AKT, FOXK2 subcellular localization was predominantly nuclear in drug-resistant cells. Also, experiments with lambda-phosphatase and Phos-tag gels suggest that FOXK2 mobility profile is altered in AKT-modulated cells. Interestingly, FOXK2 IP eluates were probed using phospho-AKT substrate antibodies, further suggesting that FOXK2 might be a substrate for AKT phosphorylation. Notably, higher levels of phosphorylated FOXK2 were found in breast tumors samples from public databanks, including serine 398 (S398), which has also been identified as a putative phosphorylation site in FOXK2 in silico and in a large-scale proteomic analysis. These findings supported the construction of phospho-deficient (S398A) and phosphomimetic (S398E) FOXK2 mutants. Notably, the S398A mutant form of FOXK2 impaired cell growth, cell viability and clonogenic capacity compared with wild type and the S398E mutant version of FOXK2, even in the presence of chemotherapeutic drugs. Finally, preliminary IP assays using anti-FLAG antibodies suggest that the S398 residue in FOXK2 is phosphorylated by AKT.

Conclusion

In summary, AKT can regulate FOXK2 by phosphorylation in drug-resistant cells and S398 turns out to be a novel potential site in AKT-FOXK2 interaction interface. Understanding AKT-FOXK2 axis contribute to potentiate the effects of AKT inhibitors in breast cancer.

FOXK2 transcription factor in cancer: expression, function and potential as a biomarker

R. Ivo Vasconcelos¹, L. Carneiro¹, R. Maia²,

R. Carvalho³, T. Hancio⁴, G. Nestal de Moraes¹

¹Universidade Federal do Rio de Janeiro, Instituto de Bioquímica Médica Leopoldo de Meis, Rio de Janeiro, Brazil

²Instituto Nacional de Câncer, Programa de Hemato-

Oncologia Molecular, Rio de Janeiro, Brazil

³Universidade Federal do Rio de Janeiro, Departamento de Biotecnologia Farmacêutica, Rio de Janeiro, Brazil

⁴Centro Nacional de Pesquisa em Energia e Materiais, Laboratório Nacional de Biociências, São Paulo, Brazil

Introduction

FOXK2 is a transcription factor that plays a dual role in cancer, acting either as a tumor suppressor or an oncogene, depending on the tissue type. In breast cancer, FOXK2 acts as a tumor suppressor, preventing carcinogenesis and favoring drug responses. Therefore, we aimed to evaluate FOXK2 gene expression as a potential biomarker in different tumor types and the role of FOXK2 at the interface between chemosensitivity and tumor progression in breast cancer.

Material and method

An in silico analysis compared FOXK2 gene expression between normal and tumor patient's samples in different tumor types by analyzing transcriptome-level data from TNMplotter platform. The impact of FOXK2 on patient's overall survival was evaluated by Kaplan-Meier curves from KMplotter. FOXK2 promoter methylation status was assessed by OncoDB; copy number variation and FOXK2 mutational status by XENA platform. The role of FOXK2 modulation in breast cancer was assessed by shRNA viral transductions in MCF-7 (chemosensitive) and MDA-MB-231 (chemoresistant) cell lines. The validation of these shFOXK2 cells was assessed by western blotting and real time RT-qPCR assays. Docetaxel and doxorubicin-induced cytotoxicity was evaluated by MTT and colony formation by clonogenic assays. To link FOXK2 gene expression and response to therapy on breast cancer patient's samples, we evaluated patient's pathological complete response to therapy and relapse-free survival at 5 years by ROCplotter.

Result and discussion

We have found FOXK2 overexpression in most tumor types, which was associated with high copy number variation, but not with FOXK2 gene mutations or promoter methylation status. This points to additional transcriptional or post-translational mechanisms governing FOXK2 regulation. From all tumors analyzed, low FOXK2 levels in patients with kidney renal clear cell carcinoma and liver hepatocellular carcinoma showed up a remarkable improvement on overall survival. Also, our in vitro results show that knocking-down FOXK2 renders breast cancer cells more resistant to chemotherapeutics. Additionally, grade II patients who received chemotherapy and relapsed before 5 years showed low FOXK2 expression. Similarly, reduced FOXK2 expression has also been found in non-responders patients, particularly luminal B, treated with the FEC chemotherapeutic combination. Therefore, FOXK2 low expression has been related to poor responses to treatment in breast cancer. Finally, ongoing in vitro experiments with shFOXK2 drug resistant cells are currently exploring the interface between breast cancer drug resistance and tumor progression.

Conclusion

Altogether, our findings suggest that analyzing FOXK2 gene expression might be a good predictor of response to therapy, diagnosis and prognosis in some tumor types.

EACR25-0601**Targeting DUSP6 to combat therapy resistance and brain metastasis in HER2-positive breast cancer**

S. Bhardiya^{1,2}, M. Tienhaara^{3,4}, O. Denisova^{1,5}, J. Westermarck^{1,6,7}

¹*University of Turku, Turku Bioscience Centre, Turku, Finland*

²*University of Turku, InFlames Research Flagship Centre, Turku, Finland*

⁴*Turku Bioscience Centre, Turku, Finland*

⁵*InFlames Research Flagship Centre, Turku, Finland*

⁶*InFlames Research Flagship Centre, Turku, Finland, University of Turku*

⁷*Institute of Biomedicine, Turku, Finland*

Introduction

Dual-specificity phosphatase 6 (DUSP6) is implicated in cancer progression and therapy resistance (2). In HER2-positive (HER2+) breast cancer, DUSP6 expression increases significantly during the transition from drug-tolerant persister (DTP) cells to expanding persister (DTEP) cells, a key stage in acquired resistance to HER2 inhibitors (HER2i). Elevated DUSP6 levels enhance apoptosis resistance, while its pharmacological inhibition restores HER2i sensitivity. Mechanistically, these effects are mediated by the impact of DUSP6 on the HER3-neuregulin axis, which is pivotal in breast-brain metastasis and therapy tolerance (1).

Material and method

Clonogenic assays assessed proliferation following treatment with HER2i (lapatinib) and DUSP6 inhibitor (BCI). Stable DUSP6 overexpression was achieved in the BT474 cell line via lentiviral transduction. Fluorescence-activated cell sorting was used to isolate highly EGFP-expressing cells, which were subsequently employed in ex vivo brain slice culture and live-cell imaging. In addition, intracranial xenograft models in mice were utilised to evaluate the impact of DUSP6 inhibition on tumour progression and therapeutic response.

Result and discussion

DUSP6 promotes therapeutic resistance in HER2+ breast cancer. Pharmacological inhibition of DUSP6 combined with HER2i resulted in a potent anti-proliferative effect in HER2i-resistant MDA-MB-453 cells, as demonstrated by clonogenic assays. Ex vivo brain slice culture further showed increased cell death in disseminated tumour cells upon combined DUSP6 and HER2 inhibition, underscoring the therapeutic relevance of this strategy in a physiologically representative environment. This model preserved brain architecture while enabling controlled experimental conditions. Conversely, DUSP6 over-expression in HER2i-sensitive BT474 cells conferred resistance to HER2i-induced apoptosis, as revealed in clonogenic assays. In vivo, intracranial xenograft models demonstrated that DUSP6-overexpressing cells induced tumour outgrowth, even when using non-brain-tropic cells, resulting in increased brain tumour burden, weight loss, and neurological symptoms in mice. These findings highlight the role of DUSP6 in facilitating brain metastasis and resistance to HER2-targeted therapies.

It is essential to investigate the molecular oncogenicity of DUSP6 and its contribution to brain colonisation.

Conclusion

DUSP6 is a candidate driver of HER2i resistance in brain metastasis. Dual inhibition of HER2 and DUSP6 exerts a significant synergy, suggesting a promising therapeutic approach. Subsequently, we aim to identify and characterise novel allosteric DUSP6 inhibitors. Developing and evaluating these inhibitors using preclinical models offers potential new therapeutic strategies for breast cancer and other subtypes.

EACR25-0637**Understanding and targeting mechanisms of resistance to the cytidine deaminase biodegrader and gemcitabine combination in cancer**

M. Cristol¹, M. Sorbara¹, D. Varry¹, P. Cordelier¹, J. Torrisani¹, N. Béry¹

¹*Cancer Research Center of Toulouse, Inserm, Toulouse, France*

Introduction

Despite the endeavours and achievements made in treating cancers during the past decades, resistance to classical chemotherapeutic agents and/or novel targeted drugs remains a major problem in cancer therapies. Indeed, drug resistance, either existing before treatment (intrinsic) or generated after therapy (acquired), is responsible for most relapses of cancer, which are one of the major causes of death of the disease. Deoxycytidine analogues (e.g. gemcitabine, cytarabine) belong to the antimetabolites class of chemotherapeutic agents, used to treat a variety of cancers. Cytidine deaminase (CDA) has been identified as a key regulator of resistance to these therapies by promoting their deamination and inactivation. In this context, the team developed a CDA biodegrader to deplete CDA in cells and tumours and sensitise them to deoxycytidine analogues. In vivo, while the combination CDA biodegrader and gemcitabine induced a first phase of tumours regression, it is followed by a second phase in which the tumours relapsed. These data suggest the appearance of mechanisms of resistance to this combination.

Material and method

We modelled this resistance in vitro by following the confluence of clonal populations of cancer cells expressing, or not, the biodegrader and treated, or not, with gemcitabine, by using real-time microscopy. Resistant cell lines (clones) were amplified and characterised (proliferation, IC50). Then, RNAseq was performed on one resistant clone to identify the molecular mechanisms that could be responsible for this resistance. We confirmed the RNAseq data at the transcriptional and protein levels. Finally, we will perform functional validation and targeting of these mechanisms by using siRNA and shRNA.

Result and discussion

We obtained three different resistant clones from our in vitro modelling experiments. Characterisation of these clones showed that the CDA biodegrader is still functional, suggesting that CDA-independent

mechanisms emerge to induce resistance. RNAseq data on one resistant clone show that a pathway is significantly and specifically altered in the resistant clone. We confirmed this at the transcriptional (RT-qPCR) and protein (Western blotting) levels. We also confirmed the expression of the driver of this pathway in all the resistant clones we obtained. Ongoing studies are focused on evaluating the impact of targeting and over-expressing this driver on the emergence of resistance.

Conclusion

This project contributes to the identification of resistance mechanisms to the CDA biodegrader/gemcitabine combination in cancer cells, in order to target them and improve the long-term efficacy of this innovative therapeutic strategy.

KRAS silencing impacts chromatin organization and transcriptional activity in colorectal cancer cells

F. Martins¹, A. Machado¹, S. Mendonça Oliveira¹, J. Carvalho¹, R. Matthiesen², V. Backman³, S. Velho¹

¹i3S - Institute for Research and Innovation in Health, Tumor and Microenvironment Interactions group, Porto, Portugal

²Nova Medical School, Chronic Diseases Research Centre, Lisbon, Portugal

³Northwestern University, Biomedical Engineering, Evanston, IL, United States

Introduction

The swift development of resistance to targeted inhibition of a critical oncogene to which cancer cells are addicted is a remarkable and complex phenomenon standing in the way of curing cancer patients. Colorectal cancer responses to the recently developed mutant-specific KRAS inhibitors fully typify this addiction/resistance paradox: although mutant KRAS is the most frequent oncogenic driver of colorectal cancer, in the clinic, no effective cell killing is achieved with its inhibition. Instead, tumor cells enter a cell cycle-arrested state, resuming growth shortly after treatment initiation. Our work focused on answering a critical question: how do mutant KRAS colorectal cancer cells so readily adapt to and tolerate KRAS inhibition?

Material and method

To answer this question, our analyses were contextualized within the framework of differing sensitivities to KRAS silencing observed in 3-dimensional spheroid cultures of mutant KRAS CRC cell lines. siRNA was used to silence KRAS expression. Cells were grown into spheroids and then analyzed by mass spectrometry. The expression of significantly altered proteins was validated by western blotting. Additionally, we investigated chromatin states using transmission electron microscopy, partial wave spectroscopic microscopy, and Hi-C. Transcriptional plasticity was evaluated through RNA sequencing.

Result and discussion

Our results showed that upon KRAS silencing, KRAS-silencing sensitive cell lines presented a significant reduction in the number of cells, accompanied by changes in the cell cycle and apoptosis, which supported their KRAS-dependency. Proteomics analysis revealed a

differential expression of several proteins associated with gene expression regulation, mRNA splicing and processing, and nucleosome assembly and repositioning in KRAS-silenced sensitive cells. Furthermore, these cells exhibited changes in the 3D physical organization of chromatin, namely alterations in eu/heterochromatin ratios, chromatin domain packing scaling, alterations in TAD number, and A/B compartment distribution. Additionally, longitudinal RNA sequencing following KRAS silencing revealed changes in the transcriptional performance in KRAS-inhibition sensitive cell lines.

Conclusion

Collectively, our findings highlight a potential mechanism involved in the rapid adaptation of mutant KRAS colorectal cancer cells to KRAS loss mediated by profound alterations in chromatin organization, emphasizing potential epigenetic vulnerabilities that could be exploited to enhance therapeutic efficacy.

EACR25-0659

Characterization of TRIB2 role in pancreatic cancer chemoresistance

I. Grenho^{1,2}, W. Link³, B. Ferreira^{1,4}

¹ABC-Ri, Cancer & Ageing Lab, Faro, Portugal

²Universidade do Algarve, Faculdade de Medicina e Ciências Biomédicas, Faro, Portugal

³Spanish National Research Council, Sols-Morreale Biomedical Research Institute, Madrid, Spain

⁴Faculdade de Medicina e Ciências Biomédicas, Faro, Portugal,

Introduction

Pancreatic cancer (PC) is classified as one of the most aggressive and deadliest cancers in the world (5-year survival rate of 10-25%; mortality/incidence ratio of 95%). However, the treatment options for these patients have not advanced significantly throughout the years and are frequently associated with the development of therapy resistance and patients' relapse. Recently, we discovered a novel mechanism of therapy resistance mediated by Tribbles homolog 2 (TRIB2). TRIB2 is a pseudo serine/threonine kinase that has shown to have a critical role in tumorigenesis and resistance to therapy. Higher TRIB2 levels seem to be associated with a worst prognosis in several solid tumors, including PC. However, the potential role of TRIB2 in pancreatic cancer chemoresistance remains unclear.

Material and method

To unveil the potential role of TRIB2 in PC, we generated gemcitabine-resistant cells. To achieve this, we treated the cells with consecutive cycles of 2',2'-difluoro-deoxycytidine (gemcitabine), increasing the dosage each time, over the course of 9 months. We further characterized these cells regarding their resistance, proliferation, cell death and wound-healing ability and analyzed TRIB2 mRNA and protein expression using RT-PCR and Western Blot techniques.

Result and discussion

During the generation of the resistant cells, we observed that gemcitabine induced morphological changes in the cells, that switch from an epithelial to a fibroblastic-like phenotype. However, this switch was reversible over time in the absence of the drug. Using the protocol described, we were able to generate resistant cells,

increasing their half maximal inhibitory concentration (IC₅₀). These cells seem to present lower cell death and higher cell viability when acutely treated with gemcitabine when compared with the parental cell line, but also an unexpected decreased migration ability (15-hour assay). Analysis of TRIB2, at the transcriptional and protein levels, revealed an increased TRIB2 expression in the resistant cell lines, when compared to the parental cells, which showed little to no expression of this protein. Higher levels of TRIB2 were detected in the emerging phenotypes, during the phenotypic switch, while the cells were being treated with gemcitabine.

Conclusion

Our results indicate a potential role of TRIB2 in the mechanism behind gemcitabine-resistance in PC, that could hypothetically involve the phenotypic switch during the generation of the resistant cells. With this project, we aim to investigate the role of TRIB2 in this mechanism and study its impact and clinical relevance in PC patient's standard of care.

³Center for Translational Cancer Research (TranslaTUM), School of Medicine, Technical University of Munich, Munich, Germany

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with poor prognosis, driven predominantly by the KrasG12D mutation. Targeting KRASG12D with inhibitors such as MRTX1133 has shown promise, but resistance mechanisms including pathway rewiring limit efficacy. This study aims to identify therapeutic vulnerabilities of KrasG12D resistant PDAC models.

Material and method

A large and representative panel of molecularly characterized cell lines derived from murine PDAC (mPDAC) tumors were employed to identify resistant cell lines towards KrasG12D inhibition. Uniform manifold approximation and projection (UMAP) analysis from bulk RNA sequencing (RNA-seq) was used to assess transcriptomic diversity within the cohort. Drug response to MRTX1133 was conducted across 55 cell lines using a 3-fold 5-point concentration. Following seeding, cells were treated for 72 hours, and cell viability was measured using the CellTiterGlo assay. A systematic high-throughput combinational drug screen was conducted using two resistant mPDAC cell lines. The drug library consisted of DMSO controls and 95 compounds in preclinical and clinical investigation

targeting key oncogenic pathways. Drug interactions were assessed using ΔAUC-based synergy scoring, and top candidate synergistic drugs were further validated using colony formation assays. Bliss synergy score was used to assess the synergism between drug combination.

Result and discussion

Our mPDAC panel includes both KrasG12D-driven cell lines ($n = 51$) as well as Pi3k-driven cell lines ($n = 4$) to confirm the specificity of targeting KrasG12D. Furthermore, the panel encompasses key genetic alterations commonly found in PDAC, including Cdkn2a (p16), Tp53, Smad4, and Tgfb2 as well as a balanced representation of PDAC subtypes: epithelial, quasi-mesenchymal, and mesenchymal. Pi3k-driven cell lines showed resistance – thus underscoring the target specificity of MRTX1133 to KRASG12D – while KrasG12D-driven cell lines showed heterogeneous response. To investigate the resistance mechanism and identify the drugs synergizing with KrasG12D inhibition, we performed a systematic high-throughput combinational drug screen using two mesenchymal resistant mPDAC cell lines established in our lab. We found that Nintedanib, a multi-kinase inhibitor, was among the top synergistic hits. Clonogenic assays validated its synergistic effect in combination with MRTX1133 as bliss synergy scores above 10 in both cell lines.

Conclusion

Our study highlights the heterogeneity of KRASG12D-driven PDAC towards MRTX1133. Through high-throughput drug screening, we found that Nintedanib synergizes with MRTX1133 to overcome resistance in mesenchymal PDAC cell lines. These findings provide a potential combination strategy to improve therapeutic outcomes in KRASG12D-mutant PDAC.

EACR25-0713

Potential therapeutic implication of Epithelial Protein Lost in Neoplasm (EPLIN) in head and neck cancer and chemotherapy resistance

C. Wang¹, J. Zeng¹, T. Martin¹, X. Song², E. Khan³, Q. Dou³, W. Jiang¹

¹CCMRC, Cardiff University School of Medicine, Cardiff, United Kingdom

²Department of Otorhinolaryngologic Diseases, Yantai Yuhuangding Hospital, Shandong, China

³Karmanos Cancer Institute, Department of Oncology, Wayne State University School of Medicine, Detroit, United States

Introduction

Epithelial Protein Lost in Neoplasm (EPLIN), also known as LIMA1, is an actin-binding protein implicated in cytoskeletal remodelling and tumour progression. While traditionally considered a tumour suppressor, emerging evidence suggests that EPLIN plays a potential oncogenic role in head and neck cancer (HNC). EPLIN has been linked to enhanced invasion and metastasis, but its role in drug resistance remains unclear in HNC. This study aims to investigate the relationship between EPLIN expression and drug response in HNC.

Material and method

EPLIN-overexpressing (Exp) and knockdown (KD) human head and neck cell models were established to evaluate the impact of EPLIN on drug sensitivity. Potential EPLIN-binding drugs were screened through molecular modelling and docking studies. Cytotoxicity assays were performed to assess cellular responses to chemotherapy (docetaxel, paclitaxel, neratinib, and cisplatin) and candidate drugs (digoxin). EPLIN expression levels in HNC tissues and their correlation with patients' drug response were evaluated using public datasets.

Result and discussion

Cell-based drug sensitivity evaluation indicated that high levels of EPLIN in HNC cells rendered resistance to cisplatin ($p = 0.01$) and, to a limited degree, to docetaxel ($p = 0.09$). The relationship between EPLIN and docetaxel response was further validated in HNC cell models. EPLIN knock down sensitised the cells to docetaxel with a decreased IC₅₀ at 1.04 μ M compared with control cells at 2.62 μ M. Conversely, EPLIN overexpression resulted in an increased IC₅₀ for docetaxel (1.91 μ M) compared to WT cells (0.7 μ M), indicating an elevated resistance to the drug. Digoxin, identified through molecular docking as a potential EPLIN-interacting drug, exhibited EPLIN expression-dependent drug resistance in HNC cells. Upon EPLIN knockdown, the IC₅₀ of digoxin in HNC cells was significantly reduced (98.48 μ M vs. 2.95 μ M). Conversely, EPLIN overexpression led to an increased IC₅₀ compared to WT cells (7.15 μ M vs 17.85 μ M), suggesting that EPLIN may contribute to digoxin resistance in HNC. These results highlight EPLIN's potential role in modulating digoxin sensitivity and its implications in therapeutic resistance. After EPLIN knockdown, HNC cells treated with 10 μ M digoxin exhibited further reductions in proliferation, adhesion, migration, and invasion, suggesting that EPLIN knockdown enhances the cytotoxic effects of digoxin and may contribute to increased drug sensitivity in HNC.

Conclusion

The present study is the first to report the connection between EPLIN expression and drug resistance in HNC, demonstrating that high EPLIN levels contribute to resistance against docetaxel, while EPLIN knockdown enhances drug sensitivity. Notably, digoxin exhibited significant EPLIN-dependent drug resistance, and this relationship provides a new potential therapeutic direction for the treatment of head and neck cancer.

Combination therapy with YAP/TEAD and RAS inhibitors overcomes phenotypic cell plasticity-driven resistance in NRAS-mutated melanoma

M. Kahil¹, W. Mohager¹, F. Larbret¹, N. Dumaz², L. Larue³, M. Deckert¹, S. Tartare-Deckert¹

¹Université Côte d'Azur, INSERM U1065, C3M, Nice, France

²Université Paris Cité, INSERM U976 - Hôpital Saint Louis, Paris, France

³Institut Curie, UMR3347 CNRS, INSERM U1021, Orsay, France

Introduction

Melanoma is the most aggressive skin cancer, characterized by remarkable cancer cell plasticity, contributing to intra-tumoral heterogeneity and therapeutic resistance. NRAS-mutant melanoma remains a clinical problem, particularly in patients who do not respond to immunotherapies. As a second-line option, MEK inhibitors as single agents fail to provide a significant overall survival benefit. Therefore, there is an unmet need for new therapeutic strategies to improve the management of NRAS-mutant melanoma. Here we assessed in vitro and in vivo the response of NRAS-mutant melanoma cells to RMC-6236, a novel non-covalent inhibitor of both oncogenic and wild type RAS isoforms currently undergoing clinical investigation in various cancers.

Material and method

Loss-of-function approaches using RMC-6236, IAG933 (a YAP-TEAD interaction inhibitor), or siRNAs were employed to evaluate the impact of NRAS inhibition on phenotypic adaptation (RNA-seq, RT-qPCR, western blot analyses) as well as cell proliferation and survival (colony formation assay, flow cytometry) in human and murine NRAS-mutant cell line models. A murine melanoma model using MaNRAS cells grafted into syngeneic C57BL/6 mice was used to assess the effect of RMC-6236 on tumor growth and mouse survival.

Result and discussion

Our transcriptomic and proteomic analyses revealed that the anti-proliferative effect of RMC-6236 on NRAS-mutant melanoma cell lines is characterized by a phenotypic transition towards a less differentiated state, with increased expression of mesenchymal and extra-cellular matrix remodeling markers, along with the activation of a YAP-driven transcriptional signature and focal adhesion kinase (FAK) signaling. In vivo RMC-6236 slowed tumor growth and improved mouse survival. Melanoma cells treated with RMC-6236 in vivo exhibited reduced pigmentation and expressed mesenchymal and neural crest stem cell markers and YAP-target genes. The combination of RMC-6236 and IAG933 synergistically reduced proliferation, prevented phenotypic transition, and induced apoptosis in NRAS-mutant cells. These findings suggest that YAP-TEAD pathway inhibition by IAG933 targets the adaptive response induced by RMC-6236 and enhances treatment efficacy in vitro.

Conclusion

NRAS inhibition in melanoma cells induces a mesenchymal phenotypic transition linked to YAP pathway activation. YAP/TEAD inhibition can overcome resistance to NRAS inhibition by preventing adaptive phenotype switching and inducing tumor cell death. This work provides a scientific rationale for treating NRAS-mutant melanomas with a combination of RAS and YAP-TEAD inhibitors.

³*University of New South Wales, School of Biomedical Sciences, Sydney, Australia*

⁴*Children's Cancer Institute, Bioinformatics Network, Sydney, Australia*

⁵*Sydney Children's Hospital, Kids Cancer Centre, Sydney, Australia*

Introduction

The BRAFV600E mutation has been identified as a driver mutation in a subset of pediatric high-grade gliomas (pHGG). These tumors initially respond well to targeted BRAF and MEK inhibitors. Unfortunately, resistance inevitability develops, resulting in disease progression. There is limited understanding of the mechanisms underlying drug resistance in BRAFV600E pHGG, and no effective counter-therapies exist. This study aimed to identify drivers of resistance in BRAFV600E pHGG, enabling the identification of novel therapeutic targets.

Material and method

BRAF inhibitor-resistant, MEK inhibitor-resistant and BRAF+MEK inhibitor-resistant BRAFV600E pHGG cultures were derived through chronic exposure of a BRAFV600E patient-derived culture to vemurafenib (BRAFi), trametinib (MEKi) or a combination of both drugs, respectively. An omics-based approach (RNAseq/proteomics) was undertaken to identify mechanisms of resistance, allowing the subsequent identification of therapeutic targets.

Result and discussion

In vitro cytotoxicity assays confirmed the resistant nature of the BRAFV600E pHGG cultures. Similarly, dabrafenib (BRAFi)-treated animals orthotopically administered with the vemurafenib-resistant culture had significantly reduced survival compared to treated animals administered with the matched parental cells (65 days vs 79 days). All three resistant cell lines spontaneously transformed from a spheroid phenotype to adherent growth; proteomics pathway analysis correspondingly identified enrichment of extracellular matrix and cytoskeletal pathways. RNAseq identified >1500 differentially expressed genes in each resistant cell line, being enriched for neural development and plasma membrane/cell adhesion. Furthermore, the receptor tyrosine kinase (RTK) gene sets identified potent upregulation of several RTKs in vemurafenib-resistant cells, including NTRK2, SRC and EGFR, suggesting a key mediator of the acquired resistance and providing promising therapeutic targets. Repotrectinib (NTRK2/SRCi) and dacomitinib (EGFRi) were found to display potent synergistic activity when used in combination with vemurafenib (BRAFi) against both vemurafenib-resistant BRAFV600E pHGG cells and matched parental cells in vitro. EGFR/BRAF/MEK inhibition produced an even more potent triple combination therapy. Furthermore, scaffold proteins, integral to BRAF dimerisation, were also upregulated; the pan-RAF inhibitor, tovorafenib,

subsequently displayed potent synergy in combination with trametinib (MEKi).

Conclusion

This study has demonstrated that analyzing tumor mechanisms is a powerful tool for identifying effective therapies in treatment-refractory tumors. Using an omics-based approach in BRAFV600E pHGG, we have identified novel drivers of drug resistance, key therapeutic targets and several promising therapeutic options.

EACR25-0764

Targeting low fidelity polymerases to prevent acquired resistance mutations to EGFR-targeted therapy in lung cancer

M. Van Daele¹, H. Konsker¹, Y. Yarden¹

¹*Weizmann Institute of Science, Rehovot, Israel*

Introduction

Since the development of small-molecule inhibitors targeting mutated EGFR, lung cancer patients' outcomes have significantly improved. Nonetheless, tumors eventually develop resistance to these inhibitors, resulting in ineffective therapy and relapse. A major mechanism behind therapy resistance is the emergence of new mutations leading to amino acid substitutions in EGFR, such as T790M and C797S, which evade the inhibition. Although it is clear that EGFR-inhibitors cause an increased mutagenesis, the DNA damage mechanism behind the emergence of specific resistance mutations remain poorly understood. Aim: In this project, we study the role of low-fidelity polymerases (TLS) in the emergence of de novo resistance mutations in NSCLC.

Material and method

Frequency of resistance mutations was determined by digital droplet PCR (ddPCR); NSCLC cell lines were treated for 10 or 28 days with EGFR-TKI alone or combined with other pharmacological inhibitors. At appropriate time points, gDNA was harvested and subjected to ddPCR for T790M or C797S quantification using Taqman probes (BioRad). To determine cell viability, cells were incubated for 72h with the appropriate drug treatment, and cell viability was assessed by MTT assay. Gene expression levels were determined by RT-PCR. REV3L knock down was achieved by 2nd generation lentiviral transduction.

Result and discussion

We established an in vitro ddPCR assay to detect the mutations in a highly sensitive way, following their emergence over a 28-day time frame. As C797S was detected in several NSCLC cell lines prior to drug treatment, we are currently performing a fluctuation assay to distinguish colonies derived from pre-existing resistant clones, and de novo induced resistance mutations. Following TKI-exposure, REV3L, REV1 and other TLS polymerases were upregulated in PC9 cells. JH-RE06, a REV1-REV7 inhibitor that previously showed superiority in melanoma and colorectal cancer, did not affect the sensitivity of PC9 cells to erlotinib or osimertinib (MTT assay), however might prevent the emergence of resistance mutations. Similarly, REV3L and REV1 knockdown cell lines have been established,

and will be assessed for their mutability in response to EGFR-TKIs in vitro.

Conclusion

If our promising preliminary results of TLS inhibition preventing resistance mutations will be confirmed, *in vivo* PDX studies will be performed to further assess the efficiency of JH-RE06 to prevent relapses in NSCLC. This work will pinpoint new opportunities for drug development to overcome the current major drawback of anti-EGFR therapy and will overall aid in improving lung cancer patients' survival outcomes.

Targeting ErbB receptor family to intercept therapy adaptation in ALK-positive lung cancer

J. Tao¹, F. Bersani², F. Picca², H. Munir³, L. Giordanengo², V. Botta², M. Sornatale², P. Bironzo⁴, S. Novello⁴, R. Tauli²

¹University of Turin, Department of Oncology, Turin, China

²University of Turin, Department of Oncology, Turin, Italy

³University of Turin, Department of Oncology, Turin, Pakistan

⁴S. Luigi Gonzaga Hospital, Department of Oncology, Turin, Italy

Introduction

Anaplastic lymphoma kinase (ALK) translocations are found in about 3–5% of non-small cell lung cancer cases. Lorlatinib is a potent third-generation anti-ALK tyrosine kinase inhibitor (TKI) particularly effective in ALK-rearranged patients. Although lorlatinib is able to overcome acquired resistance to first- and second-generation ALK inhibitors, a fraction of patients treated in first line with this inhibitor rapidly relapse, suggesting early adaption to the third-generation TKI.

Material and method

ALK-rearranged H3122 cell line was interrogated by Human Phospho-RTK Array to define potential mechanisms of bypass signaling involved in adaptability to lorlatinib therapy. Western blot, Real-Time PCR, cell cycle and crystal violet analyses were performed to study and characterize the presence of drug tolerant cells upon lorlatinib treatment. H3122 cells were genetically engineered to express both Luciferase and EGFP (H3122-EGFP/Luc) for monitoring overtime the effects of single and combo regimens on drug tolerant cell survival and evolution.

Result and discussion

Lorlatinib treatment of H3122 cells resulted in growth arrest and apoptosis of the bulk population. However, a subpopulation, which we termed lorlatinib tolerant persisters (LTPs) rapidly emerged. LTPs were characterized by the upregulation, at the transcriptional and post-transcriptional level, of ErbB family members. The upfront combination treatment of the bulk population with the pan-ErbB inhibitor afatinib along with lorlatinib severely impacted on LTP viability. The long-term efficacy of single and combo regimens was then tested in hundreds of small pools of LTP-derived colonies that emerged upon lorlatinib treatment in 96-well plates. After

5 months of live cell tracking, the combination treatment completely eradicated 80% of LTP-derived colonies.

Conclusion

Overall, these data suggest that in a fraction of ALK-rearranged NSCLC tumors, drug tolerant cells could exploit ErbB signaling to overcome lorlatinib treatment. Targeting the ErbB family in combination with lorlatinib may represent a valuable therapeutic strategy to improve the clinical outcome of these patients by interfering with LTP survival and evolution.

EACR25-0797

The Role of NRG-1 in Resistance to Targeted Cancer Therapies in ERBB2-Amplified Breast Cancer

M. Karbasian¹, K. Kurppa¹, K. Elenius¹

¹1) MediCity Research Laboratories and Institute of Biomedicine, University of Turku 2) Turku Bioscience Centre, University of Turku and Åbo Akademi University, Turku, Finland

Introduction

Receptor tyrosine kinases (RTK) and their ligands frequently play a crucial role in oncogene-addicted cancers. Consequently, targeting RTKs has become a cornerstone of cancer therapy, significantly improving survival rates. However, both intrinsic and acquired resistance to RTK inhibitors present significant challenges, necessitating further research to optimize therapeutic strategies. Among the various mechanisms of resistance, the role of RTK ligands remains critical, yet underexplored. This study aims to investigate the impact of neuregulin-1 (NRG1), an ERBB3 ligand, as a micro-environmental factor that confers resistance to ERBB inhibitors in ERBB2-amplified breast cancer.

Material and method

To validate and quantify NRG1-induced resistance, ERBB2-amplified breast cancer cell lines (BT-474 and SKBR3) were treated with ERBB2-targeting tyrosine kinase inhibitors (TKI) and analyzed with various cell-based assays, protein analysis techniques, and functional genomics approaches. These included cytotoxicity assays, Western blotting, high-throughput phosphoprotein arrays, and kinase- and phosphatome-wide siRNA screening.

Result and discussion

In ERBB2-amplified breast cancer cell lines, the phenomenon of NRG1-induced resistance was recapitulated with various ERBB2-targeting TKIs. Based on the findings, ERBB3 appears to be the key player in NRG1-induced resistance, despite being widely recognized as a pseudokinase that requires ERBB2 for activation. Interestingly, our data suggest that ERBB3 remains active in the presence of NRG1, even when the phosphorylation of other ERBB family members (EGFR, ERBB2, and ERBB4) is effectively inhibited by a pan-ERBB inhibitor such as neratinib. We hypothesize that NRG1-ERBB3-induced resistance may occur independently of ERBB2 activation, potentially involving previously uncharacterized kinase signaling pathways.

Conclusion

These findings highlight a critical mechanism of resistance that could inform the development of more effective therapeutic strategies.

EACR25-0897**Unraveling the Hidden Player: miR-188-5p at the Crossroads of DDR and PARP****Inhibitor Resistance in Ovarian Cancer**

E. Aydin¹, B. Giray², D. Vatansever², C. Taskiran², I. Sahin^{2,1}

¹Koç University, Research Center for Translational Medicine (KUTTAM), Istanbul, Turkey

²Koç University, School of Medicine, Istanbul, Turkey

Introduction

MicroRNAs (miRNAs) play a critical role in chemo-resistance to poly(ADP-ribose) polymerase (PARP) inhibitors by modulating DNA damage response (DDR) pathways. PARP inhibitors (PARPi) induce synthetic lethality in homologous recombination (HR)-deficient tumors, particularly BRCA1/2-mutant ovarian cancers. However, resistance emerges through mechanisms such as HR restoration and activation of alternative DNA repair pathways. While the role of miR-188-5p in DDR and PARPi resistance remains unclear, previous studies suggest its involvement in tumor progression via the AKT/mTOR pathway. However, its specific role in high-grade serous ovarian cancer (HGSOC) is largely unexplored. This study aims to elucidate the regulatory network of miR-188-5p and its potential as a therapeutic target in PARPi-resistant HGSOC.

Material and method

To identify differentially expressed miRNAs in drug-resistant versus sensitive ovarian cancer models, we performed microarray and qRT-PCR analyses on in vitro and ex vivo cultured cells, as well as formalin-fixed paraffin-embedded (FFPE) patient samples [1]. Olaparib (Lynparza®)-resistant cell lines were transfected with miR-188-5p mimics using Lipofectamine®. Apoptosis and DDR mechanisms were assessed via Annexin-V/PI staining (flow cytometry), p-H2AX immunofluorescence staining, and expression analysis of DDR and apoptosis-related genes/proteins using Western blot and qPCR.

Result and discussion

miR-188-5p expression was significantly downregulated in olaparib-resistant OVCAR-3 cells, resistant FFPE HGSOC patient samples, and ex vivo patient-derived cultures. Combination therapy with olaparib and miR-188-5p mimics resensitized resistant cells in vitro and ex vivo, inducing apoptosis via caspase cascade activation, as evidenced by an increase in cleaved-caspase-3 and cleaved-PARP expression. Western blot analysis revealed decreased p-AKT levels in miR-188-5p mimic-transfected resistant cells, indicating suppression of survival pathways. This AKT inhibition led to Bid and Bim upregulation, promoting mitochondrial apoptosis. Additionally, p-AKT suppression triggered ATR phosphorylation, enhancing γ-H2AX-mediated DDR activation.

Conclusion

This study provides new insights into miRNA-mediated drug resistance mechanisms and their potential for enhancing PARP inhibitor efficacy in HGSOC. Our findings suggest that miR-188-5p re-expression restores DDR activation and apoptosis, overcoming chemo-resistance. These results highlight the therapeutic potential of miRNA-based strategies to improve patient

outcomes and combat chemotherapy resistance in clinical settings. The authors declare no financial conflicts of interest related to this study.

EACR25-0923**Decoding drug resistance in cervical cancer cell lines: an AKT-independent mechanism**

N. Bou Antoun¹, R. Grose², H. Modjtahedi¹, A. Walker¹, A. Chioni¹

¹Kingston University London, Biomolecular Sciences Department, London, United Kingdom

²Queen Mary University of London, Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom

Introduction

Activation of the Fibroblast Growth Factor Receptor (FGFR) axis is important in cell proliferation, differentiation, migration and cell survival and its aberrant signalling is associated with cancer progression and drug resistance. The Aim of this study was to identify mechanisms of drug resistance in cervical cancer by generating three drug resistant (DR) human cervical cancer cell lines (HCCCL; Caski, HeLa and SiHa) to an FGFR inhibitor, PD173074 (PD).

Material and method

Transcriptomic analysis was performed to detect differentially expressed genes (DEGs) and protein-protein interactions between DR and parental HCCCLs. Findings were validated and signalling pathways further investigated via PCR, immunocytochemistry and western blot. The functional effect of altering these signalling pathways were assessed by cell proliferation, apoptosis and migration assay.

Result and discussion

Transcriptome analysis identified several DEGs in DR HCCCL. Protein-protein interaction modelling revealed that integrin alpha 2 interacts with the products of most DEGs shared by all three DR HCCCL. Phosphorylated FAK was localised in both cytoplasm and nucleus and increased in all three DR HCCCL compared to parental counterparts. In addition, in DR cells, integrin alpha 2 mainly localised to the cytoplasm, unlike the parental cells in which it was cell surface expressed. However, they exhibited higher levels of cytoplasmic expression compared to parental. Biochemical studies revealed no difference in AKT phosphorylation at either Ser(473) or Thr(308) sites in the presence or absence of PD after FGF2/4/7 stimulation in both parental and DR cells. However, Phospho-S6 was more abundant in DR cell lines compared to parental, independent of PD treatment. FAK phosphorylation and integrin alpha 2 protein levels were higher in all DR cells. FGF2 stimulation, in the presence of a FAK inhibitor, abolished FAK phosphorylation in parental cells, but it remained unchanged with or without inhibitor in all DR cells. S6 phosphorylation was elevated in DR cell lines compared to parental, with or without FAK inhibitor treatment. Interestingly, after FGF2 stimulation, phosphorylation of S6 was abolished in parental cells upon mTORC1 inhibition but remained unchanged in all DR cells.

Conclusion

Our findings suggest that activation of FAK and AKT independent mTOR pathways, as well as integrin alpha 2 protein expression, might play a key role in mediating drug resistance in HCCCLs.

EACR25-0975

Rituximab resistance shapes sensitivity to effector-cell mediated cytotoxicity in B-cell lymphoma

A. Kusowska^{1,2,3}, D. Kalińska-Lysiak^{4,5}, S. Wingert⁶, C. Watzl⁶, M. Winiarska³, M. Bobrowicz⁷

⁷*Medical University of Warsaw, Department of Internal Medicine and Endocrinology, Warsaw, Poland*

Introduction

For over 30 years, rituximab (RTX) has played a pivotal role in the immunotherapy of CD20-positive B-cell lymphomas. Despite its efficacy, resistance develops in over one-third of patients, posing a significant clinical challenge. Although extensively studied, the mechanisms underlying RTX resistance remain unclear. Notably, our characterization of RTX-resistant cell lines revealed reduced sensitivity to effector-mediated cytotoxicity. This study aimed to identify molecular mechanisms responsible for this decreased sensitivity in response to effector cells such as NK and CAR-T cells.

Material and method

Three established B-cell lymphoma cell lines (SU-DHL4, Raji, RL) with acquired RTX resistance were used as in vitro models. Fluorochrome-conjugated antibodies were used to assess changes in the expression of activating and inhibitory ligands, adhesion molecules, and death receptors on the surface of these cells. Sequential stages of recognition and killing by primary NK and NK92 cells were analyzed using flow cytometry-based methods to evaluate degranulation, conjugate formation, and detachment. NK cell cytotoxicity was assessed with inhibitors targeting perforin (concanamycin A), granzyme B (3,4-dichloroisocoumarin), caspases (zVAD), and caspase 8 (z-IETD). RNA sequencing was employed to identify differentially expressed genes and signaling pathways.

Result and discussion

RTX-resistant cell lines exhibited heterogeneous surfaceome alterations:

- (i) key NK cell activating ligands (MICA/B, ULBPs, PVR, CD112, B7H6) were either unchanged or absent;
- (ii) among inhibitory ligands, only MHC class I was upregulated but did not affect NK cell sensitivity; and

(iii) adhesion molecules (CD54, CD58, CD59, CD102) and death receptors (TRAIL-R, Fas) varied across cell lines.

These alterations did not contribute to reduced sensitivity to effector cells. NK and NK92 cells retained their ability to degranulate, form conjugates, and detach from RTX-resistant cells at levels comparable to wild-type counterparts, indicating intact target-effector interactions. Studies with selective inhibitors demonstrated that NK cell mediated cytotoxicity primarily depends on degranulation and effective delivery of perforin and granzyme B. RNA sequencing further revealed differentially expressed apoptosis-related signaling pathways, with key resistance-associated proteins, including Bax, Bak, and Bcl-2 family members, involved in mitochondrial apoptosis.

Conclusion

Decreased sensitivity of RTX-resistant B-cell lymphoma cell lines to effector cells is driven by deregulation of apoptosis-related pathways, rather than defects in target effector cell interactions.

EACR25-0984

Inhibition of the extracellular signal-regulated kinase 5 (ERK5) increases EGFR expression and its nuclear localization in HCC, generating new targeting opportunities

A. Menconi¹, I. Tusa¹, F. Marra², E. Rovida¹

¹*University of Florence, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Florence, Italy*

²*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy*

Introduction

Hepatocellular Carcinoma (HCC) is the most common form of liver cancer and accounts for 90% of cases. Nonetheless, available molecular-targeted therapies are still unsatisfactory, so additional therapeutic targets must be identified. The extracellular signal-regulated kinase 5 (ERK5) is a member of the Mitogen-Activated Protein Kinases (MAPK) family, and is highly expressed in hepatocytes, and its gene has been reported to be amplified in HCC. Moreover, we recently reported that ERK5 regulates the development and growth of HCC, so that ERK5 targeting appears as a promising approach for the treatment of this type of cancer.

Material and method

The aim of this study was to investigate the interplay between ERK5 and EGFR using two hepatocellular carcinoma cell lines, Huh7 and HepG2. Gene silencing was performed with short hairpin RNA for ERK5. For the pharmacological treatments, ERK5 (JWG-071), EGFR (Gefitinib) α/β importin (Ivermectin) inhibitors effects were evaluated after 72h of treatment in term of cell viability using MTT assay. The mRNA expression was analyzed using quantitative RT-PCR. Protein expression levels and intracellular localization were detected by Western blot and immunofluorescence in confocal microscopy.

Result and discussion

We found that ERK5 knock down (KD) increases EGFR mRNA and protein levels, and downstream PI3K/AKT activation. Furthermore, the amount of EGFR protein was increased in cells treated with the ERK5 inhibitor, JWG-071, compared to control cells. The combination of JWG-071 and the EGFR inhibitor Gefitinib resulted to be more effective than single treatments in reducing cell viability and 3D spheroid growth in both cell lines. In addition, nuclear EGFR was higher in ERK5-KD cells compared to controls. Since EGFR shuttles to the nucleus via the α/β importin system, we performed combined treatment of JWG-071 and the α/β importin inhibitor, Ivermectin. This cotreatment showed a higher anti-proliferative effect than single drugs on HCC cell lines.

Conclusion

In conclusion, these results revealed new potential therapeutic strategies to explore for the treatment of HCC.

EACR25-0987

Crosstalk between oncogenic signaling pathways as driver of therapy resistance against small molecule inhibitors in Glioblastoma

M. van Heumen¹, L. Hoosemans¹, B. Olaszkiewicz¹, A. Hoeben², M. Vooijs³

¹*Maastricht University Medical Center+, Department of Radiation Oncology (MAASTRO), GROW School for Oncology and Reproduction, Maastricht, Netherlands*

²*Department of Medical Oncology, GROW School for Oncology and Reproduction, Maastricht, University Medical Center+, Maastricht, Netherlands*

³*Maastricht University Medical Center+, University Medical Center+, Maastricht, Netherlands*

Introduction

Glioblastoma (GBM) is the most prevalent primary brain tumor in adults, with a median survival of 14 months despite multimodal treatment. Small molecule inhibitors (SMIs) targeting mutational drivers, such as the RAS/MEK/ERK-pathway, offer potential therapeutic avenues, yet clinical trials have not improved GBM survival outcomes. Using patient-derived GBM models (pdGBMs), we evaluated the cytotoxicity of SMI mono- and combi therapy and explored aberrant signaling pathways driving treatment resistance. Our analysis specifically focused on combinations with trametinib, which demonstrated the highest cytotoxic potential.

Material and method

Eight BBB-penetrable and clinically approved SMIs were used to target key GBM driver oncogenes. Cell viability was measured via CellTiter-Glo and the IC₅₀ for each inhibitor was determined for six molecularly distinct pdGBMs. Changes in phosphokinase activity after SMI monotherapy were assessed via WB and phosphokinase screening. Based upon these results, SMI combinations were made, targeting compensatory pathways driving treatment resistance. Bliss scores were established to test synergistic SMI combinations.

Result and discussion

SMIs targeting downstream effector kinases (Trametinib, Buparlisib, Abemaciclib; IC₅₀ 70nM-1μM) or

membrane-bound tyrosine kinase receptors (Afatinib, Capmatinib, Axitinib; IC₅₀ 1-15μM) reduced cell viability. However, residual cell proliferation was seen in all pdGBMs following single-agent SMI treatment, indicative for clonal expansion of treatment resistant tumor cells. Western blot analysis confirmed on-target drug activity. Subsequently, MEK-inhibition with trametinib induced compensatory signaling, including MEK/AKT-crosstalk, JNK/c-JUN upregulation and most notably MEKSer221 hyperphosphorylation. Combined trametinib and SP600125 (JNKi) mitigated JNK/c-Jun activation and synergistically reduced cell viability (Bliss >20), but failed to suppress MEKSer221 hyper-phosphorylation. In a small-scale SMI drug screen, trametinib combined with VEGFRi, axitinib significantly abrogated MEKSer221 hyperphosphorylation and led to a synergistic reduction in cell viability (Bliss >20). In contrast, co-treatment with Afatinib (EGFRi) or CHIR99021 (GSK3βi) did not exhibit synergistic effects (Bliss <10).

Conclusion

Trametinib reduces cell viability but triggers compensatory signaling, including MEKSer221 hyperphosphorylation. This study presents a mechanistically driven selection of tumor-tailored combination treatments to overcome resistance to SMI monotherapy in pdGBM models, highlighting VEGFR co-inhibition as a promising combinatorial strategy with trametinib.

EACR25-1015

Targeting Drug Resistance in Hepatocellular Carcinoma: Uncovering Metabolic Vulnerabilities for Therapeutic Re-Sensitization

D. Halilovic¹, C. Haan¹, C. Rolvering¹, M. Kirchmeyer¹, I. Behrmann¹

¹*University of Luxembourg, Department of Life Science and Medicine, Esch-sur-Alzette, Luxembourg*

Introduction

Hepatocellular carcinoma (HCC) is the most common form of primary liver cancer, often arising from chronic liver inflammation due to hepatitis B virus, hepatitis C virus, alcohol-related liver disease (ALD), or metabolic-dysfunction-associated steatotic liver disease (MASLD). Current treatment options for advanced HCC include multi-kinase inhibitors (e.g., Lenvatinib, Sorafenib and Regorafenib) and immune checkpoint inhibitors, but these therapies are limited by drug resistance, which significantly reduces patient survival. Identifying novel vulnerabilities in resistant HCC cells is crucial to restoring treatment efficacy.

Material and method

To model drug-resistant HCC, three HCC cell lines (Hep3B, Huh7, Huh1) were adapted to a modular physiologic medium (MPM) recently established in our lab, providing a more physiologically relevant culture system. Dose-response experiments in the presence of key growth factors were performed to determine sensitivities to five kinase inhibitors: Lenvatinib, Sorafenib, Regorafenib, Roblitinib, and Erdafitinib, the latter two being fibroblast growth factor receptor inhibitors currently in clinical trials. To mimic tumour

conditions, HCC-oriented media enriched with growth factors were optimized to promote spheroid formation.

Result and discussion

Initial results demonstrated that MPM adaptation altered drug response patterns, underscoring the importance of physiologically relevant conditions. Next steps include the screening of a metabolism-oriented library to highlight metabolic vulnerabilities that could be leveraged to overcome resistance. The screen will identify promising candidate compounds capable of re-sensitizing resistant cells to kinase inhibitors. Further, advanced 3D models incorporating extracellular matrix, hypoxia, and other cell types (fibroblasts and endothelial cells) will be utilized to refine therapeutic windows and validate drug combinations in conditions that better reflect the tumour microenvironment.

Conclusion

This study aims to provide a framework for targeting metabolic vulnerabilities in HCC, offering potential new therapies to enhance treatment efficacy and to break or delay drug resistance. By integrating physiologically relevant culture systems and metabolic reprogramming strategies, future findings could contribute to the development of more effective interventions for overcoming therapeutic resistance in HCC.

EACR25-1057

Investigating estrogen receptor fusion proteins as a mechanism of resistance to endocrine therapies in breast cancer

A. Alataki¹, N. Koenig¹, Y. Leung¹, C. Coombes¹, L. Buluwela¹, S. Ali¹

¹Imperial College London, Department of Surgery & Cancer, London, United Kingdom

Introduction

Breast cancer is the most common cancer worldwide, with approximately 80% of cases classified as estrogen receptor-positive (ER+). In these cancers, estrogen activates ER, driving tumour growth through gene regulation. Endocrine therapies (ET) targeting ER are the standard-of-care treatment for ER+ breast cancer. However, over 20% of patients develop drug-resistant disease, highlighting the need for alternative therapeutic strategies. Chromosomal translocations involving ESR1, the gene encoding ER, have emerged as a resistance mechanism. These translocations generate ER fusion proteins that lack the ligand-binding domain, making them insensitive to ET, including selective ER down-regulators (SERDs), such as fulvestrant. Understanding the mechanisms of action of ER fusion proteins will be essential for developing appropriate therapeutic approaches.

Material and method

Towards this end, we have generated breast cancer cell lines expressing the ESR1-YAP1 fusion using CRISPR/Cas9 genome editing. RNA sequencing was performed on these models alongside wild-type ESR1 cells treated with fulvestrant or vehicle-control. Differential gene expression was analysed using DESeq2 and gene set enrichment analysis using Hallmark and breast cancer-specific gene sets identified enriched pathways. Heatmaps were generated using pheatmap with hierarchical

clustering and Z-score normalisation. Growth assays assessed cell proliferation in response to ET.

Result and discussion

ESR1-YAP1 fusion clones showed reduced expression of estrogen response gene sets, suggesting reduced estrogen-driven transcription, while showing positive enrichment for proliferation gene sets, indicating enhanced ligand-independent growth signalling. In fulvestrant-treated cells, the expression of estrogen-responsive genes was maintained in ESR1-YAP1 cells, whereas it was reduced in ESR1 wild-type cells. Consistently, the growth of ESR1-YAP1 cells was refractory to inhibition by ETs, including fulvestrant.

Conclusion

Our work underscores the potential role of ER fusions in mediating resistance to ET in breast cancer. Such models represent powerful isogenic models for investigating mechanisms by which ESR1 fusion genes drive breast cancer cell growth and offer the potential for identifying alternative treatment strategies following the emergence of ER fusion-directed resistance to ETs.

Increased Sensitivity to BCL-2 Inhibition in EGFR-TKI Resistant NSCLC Cell Lines

S. Weller¹, M. Jares¹, T. Beigl¹, J. Wiepcke¹, T. Löschmann¹, H. Kopp², F. Essmann¹

¹Robert Bosch Center for Tumor Diseases, Stuttgart, Germany

²Robert-Bosch-Hospital, Stuttgart, Germany

Introduction

Among cancer entities lung cancer ranks first in incidence and mortality, with ~85% of cases classified as non-small cell lung cancer (NSCLC). In lung cancer, driver mutations are commonly found in receptor tyrosine kinases with Epidermal Growth Factor Receptor (EGFR) constituting the major driver of oncogenesis (29%, Chevallier et al. 2021). Mutant EGFR is targeted by multiple specific tyrosine kinase inhibitors (RTKis) for anti-cancer therapy. Therapy resistance against such RTKis and subsequent disease progression occurs frequently and remains a severe challenge. A promising approach to overcome resistance is the combination of RTKi with BH3-mimetics or proteasome inhibition (Muenchow et al. 2021, Tanimoto et al. 2021, Weller et al. 2022). The proposed mechanism is the induction of NOXA, which inhibits the anti-apoptotic Bcl-2 protein MCL-1. In this study, we assess the role of BCL-2 proteins in RTKi resistance in NSCLC cell lines and the effect of direct BCL-2 inhibition.

Material and method

NSCLC cell lines of differing EGFR mutation status (HCC4006 [ex19del] and H1975 [L858R/T790M]) were cultured in the presence of EGFR-TKI osimertinib (OSI) to generate EGFR-TKI resistant cell lines. Successful generation of resistance was verified via flow cytometric analysis of apoptotic cell death induction and via live-cell imaging-based proliferation assessment. Expression of Bcl-2 proteins was analyzed by RNAseq and Western Blot. Cells were incubated with OSI and/or Bcl-2 inhibitors and apoptotic cell death induction as well as cell viability were measured by flow cytometry and luminescence-based assays.

Result and discussion

RNAseq revealed an upregulation of BCL-2 in the RTKi resistant cell lines and derived clonal cell lines suggesting a resistance mechanism. We found resistant cell lines to be more sensitive to apoptosis induction via BCL-2 inhibition than parental cells, highlighting their dependency on anti-apoptotic proteins. Especially BCL-xL- and MCL-1-specific inhibitors demonstrated strong efficacy in combination with RTKi in NSCLC cells and RTKi-resistant NSCLC cells. Furthermore, combination of osimertinib with BCL-2i was sufficient to overcome RTKi resistance likely mediated by BCL-2 overexpression.

Conclusion

We find that RTKi resistant NSCLC cell lines show increased sensitivity towards inhibition of Bcl-2 proteins and that RTKi resistance of NSCLC cells is overcome through inhibition of these proteins by specific Bcl-2 inhibitors. These findings represent a general therapeutic approach that relies on the simultaneous blockade of driver mutation mediated EGFR activity and survival-promoting Bcl-2 proteins.

EACR25-1107

SPOCK1 is Linked to Mesenchymal-like Features and Drug Resistance in Melanoma Cells Treated with BRAF and MEK Inhibitors

C. Solé-Blanch¹, T. Montserrat², A. de la Puente¹, S. España³, O. Marin-Bejar¹, A. Esteve-Codina², J. Manzano³, A. Martínez-Cardús¹

¹Institut Germans Trias i Pujol, Badalona, Spain

²CNAG, Barcelona, Spain

³Catalan Institute of Oncology (ICO)- Medical Oncology Service, Badalona, Spain

Introduction

In cutaneous melanoma, 52% of cases harbour mutations in the BRAF gene. Although targeted therapy, which involves the combination of BRAF and MEK inhibitors (BRAFi+MEKi), has revolutionized the treatment of BRAF-mutated melanoma, most patients experience disease progression within 8–12 months due to acquired drug resistance. Additionally, there are poor responders to immunotherapy-based second-line treatments. Understanding resistance mechanisms is thus of significant clinical interest. A previous study, using an *in vitro* resistance model revealed that BRAFi+MEKi resistance acquisition involves the enrichment of clones over-expressing genes characteristic of invasive and mesenchymal-like phenotypes, such as SPOCK1. Hence, our aim is to elucidate the role of SPOCK1 as biomarker and potential therapeutic vulnerability in resistance acquisition scenario.

Material and method

SPOCK1 RNA expression was analysed *in silico* in other melanoma BRAFi+MEKi resistant *in vitro* models (GSE134432 and GSE75299) and in melanoma tissue before treatment and at progression (GSE77940 and GSE61992). Additionally, an *in vitro* SPOCK1 knock-down was established using shRNA technique and functional studies of resistance reversion, proliferation,

migration and invasion were performed by using MTT, wound-healing and transwell assays.

Result and discussion

In silico analysis corroborated that SPOCK1 gene expression was increased in other melanoma cell lines resistant to targeted therapy. Furthermore, SPOCK1 expression was mainly higher in the resistant tumours compared to the basal ones. Functional *in vitro* analyses revealed that inhibiting the SPOCK1 gene did not reverse resistance to BRAF+MEK inhibitors, suggesting that SPOCK1 does not directly contribute to the molecular processes underlying resistance acquisition. However, SPOCK1 inhibition significantly reduced cell proliferation, migration, and invasion, suggesting its potential role in mesenchymal phenotype development and as a therapeutic vulnerability. Nevertheless, further studies in advanced preclinical models are guaranteed.

Conclusion

SPOCK1 is identified as a biomarker of acquired resistance to BRAFi+MEKi and it postulates as potential therapeutic vulnerability in resistance acquisition context.

EACR25-1127

Combinatorial assessment of DXd-based antibody drug conjugates with DNA damage response inhibitors in ovarian and endometrial cancers

Y. Li¹, L. Stockmann¹, L. Tschirner¹, J. Crown², N. Conlon¹

¹Dublin City University, Life Sciences Institute, Dublin, Ireland

²St. Vincent's Hospital, Dublin, Ireland

Introduction

Antibody-drug conjugates (ADCs) provide a novel treatment modality for target anti-cancer drug delivery. In this study, we investigated the *in vitro* efficacy of ADC-containing drug combinations in ovarian (OC) and endometrial (EC) cancers. As TROP2 and HER2 are commonly over-expressed in OC and EC, respectively, the TROP2 targeting datopotamab deruxtecan (Dato-DXd) and HER2-targeting trastuzumab deruxtecan (T-DXd) were chosen. As both ADCs use a potent topoisomerase I inhibitor payload (DXd), which induces irreparable DNA double-strand breaks, we aimed to uncover potential synergies between Dato-DXd and T-DXd and DNA damage response inhibitors (DDRIs), targeting ATM (AZD1390) and ATR (AZD6378), and chemotherapeutic agents in 2D cancer cell models. This study aimed to determine the potential of DXd-ADCs in combination with DDRIs and current first line chemotherapies.

Material and method

This study utilised a panel of six OC (PEO1, PEO4, IGROV-1, SKOV3, OVCAR4, COV318) and three EC lines (AN3CA, HEC1B, MFE280) cell lines. The anti-proliferative effects of Dato-DXd and T-DXd was assessed in their respective panels by 5-day acid phosphatase assay. Synergy with the DDRIs, AZD1390 and AZD6378, and chemotherapies, carboplatin and paclitaxel, were assessed by matrix proliferation assays

and analysed by Combenefit software. TROP2 and HER2 protein expression was examined by Western blotting.

Result and discussion

Dato-DXd showed single agent efficacy in the three highest TROP2 expressing OC cell lines (PEO1, PEO4, OVCAR4). Dato-DXd demonstrated synergy with carboplatin in these three cell lines and additivity in the lower TROP2 expressing cell lines. Paclitaxel did not enhance the anti-proliferative effect of Dato-DXd in the OC panel. However, synergy was observed across all cell lines with AZD1390 and in 4/6 cell lines with AZD6738. MFE280 showed the highest HER2 expression and sensitivity to T-DXd. Both AZD1390 and AZD6738 plus T-DXd were synergistic in all cell lines and outperformed carboplatin and paclitaxel.

Conclusion

Our findings indicate that combining Dato-DXd and T-DXd with specific DDR inhibitors potentially enhances anti-tumour activity in ovarian and endometrial cancer models, which offers potential pathways for clinical translation. These combinations, particularly those involving ATM and ATR inhibitors, support the need for further investigation in clinical settings.

Unraveling Therapeutic Resistance in Patients with Early-Stage HER2-Negative Breast Cancer in the I-SPY2 Clinical Trial

T. But^{1,2}, D. Wolf¹, R. Sayaman¹, C. Yau³, J. P. Coppé⁴, L. Brown-Swigart¹, L. Pusztai⁵, L. Esserman³, E. Petricoin⁶, L. Van 't Veer¹

³University of California San Francisco, Department of Surgery, San Francisco, United States

⁴University of California San Francisco, Department of Radiation Oncology, San Francisco, United States

⁵Yale School of Medicine, Yale Cancer Center, New Haven, United States

⁶George Mason University, Center for Applied Proteomics and Molecular Medicine, Manassas, United States

Introduction

We previously established Responsive Predictive Subtypes (RPS) using pre-treatment gene expression (GE), reverse-phase protein array (RPPA), and clinical data from ~990 breast cancer patients of the I-SPY2 neoadjuvant platform trial (NCT01042379) that can guide treatment selection to maximize pathologic complete response (pCR) rates with subtype-matched therapies (Wolf et al, Cancer Cell 2022). Tumors of 29% of patients in the I-SPY2 cohort were characterized by low expression of immune genes and no DNA repair deficiency (DRD) (HER2-/Immune-/DRD-) and these patients experienced very low pCR rates with any modern therapy. The goal of our current analysis is to identify targetable biological processes that could improve treatment sensitivity in these cancers.

Material and method

Published transcriptomic and (phosho)protein I-SPY2-990 data were analyzed for enrichment of canonical

signaling pathways (Molecular Signatures Database gene sets, n = 2152) and epigenetic modulator genes (n = 94) to study two subsets of HER2-/Immune-/DRD- tumors: 1) hormone receptor-positive, HER2-negative (HR+ HER2-)/Immune-/DRD- (n = 191) vs. other HR+HER2-tumors (n = 185), and 2) triple-negative (TN)/Immune-/DRD- (n = 93) vs. other TN tumors (n = 270).

Comparisons were made using Wilcoxon rank sum tests, with p-values adjusted for multiple comparisons using the Benjamini-Hochberg method. All reported results have adjusted p-values <0.05.

Result and discussion

HER2-/Immune-/DRD- tumors had lower expression of a broad range of biological processes, measured by both GE and RPPA. HR+HER2-/Immune-/DRD- tumors, specifically, had low expression of proliferation signatures compared with other HR+HER2- tumors, whereas TN/Immune-/DRD- had similar proliferation levels compared with other TNs, reflecting subtype-specific differences. Interestingly, HER2-/Immune/DRD-tumors of both subtypes expressed higher levels of many epigenetic modulator genes, including HDACs and KATs, suggesting that epigenetic silencing may play a role in these non-responsive tumors. Moreover, both HER2-/Immune-/DRD- subtypes had higher enrichment of Wnt/beta-catenin, Hedgehog, TGF-β/Smad, and PPARγ signaling pathway gene sets compared with other tumors. Additionally, higher ER, pAR, and Cyclin D1 signaling (by GE and RPPA) were found in HR+HER2-/Immune-/DRD-, which previously have been associated with low proliferation and non-response.

Conclusion

HER2-/Immune-/DRD- resistant tumors are characterized by low expression of many cancer-relevant biological processes, including proliferation in HR+HER2/Immune-/DRD-, though HER2-/Immune-/DRD- cancers have higher expression of Wnt/beta-catenin, Hedgehog, TGF-β/Smad, PPARγ and AR pathways and epigenetic modulator genes known to participate in gene silencing. Our findings suggest potential novel targetable vulnerabilities to increase treatment sensitivity in these treatment-resistant tumors.

Introduction

The alpha isoform-specific PI3K inhibitor Alpelisib improved the treatment outcomes for hormone receptor-positive, Her2-negative, and PIK3CA-mutated metastatic breast cancer patients. However, the emergence of resistance, often due to aberrant activation of the mTOR complex 1 (mTORC1) pathway, presents a significant clinical challenge. This study investigates targeting mTORC1-induced metabolic vulnerabilities in Alpelisib-resistant breast cancer.

Material and method

We compared therapy-naïve and Alpelisib-resistant PIK3CA-mutated breast cancer cells, T47D and MCF7, in response to the metabolic inhibitors dichloroacetate (DCA) and Metformin using competitive co-cultures, proliferation, cell viability, and apoptosis assays. The mTOR-dependence of metabolic drug responses was analyzed with mTOR kinase inhibitors. The role of autophagy in energetic homeostasis under metabolic perturbation was examined through untargeted metabolomics, autophagy flux analyses, fluorescence microscopy, western blot analyses, and CRISPR/Cas9-generated autophagy-knockout cells. The efficacy of metabolic compounds in eradicating PI3Ki-resistant and CRISPR/Cas9-engineered autophagy-deficient breast cancer cells was tested in vivo using an orthotopic xenograft mouse model. Immunohistochemistry was used to analyze a tissue microarray (TMA) from the breast cancer patient GAIN cohort to correlate overall survival with phosphorylation of the mTORC1 target 4E-BP1T37/46 and accumulation of the autophagy cargo protein p62/SQSTM1 as potential biomarkers for metabolic therapy response.

Result and discussion

Alpelisib-resistant PIK3CA-mutated breast cancer cells exhibited increased sensitivity to metabolic inhibitors due to mTORC1 activation, which promoted Alpelisib-resistance while inhibiting autophagy. In resistant and autophagy-knockout cells, metabolic inhibitors induced severe energy stress, leading to a critical depletion of aspartate, and ultimately apoptosis, whereas therapy-naïve breast cancer cells survived via autophagy both in vitro and in vivo. TMA analyses identified a correlation between 4E-BP1T37/46 phosphorylation and p62/SQSTM1 accumulation, with their combination serving as a biomarker for poor survival in hormone receptor-positive, Her2-negative breast cancer patients.

Conclusion

This study reveals that mTORC1 upregulation, a common cause of Alpelisib-resistance in breast cancer, creates vulnerabilities to metabolically active drugs by suppressing autophagy, and identifies the combination of 4E-BP1T37/46 and p62 as a biomarker for poor survival, indicating potential for identifying patients who may benefit from metabolic therapies in a novel precision medicine approach.

Introduction

Sorafenib, a multi-target tyrosine kinase inhibitor for advanced hepatocellular carcinoma (HCC), provides only modest survival benefits due to acquired resistance. In our previous work, the novel platinum-based drug, [PtII (C^NN)(NHC₂Bu)]PF₆ (Pt1a), has demonstrated anti-cancer properties by targeting the epithelial-mesenchymal transition marker vimentin. As vimentin is a known mediator of sorafenib resistance, we investigated whether Pt1a can sensitize HCC cells to sorafenib.

Material and method

HCC cell lines and patient-derived organoids were used to assess the inhibition effect induced by the single or combination drug treatment of sorafenib and Pt1a in vitro, whereas the subcutaneous injection of HCC patient-derived xenograft and proto-oncogene (NRAS+ AKT)-driven HCC was employed as the in vivo mouse model. Thermal proteome profiling (TPP) was utilized to evaluate the interaction of the small molecule drugs with proteins. RNA sequencing (RNA-seq) was performed to explore the transcriptomic changes following different

drug treatments while glyoxal and nitrite-mediated deamination of unmethylated adenosines sequencing (GLORI-seq) was conducted to assess the RNA m6A levels at single base resolution. Pathway analysis of HCC datasets or in-house sequencing data was carried out by GO and GSEA analysis methods.

Result and discussion

In cultured HCC cells and patient-derived organoids, the combination of sorafenib and Pt1a synergistically reduced cell viability, attenuated self-renewal, and promoted cell apoptosis compared to single-drug treatment. In contrast, this synergistic effect was not observed in an immortalized human hepatocyte cell line. These findings were further validated in patient-derived xenograft and NRAS+AKT-driven HCC mouse models. Notably, in the NRAS+AKT-driven HCC mouse model, the combination of sorafenib and Pt1a demonstrated superior efficacy compared to anti-VEGF-A combined with anti-PD-L1 antibodies treatment, which is the current first-line treatment for HCC. Mechanistically, RNA-seq and TPP revealed enrichment of m6A-related pathways under combination treatment, with an elevated m6A level confirmed by m6A dot blotting. The m6A writer METTL14 was identified as a potential mediator of the synergistic effect through functional CRISPR-knockout experiments. Deregulated genes identified from RNA-seq, in common with genes containing m6A modification sites identified from GLORI-seq, were used to generate a combined signature, which predicted a better prognosis in HCC patients.

Conclusion

Our findings suggested Pt1a could synergize with sorafenib to inhibit HCC through METTL14-mediated m6A modification. This research provides valuable insights into the potential of Pt1a to overcome sorafenib resistance and opens avenues for novel treatment strategies for HCC.

EACR25-1275

SOAT1 Promotes Methotrexate Resistance in Choriocarcinoma

M. Zheng¹, W. Lu¹

¹*Women's Hospital, Zhejiang University School of Medicine, Department of Gynecological Oncology, Hangzhou, China*

Introduction

Choriocarcinoma (CC), a highly aggressive subtype of gestational trophoblastic neoplasia, is generally characterized by favorable responses to methotrexate (MTX)-based chemotherapy. Nevertheless, a subset of patients experience disease recurrence or MTX resistance after initial treatment. The molecular mechanisms of MTX resistance remain unclear, so further research to optimize clinical management is imperative. Our study identifies sterol O-acyltransferase 1 (SOAT1), a pivotal enzyme in cholesterol esterification, as a critical mediator of MTX resistance in CC.

Material and method

Transcriptomics combined with bioinformatics were used to screen differentially expressed genes between MTX-sensitive (JAR, JEG3) and MTX-resistant (JARR, JEG3R) CC cell lines. The expression profiles of SOAT1 were validated through qRT-PCR and Western blot in

these cell lines. Chemosensitivity was systematically evaluated using CCK-8 assay and cell apoptosis assay. To investigate the potential role of SOAT1 in vivo, we constructed mouse xenograft model by subcutaneously injecting JEG3R cells with or without stable SOAT1 knockdown.

Result and discussion

Our data revealed a significant upregulation of SOAT1 expression at both mRNA and protein levels in MTX-resistant CC cell lines relative to MTX-sensitive cell lines. SOAT1 knockdown markedly enhanced the chemosensitivity of MTX-resistant cells (JARR, JEG3R) to MTX, whereas SOAT1 overexpression conferred MTX resistance in parental CC cells (JAR, JEG3). In vivo experiments, SOAT1 knockdown significantly reduced the volume and weight of tumors, proving that SOAT1 knockdown could promote the efficacy of MTX in vivo. Mechanically, SOAT1 knockdown upregulated USP24 expression, a deubiquitinating enzyme, through a ubiquitin-dependent pathway.

Conclusion

This study provides novel insights into the role of SOAT1 in regulating MTX resistance, identifying its potential as a therapeutic target for reversing chemo-resistance in CC patients. These findings highlight the promise of targeting SOAT1 as a strategy to enhance chemotherapeutic efficacy in clinical practice.

EACR25-1297

Creating Repotrectinib Resistance in a Ba/F3 SLC34A2-ROS1 NSCLC cell line

P. Korthuis¹, C. Dijkhuizen¹, T. van Eijk¹, M. de Looff², L. Drayer³, J. Hiltermann³, F. Milder², A. van den Berg⁴, A. van der Wekken³

¹*Hanze University of Applied Sciences, Institute For Life Science and Technology, Research Centre Biobased Economy, Groningen, Netherlands*

²*Hanze University of Applied Sciences Hogeschool, Institute For Life Science and Technology, Research Centre Biobased Economy, Groningen, Netherlands*

³*University Medical Centre Groningen, Department of Pulmonology, Groningen, Netherlands*

⁴*University Medical Centre Groningen, Department of Medical Biology and Pathology, Groningen, Netherlands*

Introduction

1-2% of non-small cell lung cancer (NSCLC) is driven by constitutive activation of ROS1 due to a ROS1 rearrangement. ROS1+ NSCLC is treated with tyrosine kinase inhibitors (TKI) which inhibit the phosphorylation of ROS1 and as a consequence its downstream pathways. Treatment with TKIs is palliative and will eventually lead to resistance via accumulation of additional genomic aberrations in either the tyrosine kinase domain of ROS1 (on-target) or other genes leading to alternative survival routes (off-target). In this study we aim to generate a repotrectinib resistant cell line by long term treatment with TKIs to study treatment induced resistance mechanisms.

Material and method

Ba/F3 cells were transfected with a pCDNA3.4 plasmid containing the SLC34A2-ROS1 fusion gene. Sensitivity for repotrectinib was measured by Western blot for phosphorylated ROS1, MTS assays and calculation of the

IC₅₀ value. To generate resistant cells, we treated the Ba/F3 SLC34A2-ROS1 cells with an increasing dose of repotrectinib during the course of 4 months until growth at a 100-fold increase of the IC₅₀ value was observed. MTS assays were performed on the resistant cells cultured either one or two weeks with and without repotrectinib before conducting the MTS assay.

Result and discussion

IC₅₀ value of the parental Ba/F3 SCL34A2-ROS1 treated with repotrectinib was 0,15nM. Effective treatment was confirmed by western blot for phospho-ROS1 showing a strongly reduced phosphorylation between 0,1 and 1nM of repotrectinib. Resistance cell cultures were made using 5, 10 and a final concentration of 15nM repotrectinib. IC₅₀ values of the resistance levels cultured for one week without repotrectinib pressure were 3,56, 3,69 and 5,16nM for the 5, 10 and 15nM respectively. IC₅₀ values of cells continuing to grow with repotrectinib were higher with 9,32 and 11,07nM for the 10 and 15nM repotrectinib cultures. For the 5nM culture the IC₅₀ was as high as 47nM, this is possibly due to hormesis. These data show that removal of repotrectinib from the medium might make the cell lines more sensitive to repotrectinib again. Cells cultured with repotrectinib were smaller in size compared to the parental cells. When repotrectinib pressure was removed cells regained similar size as the parental cells but did however clump together which is not observed in the parental cell line.

Conclusion

We generated three Ba/F3 SLC34A2-ROS1 repotrectinib resistant cell lines. A short term repotrectinib withdrawal makes the resistant cells more sensitive to repotrectinib. Mechanisms underlying the observed resistance such as mutations in the tyrosine kinase domain or in genes affecting alternative signaling pathways are currently being examined.

³Quirón Dexeus University Hospital, Dr Rosell Oncology Institute, Barcelona, Spain

⁴University Medical Center Groningen, Department of Pulmonology, Groningen, Netherlands

⁵University Medical Center Groningen, Department of Medical Biology and Pathology, Groningen, Netherlands

Introduction

ROS1 fusion gene-positive (ROS1+) is found in 1-2% of the non-small cell lung cancer (NSCLC) patients. Initially these patients are treated effectively with tyrosine kinase inhibitors (TKIs), however patients

generally develop resistance to TKI treatment due to on- and off-target resistance mutations. In this study, we assessed TKI sensitivity of two new patient-derived ROS1+ cell lines as in vitro models for investigating the resistance mechanisms to ROS1 TKI treatment.

Material and method

Two cell lines were generated from pleural effusions obtained from CD74-ROS1+ NSCLC patients. The cell line from patient 1 was derived from cells obtained upon resistance to crizotinib (PC1 cells). The cell line from patient 2 was generated from cells obtained upon resistance to crizotinib followed by resistance to lorlatinib treatment (PC2 cells). The Archer lung fusion cancer and TSO500 panels were used to identify potential resistance mechanisms in these cell lines. To assess efficacy of TKIs in the patient derived cell lines, IC₅₀ values were compared to CD74-ROS1 Ba/F3 cells. Sensitivity to TKIs crizotinib, entrectinib, lorlatinib, repotrectinib and zidesamtinib was assessed using MTS assays.

Result and discussion

Presence of the CD74-ROS1 fusion gene was confirmed in all three cell lines. The IC₅₀ values of unmutated ROS1+ Ba/F3 cells for crizotinib, entrectinib, lorlatinib, repotrectinib and zidesamtinib were 31.4; 44.6; 14.3; 14.9 and 29.9 nM, respectively. PC1 cells had a TP53 p.M246I mutation and IC₅₀ values above 3000 nM for all five ROS1 inhibitors. Interestingly, these cells were resistant to lorlatinib, while the patient is – after being treated with lorlatinib+cis-platinum+pemetrexed, now currently successfully treated with lorlatinib mono-therapy. PC2 cells had a ROS1 p.G2032R mutation, along with mutations in PIK3CA, PIK3CG and ARID1A. These cells responded to repotrectinib (IC₅₀ 57 nM) and lorlatinib (IC₅₀ 556 nM), while response to zidesamtinib, crizotinib and entrectinib was poor with IC₅₀ values above 1500 nM. The p.G2032R mutation is a known resistance mutation for crizotinib and lorlatinib, but was shown to be responsive to repotrectinib and the ROS1 specific zidesamtinib. Thus, the results from the PC2 cell line indicate presence of other off-target resistance mechanism that lead to resistance to zidesamtinib.

Conclusion

In this study we showed that PC1 cells generated from a crizotinib-resistant patient were resistant to all ROS1 inhibitors tested. The G2032R mutated PC2 cells generated from a crizotinib and lorlatinib resistant patient were sensitive to repotrectinib, but not to zidesamtinib. This PC2 cell line can be used to assess off-target resistance mechanism to zidesamtinib.

⁶*Universidade de Trás-os-Montes e Alto Douro (UTAD), Vila Real, Portugal*

Introduction

Both primary and secondary resistance to antineoplastic treatments remains a major challenge in colorectal cancer (CRC). This underscores the urgent need to develop tools that can predict and assess the response to antitumor therapies. Fascin, a protein involved in tumour invasion and metastasis, has recently been identified for its role in resistance to chemotherapy and immune checkpoint inhibitors, such as anti-PD1 in breast cancer. Given this, our group has extensive experience in characterizing fascin in CRC and discovering new drugs with anti-fascin activity. The main aim of this work is to evaluate the effectiveness of anti-fascin compounds in reversing oxaliplatin chemoresistance in in vitro CRC models.

Material and method

Eight colorectal cancer cell lines were used, four sensitive to oxaliplatin (HT29, LoVo, DLD1 and LS513) and four resistant derivatives of the former (HTOXAR, LoVOXAR, DLDOXAR and LSOXAR). These were cultured according to ATCC recommendations, under standard incubation conditions at 37°C with 5% CO₂. The cells were treated with oxaliplatin and fascin inhibitors (Imipramine and NP-G2-044), in monotherapy and in combination. Cell viability was assessed using the colorimetric XTT assay. Fascin levels in these lines were obtained from microarray data available in the GEO database, specifically from the GSE30011 study, and immunohistochemistry (IHC).

Result and discussion

In resistant cell lines, a higher IC₅₀ for oxaliplatin was confirmed comparatively to the sensitive lines, indicating a resistance to the drug. The anti-fascin compounds NP-G2-044 and imipramine, in monotherapy, reduced cell viability in all lines, with NP-G2-044 being the most effective. The combination of NP-G2-044 or imipramine with oxaliplatin significantly decreased viability in HTOXAR and DLDOXAR (up to 40% and 30%, respectively). In LoVOXAR, only the combination with NP-G2-044 was effective, reducing viability by 30%, suggesting a synergistic effect capable of reversing oxaliplatin resistance. However, in LSOXAR, the tested combinations did not improve the response to oxaliplatin. FSCN1 expression increased with oxaliplatin resistance in all the lines, except for LSOXAR, being notable in HTOXAR and DLDOXAR, which could explain the high efficacy of the combination treatments in the latter cell lines. IHC analysis further validated these results, confirming fascin's differential levels related to oxaliplatin resistance.

Conclusion

Our findings highlight the key role of fascin in oxaliplatin resistance in CRC. Although the anti-fascin compounds NP-G2-044 and imipramine in monotherapy could be viable therapeutic options, higher concentrations

would be required to achieve inhibitory effects comparable to oxaliplatin in resistant cells. However, the combination of fascin inhibitors with oxaliplatin exhibited a great ability to reverse drug resistance, showing promising therapeutic potential to overcome chemoresistance.

EACR25-1339

Abstract: Transcriptional Upregulation of ERG11, MDR1, and CDR1 Genes in Azole Resistance Among Candida Species from Head and Neck Cancer Patients

R. Chourasia¹, S. Bhattacharya², T. Selvaraju³, G. Gayathri¹

¹Vels Institute of Science, Technology, and Advanced Studies, Microbiology, Chennai, Tamilnadu, India

²Fakhruddin Ali Ahmed Medical College and Hospital (FAAMCH), Microbiology, Barpeta, Assam, India

³Barpeta Cancer Centre, Radiation Oncology, Barpeta, Assam, India

Introduction

Head and neck cancer patients are highly susceptible to opportunistic infections, notably candidiasis, due to immunocompromised. *Candida* species, particularly *C. albicans* and *C. tropicalis*, are frequent colonisers in these patients, with azole antifungal resistance posing a significant clinical challenge. Resistance is often linked to the transcriptional up-regulation of efflux pump genes (MDR1, CDR1) and the ergosterol biosynthesis gene (ERG11).

Material and method

A prospective study was conducted at a tertiary care hospital in Northeastern India, enrolling 57 HNC patients from March 2023 to February 2025. Oropharyngeal swabs were collected and cultured on SDA. *Candida* spp. identification was performed using standard microbiological techniques. Antifungal susceptibility testing was conducted via the disk diffusion method against fluconazole, itraconazole, and voriconazole. Azole-resistant isolates underwent RNA extraction and qRT-PCR to assess transcriptional upregulation of ERG11, MDR1, and CDR1, using GAPDH as a housekeeping gene. Fold changes were calculated relative to a susceptible *C. albicans* reference strain. Data were analysed using SPSS v25 software.

Result and discussion

Of the 57 patients, 35 (62.1%) exhibited *Candida* spp. growth, with *C. albicans* (54.3%, n = 19) and *C. tropicalis* (34.3%, n = 12) predominating, alongside minor isolates of *C. glabrata* (11.4%, n = 4). Antifungal susceptibility testing revealed resistance in 14 isolates (40% of *Candida*-positive cases): fluconazole resistance in 12 isolates (85.7%), itraconazole in 9 (64.3%), and voriconazole in 5 (35.7%). Among resistant isolates, qRT-PCR showed significant transcriptional up-regulation: ERG11 was upregulated in 10 isolates (mean fold change: 3.8, range: 2.1–5.6), MDR1 in 8 (mean fold change: 4.2, range: 2.5–6.8), and CDR1 in 11 (mean fold change: 5.1, range: 3.0–7.9), with p < 0.01 for all genes compared to controls. *C. tropicalis* isolates exhibited higher CDR1 upregulation (mean: 6.3) than *C. albicans* (mean: 4.2), suggesting species-specific resistance.

patterns. These findings align with prior studies linking efflux pump overexpression and ERG11 alterations to azole resistance, though the high resistance rate in this cohort underscores the role of local factors, such as antifungal overuse in Northeastern India.

Conclusion

This study demonstrates that transcriptional upregulation of ERG11, MDR1, and CDR1 is a key driver of azole resistance in *Candida* spp. from HNC patients in Northeastern India, with *C. albicans* and *C. tropicalis* as dominant pathogens. The significant resistance rates and pronounced gene upregulation highlight an urgent need for tailored antifungal stewardship and alternative therapies in this region. These insights enhance our understanding of resistance mechanisms and advocate for routine molecular screening to guide treatment, ultimately improving outcomes in this vulnerable population.

Discovery of Molecular and Epigenetic Candidates Underlying Chemosensitivity of Colorectal Cancer

S. Selvi¹, K. Honkova², K. Seborova³, M. Kroupa¹, V. Vymetalkova¹

¹*Institute of Experimental Medicine, Czech Academy of Sciences, Department of Molecular Biology of Cancer, Prague, Czech Republic*

²*Institute of Experimental Medicine, Czech Academy of Sciences, Department of Toxicology and Molecular Epidemiology, Prague, Czech Republic*

³*National Institute of Public Health, Department of Toxicogenomics, Prague, Czech Republic*

Introduction

Oxaliplatin (OXA)-based chemotherapy is the therapeutic regimen for patients with advanced colorectal cancer (CRC). Although OXA treatment improves mortality and tumor recurrence, its long-term effectiveness is limited by acquired resistance. This study aims to identify novel genes contributing to chemo-resistance in CRC using parental (WT) and OXA-resistant (OXAREZ) CRC cell lines.

Material and method

The OXAREZ cell line was generated by introducing increasing concentrations of OXA to DLD-1 cell line. All the experiments were performed on WT cells compared to OXAREZ cell lines. Behavioral tests such as cytotoxicity, proliferation, colony formation, and wound healing abilities of the DLD-1 cell lines were evaluated under OXA exposure. Genome-wide DNA methylation profiling and total RNA sequencing were conducted to identify underlying molecular mechanisms of OXA-based chemoresistance. CRC stem cell markers, apoptosis, and cell cycle arrest profiles were measured using flow cytometry.

Result and discussion

The behavior of the resistant cells was remarkably altered compared to the WT cell line. The OXAREZ cells exhibited enhanced colony formation and proliferation upon OXA treatment, indicating an adaptive advantage that promotes survival under chemotherapeutic pressure. Additionally, the expression patterns of key stem cell

markers underwent notable changes following the development of OXA resistance. Notably, OXAREZ cells showed a complete loss of CD133 expression, a marker commonly associated with cancer stem-like properties, suggesting a shift in the cellular phenotype. Furthermore, DNA methylation analysis revealed hypermethylation differences in the promoter shelf regions of OXAREZ cells compared to WT cells, highlighting potential epigenetic modifications associated with chemoresistance. RNA sequencing identified several differentially expressed genes involved in crucial cellular processes, such as cell cycle regulation, apoptosis, and migration. Additional CRC cell lines are currently being generated to acquire OXA resistance. Comparative analyses between these resistant cell lines will provide deeper insights into common and cell line-specific mechanisms of chemoresistance.

Conclusion

This study explores the impact of OXA resistance on the CRC cell's behavior, revealing significant molecular and functional changes associated with acquired chemoresistance. Substantial modifications in DNA methylation patterns and gene expression profiles were identified, highlighting potential biomarkers and key pathways involved in resistance. The ongoing analyses aim to refine these findings and pinpoint actionable targets for therapeutic intervention.

The study was supported by the National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102), funded by the European Union–Next Generation EU, and Czech Science Foundation (Project No. GX21-04607X).

EACR25-1350

The mechanism of PPAR α -mediated cholesterol metabolism in regulating paclitaxel resistance in ovarian cancer cells

M. Chen¹, H. Wu², X. Wang¹, Y. Xi^{3,2}

¹*The First Affiliated Hospital, Zhejiang University School of Medicine, Department of Obstetrics and Gynecology, Hangzhou, China*

²*Developmental Disorders, Zhejiang University School of Medicine, Hangzhou, China*

³*Women's Hospital, School of Medicine, Zhejiang University, Hangzhou, China*

Introduction

Ovarian cancer, the deadliest gynecological malignancy, has a poor prognosis, with over 75% of cases diagnosed at late stages and a global 5-year survival rate below 45% due to frequent chemoresistance. Dysregulated lipid metabolism is closely associated with chemoresistance. Peroxisome proliferator-activated receptor alpha (PPAR α), a key regulator of lipid metabolism, enhances drug sensitivity by promoting apoptosis, but its role in chemoresistance via lipid metabolic pathways remains unclear.

Material and method

Human serous ovarian cancer cell lines A2780 and SKOV3 were used as experimental models in this study. Paclitaxel (PTX)-resistant cell lines (A2780/TR and SKOV3/TR) were established via continuous low-dose PTX exposure. Resistance was assessed using CCK-8

assays, flow cytometry (apoptosis), and western blot (multidrug resistance protein 1 expression). Lipid droplets within cells were visualized using Nile Red staining. Untargeted lipidomics was performed on sensitive (A2780, SKOV3) and resistant (A2780/TR, SKOV3/TR) cells using ultra-performance liquid chromatography-mass spectrometry (UPLC-MS). Log₂(FC) values were calculated via Fold-Change, and significantly altered lipids were screened. Cholesterol (Chol) levels were measured using a Chol quantification kit, while key Chol regulatory factors were detected by western blot. PPAR α expression was modulated through knockdown, overexpression, and treatment with the pharmacological inhibitor GW6471 or agonist fenofibrate.

Result and discussion

Resistant cells exhibited fewer but larger lipid droplets ($P < 0.05$) and elevated CE levels ($\log_2(\text{FC}) > 9$). Total Chol and key metabolic proteins, including sterol regulatory element-binding protein 2 (SREBP2), 3-hydroxy-3-methylglutaryl-CoA Reductase (HMGCR), low-density lipoprotein receptor (LDLR), and acetyl-CoA acyltransferase 1 (ACAT1), were significantly upregulated in resistant cells ($P < 0.05$). Simvastatin treatment reduced resistance ($P < 0.01$), linking Chol metabolism to chemo-resistance. PPAR α was upregulated in resistant cells ($P < 0.05$), and its knockdown or inhibition increased resistance in sensitive cells ($P < 0.001$), while over-expression or activation reduced resistance in resistant cells ($P < 0.01$). Mechanistically, knockdown of PPAR α upregulated Chol levels ($P < 0.001$) and SREBP2, HMGCR, LDLR, ACAT1 expression ($P < 0.05$), while overexpression had the opposite effect ($P < 0.05$). PPAR α knockdown reversed simvastatin-induced resistance reduction ($P < 0.001$), indicating PPAR α regulates paclitaxel resistance via Chol metabolism. Future studies will validate these findings in clinical samples and murine models.

Conclusion

PPAR α regulates PTX resistance in ovarian cancer by modulating Chol metabolism. Targeting PPAR α and its downstream pathways may offer novel therapeutic strategies to overcome chemoresistance.

SRSF9-mediated alternative splicing impairs anti-tumor immunity and drives resistance to PD-L1/VEGF-A blockade in hepatocellular carcinoma

J. Luo¹, N. Yu¹, R. Ji², B. Ru³, L. Gong¹, P. Jiang³, X. Guan¹

¹The University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong, China

²The University of Hong Kong, School of Public Health, Hong Kong, Hong Kong, China

³National Institutes of Health, Center for Cancer Research, National Cancer Institute, Bethesda, Maryland, United States

Introduction

Immune resistance remains a significant barrier to the clinical efficacy of PD-L1/VEGF-A blockade in hepatocellular carcinoma (HCC). In this study, we identify

SRSF9, an RNA splicing factor, as a critical regulator of immune evasion in HCC and elucidate the mechanisms underlying treatment resistance.

Material and method

We conducted a CRISPR-based genome-wide knockout screen in an orthotopic HCC model receiving dual PD-L1/VEGF-A antibody treatment to uncover novel regulators of immune evasion. Key hits were validated using both the orthotopic HCC mouse model and lucOS-MYC/CTNNB1-driven spontaneous HCC model. We assessed the impact of SRSF9 knockout on T cell function, immune cell infiltration, and tumor growth, and evaluated whether the natural compound Apigenin could modulate SRSF9 expression and splicing activity to enhance the efficacy of PD-L1/VEGF-A blockade. Furthermore, to explore how SRSF9-mediated alternative splicing reshapes the tumor microenvironment (TME) and drives resistance to PD-L1/VEGF-A blockade, we then performed comprehensive analyses including bulk RNA sequencing, single-cell transcriptomics, and enhanced crosslinking and immunoprecipitation sequencing (eCLIP-seq).

Result and discussion

Our CRISPR screen identified SRSF9 as a key driver of immune resistance in HCC. Knockout of SRSF9 in tumor cells significantly enhanced CD8+ T/NK cell cytotoxic activity, suppressed M2 tumor-associated macrophage polarization, and reversed resistance to PD-L1/VEGF-A blockade. Transcriptomics and eCLIP-seq analyses revealed that SRSF9 directly binds and regulates the alternative splicing of critical immune signaling genes (e.g. CSDE1), thereby modulating both T cell function and TME composition. Importantly, treatment with Apigenin reduced SRSF9 expression and altered the splicing patterns of SRSF9 target genes, leading to improved T cell activation and significant anti-tumor responses, with synergistic effects when combined with PD-L1/VEGF-A blockade.

Conclusion

Our findings demonstrate that SRSF9 plays a crucial role in promoting immune resistance in HCC. Targeting SRSF9 with Apigenin represents a promising strategy to overcome immune evasion and boost the efficacy of immune checkpoint inhibitor-based therapies in patients with advanced or refractory HCC.

EACR25-1413

Revealing Distinct Oxaliplatin Resistance Mechanisms in HCT116 Cells Through Genomic and Transcriptomic Analysis Under Continuous and Intermittent Treatment Regimens

G. Yilmaz¹, O. Basar¹, K. Yilmaz¹, A. Acar¹

¹Middle East Technical University, Molecular Biology and Genetics, Ankara, Turkey

Introduction

Chemotherapy resistance remains a major challenge that reduces treatment effectiveness and accelerates disease progression in colorectal cancer. Identifying the underlying molecular interactions driving resistance development; therefore, is essential for improving novel therapeutic strategies. Additionally, development of drug

resistance under different treatment regimens may result in distinct molecular changes, which may eventually influence the outcomes of the treatments. We aimed to investigate both genomic and transcriptomic alterations associated with drug resistance in CRC cells through the implementation of two different treatment regimens. By integrating whole-exome sequencing (WES) and RNA sequencing (RNA-seq) data, we sought to clarify molecular mechanisms contributing to resistance development under different treatment conditions.

Material and method

To generate resistant cell populations, HCT116 cell lines were treated with oxaliplatin under two different treatment regimens. Cells were subjected to either constant drug exposure or periodic withdrawal and re-exposure. Once resistance was confirmed via cell viability assay, WES and RNA-seq were performed to reveal both genomic and transcriptomic alterations specific to each regimen to identify differentially expressed genes, enriched pathways, and potential resistance mechanisms.

Result and discussion

WES analysis revealed differences between mutational landscapes, whereas RNA-seq analysis further emphasized the differential expression patterns between intermittent and continuous treatment regimes. These findings suggest that drug exposure patterns have a significant impact on the adaptive resistance mechanisms in HCT116 cell lines, highlighting the potential of treatment optimization to prevent chemotherapy resistance.

Conclusion

In summary, we demonstrated that oxaliplatin resistance in HCT116 cell lines is driven by both genomic and transcriptomic alterations and treatment specific adaptations in response to drug exposure regimens. These findings indicate the importance of implementing optimized treatment strategies in colorectal cancer treatment to enhance treatment efficacy.

AP-1 transcription factor is a targetable mediator of osimertinib resistance in EGFR-mutant non-small cell lung cancer

S. Eris¹, B. Dayanc¹, N. Gulfirat¹, G. Ozden-Yilmaz¹, E. Cakiroglu¹, O. Coskun Deniz¹, G. Karakulah¹, S. Erkek-Ozhan², S. Senturk¹

¹Dokuz Eylul University, Izmir International Biomedicine and Genome Institute, Izmir, Turkey

²Izmir Biomedicine and Genome Center, Izmir, Turkey

Introduction

Non-small cell lung cancer (NSCLC), which constitutes 85% of all lung cancer cases, is often driven by oncogenic mutations within the kinase domain of the epidermal growth factor receptor (EGFR). Osimertinib, a third-generation EGFR tyrosine kinase inhibitor (EGFR-TKI), has revolutionized the treatment of EGFR-mutant non-small cell lung cancer (NSCLC). However, acquired resistance remains a major challenge, with non-genetic mechanisms increasingly recognized as key drivers. Here, we employ a multi-omics approach to characterize genome-wide chromatin accessibility and transcriptional landscapes between osimertinib-sensitive and -resistant

EGFR-mutant NSCLC cells. Our findings reveal a strong correlation between epigenetic remodeling and transcriptomic alterations that define the resistant state.

Material and method

Osimertinib-resistant subclones of HCC827, PC9, and H1975 cells, lacking secondary EGFR mutations, were generated using a dose-escalation approach. CRISPR/Cas9-based functional genomics screen targeting epigenetic regulators and transcription factors identifies critical resistance-associated regulatory networks, prominently featuring the NuRD and PRC2 complexes. Notably, among the top hits, FOSL1 and JUN – core components of the AP-1 transcription factor – emerge as central mediators of resistance. Mechanistically, we demonstrate that cis-regulatory elements with altered chromatin accessibility in resistant cells are enriched for AP-1 binding motifs, allowing AP-1 to drive a gene expression program that sustains the druggable MEK/ERK signaling axis, thereby enhancing cell viability and fitness.

Result and discussion

Crucially, genetic depletion or pharmacological inhibition of AP-1 restores osimertinib sensitivity and reverses resistance-associated phenotypes, including epithelial-to-mesenchymal transition, upon anti-EGFR rechallenge. This effect is mediated through suppression of AKT and ERK signaling, underscoring AP-1 as a key vulnerability in the resistant state.

Conclusion

These findings provide novel insights into the epigenetic and transcriptional regulation of osimertinib resistance in EGFR-mutant NSCLC. Targeting AP-1 represents a promising therapeutic strategy to overcome osimertinib resistance and enhance the efficacy of EGFR-TKIs in NSCLC.

Overactivation of oncogenic signaling steers cancer cells toward less malignant phenotypes

C. Papagianni¹, M. Dias¹, N. Pouliopoulou¹, R. Bernards²

¹Netherlands Cancer Institute, Amsterdam, Netherlands

²Netherlands Cancer Institute, Am, Netherlands

Introduction

Over the past few decades, extensive research has been conducted on cancer and a myriad of compounds have been developed. Despite significant progress for some cancers, the overall efficiency of these drugs remains limited by the emergence of resistance. Cancer cells often acquire resistance to targeted therapies by gaining further oncogenic alterations, reactivating feedback loops, and becoming more aggressive and refractory to subsequent treatments. We recently proposed an unconventional approach for cancer therapy involving the activation of oncogenic signaling along with the inhibition of stress responses. The underlying rationale is that in cancer cells, the aberrant oncogenic signaling is accompanied by cellular stress which increases the necessity for stress responses to maintain cell viability. Therefore, the overactivation of oncogenic signaling can overload cancer cells with cellular stress and be highly toxic to

them, especially when combined with stress-response inhibitors. We have recently shown that the inhibition of protein phosphatase 2A (PP2A) led to hyperactivation multiple oncogenic signaling pathways in colon cancer models and was associated with engagement of multiple stress response pathways. Compound and CRISPR screens revealed that the inhibition of the mitosis gatekeeper kinase WEE1 as the major vulnerability of such hyperactivated cells. The combination of PP2A and WEE1 inhibitors proved very efficient in killing different cancer cell in vitro and in vivo. As for any other treatment, resistance to this approach can also emerge. Given the fundamentally different mechanism of toxicity, we aimed to explore how cancer cells acquire resistance to overactivation therapy.

Material and method

The experiments were performed on colorectal cancer cell lines. We performed viability, invasion and seahorse assays, genome-wide screens, RNA sequencing and animal experiments.

Result and discussion

Our study showed that the resistance to the combination of PP2A and WEE1 inhibitors led to transcriptional suppression of oncogenic signaling and cellular stresses. Moreover, the resistant cells switched from glycolysis to oxidative phosphorylation for their metabolic needs. In line with the in vitro data, the acquired resistance restrained the ability of cancer cells to form tumors in vivo. Altogether, our data suggest that the acquired resistance, developed to evade the stressful state caused by the activation therapy, is related with reduced tumorigenicity.

Conclusion

These data suggest that the combination of overactivation of oncogenic signaling together with suppression of stress responses can force cancer cells to give up their malignant traits. Our study proposes that this unconventional approach targets the pathological behavior of cancer cells and can be explored therapeutically as it may provide unforeseen ways to suppress oncogenic signaling.

EACR25-1461

An unbiased in vitro screen for uncovering HER2 drug resistance mutations

I. Farahani¹, K. Kurppa¹, K. Elenius¹

¹*University of Turku, Turku Bioscience Centre, Turku, Finland*

Introduction

The HER2 receptor tyrosine kinase (RTK), also known as ERBB2, has been extensively studied for developing tyrosine kinase inhibitor (TKI) drugs. HER2-activating point mutations and small indels have been found in various human cancers. These mutations can drive malignancies similar to HER2 amplification and are responsive to HER2-targeted TKIs. However, recent studies have revealed disease progression in cancer patients treated with TKIs due to the development of additional on-target mutations. Moreover, different TKIs might retain activity in the presence of on-target resistance mutations for another specific TKI. Therefore, it is crucial to identify the resistance mutation spectrum

of different HER2 TKIs. This study addresses the development of on-target HER2 resistance mutations using the in vitro screen for activating mutations (iSCREAM), a functional genetics screen previously developed in our laboratory.

Material and method

To perform a modified version of iSCREAM, a retroviral library of randomly mutated HER2 containing one of the well-known HER2 activating mutations (S310F and V777L) is utilized to generate stable Ba/F3 lines ectopically expressing the HER2 mutant library. Ba/F3 cells, which rely on exogenous Interleukin-3 (IL-3) for survival, are induced to gain IL-3 independence through the expression of HER2 oncogenes. The cells are grown under IL-3-depleted conditions to establish a population independent of IL-3. Under HER2 TKI treatment, clones containing on-target resistance mutations are selectively enriched. Sequencing of the HER2 retroviral insert from the surviving Ba/F3 cell pool is performed to identify these mutation hits. The identified mutation hits will be further validated through in vitro cell models and in silico analysis.

Result and discussion

In IL-3-independent Ba/F3 cells with HER2 mutations, different proliferation rates and HER2 TKI sensitivities confirmed the efficacy of the activating mutation panel for iSCREAM. Cells addicted to HER2S310F and HER2V777L showed higher growth rates and TKI sensitivity. Additionally, the proliferation of HER2S310F and HER2V777L Ba/F3 cells, with and without random mutations under TKI treatment, indicates that random mutational variations promote TKI resistance. The ability of surviving cells to regrow under HER2 TKI pressure largely depends on the mutations present within the library.

Conclusion

Oncogene-targeted therapy using TKIs may lead to resistance due to on-target mutations that kill the activity of the drugs. On the other hand, some other targeted TKIs may retain functionality in the presence of on-target resistance mutations. Therefore, this study will identify and validate the HER2 on-target resistance mutation spectrum of different HER2 TKIs. This can provide invaluable information in choosing suitable HER2 TKI therapy for tumors harboring HER2 resistance mutations to other TKIs.

³*The Christie NHS Foundation Trust, Colorectal & Peritoneal Oncology Centre, Manchester, United*

Kingdom

⁴The University of Manchester, Division of Pharmacy and Optometry, Faculty of Biology Medicine and Health, School of Health Sciences, Manchester, United Kingdom

Introduction

Cancer may affect systems parameters, including the abundance of drug-metabolizing enzymes (DMEs) and transporters, leading to high variability in pharmacokinetics. However, such data are scarce, especially for rare cancer types. Appendix tumours are rare entities that usually metastasize to the peritoneum, for which there is no targeted treatment. This study aimed to quantify, for the first time, DMEs and transporters in the appendix, peritoneum and exosomes from plasma from patients with appendix tumours (AT) and healthy subjects.

Material and method

Tissues were homogenized, and epithelial cells were extracted from appendix (5 healthy, 16 non-tumor peri-carcinomatous, 15 tumor) and peritoneum (44 non-tumor peri-carcinomatous, 63 tumor) tissues. Exosomes from plasma (6 healthy subjects, 19 patients with appendix tumors) were prepared (liquid biopsy). Filter-aided sample preparation was used for protein digestion, and global liquid chromatography–mass spectrometry for quantification of proteins.

Result and discussion

Among cytochrome P450 (CYP) enzymes, CYP3A4 showed the most significant change in cancer patients; 400-fold decrease in tumor compared with non-tumor appendix, and 4-fold decrease in tumor compared with non-tumor peritoneum. On the contrary, CYP1B1 increased (2-fold) in tumour appendix and peritoneum. Uridine 5'-diphospho-glucuronosyltransferases (UGTs) also showed differential expression. For example, UGT2B17 was 70-fold lower in tumor relative to non-tumour appendix, and 16-fold lower in tumour relative to non-tumour peritoneum. However, UGT2B4 and UGT2B15 were upregulated in tumor appendix. Non-CYP and non-UGT DMEs (carboxylesterases, flavin-containing monooxygenases, microsomal glutathione S-transferases, sulfotransferases, aldehyde oxidase, aldehyde dehydrogenases, alcohol dehydrogenases etc.) were also quantified. They were generally decreased in tumor compared with non-tumor peritoneum.

Interestingly, most of them were upregulated in tumor and non-tumor appendix compared with healthy controls. ATP-binding cassette (ABC) transporters showed distinct expression profiles in cancer too; for example, BCRP was lower in tumor compared with non-tumor (9-fold) and healthy (3-fold) appendix, while P-gp was not detected in tumor. However, BCRP and P-gp showed similar levels in tumor and non-tumor peritoneum. In exosomes, differential expression was also observed; for example, ADH1B, CES1/2, EPHX1, MGST1, UGT1A1, P-gp and MRP3 were exclusively detected in AT patients, whereas NAT1 was only detected in healthy samples.

Conclusion

Overall, the abundance of DMEs and transporters is altered in patients with AT. This may affect the clearance and disposition of drugs metabolized by these DMEs or transported via these transporters. Therefore, our findings could facilitate informed clinical decisions related to drug

exposure, resistance and response to treatment for appendix tumors.

⁶UNICANCER, Comprehensive Cancer Center François Baclesse - Department of Surgery, Caen, France

Introduction

Ovarian cancer has a poor clinical prognosis due to innate or acquired chemoresistance following carboplatin/paclitaxel treatment. Although PARP inhibitors have revolutionised patient management, they are only offered to patients with Homologous Recombination Deficiency (HRD) who have responded to carboplatin treatment. As carboplatin and PARP inhibitors are genotoxic agents that exploit the HR DNA repair pathway, cross-resistance between these two therapeutic classes is emerging, suggesting at least partial overlap in resistance mechanisms. Our understanding of the mechanisms involved in the acquisition of chemo-resistance remains very limited and no relevant tools are currently available to guide treatment in patients who can no longer benefit from these therapies. Definition of the molecular alterations and vulnerabilities to be targeted during chemoresistance is though crucial for ovarian cancer management. As access to biological samples from patients resistant to carboplatin and PARP inhibitors is very complex, we have focused on Patient-Derived Tumor Organoids (PDTOs) models which are world-renowned for reflecting molecular characteristics of the tumor and patient’s clinical response. In this context, we have established chemoresistant PDTOs from sensitive PDTOs that have undergone repeated treatments with carboplatin. This model would accurately enable us to follow the mechanisms involved in acquired chemoresistance.

Material and method

Three chemosensitive ovarian PDTOs lines were treated

with 10 μ M carboplatin (corresponding to their IC50) during 1 week for 6 cycles and CellTiterGlo assay was performed to estimate PDTOs viability and IC50 at the end of the 6th cycle. After each cycle, PDTOs were harvested to realize transcriptomic and proteomic analyses, to perform immunochemistry assay and to assess HRD profile.

Result and discussion

Six cycles of carboplatin were sufficient to induce resistance in PDTOs to carboplatin and 2 PARP inhibitors (Olaparib and Niraparib), assessed by the increase of IC50 between the 1st and the 6th cycles. The preliminary results indicate that chemoresistance acquisition is accompanied by an increase expression of the anti-apoptotic protein Bcl-xL and a decrease expression of the pro-apoptotic proteins Puma and Noxa resulting in an imbalanced ratio that prevent apoptosis. In addition, activating phosphorylation of NF κ B (P-p65Ser536), a transcription factor known to be involved in carboplatin resistance in ovarian cancer, was also increased in resistant lines, supporting the reliability of our model.

Conclusion

For the first time, our study highlights the possibility to establish an acquired resistance to carboplatin and PARP inhibitors in ovarian PDTO model. Future characterization of molecular pathways activation and biomarkers expression kinetics will represent an important scientific breakthrough and will offer new hope for second-line treatment of ovarian cancer.

CIC: The Master Regulator of Resistance to MAPK Pathway Inhibition

J. Neto¹, L. Bouwmeester¹, K. Jastrzebski¹, P. Odello¹, E. Bosdriesz², R. Beijersbergen¹, R. Bernards¹, L. Wessels¹

¹The Netherlands Cancer Institute, Amsterdam, Netherlands

²Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Introduction

Drug resistance continues to be the main obstacle to achieving cures in patients with cancer. We recently developed Multiple Low Dose (MLD) therapy, having shown that partial inhibition of the EGFR-RAF-MEK-ERK kinases using a low dose (IC20) of small molecule inhibitors targeting each of these kinases stands out from conventional High Dose (HD) single-agent strategies because of its ability to prevent resistance. However, the underlying mechanism(s) that result in the effectiveness of the MLD strategy are not fully understood.

Material and method

To identify modulators of response to MLD therapy, we generated lung adenocarcinoma PC9 cells resistant to EGFR, RAF, MEK and ERK inhibitors, respectively, and performed a genome-wide loss-of-function CRISPR-Cas9 screen on the parental line.

Result and discussion

We found that PC9 cells were able to acquire spontaneous resistance to treatment with high doses of EGFR, RAF, MEK, ERK or RAF+MEK inhibitors. This was achieved via different mechanisms, all of which ultimately lead to MAPK pathway reactivation.

Interestingly, all these drug-resistant cells are still responsive to MLD therapy. However, knock-out of Capicua transcriptional repressor (CIC) renders PC9 cells resistant to all treatment strategies, independent of MAPK pathway reactivation. Furthermore, we also find CIC LOF mutations in tumors from patients resistant to MAPK pathway inhibitors.

Conclusion

These observations suggest that CIC is a Master regulator of resistance to MAPK pathway inhibition, paving the road for future clinical studies to assess CIC's expression as a predictive biomarker of response to MAPK pathway inhibitors.

EACR25-1569

Lysosomal Ca²⁺ release via TRPML3 enhances drug sensitivity of gefitinib-resistance NSCLC cells

S. Yang¹, M. Kim², M. Kim²

¹Wonkwang University Hospital, Department of Internal Medicine, Iksan, Korea (Republic of)

²Wonkwang University, Department of Oral Physiology, Iksan, Korea (Republic of)

Introduction

Lysosomes have recently gained prominence as pivotal signaling hubs implicated in drug resistance within cancer cells. However, the precise role of Transient receptor potential mucolipin 3 (TRPML3), an endolysosomal Ca²⁺-permeable channel known to regulate lysosomal trafficking during endocytosis and autophagy, remains enigmatic in the context of cancer progression. This study aimed to elucidate the involvement of TRPML3 in modulating exosomal release triggered by lysosomal exocytosis during the development of gefitinib resistance in non-small cell lung cancer (NSCLC).

Material and method

Exosomal counts and cell-cycle analysis were conducted by flow cytometry and western blot analysis. Ratiometric assays and enzymatic activity assessments were performed to investigate Ca²⁺ signaling, lysosomal pH, and lysosomal exocytosis

Result and discussion

Our finding revealed that gefitinib-resistant NSCLC cells, HCC827/GR, exhibited significantly higher basal exosomal release and lysosomal exocytosis compared to gefitinib-sensitive NSCLC cells, HCC827. This difference was associated with an increased expression of TRPML3 in HCC827/GR cells. Furthermore, we observed a close correlation between the elevated exosomal release and lysosomal exocytosis and the upregulation of TRPML3 expression. Notably, the triggering of lysosomal Ca²⁺ release through TRPML3 was facilitated by gefitinib-induced elevation of lysosomal pH. Our investigation demonstrated that deficiency of TRPML3 resulted in gefitinib-induced cell death, as indicated by the accumulation of Sub-G0 population, hindered cell proliferation, and facilitated poly (ADP-ribose) polymerase cleavage.

Conclusion

In summary, our data demonstrate the emerging role of TRPML3 as a molecular factor in anti-cancer drug resistance. By effectively sensing lysosomal pH acidification, TRPML3 orchestrates lysosomal Ca²⁺

release, subsequently influencing lysosomal trafficking, exocytosis, and exosomal release. This study contributes to comprehending the defense mechanisms that developed by acquired drug resistance to tyrosine kinase inhibitor gefitinib in NSCLC cells.

Introduction

Gasdermin B (GSDMB) protein has a dual function in cancer, rendering it as a potential therapeutic target. On the one hand, this protein has the intrinsic capacity to induce pyroptosis, a mechanism that may be capable of eradicating certain tumor cells. On the other hand, data from our lab revealed that GSDMB is overexpressed in a subset of HER2+ breast (BC) and gastro-esophageal tumors, where it correlates with unfavorable clinical outcomes, facilitating multiple pro-tumor activities, including invasion, progression, metastasis, and resistance to anti-HER2 therapies. In view of the above, the objective of this study is to identify and characterize novel GSDMB-targeted anti-tumor compounds.

Material and method

Using different HER2/GSDMB+ BC models, we tested the effects of compound A selected through high-throughput drug screening, using different complementary in vitro approaches such as cell viability (Alamar Blue) assay or lactate dehydrogenase (LDH) enzyme release assays and others. Additionally, protein expression analyzed by Western blot and in silico docking studies were performed. Furthermore, these findings were tested and validated in preclinical animal models.

Result and discussion

Following a large high-throughput screening, one orphan FDA-approved compound (compound A) was identified as a potential hit, and subsequently validated, exhibiting a positive GSDMB-dependent cytotoxic effect reducing the viability of GSDMB-overexpressing tumor cells.

Preliminary in silico studies indicated a potential direct binding of compound A with GSDMB, suggesting the possibility of a thermodynamically stable complex and reinforcing the concept of drug-target specificity. Consequently, we tested the potential induction of pyroptosis following compound A treatment.

Interestingly, this compound not demonstrably influence pyroptotic cell death (as measured by LDH release), suggesting that it may eradicate GSDMB+ cells through alternative cell death mechanisms. While no evidence of apoptosis has been observed, but a slightly induce senescence was observed. Finally, the therapeutic capacity of this compound was evaluated in preclinical in vivo mouse models using mice bearing orthotopically injected GSDMB-expressing and silencing HER2+ BC cells. These results demonstrated a reduction in tumor growth and tumor weight ex vivo, as well as a higher percentage of tumor necrosis ex vivo in those tumors expressing GSDMB versus those silenced, indicating a promising therapeutic efficacy of this compound in vivo.

Conclusion

The potential utility of compound A as a novel drug targeting GSDMB has been identified and validated at least in HER2 BC. This drug could preferentially reduce the viability of GSDMB-overexpressing BC cells, and it may serve as a starting point for the development of a novel and effective therapeutic approach for HER2/GSDMB+ BC.

EACR25-1592

FGFR signaling as a key mediator of resistance to alpelisib/fulvestrant combination in PIK3CA-mutant luminal A breast cancer

M. Oguz¹, E. Emirmustafaoglu¹, O. Sahin², O. Cizmecioglu¹

¹Ihsan Dogramaci Bilkent University, Molecular Biology and Genetics, Ankara, Turkey

²Medical University of South Carolina, Department of Biochemistry and Molecular Biology, Charleston, SC, United States

Introduction

Luminal A breast cancer is characterized by HR positivity and HER2 negativity. Mutations in the PI3K pathway are common in these tumors. While PI3K inhibitors, such as alpelisib, are FDA-approved for treating PIK3CA-mutant breast cancers, the inhibition of the PI3K pathway can lead to the activation of compensatory signaling pathways, resulting in drug resistance. The objective of this study is to identify possible resistance mechanisms associated with the FDA-approved combined use of alpelisib and fulvestrant in the treatment of PIK3CA mutant breast cancer. Transcriptomic analysis reveals the activation of FGFR signaling as a key resistance mechanism. We further demonstrate the synergistic growth inhibition activity of pemigatinib, an

FDA-approved pan-FGFR inhibitor, when combined with alpelisib in cell lines and 3D tumor spheroids resistant to alpelisib/fulvestrant treatment.

Material and method

MCF7 and T47D cell lines with acquired resistance to the alpelisib/fulvestrant combination were generated and subjected to comparative transcriptome analysis to identify potential resistance networks. Immunoblotting was used to validate key components of the resistance-associated signaling pathways. To elucidate the functional impact of FGFR-dependent resistance mechanisms, resistant cells, and 3D tumor spheroid models were treated with the combination of alpelisib/pemigatinib. Additionally, FGFR2 was overexpressed in fulvestrant-resistant cells to assess its role in acquired alpelisib resistance. Ongoing *in vivo* experiments are being conducted to evaluate the efficacy of this combination treatment in preclinical tumor models.

Result and discussion

Transcriptome analysis implicated FGFR and downstream MAPK signaling pathways as key factors contributing to resistance. Immunoblotting confirmed the activation of these pathways in resistant cells. Treatment with the combination of alpelisib/pemigatinib demonstrated synergistic growth inhibition in 2D cells and 3D tumor spheroids. Notably, combinatorial treatment in both models led to a pronounced reduction in S6 phosphorylation and resulted in lasting tumor regression in 3D spheroids, surpassing the effects of individual treatments. Furthermore, overexpression of FGFR2 in fulvestrant-resistant cells significantly increased alpelisib resistance, suggesting that FGFR signaling may have a critical role in the acquired alpelisib/fulvestrant resistance. The combinatorial effects of alpelisib and pemigatinib on *in vivo* tumor growth are being evaluated.

Conclusion

Our study identifies FGFR signaling as a key mediator of resistance to alpelisib and fulvestrant in PIK3CA-mutant luminal A breast cancer cells. These findings suggest that targeting the FGFR pathway in combination with PI3K inhibition may represent a potential strategy to overcome drug resistance in advanced-stage luminal A breast cancer.

Targeting Ferroptosis to Enhance the Efficacy of BRAF/MEK Inhibitors in Overcoming Resistance in Melanoma

M. Quindos-Varela¹, R. Lesta-Mellid¹, I. Santamarina-Cainzos¹, S. Rodríguez-Varela¹, I. Martínez-Martín¹, M. Fraga¹, M. Quintela², M. Arufe³, J. Fafian-Labora³

¹*CHUAC-INIBIC, A Coruña, Spain*

²*Cardiff University, Wales, United Kingdom*

³*Universidade da Coruña-INIBIC-CICA, A Coruña, Spain*

Introduction

Melanoma is one of the most aggressive cancers, often displaying resistance to targeted therapies, particularly those involving BRAF/MEK inhibitors. While these therapies offer significant benefits in certain melanoma subtypes, acquired resistance remains a critical challenge. Ferroptosis, an iron-dependent form of cell death, has

recently emerged as a promising strategy to counteract this resistance. This study aims to explore the role of ferroptosis in melanoma and evaluate its potential as a therapeutic strategy in combination with BRAF/MEK inhibitors.

Material and method

Human melanoma cell lines (A375, SK-MEL-28) with BRAF mutations were used to model melanoma resistance. Ferroptosis induction was assessed using specific inhibitors and activators of this pathway, such as RSL3 and erastin. Cell viability assays, gene expression analysis, and western blotting were performed to measure the effects of ferroptosis induction alone and in combination with BRAF/MEK inhibitors (e.g., vemurafenib and trametinib). Additionally, the response of melanoma cells to this combination treatment was evaluated through oxidative stress and cell death markers.

Result and discussion

Our results show that induction of ferroptosis in melanoma cells significantly reduced cell viability and enhanced cell death, particularly when combined with BRAF/MEK inhibitors. Ferroptosis induction elevated oxidative stress levels, which appeared to sensitize melanoma cells to the effects of BRAF/MEK inhibitors. The combination treatment resulted in a synergistic therapeutic response, overcoming the resistance commonly seen with BRAF/MEK monotherapy. Gene expression analysis revealed upregulation of pro-ferroptotic and stress-response genes, supporting the potential of ferroptosis in combination therapy.

Conclusion

The induction of ferroptosis presents a promising strategy for enhancing the efficacy of BRAF/MEK inhibitors in the treatment of melanoma. Our findings suggest that ferroptosis could overcome treatment resistance and improve therapeutic outcomes in patients with advanced melanoma. Further preclinical and clinical studies are warranted to validate these results and optimize combination strategies involving ferroptosis and targeted inhibitors.

SOS1 inhibition enhances the efficacy of and delays resistance to oncogene-targeted therapies in lung adenocarcinoma

B. Daley¹, P. Theard¹, J. Hughes¹, N. Sealover¹, M. Hofmann², K. Kostryko², R. Schenk², R. Kortum¹

¹*Uniformed Services University of the Health Sciences, Pharmacology and Molecular Therapeutics, Bethesda, United States*

²*Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria*

Introduction

Lung cancer is the leading cause of cancer-related death worldwide; adenocarcinoma is the most common subtype of lung cancer. Oncogenic driver mutations in the RTK/RAS pathway occur in 75–90% of lung adenocarcinoma (LUAD). Receptor Tyrosine Kinase (RTK) and RAS pathway-targeted therapies have substantially improved outcomes in LUAD. However, in most cases both intrinsic and acquired resistance to these agents limits

their long-term effectiveness. Resistance to osimertinib in EGFR-mutated tumors, KRASG12C inhibitors in KRASG12C-mutated tumors, or the MEK inhibitor trametinib in KRAS-mutated and NF1-LOF tumors most often develops via activation of multiple RTKs, often within the same tumor. These data suggest that combating therapeutic resistance via individual RTK inhibitors will be ineffective. In contrast, we hypothesize that broad inhibition of RTK signaling via a common downstream signaling node has the potential to enhance the efficacy of and delay resistance to targeted therapies in a majority of LUADs.

Material and method

To test this hypothesis, we built an experimental framework that models the evolution of cancer cells to therapeutic pressure *in situ*. Using this framework, we assess for therapeutic combinations that (i) enhance therapeutic efficacy to overcome intrinsic/adaptive resistance, (ii) limit the survival of drug-tolerant persister (DTP) cells capable of driving acquired resistance, and (iii) delay the onset of and/or block the development of resistant cultures.

Result and discussion

Using this framework we show that proximal RTK signaling intermediates SHP2, SOS1, and SOS2 are therapeutic targets whose inhibition both enhance the efficacy of and delay resistance to RTK/RAS pathway-targeted therapies by targeting DTPs in EGFR-mutated, KRASG12-mutated, and NF1-LOF LUAD cells. We further show that the effectiveness of co-targeting proximal RTK signaling showed genotype-specificity; SOS1 inhibitors did not synergize with or prevent resistance to MEK inhibitors in KRASQ61-mutated cells or cells harboring PIK3CA co-mutations. Finally, we show that SOS1i can re-sensitize G12Ci and EGFRi DTPs to oncogene-targeted therapies, and combined EGFRi+SOS1i treatment inhibited EGFR-mutated tumor growth *in vivo* to a greater extent than EGFRi alone.

Conclusion

Our data present a framework for rapidly evaluating and selecting optimal combinations therapies prior to moving into extensive longitudinal pre-clinical animal studies. Our data further show that targeting proximal RTK signaling in combination therapy using a SOS1 inhibitor is a potential strategy to prolong the effectiveness of oncogene-targeted therapies for a majority of LUAD patients.

²*Balikesir University, Molecular Biology and Genetics, Balikesir, Turkey*

Introduction

Hepatocellular carcinoma (HCC) is the most common primary liver cancer, accounting for 85–90% of cases and is a leading cause of cancer-related mortality worldwide. HCC represents a classic paradigm of inflammation-

related cancer, with various risk factors contributing to chronic liver inflammation and subsequent tumor development. It is characterized by high intrinsic drug resistance, leading to limited chemotherapeutic efficacy and relapse after treatment. Sorafenib is an FDA-approved first-line drug for the treatment of advanced HCC, which can extend overall survival in patients. As a multikinase inhibitor, sorafenib inhibits tumor cell proliferation and angiogenesis while inducing cancer cell apoptosis. However, its efficacy is limited due to primary and acquired resistance, poor solubility, fast metabolism, and low bioavailability. The ongoing research aims to overcome sorafenib resistance and improve its efficacy in HCC treatment. Understanding these mechanisms is crucial for developing novel therapeutic strategies to overcome drug resistance and improve patient outcomes in HCC treatment. In this study, we will examine the expression of genes involved in multidrug resistance after sorafenib resistance in hepatocellular cell model Hep3B cells.

Material and method

Hep3B cells were cultured in high glucose DMEM containing 10% FCS and treated with predetermined sorafenib. After sorafenib resistance is established, resistance formation will be checked by the MTT assay, colony formation, and scratch test. Hep3B-SR and Hep3B cells were trypsinized, and the cell pellets were collected. Total RNA was isolated using a cell pellet with an RNA extraction kit. Total RNA was reverse transcribed into cDNAs using a cDNA synthesis kit. cDNA was used as a template for real-time analysis. The human beta microglobulin gene was used as an internal control. MDR1, MRP1, MRP2, MRP3, and BCRP in multidrug resistance-associated gene expressions were determined using specific primers at the mRNA level.

Result and discussion

Sorafenib resistance in Hep3B-SR cells was demonstrated by MTT assay, scratch test, and colony formation. Gene expression analysis also showed that MDR1, MRP1, MRP2, MRP3, and BCRP genes, which are related to drug resistance, were differentially regulated in their expression.

Conclusion

The observed sorafenib resistance in Hep3B-SR cells is likely the result of a multifaceted process involving the upregulation of various drug efflux transporters. This understanding could potentially lead to the development of targeted therapies to overcome sorafenib resistance in HCC, possibly by inhibiting specific transporters or their regulatory pathways.

Introduction

Anaplastic Large Cell Lymphoma (ALCL) is a T-cell lymphoma driven by the constitutive activation of the Anaplastic Lymphoma Kinase (ALK) due to a chromosomal translocation of the gene, resulting in the formation of the oncogenic chimeric protein NPM-ALK. Many patients with ALK+ ALCL tumors that undergo remission for years quickly relapse upon TKI cessation due to a re-activation of drug-tolerant persister cells (DTPC). We have demonstrated a role for the tumor microenvironment (TME) as a key element in supporting the survival of DTPCs. We identified a role of the CCL19/21-CCR7 survival pathway in DTPCs resistant to ALK TKI. In this work, we investigate whether blocking CCR7 with a newly developed IgG human antibody (CAP-100), combined with ALK TKI crizotinib can prevent relapses by eradicating DTPCs.

Material and method

CCR7 expression and CAP-100 binding were tested by flow cytometry with a commercial CCR7 antibody and CAP-100 in ALK+ ALCL cell lines and PDX-derived cell line. Patient-Derived Xenograft (PDXs) mouse models were made by subcutaneously injecting ALK+ ALCL cells in NSG mice (PDX-DN and PDX-MTK). For in vivo experiments mice were split into four cohorts of treatment: vehicle, CAP-100, crizotinib, and a combination of both drugs. Crizotinib was given orally at 50 mg/kg/day in PDX-DN and at 100 mg/kg/day in PDX-MTK; CAP-100 was given by peritoneal injection every 3 days at a dosage of 10mg/kg in both PDX models. Tumor growth was tracked with a caliper every three days. Mice were euthanized at a human endpoint. Tumors were resected and snap-frozen or formalin-fixed for further analysis. Immunohistochemistry (IHC) analysis was performed to assess ALK positivity on tumor tissues and organs.

Result and discussion

CCR7 expression was assessed in ALK+ALCL cell lines and both PDX models, showing positivity in all lines and PDXs with some heterogeneity. In therapeutic experiments, after two weeks of treatment, mice treated with crizotinib alone or with the combo showed decreased tumor mass in both PDX models. In PDX-DN model, after treatment suspension mice that received crizotinib alone all relapsed. In contrast, mice treated with the combo crizotinib+CAP100 had significantly extended survival, and only one out of eight mice had a late relapse. In the PDX-MTK model, mice treated with crizotinib alone developed brain dissemination; mice treated with the crizotinib+CAP100 showed significantly less brain involvement, also confirmed by immunohistochemistry for ALK

Conclusion

CAP-100 boosts crizotinib activity in ALK+ ALCL PDX models by aiding the killing of DTPC in a subset of mice. The addition of CAP-100 to crizotinib markedly reduced the dissemination of lymphoma cells to the brain confirming our previous data that showed that genetic knock-out of CCR7 impaired lymphoma dissemination to the brain. Overall, these data show that the addition of CAP-100 to an ALK TKI could improve the cure rate and prevent lymphoma spread to critical sites like the brain.

EACR25-1655

Intrinsic Mechanisms of Resistance to CDK4/6 Inhibitors in Luminal Metastatic Breast Cancer

M. Aybar¹, C. Abuín¹, L. Pedrouzo¹, P. Palacios², T. Curiel², J. Cueva², C. Rodriguez², R. López², C. Costa¹

¹FIDIS, Oncology, Santiago de Compostela, Spain

²SERGAS, Oncology, Santiago de Compostela, Spain

Introduction

Hormone receptor-positive (HR+) and HER2-negative breast cancer accounts for approximately 70% of cases. In early stages, standard treatment includes surgery and endocrine therapy (ET), reducing the risk of late recurrence. However, over 30% of patients develop advanced disease, for which CDK4/6 inhibitors (CDKi) represent the standard treatment. Approximately 20% of patients show intrinsic resistance to combined therapy, and no reliable tools exist to predict treatment response. Therefore, managing patients with resistance to CDKi presents a significant clinical challenge. Preliminary studies from our group have shown increased STAT3 expression in circulating tumour cells from patients treated with CDKi who did not respond to first-line treatment (recurrence within 6 months by RECIST criteria). Therefore, we aim to demonstrate whether STAT3 is associated with the mechanisms underlying intrinsic resistance to CDKi in HR+/HER2- metastatic breast cancer.

Material and method

In vitro assays were performed using luminal breast cancer cell models. STAT3 was activated with IL-6 and inhibited using C188-9, a STAT3 inhibitor. STAT3 modulation was confirmed by Western blot. MTT assays were performed to study cell viability and resistance to CDKi (Palbociclib). Transwell migration assays were conducted to assess functionality. Transcriptomic analysis by RNA sequencing was performed externally. Statistical significance was determined by the Mann-Whitney U test ($p < 0.05$) or Wald binomial test ($|fc| \geq 2$ and raw p -value < 0.05).

Result and discussion

IL-6-induced cell models showed enhanced STAT3 activation, as indicated by the STAT3/p-STAT3 ratio by Western blot. In contrast, inhibited cell models showed reduced phosphorylation levels in STAT3, confirming the inhibitory effect of C188-9. Thus, they are suitable models for studying the link between STAT3 activation and resistance to CDKi. The activation of STAT3 (via IL-6) induces resistance to CDKi, and its inhibition in induced cells increased the sensitivity to CDKi ($p = 0.028$), suggesting that STAT3 inhibition may reverse resistance to CDKi. Moreover, STAT3 activation

associates with increased cell migration and enhanced viability. Differential gene expression analysis between cell lines with activated/inhibited STAT3 identified a set of genes that by Gene Ontology analysis revealed an enrichment in key pathways related to tumour progression and therapy resistance (PPI enrichment p-value: 0.00148) that need further validation.

Conclusion

Preliminary data suggest that STAT3 activation induces resistance to CDK inhibitors in HR+/HER2-cells, while its inhibition sensitises these cells to treatment. These findings highlight the potential of STAT3 as a response biomarker and a possible therapeutic target to counteract resistance to CDK inhibitors in this breast cancer subtype.

EACR25-1664

Genomic Instability and Epigenomic Dysregulation as Hallmarks of mCRC Therapy Resistance – Findings from Broad ctDNA Molecular Profiling (METACC)

D. Cambor¹, F. Gimeno-Valiente^{1,2}, J. Martín-Arana^{1,3}, B. García-Micó^{1,3}, B. Martínez-Castedo^{1,3}, C. Martín-Bravo⁴, B. Palomar de Lucas^{1,5}, C. Martínez-Ciapaglini^{1,3,5}, A. Cervantes^{1,3}, N. Tarazona^{1,3}

¹INCLIVA Biomedical Research Institute, Medical Oncology, Valencia, Spain

²University College London Cancer Institute, Cancer Evolution and Genome Instability Laboratory, London, United Kingdom

³Instituto de Salud Carlos III, CIBERONC, Madrid, Spain

⁴Hospital Regional Universitario, Málaga, Spain

⁵INCLIVA Biomedical Research Institute, Department of Pathology, Valencia, Spain

Introduction

Despite its significance, the mechanisms behind therapy resistance in metastatic colorectal cancer (mCRC) remain poorly understood. Circulating tumor DNA (ctDNA) offers a unique opportunity to explore them, as it thoroughly captures intratumor heterogeneity and facilitates longitudinal monitoring. However, most studies have focused on known mutations, mainly related to anti-EGFR resistance. The METACC study aims to go beyond mutation-centric approaches to uncover novel mCRC therapy resistance mechanisms.

Material and method

We analyzed a retrospective cohort of 30 microsatellite-stable mCRC patients, with plasma samples collected at diagnosis and at progression to first-line therapy (chemotherapy ± anti-VEGF or anti-EGFR). Whole-exome sequencing (WES) was performed on both timepoints and on matched WBCs (to exclude non-tumoral variants). Unique molecular identifiers and high-sensitivity variant calling enabled robust detection of low-frequency variants. McNemar's test identified mutations enriched at progression, and multivariable Cox regression assessed their impact on survival. Methylation changes were analyzed using Infinium MethylationEPIC v2.0 BeadChips (~930k CpGs) with a plasma-adapted

workflow. SeSAMe processing and subsequent DMRCate analysis identified differentially methylated regions (DMRs), prioritizing those overlapping with regulatory regions.

Result and discussion

Plasma WES identified ARID1A mutations as the main acquired event (progression vs. diagnosis: 14/30 vs. 5/30; p = 0.022), shortening time to progression (HR = 3.2, p = 0.036). Variant allele frequency (VAF) gains in ARID1A correlated with increases in the tumor mutational burden (TMB) ($\rho = 0.37$; p = 0.037), in line with the gene's role in maintaining genomic integrity. Progression also concurred with VAF increases in genes associated with therapy resistance via 1) epigenetic dysregulation (e.g.: NF1, KMT2D), and 2) DNA mismatch repair (MSH2, MLH1). The latter strongly correlated with TMB ($\rho = 0.72$; p < 0.001), further implicating genomic instability. Differential methylation analysis identified 16,026 DMRs (198 with $|\Delta\beta| > 0.2$), including the hypermethylation of an ARID1A enhancer ($\Delta\beta = 0.29$), suggesting a dual mechanism of ARID1A inactivation. Enrichment analysis linked these epigenetic alterations to three major pathway groups: 1) tumor metabolism and microenvironment, 2) anti-EGFR resistance, and 3) longevity/mTOR signaling pathways. Notably, hypermethylation of the mTOR inhibitor DEPTOR ($\Delta\beta = 0.35$) and hypomethylation of SOX2-OT ($\Delta\beta = -0.33$) suggest a role in enhancing tumor plasticity and stemness.

Conclusion

Comprehensive ctDNA profiling reveals tumor plasticity as a key mechanism of resistance to therapy in mCRC, driven by both genomic instability and epigenomic dysregulation. Expanding the METACC cohort will help explore actionable biomarkers like ARID1A loss, which may inform immunotherapy strategies.

EACR25-1689

Overcoming Antibody-Drug Conjugate Resistance in HER2-Positive Breast Cancer: Insights into Molecular Mechanisms and Targeted Therapeutic Approaches

O. Yong¹, T. Lee¹, B. Lipert¹, E. Leung¹, M. Flinterman¹, S. Jamieson¹

¹University of Auckland, Auckland Cancer Society Research Centre, Auckland, New Zealand

Introduction

HER2-positive breast cancer accounts for 15–20% of all breast cancer cases. Second-generation antibody-drug conjugates (ADC) trastuzumab deruxtecan (T-DXd; Enhertu®) and trastuzumab duocarmazine (SYD985) have shown effectiveness in HER2-positive and HER2-low metastatic breast cancer. However, not all patients respond due to intrinsic or acquired resistance, as observed with other HER2-targeting therapies. Efforts to understand the mechanisms involved in resistance are essential for identifying strategies to overcome it.

Material and method

Cas9 expressing HER2-positive HCC1954 and MDA-MB-361 cells were transduced with the MinLibCas9 single guide RNA (sgRNA) library and exposed to T-

DXd and a SYD985 biosimilar as well as their respective cytotoxic payloads (DXd, a topoisomerase 1 inhibitor and DUBA, a DNA alkylator) for 30–45 days. High-throughput sequencing identified gene knockouts enriched or depleted in response to treatment. BT-474, HCC1954, and MDA-MB-361 cells were continuously cultured in T-DXd for 30–45 days to establish resistant models. RNA was extracted and subjected to RNA sequencing (RNASeq) to identify transcriptional changes associated with resistance. Antiproliferative activity of treatments was evaluated by thymidine incorporation assay.

Result and discussion

Whole-genome CRISPR/Cas9 screens revealed a high correlation of gene hits between the ADCs and their payload, particularly for T-DXd and DXd. Gene hits showed limited overlap between T-DXd and the SYD985 biosimilar, suggesting distinct resistance mechanisms for different ADCs. The top 500 candidate genes were identified for further validation using a focused sgRNA library. T-DXd resistance emerged after continuous culture in all three cell lines. HER2 expression was retained in BT-474 and MDA-MB-361 but decreased in HCC1954 cells. BT-474 and MDA-MB-361 resistant cells retained sensitivity to the ADC trastuzumab emtansine and the tyrosine kinase inhibitors neratinib and lapatinib. All resistant models also exhibited cross-resistance to the DXd payload. RNASeq analysis revealed upregulation of interferon-alpha and interferon-gamma signalling pathways across all resistant cell lines, while RET emerged as the most significantly down-regulated gene. Combination therapy with T-DXd and the RET inhibitor selretinib demonstrated synergy in all three treatment-naïve cell lines.

Conclusion

Our study provides insight into the molecular basis of ADC resistance, identifying potential targets to overcome resistance and enhance ADC efficacy in HER2-positive breast cancer. The identification of RET downregulation in resistant cells and the observed synergy between T-DXd and selretinib highlight a potential strategy for limiting T-DXd resistance.

Exploring potential strategies overcoming the PARPi resistance in the Olaparib induced MDA-MB-436 resistant model

Q. Li¹, F. Fan¹, J. Xiang¹, X. Qiang², L. Zhou¹, W. Zhang¹, H. Ni¹, J. Zhang¹, Y. Lei¹, Q. Gu²

¹*WuXi AppTec, In Vivo Pharmacology Unit, WuXi Biology, Suzhou, China*

²*WuXi AppTec, In Vivo Pharmacology Unit, WuXi Biology, Shanghai, China*

Introduction

Poly (ADP-ribose) polymerase inhibitors (PARPi) have emerged as a promising therapeutic approach in the treatment of various cancers, particularly those with deficiencies in DNA repair mechanisms. However, the clinical efficacy of PARPi is often limited by the development of resistance, which poses a significant challenge to their long-term use. Elucidating the molecular mechanisms underlying PARPi resistance is crucial for developing novel therapeutic agents and

strategies to overcome this resistance and optimize patient treatment regimens.

Material and method

Olaparib-resistant MDA-MB-436 breast cancer cell line was generated through prolonged in vitro exposure to escalating doses of Olaparib. In vitro and in vivo efficacy studies were conducted to validate the resistance to Olaparib.

Result and discussion

The MDA-MB-436-R-Olaparib model exhibited robust drug tolerance both in vitro and in vivo, with cross-resistance to other PARP inhibitors. Notably, cell viability assays revealed that the MDA-MB-436-R-Olaparib cells had reduced sensitivity to cisplatin compared to parental MDA-MB-436 cells.

Conclusion

In summary, this Olaparib-resistant model facilitates a systematic investigation of PARPi resistance mechanisms and discovery of combinatorial therapeutic strategies.

EACR25-1707

Chlorpromazine nanoparticles enhance anti-cancer effect of Doxorubicin nanoparticles preventing their extrusion

A. Mishra¹, N. Singh¹, P. Chattopadhyay¹

¹*AIIMS, New Delhi, Biochemistry, New Delhi, India*

Introduction

Anti-cancer agents like Doxorubicin (DOX) encapsulated in biodegradable PLGA nanoparticles (NPs) can be used to overcome challenges like off-target effects, drug resistance and dose limiting toxicity. Previous findings in our lab show that NPs are also actively exocytosed out of the cell and modulation of intracellular trafficking of NPs through the subcellular membranous structures, using small molecules like Chlorpromazine (CPZ), may play a key role in enhancing NPs retention within the cells and allow greater drug unloading in a single pass. We have tested this effect of CPZ to enhance anti-cancer effect of Doxorubicin (DOX) incorporated NPs.

Material and method

DOX and CPZ drug incorporated PLGA NPs were synthesized by single emulsion solvent evaporation method and characterized. Drug encapsulation efficiency was calculated. The IC₅₀ of DOX and CPZ was calculated in three cell lines: LN229, HeLa and U87 MG for 48hr treatment. Percentage viability of cells following 48hr treatment with various combinations of DOX and CPZ NPs were checked in the three cancer cell lines by MTT assay with appropriate controls.

Result and discussion

The average size of nanoparticles was less than 230nm and average zeta potential was less than -7mV. MTT assay 48 hrs following treatment with various combinations of DOX and CPZ NPs demonstrated:

- i) PLGA NPs itself were not toxic.
- ii) Significant cytotoxicity was observed by both DOX in solution and DOX incorporated NPs when given at doses below IC₅₀.
- iii) CPZ has some cytotoxic effects of its own when given in solution whereas no significant cytotoxicity was observed when incorporated within NPs.
- iv) Cytotoxicity due to DOX NPs was significantly enhanced in the presence of CPZ in solution as well as

CPZ-NPs but co-treatment with CPZ NPs showed better cytotoxicity as compared to CPZ in solution.

Conclusion

Our results demonstrate that co-treatment of DOX-NPs along with CPZ in solution or as CPZ NPs significantly enhance the cytotoxic efficiency of the anticancer drug, thereby reducing the dose of anticancer drug required. Co-treatment of DOX-NPs with CPZ-NPs showed better cytotoxicity as compared to CPZ in solution.

⁵*Izmir Tinaztepe University, Department of Medical Biology, Faculty of Medicine, Izmir, Turkey*

Introduction

Prostate cancer (PCa) is one of the most common cancers worldwide, and its incidence is still increasing. Androgen deprivation therapy (ADT) is an essential treatment method in the management of PCa. However, most patients will eventually develop resistance to ADT and will have a poor prognosis. c-Met is a receptor kinase causing ADT resistance. Research showed an inverse correlation between androgen receptor (AR) and c-Met in the primary PCa tumors. Recently, miRNA-related therapeutic approaches have gained attention due to their potential in reversing the pathology of diseases. In this study, we investigated the role of miRNAs in regulating AR and c-Met signaling in the progression of PCa.

Material and method

Large patient cohorts were analyzed by bioinformatic tools to determine the expression pattern of c-Met, AR, and miRNAs in PCa. TransmiR were used to find miRNAs transcriptionally regulated by AR. Precursors and mature-miRNA, AR, and c-Met expressions were studied in PCa cells by qPCR. The activation and expression level of c-Met and AR were analyzed by Western Blot (WB). Cells were transfected with miRNA oligos (mimic or inhibitor) and their controls to investigate the effect of miRNA on c-Met and/or AR signaling and biological behaviors of cells.

Result and discussion

In silico analysis of AR, miR-181a-5p and c-Met expression confirmed that AR and miR-181a-5p levels are higher in the PCa primary tumors than in normal prostate tissues, whereas c-Met expression levels were lower in the same cohort. Bioinformatic analysis revealed that AR might regulate miR-181a-5p expression because hsa-mir-181a-2 and hsa-mir-181a-1 genes, which form mature miR-181a-5p, have “androgen response element” in their promotor regions. Moreover, AR negative cell line (PC3) expressed high c-Met and miR-181a-5p,

whereas cells (LNCaP) with high AR levels have low c-Met expression. Transfections with miRNA-oligos showed that miR-181a-5p regulates c-Met signaling and the biological behaviors of PCa cells, including the proliferation migration and clonogenicity. Overall, it seems that in prostate cancer progression, AR regulates miR-181a-5p expression to suppress c-Met expression; however, when signaling is inhibited by AR-targeted therapies, a decrease in miR-181a-5p expression is observed.

Conclusion

These findings display a novel molecular mechanism of AR/miR-181a-5p/c-Met axis in the progression of PCa. Strategies to increase miR-181a-5p levels might be an alternative approach for the inhibition of c-Met to prevent resistance to ADT.

This project is funded by TUBITAK (project #223S749).

miR-212-3p Down-Regulates the MAPK/ERK Pathway to Mitigate Oxaliplatin Resistance in Colorectal Cancer

T. Hsu¹, C. Chu¹, L. Hung¹

¹*National Cheng Kung University, Department of Biotechnology and Bioindustry Sciences, Tainan, Taiwan*

Introduction

Colorectal cancer (CRC) is one of the three most lethal cancers in the world. Chemotherapy, such as FOLFOX, is an oxaliplatin-based regimen used as an adjuvant treatment. However, prolonged chemotherapy often leads to drug resistance, reducing efficacy and increasing recurrence rates. It was reported that the ERK signaling pathway is involved in regulating oxaliplatin resistance. MicroRNAs (miRNAs) are critical regulators of chemotherapy resistance and drug efflux. We found that miR-212-3p is related to the MAPK/ERK pathway. This study investigates the role of miR-212-3p in overcoming drug resistance and highlights its potential as a therapeutic target to enhance treatment outcomes in CRC.

Material and method

Human CRC cell lines (HCT116, LoVo, SW480) and their corresponding oxaliplatin-resistant cells (oxaR#9, LoVoR, SW480R) were used to investigate the potential mechanisms of oxaliplatin resistance. After the transfection of miRNA mimics or siRNA, the expression level of miR-212-3p and FGF7 was analyzed by qPCR, and the ERK pathway-related proteins were detected by Western blot analysis. The CCK-8 assay and colony formation were used to evaluate the cell viability of oxaliplatin-resistant CRC.

Result and discussion

Previous reports and our results demonstrated that the ERK signaling pathway is highly activated in oxaliplatin-resistant CRC cells. A synergistic effect was observed when the ERK inhibitor trametinib was combined with oxaliplatin, resulting in enhanced anti-tumor effect of oxaliplatin-resistant CRC cells. We identified that the miR-212-3p had significantly reduced expression in oxaliplatin resistant CRC cells and associated with poor prognosis. Overexpression of miR-212-3p in drug-resistant CRC cells reduced oxaliplatin resistance,

induced apoptosis, and inhibited the ERK pathway. Additionally, FGF7 was confirmed as an miR-212-3p downstream gene. The high expression level of FGF7 was associated with poor prognosis, and its expression is significantly higher in resistant cells than in parental cells.

Conclusion

In this study, we showed that the overexpression of miR-212-3p significantly reduced drug resistance in CRC cells and inhibited ERK signaling. MiR-212-3p can directly regulate FGF7, and its overexpression is associated with poor prognosis. The potential of miR-212-3p as a biomarker to identify oxaliplatin-resistant patients who may respond to trametinib provides new options for personalized treatment approaches.

⁵CEITEC – Central European Institute of Technology, Masaryk University, Bioinformatics Core Facility, Brno, Czech Republic

Introduction

Breast cancer (BC) is a prevalent oncological disease among women worldwide. Although therapeutic options for BC have improved significantly in recent years, the emergence of therapeutic resistance substantially decreases treatment efficacy. Doxorubicin (DOX), a chemotherapeutic agent classified as a topoisomerase II inhibitor, is commonly used in the treatment of triple-negative BC and is also employed in advanced stages of hormone receptor-positive or HER2-positive BC. This work describes the derivation of a cell line model to explore the mechanisms contributing to acquired DOX resistance in BC.

Material and method

DOX-resistant cancer cells were derived from three BC cell lines (MDA-MB-231, JIMT-1, and T-47D) through continuous exposure to increasing DOX concentrations. A luminescent cell viability assay was used to assess the sensitivity of BC cells to chemotherapy. Functional assays included cell proliferation and migration analysis using the IncuCyte ZOOM system, *in vivo* tumorigenicity tests in SCID/bg immunodeficient mice, and β -galactosidase staining. Molecular and genomic changes in the resistant cancer cells were assessed using the RT2

Profiler PCR array, qRT-PCR, western blotting, array-based comparative genomic hybridization, and whole exome sequencing.

Result and discussion

The derived BC cells exhibited a 5 to 8-fold increase in IC₅₀ values upon the treatment with DOX, confirming their resistant phenotype. Cell proliferation and tumor growth were decreased in DOX-resistant cancer cells, but no statistically significant changes in cell migration were observed. Additionally, MDA-MB-231 and T-47D DOX-resistant cells displayed reduced β -galactosidase activity, a marker of cellular senescence. Molecular analysis revealed the deregulation of genes involved in drug resistance mechanisms, including those encoding ABC-transporters, genes involved in apoptotic signaling, drug metabolism, and genes and proteins implicated in DNA methylation processes. These changes partially corresponded with the observed copy number alterations in drug-resistant cells. Finally, single-nucleotide variants were prevalent mutations in the resistant cancer cells, affecting multiple genes, including the target enzyme of DOX.

Conclusion

The acquisition of DOX resistance in BC is a complex process involving diverse changes at genomic, molecular, and functional levels. These changes include well-described multi-drug resistance mechanisms, alterations specific to DOX resistance, and newly observed changes in drug-resistant BC cells that warrant further investigation.

³Université de Caen Normandie, UR 4258 CERMN, Normandy Center for Drug Studies and Research, Caen, France

Introduction

Ovarian cancers (OC) represent the leading cause of death from gynecological cancers worldwide, advanced stages displaying a survival rate below 40%. First-line treatment associates surgery and chemotherapy based on carboplatin and PARP inhibitors (PARPi). However, PARPi effectiveness relies on deficiencies in Homol-

ogous Recombination DNA repair (HRD status), present in 50% of OC patients. Double stranded DNA breaks can be repaired by Non-Homologous End Joining (NHEJ) or Homologous Recombination (HR) pathways. While HR is considered faithful, NHEJ is not and leads to cell death. Hence, defects in HR (HRD) sensitize to DNA damaging drugs. Our project is to develop a precision medicine approach to induce an HRD phenotype via UBE2N inhibition, an essential mediator of HR, to sensitize ovarian tumours to DNA damaging drugs (carboplatin and PARPi).

Material and method

We used an ovarian cancer cell line and PDTO (Patient-Derived Tumor Organoids) models generated from tumor of patients grown in 3D in extracellular matrix. To inhibit UBE2N, we use an inhibitor described by the literature, NSC697923 and the lipotransfection of Cas9-RNP. HR DNA repair following UBE2N inhibition (UBE2Ni) will be assessed using multiple approaches: the comet assay (DNA damage), the RECAP test (activation of HR DNA repair mechanisms), the DR-GFP reporter system (effective HR DNA repair), and micronuclei quantification, a marker of genomic instability induced by the HRD phenotype. In parallel, we will investigate a potential correlation between the increase in DNA damage and/or the decrease in DNA repair by HR induced by UBE2N inhibition and its ability to sensitize cells to the action of DNA-damaging therapies (carboplatin, PARPi). Sensitization will be assessed by monitoring cell morphology using the IncuCyte S3 and CellDiscoverer 7 real-time imaging systems, as well as through viability assays and colony-forming assays.

Result and discussion

UBE2Ni by the NSC697923 or by knockout increases micronuclei and DNA damage and decrease HR DNA repair. In addition, UBE2Ni sensitizes an ovarian cancer cell line and a PDTO HRP model to PARPi whereas it does not sensitize an already HRD model.

Conclusion

These encouraging preliminary results will be validated in more PDTO models, and the effects on DNA repair more finely characterized. They underscore the interest of UBE2Ni to sensitize OC to PARPi and justify the establishment of a drug design program with the Normandy Center for Drug Studies and Research (CERMN) to identify UBE2Ni for clinical using. Our strategy could be applied to other cancer locations where DNA-damaging therapies are currently used such as pancreatic cancer (oxaliplatin-based chemotherapy and PARPi), breast cancer (carboplatin, PARPi), and head and neck cancers (radiotherapy and cisplatin), thereby increasing its relevance in oncology.

EACR25-1827

A not expected effect of longterm temozolamide treatment on resistance of glioblastoma cells – an in vitro study

C. von Montfort¹, N. Klahm², A. Reichert², P. Brenneisen²

¹Heinrich Heine University Duesseldorf, Medical Faculty, Institute of Biochemistry and Molecular Biology I, Duesseldorf, Germany

²Heinrich Heine University Duesseldorf, Medical

Faculty, Biochemistry and Molecular Biology I, Duesseldorf, Germany

Introduction:

Glioblastoma multiforme (GBM) is the most common malignant brain tumor with a very poor prognosis. The standard treatment for GBM is surgical resection followed by chemoradiotherapy with temozolamide (TMZ), an alkylating agent which methylates the DNA at various sites. Methylation of the guanine at the O6 position leads to a falsely inserted base nucleotide during transcription, which subsequently activates miss match repair (MMR), resulting in numerous single strand breaks and finally in cell death. Although TMZ extends the survival rate, tumors rapidly develop resistance, which is mainly based on the O6-methylguanine-DNA-methyltransferase (MGMT) expression as well as base excision repair (BER) and MMR. Clinical studies show that low expression of MGMT in glioma patients resulted in a better therapeutic outcome. To increase TMZ efficiency in GBM, a combined treatment with highly specific MGMT inhibitors like Lomeguatrib (LG) is used.

Material and method

We studied both a commercially available TMZ resistant (T98G) and non-resistant (U373) glioblastoma cell line as well as the resistant cell line U373R which was generated by us via long term TMZ treatment of U373. Normal human dermal fibroblasts (NHDF) were used as control for normal (healthy) cells. All cells were treated with increasing concentrations of TMZ from 10 µM to 1000 µM for 48 to 96h and/or 50 µM LG, respectively. Cell viability was determined by MTT and SRB Assay. MGMT occurrence was examined via western blot and qPCR. Incubation with 10 µM 5-Aza-2'-desoxycytidine (Decitabin) for 5 days was used to determine the effect of the that methylation inhibitor on MGMT expression.

Result and discussion

U373 cells show a significant decrease in cell viability after TMZ treatment compared to U373-R and T98G. For T98G, this result can be explained by a generally high expression of MGMT. Surprisingly, the U373R cells showed resistance from TMZ treatment without showing any MGMT expression. The use of the DNA-hypo-methylating agent Decitabin indicates an involvement of MGMT promotor hypermethylation in the observed downregulation of MGMT in U373R. To find out whether the MMR is also involved in the observed TMZ resistance, qPCR was performed to check for basal expression of MMR subunits, and indeed, a lowered expression of the 2 subunits MSH2 and MSH6, being major players in MMR, was observed in U373R compared to U373 and T98G.

Conclusion

The observed data verify that there are different resistance mechanisms in GBM cells to overcome TMZ toxicity. Although it is known that other resistance mechanisms apart from MGMT overexpression exist in GBM, it was shown for the first time that long term treatment with TMZ results in a loss of MGMT instead of an increase in expression. Those mechanisms must be evaluated to get a better understanding of the origin of the resistance, and these data may support the development of new treatment strategies.

EACR25-1885**Intercellular Communication via Therapy-Induced Secretome Drives****Chemoresistance in Ovarian Cancer Cells**

P. Shnaider¹, A. Lashkin¹, M. Lukina¹, S. Provolovich¹, O. Ivanova¹, G. Arapidi¹, K. Anufrieva¹, I. Bekbaeva¹, M. Lagarkova¹, V. Shender¹

¹Lopukhin Federal Research and Clinical Center of Physical-Chemical Medicine of Federal Medical Biological Agency, Moscow, Russia

Introduction

A key difference between cancer and healthy tissues is the significant plasticity of cancer cells in response to stress. Recent studies have demonstrated that this adaptation is mediated not only by intracellular signaling pathways but also by enhanced intercellular communication. Using ovarian cancer cell lines, we showed that the secretome of apoptotic cancer cells differs significantly from that of non-apoptotic cells and can induce phenotypic changes in recipient tumor cells, leading to the development of chemoresistance.

However, the molecular mechanisms underlying this process remain largely unexplored.

Material and method

We investigated the therapy-induced secretion (TIS) of apoptotic cancer cells and its impact on chemoresistance using ovarian cancer cell lines SKOV3, OVCAR3, and MESOV. Non-cancerous cell lines (HaCaT, FT282, and fibroblasts) were used as controls. Proteomic analysis was performed using a Q Exactive HF mass spectrometer. Recipient cells incubated with therapy-induced or control secretomes were analyzed using the Illumina HiSeq 2500 sequencing system. Drug sensitivity was assessed using the MTT assay. Functional assays, including immunocytochemistry, fluorescence microscopy, and flow cytometry, were conducted to evaluate DNA repair activity and cell cycle progression. Calcium dynamics were measured using transient transfection with a calcium sensor combined with live fluorescence imaging on the Celena X system.

Result and discussion

TIS specifically induced chemoresistance in cancer cells but not in normal cells. Proteomic analysis revealed that chemotherapy-induced secretion is a dynamic process, different sets of proteins secreted at different time points. These proteins were involved in metabolism, DNA repair, translation, pre-mRNA splicing, and cell cycle regulation, including factors which were not previously recognized as secreted molecules. Functional studies confirmed that incubation with TIS led to the upregulation of molecular pathways associated with DNA repair and cell cycle progression in recipient cells. Furthermore, incubation with TIS led to the acquisition of resistance to DNA-damaging agents by prolonging the S-phase of the cell cycle and activating the DNA repair system.

Conclusion

Our findings demonstrate that chemotherapy triggers a dynamic secretion of signaling molecules that modulate the cell cycle and enhance DNA repair in recipient cancer cells, thereby promoting chemoresistance. These findings suggest a complex regulatory mechanism underlying therapy-induced intercellular communication, which may

be an important factor in tumor adaptation to therapy.

EACR25-1893**On-target mutations confer resistance to WRN helicase inhibitors in Microsatellite Unstable Cancer Cells**

G. Picco¹, Y. Rao², A. Al Saedi¹, S. Walker¹, S. Bhosle¹, G. Sharma³, M. Coelho¹, J. Houseley⁴, B. Schwartz³, M. Garnett¹

¹Wellcome Sanger Institute, Cambridge, United Kingdom

²GSK, Upper Providence, Pennsylvania., United States

³GSK, Cambridge, United States

⁴Babraham Institute, Cambridge, United Kingdom

Introduction

Werner helicase inhibitors (WRNi) are in clinical development for treating microsatellite instability (MSI) tumors, which depend on WRN due to defective mismatch repair. However, acquired resistance may limit their efficacy. Here, we systematically investigate resistance mechanisms to WRNi in cancer cells, focusing on on-target WRN mutations, cross-resistance among clinical-grade inhibitors, and potential therapeutic strategies to overcome resistance.

Material and method

We performed genome-wide CRISPR screens, pharmacogenomic profiling, and time-to-progression (TTP) assays to identify WRNi resistance mechanisms. Semi-saturation mutagenesis of WRN and long-term drug exposure studies were used to track resistance emergence. Structural modeling predicted the impact of mutations on drug binding, while viability assays and DNA damage markers validated cross-resistance. Patient-derived organoids (PDOs) from MSI colorectal cancer were used to assess clinical relevance.

Result and discussion

CRISPR screens confirmed WRN's essential role in MSI cells, with no genetic bypass mechanisms identified. Pharmacogenomic profiling of WRNi revealed modulators of sensitivity, including SMARCAL1, a chromatin remodeler linked to WRN-MSI synthetic lethality. TTP assays and mutagenesis identified recurrent on-target WRN mutations driving resistance, including G729D, which disrupts WRNi binding, causing broad cross-resistance, and I852F, which selectively confers resistance to HRO761 while preserving sensitivity to VVD-133214. A non-canonical splice site mutation led to exon skipping but retained WRN function, allowing continued MSI dependency. These findings were validated in PDOs, where resistance to HRO761 emerged through the same exon-splicing mutation. Notably, WRNi-resistant cells remained sensitive to ATR inhibitors and irinotecan, supporting a WRN-specific resistance mechanism.

Conclusion

Our study identifies on-target WRN mutations as key drivers of three clinical grade WRNi resistance and highlights strategies to overcome it. By characterizing cross-resistance across clinical-grade WRNi, we propose switching inhibitors with different mechanisms of action to restore sensitivity. These findings provide a framework for biomarker-driven patient stratification, resistance

monitoring through ctDNA, and combinatorial approaches to improve WRNi efficacy in MSI cancers.

EACR25-1980

BMI1 as a therapeutic target to overcome chemoresistance in high-grade serous ovarian cancer

S. Zafar¹, S. Hänninen¹, A. Laury^{1,2}, O. Carpén^{1,2}

¹University of Helsinki, Research Program in Systems Oncology, Research Programs Unit, Faculty of Medicine, Helsinki, Finland

²Helsinki University Hospital, Department of Pathology, University of Helsinki and HUS Diagnostic Center, Helsinki, Finland

Introduction

High-grade serous ovarian cancer (HGSC) is the most common and lethal form of ovarian cancer, characterized by high relapse rates and resistance to platinum-based chemotherapy. Despite advancements, chemoresistance remains a major challenge. Our previous research has contributed to understanding tumor heterogeneity and resistance mechanisms in HGSC by identifying key molecular drivers. A frequent alteration is homologous recombination deficiency, which leads to genomic instability while paradoxically sensitizing tumors to platinum-based treatment. BMI1 (B-cell-specific Moloney murine leukemia virus integration region 1), a polycomb complex protein, regulates chromatin remodeling, stemness, epithelial-mesenchymal transition, and homologous recombination-mediated DNA damage repair. High BMI1 expression has been associated with poor prognosis and chemoresistance in various cancers. Importantly, our unpublished work shows that high BMI1 expression in HGSC is an independent predictor of reduced response to platinum-based chemotherapy and overall survival, making it a potential candidate for therapeutic interventions.

Material and method

To investigate BMI1's biological role in HGSC, we generated CRISPR/Cas9-edited HGSC cell lines (e.g., CAOV3, Kuramochi, A2780) with BMI1 overexpression (BMI1-OE) and knockout (BMI1-KO) and validated them by Western blotting. We will use the cell lines to study BMI1's impact on tumor progression in vitro and in vivo. RNA sequencing and multiple (2D and 3D) functional in vitro assays (e.g., cell proliferation assay, 2D migration assay, 3D invasion assay) are used to further characterize BMI1-related pathways.

Result and discussion

We have successfully generated and validated BMI1-OE and BMI1-KO HGSC cell lines (e.g., CAOV3, Kuramochi, A2780). Preliminary functional data suggest that BMI1 overexpression promotes tumor aggressiveness, while knockdown reduces invasive properties. Our recent unpublished work showed that BMI1 expression is elevated in metastatic HGSC lesions. High BMI1 expression correlates with poor prognosis, as indicated by a shorter platinum-free interval and overall survival. Artificial intelligence (AI)-assisted RNA-ISH quantification of BMI1 further supports this correlation. An important avenue of our research is to explore how homologous recombination functionality is altered in the

BMI1-modified cell lines. Additionally, we will assess the therapeutic potential of small-molecule BMI1 inhibitors in combination with platinum-based chemotherapy in vitro and in vivo.

Conclusion

Our study highlights BMI1 as a promising prognostic marker and therapeutic target in HGSC. By integrating patient sample analysis with functional studies, we aim to provide insights into BMI1's role in chemoresistance. This research aims to develop BMI1-targeted therapies to overcome platinum resistance in HGSC.

EACR25-1999

The Role of AP-1 Target Transcript Vav3.1 in the Regulation of Osimertinib Resistance in Lung Adenocarcinoma

N. Gult�rat¹, S. Eris¹, B. Dayanc¹, S. Senturk¹

¹Izmir Biomedicine and Genome Center, Genomics and Molecular Biotechnology, Izmir, Turkey

Introduction

Lung adenocarcinoma (LUAD) is one of the deadliest cancers, with EGFR mutations – particularly EGFR-TKI sensitizing mutations – being common. Currently, osimertinib is the most used and effective FDA-approved EGFR-TKI; however, resistance is inevitable. Focusing on unknown epigenetic and transcription factors contributing to osimertinib resistance, we recently employed a CRISPR knockout screening that identified the AP1 transcription factor (FOSL1 and JUN) as a key modulator of resistance. Silencing FOSL1 or JUN restored drug sensitivity, revealing a synthetic lethal interaction with the EGFR pathway. Integrative multi-omics analyses (RNA-Seq, ATAC-Seq, CRISPR knockout screening) highlighted VAV3, a key molecular-switch in Rho-GTPase family, and specifically its major transcript VAV3.1 as a promising resistance-associated gene. Ongoing studies aim to clarify the role of VAV3.1 in the "transcriptional regulation – resistance" axis.

Material and method

To investigate the role of VAV3.1, multiple bio-informatic analyses and in vitro experiments were conducted. qRT-PCR analysis confirmed the dominance of VAV3.1 over VAV3 in HCC827-OsiR cells, also validated by RNA-Seq. VAV3.1 was then knocked out using CRISPR-Cas9 methodology. Possible synthetic lethal interactions between VAV3.1 knock-out and osimertinib were tested through 2D colony formation, competitive cell proliferation, and BrdU assays. Western blotting was performed to explore the effects of VAV3.1 on survival pathways. Vav3.1 was then overexpressed in parental HCC827 cells to assess the changes in proliferation and survival capabilities.

Result and discussion

Our findings validated that VAV3.1, containing a unique 110-nucleotide sequence that suggests a distinct promoter regulation, was the dominant transcript of VAV3 in our cells. Using integrative multi-omics studies, VAV3.1 was identified to have significant changes in expression and chromatin accessibility, suggesting a role in resistance. However, in vitro assays showed a minor effect of VAV3.1 silencing in osimertinib sensitization.

Conclusion

Here we provide the first preliminary findings of a unique VAV3 transcript, VAV3.1, as a downstream target of the AP1 family in osimertinib resistance. Our findings highlight the complexity of VAV3.1's involvement in drug resistance that could stem from the polyclonal nature and heterogeneity of our cells. Ongoing experimental strategies aim to further investigate the precise role of VAV3.1 in resistance mechanisms for a more comprehensive understanding of its function.

⁷Hospital Clínico Universitario of Valencia, Department of Medical Oncology, Valencia, Spain

Introduction

Ovarian cancer is the most lethal gynecological tumor. PARP inhibitors (PARPi) have revolutionized the high grade serous ovarian cancer (HGSOC) management. However, most of HGSOC patients will suffer disease progression, highlighting the importance of studying PARPi resistance mechanisms.

Material and method

39 archival tissue samples from diagnosis or debulking surgery were obtained of patients with platinum-sensitive relapsed HGSOC treated with PARPi as maintenance prior to 2020 in 3 Spanish institutions. Sixteen paired archival samples at progression were also retrieved. The expression of 180 genes related to DNA damage and repair was analyzed, using Nanostring technology. To identify intrinsic resistance biomarkers (BKs), PARPi progression-free survival (PFS) was analysed according to high or low gene expression (cutoff: median) in baseline samples. Differentially expressed genes (DEG) analysis between baseline and progression samples ($|FC|=1.5$; $p\text{-value} \leq 0.05$) was performed to identify acquired resistance BKs. Moreover, OVCAR3 and OVCAR4 cell lines were long term exposed with increasing doses of niraparib, generating two in vitro PARPi-resistant models.

Result and discussion

In our set of baseline samples, high expression of XRCC2 and POLE2 correlates with significantly better PFS-PARPi in patients, whereas high expression of ERCC1 is associated with significantly shorter PFS-PARPi. DEG analysis revealed that CDKN1A, CDKN1B, CDKN2C and WEE1, which are strong negative regulators of CDK-Cyclin complexes, were robustly downregulated at progression. In vitro studies showed that niraparib treatment triggered a CDK4 expression reduction, a G2/M phase arrest and increased homologous recombination activity (RAD51 increase) in PARPi-sensitive cells. In contrast, CDK4 was overexpressed in niraparib-resistant cells, enabling the cell cycle progression despite niraparib.

Conclusion

XRCC2, POLE2 and ERCC1 genes emerge as potential BKs of intrinsic resistance and that cell cycle overactivation could be an acquired resistance mechanism to PARPi in HGSOC.

EACR25-2033

Identifying miR-7-5p/KEAP1/NRF2 and miR-122-5p/ADAM10/IL-6 signaling axes in Castration and Enzalutamide-resistant prostate cancer cells

C. Zaim¹, N. Ersoy Tunali¹

¹Istanbul Medeniyet University, Molecular Biology and Genetics, İstanbul, Turkey

Introduction

Oxidative stress and inflammatory cytokines play crucial roles in developing resistance to the standard treatment approaches for castration-resistant prostate cancer (CRPC) and Enzalutamide-resistant prostate cancer (ERPC). Imbalanced oxidative stress with increased reactive oxygen species (ROS) and inflammatory cytokines, especially interleukin-6 (IL-6) sustains the AR-independent survival pathways, promoting the progression of CRPC and ERPC. The identified regulators of oxidative stress and tumor progression, KEAP1 and ADAM10, have been demonstrated to be the targets of miR-7-5p and miR-122-5p, respectively. In this study, we aimed to evaluate the involvement of miR-7-5p and miR-122-5p in CRPC and ERPC in vitro models regarding their association with total antioxidant status (TAS), total oxidant status (TOS), and IL-6 levels.

Material and method

The CRPC cell line model was generated by long-term androgen deprivation of LNCaP cells, while ERPC was modeled by the treatment of CRPC cells with increased doses of Enzalutamide for 3 months. For gene expression analyses, total RNA was isolated and the expression levels of KEAP1, NRF2, ADAM10, miR-7-5p, and miR-122-5p were assessed using qRT-PCR. The released levels of IL-6 were determined by the ELISA method, and the colorimetric TAS/TOS assay was used to determine the oxidative stress status of the cells.

Result and discussion

The expression level of miR-7-5p was shown to be significantly increased in the ERPC, compared to CRPC cells. In association with this, KEAP1 was significantly decreased in the ERPC cells, highlighting the severity of oxidative stress. NRF2 expression level was determined

to remain unchanged in ERPC cells, compared to CRPC. Both CRPC and ERPC cell lines showed highly increased oxidative stress. However, alongside NRF2 status, no significant difference was evaluated between CRPC and ERPC cells in the TOS levels, while TAS levels were found to be slightly decreased in ERPC cells. miR-122-5p expression showed a significant upregulation in ERPC, compared to CRPC cells, while its target gene, ADAM10, was shown to be significantly downregulated in ERPC cells. ADAM10 has been identified to negatively regulate IL-6, which we found to be increased in ERPC cells, though not statistically significant.

Conclusion

We showed that miR-7-5p and miR-122-5p are differentially expressed in ERPC when compared to CRPC. This may potentially impair oxidative stress balance by suppressing KEAP1, and sustain survival pathways by suppressing ADAM10, which favors IL-6 release. This study highlights the interplay among miR-7-5p, miR-122-5p, oxidative stress, and cytokine signaling, providing novel insights into the drug resistance mechanisms and potential therapeutic strategies for advanced prostate cancer.

EACR25-2034

Identification of microRNAs and their target genes associated with acquired resistance of primary melanoma cells to targeted therapy

I. Vlašić¹, A. Horvat¹, A. Tadijan¹, J. Josić¹,

C. Supina Pavić¹, N. Slade¹

¹Ruder Bošković Institute, Zagreb, Croatia

Introduction

Melanoma is aggressive skin tumor prone to metastasis with frequent mutations in the components of MAPK signaling pathway. Due to fast response, BRAF-mutated melanoma was initially treated with monotherapy targeting BRAF kinase (BRAFi), while lately therapy includes combination of inhibitors that target both BRAF and MEK kinases (BRAFi/MEKi). Although initially response to targeted therapy is promising, disease relapses due to acquired therapy resistance. It has been shown that acquisition of tumor cell resistance to treatment can be associated with altered expression levels of microRNAs (miRNAs). Nevertheless, the association of specific miRNA expression profile and acquired melanoma resistance to BRAFi or BRAFi/MEKi therapy has not been thoroughly investigated.

Material and method

Comprehensive analysis of miRNA expression using NGS technology was performed on primary melanoma cells that differ in sensitivity to targeted therapy. Differentially expressed miRNAs were determined via sRNAde toolbox between treatment-sensitive primary melanoma cells and melanoma cells with acquired resistance to BRAFi or BRAFi/MEKi targeted therapy. After identifying miRNAs and validating their altered expression using RT-qPCR, we checked which predicted target genes are regulated via selected miRNA using several tools such as TargetScan, mirDIP, miRDB and miRTarBase. After selection of target mRNA, their

differential expression between primary cell lines was confirmed by RT-qPCR.

Result and discussion

We identified 700 miRNAs by miRNA-seq, from which 58 were shown to be differentially expressed. We have chosen to validate the miRNAs whose expression between sensitive and resistant cells differs at least 5 times. Interestingly, we observed reduced expression of hsa-miR-96-5p in BRAFi and BRAFi/MEKi resistant cells compared to treatment-sensitive cells. Next, we checked which predicted target genes are regulated via differentially expressed miRNAs and identified FOXO3 as hsa-miRNA-96-5p regulated gene. We validated differential expression of FOXO3 and observed its increased expression in targeted therapy resistant cells compared to treatment-sensitive cells.

Conclusion

Our results show that primary melanoma cells resistant to BRAFi or BRAFi/MEKi have higher expression of FOXO3 gene, so our further research will be focused on unraveling molecular mechanisms of FOXO3-dependent acquisition of resistance to BRAFi or BRAFi/MEKi in melanoma cells.

²University of Chile, Institute of Nutrition and Food Technology, Santiago de Chile, Chile

³University Hospital RWTH Aachen, Aachen, Germany

⁴Heidelberg University, Heidelberg, Germany

Introduction

The tumor microenvironment is a key driver of disease progression, with mechanical cues increasingly recognised as critical regulators of cancer development, alongside genetic and metabolic factors. This study explores how mechanical stress and confinement influence the expression of oncogenic features, by mimicking the forces acting on cancer cells in the early stages of neoplastic diseases.

Material and method

Using the MDA-MB-231 cancer cell line as a triple negative breast tumour model, the cells were cultured in a polymer-based semi-degradable hydrogel scaffold. The in vitro tumour model, named Tumour-Like Microcapsules, is composed of an alginate and gelatin blend with dimensions ranging from 400 to 600 µm and was designed to mimic the elasticity of early-stage breast tumours. The cells were immobilised and grown in the 3D tumour model, without cisplatin in the culture medium, using cells cultured as suspended spheroids and cells grown in cell culture flasks as 3D and 2D control, respectively. The cells were then isolated from the 3D milieus at different time points after seeding/

immobilisation (i.e., day 1, 2, 4, 7, 10 and 14). The cell resistance to anticancer drug cisplatin was assessed after reseeding the cells in 2D to avoid mass transfer restrictions. To gain deeper insight into the molecular mechanisms underlying this resistance, we conducted a temporal proteomic analysis to compare the protein expression profiles across the different culture conditions and examine how these evolve. Alterations in cell proliferation and increased cell heterogeneity upon confinement were also investigated.

Result and discussion

Cells cultured as spheroids and in the hydrogel scaffold exhibit a time-dependent increase in resistance to the anticancer drug cisplatin, which correlated with mechanical preconditioning. Our findings indicate that resistance emerges within two days post-seeding/immobilisation in both 3D models, though the temporal patterns differ. Notably, cells cultured in the micro-capsules display a distinct decrease in cisplatin sensitivity, aligning with the 3D mechanical preconditioning. The half maximal inhibitory concentration (IC₅₀) comparison shows more than a 2-fold increase between the IC₅₀ of 2D cultured cells and the cells cultured in the microcapsules for 14 days, 8.1 µM and 19.5 µM, respectively. Preliminary transcriptomic and proteomic results show that cells cultured in the different milieus express significantly distinct protein signatures related to proliferation, senescence and xenobiotic metabolism, which suggest the contribution of mechanical stress and confinement to the increase of primary chemoresistance.

Conclusion

Overall, this study highlights the role of mechanical forces in shaping cancer cell behaviour and resistance mechanisms. Understanding these influences could provide a better treatment strategy tailored to different stages of tumour progression.

Uncovering Transcriptional Signatures of Differential Drug Response in Archetypical Malignant States in Metastatic Breast Cancer (MBC)

H. Haimov¹, M. Sklarz¹, Y. Pevzner¹, H. Ramot², R. Jeselsohn³, N. Wagle³, N. Wagle³, O. Cohen^{4,1}

¹*BGU - Ben Gurion University, Beer sheva, Israel*

²*BGU - Ben Gurion University, Beer sheva, United States*

³*Dana Farber Cancer Institute, Boston, United States*

⁴*Dana Farber Cancer Institute, Boston, US., Boston, United States*

Introduction

Cancer treatment has significantly evolved, yet metastatic breast cancer (MBC) remains challenging due to limited durable responses. Genomic data have dominated research, but transcriptional profiling offers critical insights into distinct cellular states ("Archetypes") underlying drug resistance.

Material and method

Our analysis utilized harmonized genomic, transcriptomic, and clinical data from 775 MBC samples across multiple cohorts (DFCI, Broad Institute, POG570, MET500, META-PRISM, AURORA). We employed

computational clustering to define transcriptional archetypes and correlated these with clinical outcomes.

Result and discussion

Our earlier results revealed central Archetypes in Estrogen-Receptor (ER+) MBC that represent two strategies of ER therapy resistance based on evolutionarily acquired alteration in post-treatment biopsies – (1) ER reactivation and (2) Growth Factor Receptors (GFR) bypass. In this research, we characterized each of these dominant modes of resistance, including the distinct patterns of gene expression, their metastatic potential, and profiles of drug-response in clinically annotated MBC (Fig 1B). Our study suggests that these transcriptional archetypes have clear implications for the choice of next therapies (Fig 1C, Fig 1D). To explore the global transcriptional archetypes in MBC, our ongoing efforts, we leverage the harmonized MBC data (Fig 1A) to infer the transcriptional profiles that correspond to MBC driver genes and cluster these profiles into the dominant MBC transcriptional archetypes. Finally, we use a similar approach to study primary breast cancer from TCGA14, 15 ($n = 957$) and METABRIC16 ($n = 1980$) to highlight commonalities and differences between primary (treatment-naïve) and metastatic (drug-resistant) breast cancer archetypes.

Conclusion

This study highlights transcriptional archetypes as pivotal in understanding and overcoming drug resistance in MBC, offering clinically actionable insights for personalized therapy in precision oncology.

EACR25-2063

Targeting ferroptosis resistance by inhibiting SCD1 in TNBC enhances tumor response to immunotherapy

H. Quentin¹, A. Aurélien¹, M. Laetitia¹, S. Nor Eddine¹

¹*Université de Liège, GIGA - Cancer, Liège, Belgium*

Introduction

Breast cancer (BC) is generally considered a "cold" tumor and exhibits heterogeneous phenotypes, particularly Triple-Negative Breast Cancer (TNBC), which is resistant to immune checkpoint inhibitors. To overcome this resistance, we are investigating the impact of reversing ferroptosis resistance on immunotherapy

Material and method

The assessment of human breast cancer cell lines treated with ferroptosis inducers (FINs) was performed using MTT and cell death assays with PI staining. Cells were treated with vehicle or escalating doses of RSL3, a GPX4 inhibitor, as well as FABP4 (FABP4) and SCD1 (SCD1i) inhibitors. Proteomic analysis was conducted on both conditioned medium and total cell lysates of MDA-MB231 cells. ELISA was used to quantify IL-8 and MIF levels in the medium of treated cells. Immune activation assays were performed using splenocytes incubated with conditioned medium from FIN-treated cells, followed by immune profiling via FACS analysis. In vivo response to PD-1 inhibitor, SCD1i, and their combination was evaluated using the mouse TNBC (E0771) model.

Result and discussion

In this study, we first assessed the resistance and sensitivity of several human breast cancer (BC) cell lines

to ferroptosis inducers (FINs) in vitro. These experiments revealed acute resistance to RSL3 or SCD1i in certain BC cell lines. The most sensitive cell line, MDA-MB-231, was further analyzed by proteomics after treatment with RSL3 and SCD1i. The data revealed a similar protein expression pattern, characterized by the release of proteins involved in inflammatory pathways, including IL-8 and MIF. A similar but less pronounced response was observed in cells treated with FABP4i at 6 hours, but not at 24 hours. Notably, a panel of inflammatory proteins was found to be upregulated by 26- to 46-fold following SCD1i treatment, and by 3- to 5-fold after RSL3 treatment, suggesting that SCD1 inhibition led to the release of inflammatory factors. The increased secretion of MIF and IL-8 was further validated by ELISA. Functional assays of immune cell activation on splenocytes in vitro using conditioned medium from TNBC cells treated with SCD1i or RSL3 revealed a pattern of immune checkpoint inhibitor expression in various immune cell types, suggesting a potential activating phenotype. In vivo assessment of SCD1i in combination with PD-1 inhibition in the E0771 model is revealed a higher response to the combination than single agents. Immune profiling of E0771 tumors treated with SCD1i showed an increase in PD-1⁺ macrophages and PD-1⁺ dendritic cells.

Conclusion

Taken together, our results suggest that the immune-activating markers released by cells undergoing ferroptosis may enhance the efficacy of immune check-point inhibitors in TNBC treatment. The combination of SCD1 inhibitors and PD-1 inhibitors in the E0771 TNBC mouse model resulted in an improved response compared to monotherapy.

³*Institute of Macromolecular Chemistry, CAS, Department of Biomedical Polymers, Prague, Czech Republic*

⁴*First faculty of Medicine, Charles University, Department of Otorhinolaryngology and Head and Neck Surgery, Prague, Czech Republic*

Introduction

Cancer cells often fail to respond to chemotherapeutic regimens because of either inherent or acquired resistance. Several factors contribute to the development of chemoresistance, including epigenetics, the presence of cancer stem cells, the tumor microenvironment, and changes that affect the cell's signaling pathways. Increased drug clearance by the transporter-facilitated efflux of the drugs from cancer cells is one of the critical mechanisms involved in (multi)drug resistance (MDR). It can be mediated by overexpression of membrane transporters, such as adenosine triphosphate binding

cassette (ABC) pumps, from which P-gp (ABCB1, MDR1) is the most prominent. A significant array of specific inhibitors of individual ABC family transporters exists. However, their effect is burdened with undesirable toxicities and interactions, because ABC transporters also have extensive physiological expression in healthy cells and organs. Some recently developed nanodrug delivery systems may bypass the resistance phenomenon.

Material and method

We used an amphiphilic diblock polymer nano-therapeutics containing a hydrophilic block based on the N-(2-hydroxypropyl)methacrylamide (HPMA) co-polymer and a hydrophobic poly(propylene oxide) block (PPO). The amphiphilic character of the diblock polymer ensures self-assembly into micelles with hydrodynamic radius Rh ~15 nm in aqueous solutions. The polymer conjugates were characterized in vitro using permanent tumor cell lines. In vivo, syngeneic murine tumors, namely CT26 colon carcinoma with elevated P-gp expression, and immunodeficient mice transplanted with clinical samples of head and neck tumors (PDX model) were explored.

Result and discussion

The diblock copolymer and its conjugates with doxorubicin (DB-Dox) significantly increased the intracellular concentrations of Dox and markedly sensitized multidrug resistant tumor cells to chemo-therapy. The underlying mechanisms included inhibition of P-gp-mediated drug efflux, alteration of mitochondrial membrane potential, depletion of intracellular ATP, and increased reactive oxygen species production. Moreover, the DB-Dox conjugates inhibited tumor growth in vivo more effectively when compared to corresponding HPMA-based drug delivery system. Copolymers with additional PPO loaded in the micelle core demonstrated superior efficacy in terms of P-gp inhibition, ATP depletion, and chemosensitizing effect in vitro, as well as antitumor activity in vivo. In primary human tumor cells in vitro and in PDX model in vivo, the diblock copolymers effectively decreased ATP levels, suggesting their capacity to enhance the effectiveness of chemotherapy.

Conclusion

DB-Dox conjugates loaded with PPO possess significant antitumor efficacy demonstrating their potential as an effective drug delivery system in the treatment of chemo-resistant tumors.

²*Albacete University Hospital, Animal Experimentation Unit, Albacete, Spain*

³*Albacete University Hospital, Biobank, Albacete, Spain*

Introduction

Glioblastoma multiforme (GBM) is the most aggressive brain tumor, characterized by a high recurrence rate and resistance to current treatments. Available therapies, such as radiotherapy and chemotherapy with temozolomide (TMZ), offer a median survival of only 15 months after diagnosis. Glioma-initiating cells (GICs) contribute to TMZ resistance, highlighting the need for novel therapeutic strategies. Bromodomain and extraterminal (BET) proteins regulate the transcription of key genes involved in oncogenesis and treatment resistance. BET inhibitors (BETi) have been shown to modulate genes associated with proliferation, metastasis and cancer stem cells and have demonstrated efficacy in other solid tumors such as breast cancer. CDK9 is an essential kinase in gene transcription and its overexpression is associated with poor prognosis in several cancers. CDK9 inhibition induces apoptosis, and studies suggest that the combination of BETi and CDK9 inhibitors (CDK9i) may enhance their antitumor effects, providing new treatment options for GBM. The aim of this study is to evaluate the therapeutic potential of BETi alone or in combination with CDK9i in GBM models.

Material and method

TMZ-resistant cell line (U87R) were generated from TMZ-sensitive immortalized cell line (U87) using pulse treatments. BET and CDK9 expression and prognosis were analyzed using the GlioVis and Roc Plotter databases. In addition, BET and CDK9 protein expression was determined in the GBM cell lines (A172, T98, U87, U87R) by Western blot (WB). The efficacy of BETi and CDK9i alone or in combination was assessed using MTT, flow cytometry and WB assays. Tumor characteristics such as migration, invasion and recurrence were also analyzed. The treatment's efficacy was confirmed in a subcutaneous xenograft model in mice using the resistant model (U87R). RNAseq analyses were performed.

Result and discussion

Increased expression of BRD4 and CDK9 was observed in GBM tissues compared to non-tumor tissues. A positive correlation was found between BRD4 and CDK9, suggesting that both may be effective therapeutic targets. We confirmed by WB that the resistant model showed elevated levels of BRD4 and CDK9 proteins. Combination treatment with BETi and CDK9i induced a strong synergistic effect leading to increased cell death as confirmed by flow cytometry and WB. In addition, a reduction in tumor cell migration, invasion and recurrence capacity was observed with the combination treatment compared to the single treatments. The *in vivo* experiments also showed a reduction in tumor growth with the combination therapy. Finally, RNAseq analyses were performed to elucidate how the combined pharmacological inhibition works, leading to the identification of several deregulated genes and pathways that require further analysis.

Conclusion

Combined inhibition of BRD4 and CDK9 shows promise as a potential therapeutic strategy for the treatment of GBM.

Introduction

Breast cancer (BC) poses a significant mortality risk when it metastasizes and develops treatment resistance. Hormone receptor-positive (HR+) BC, representing 75% of all BC cases, initially responds to endocrine therapy combined with CDK4/6 inhibitors (CDK4/6i), which has prolonged progression-free survival in patients with metastatic HR+ BC. Yet, a substantial number of these tumors adapt and develop resistance, a process that transcends mere genetic mutations in metastatic cells and demands a more comprehensive view of dynamic cellular adaptation mechanisms. Our study investigates cellular and molecular mechanisms in driving drug resistance and metastatic adaptation in HR+ breast cancer.

Material and method

Using an innovative lineage-tracing system with a bar-coded ZR75 cell line library (CATCH technology), we will define treatment-resistance plasticity, characterizing the phenotypic diversity in HR+/HER2-enriched BC cells at different stages of metastasis. Functional studies, including gene silencing and phenotypic assays, will be conducted to validate the candidate's role in driving resistance.

Result and discussion

To address this challenge, we performed a genome-wide CRISPR/Cas9 knockout library screening in BC cell lines combined with gene expression analysis of two patient cohorts (CDK patient cohort and CORALEEN data set), identifying key candidate genes potentially involved in CDK4/6i resistance (unpublished). Currently, we aim to: i) explore and identify the determinants of metastasis adaptive potential at a single cell resolution, mapping the transcriptomic and epigenomic landscape during metastasis drug resistance; ii) decipher and functionally validate the molecular pathways that drive phenotypic plasticity and thus enhance the adaptive potential of metastatic cells; and iii) develop a novel therapeutic strategy to target plastic metastatic cells using the basis of CAR-T technology.

Conclusion

Understanding the mechanisms that drive CDK4/6 inhibitor resistance in metastatic breast cancer is crucial for improving therapeutic strategies. By leveraging a lineage-tracing system and functional studies, our research aims to uncover key determinants of adaptive resistance and metastatic plasticity. The insights gained from this study will contribute to a more comprehensive understanding of tumor evolution under treatment pressure, paving the way for novel therapeutic approaches to counteract resistance and improve patient outcomes.

EACR25-2121**Targeting BCL-2 proteins as a Strategy Against Therapy Persistency in TNBC**

⁴*Surgical Unit, Albacete University Hospital, Albacete, Spain*

⁵*Biobank, Albacete University Hospital, Albacete, Spain*

Introduction

Triple-negative breast cancer (TNBC) is an aggressive entity lacking hormone receptors, and HER2 expression, limiting treatment to chemotherapy and radiotherapy. However, frequent resistance leads to relapses and metastasis, reducing patient survival, highlighting the urgent need of novel treatment strategies. Cells regulate death through a balance of pro- and anti-apoptotic proteins, and disruptions in this balance contribute to malignancy. In this line, targeting anti-apoptotic BCL-2 family members is a promising strategy, as their over-expression is linked to recurrence and resistance. This study shows that targeting BCL-2 proteins can overcome TNBC resistance, reducing tumor growth and metastasis *in vivo*.

Material and method

Gene expression association with prognosis and response to chemotherapy was analyzed using KM and ROC plotter databases, respectively. BCL2 levels were measured in TNBC patient biopsies via immunohistochemistry. A drug screening with BH3 mimetics was performed on a panel of 8 TNBC cell lines. Resistant TNBC cell models (MDA-MB-231R, BT-549R) were generated using a cisplatin pulse-based strategy. BCL2, MCL1, and BCL-XL expression levels were evaluated by Western blot. Effects on proliferation, colony formation, migration, invasion, and tumor progression were assessed in resistant cells, while apoptosis was analyzed by flow cytometry. Drug's efficacy was validated *in vivo* models, including patient-derived xenografts (PDX) and MMTV-PyMT. A PROTAC based strategy was used to validate the experimental approach.

Result and discussion

Gene expression levels of anti-apoptotic BCL2 family members are associated with a lack of chemotherapy response in TNBC. Moreover, high BCL-2 and BCL-XL levels correlated with poor prognosis in patients with neoadjuvant therapy. A drug screening using BH3 mimetics drugs that directly induce apoptosis by inhibiting anti-apoptotic BCL-2 family members identified Obatoclax, a pan-inhibitor, as the most efficient compound to reduce proliferation in all tested TNBC cell lines, regardless of chemotherapy sensitivity. Functional *in vitro* analysis in chemo-persistent cells demonstrated that Obatoclax effectively reduced pro-

liferation, migration, invasiveness, and clonogenic potential, while also inducing apoptosis in persistent cells. *In vivo*, the drug inhibited tumor progression and metastatic potential in mouse models: an orthotopic xenograft with resistant cells, a syngeneic TNBC model, and a taxane-refractory PDX model. Our results were reproduced using a PROTAC with a dual effect on the targets, showing no cross-resistance

Conclusion

Our findings suggest that the simultaneous targeting of BCL2 anti-apoptotic members could represent a promising therapeutic approach for chemotherapy-resistant TNBC.

EACR25-2193**Targeting Epigenetic Mechanisms to Overcome Drug Resistance in TaxaPlatin-Resistant Prostate Cancer**

¹*Koc University, Graduate School of Health Sciences, Istanbul, Turkey*

²*Koc University, Research Center for Translational Medicine, Istanbul, Turkey*

Introduction

In metastatic CR-PCa, treatment typically begins with docetaxel (Dtx) as the first-line chemotherapy due to its ability to prolong survival. However, as most patients eventually develop resistance to Dtx, platinum-based drugs are commonly introduced as the next therapeutic option. To explore the reuse of taxanes and cisplatin in these patients, we generated cisplatin resistance in taxane-resistant PCa cells, naming them "TaxaPlatin" or "super-resistant" cells. Our study focuses on understanding the mechanisms behind multi-drug resistance and investigating methods to overcome resistance through epigenetic modulation.

Material and method

Taxane and cisplatin resistance in a castration resistant cell line, generated by dose-increment method, had been used. Acquired drug resistance was assessed with cell viability and colony formation assays. Our approach involved thoroughly characterizing TaxaPlatin cells phenotypically, followed by transcriptomic analysis. Wound healing assay was performed to measure motility of cells. The apoptotic response of TaxaPlatin-resistant cells to drug treatment was assessed using Caspase 3/7 and Annexin V assays. To characterize lysosomal sequestration and exocytosis in resistant cells, a lysosomal gene panel qPCR and β-hex exocytosis assay were performed. Screening of an epigenetic library helped identify compounds that restore sensitivity to drugs in TaxaPlatin-resistant cells.

Result and discussion

Characterization of TaxaPlatin-resistant cells revealed phenotypic changes and a slower proliferation rate. Wound healing assay demonstrated significantly lower motility in resistant cells compared to parental cells. Apoptosis assays indicated that TaxaPlatin-resistant cells do not undergo apoptosis upon taxane or cisplatin treatment. The β-hexosaminidase assay showed no significant difference in exocytosis between parental and resistant

cells. During the development of TaxaPlatin-resistant cells, the expression levels of ATP7B, TFEB, MITF, TMEM205, TPP1, and PPT1 correlated with increasing cisplatin doses. Additionally, a drug library screen was performed to systematically identify epidrugs that resensitize TaxaPlatin-resistant cells to chemotherapy. The candidates obtained from the epidrug screen will be discussed within the scope of this study.

Conclusion

Our findings highlight the complexity of multidrug resistance in cancer and underscore the role of epigenetic regulation in this process. Notably, lysosomal exocytosis did not appear to be a major contributor to resistance, whereas the upregulation of lysosomal genes suggests a potential link between lysosomal biogenesis and cisplatin resistance. Candidate molecules and target epigenetic regulators will be validated using functional assays and molecular biology techniques. These findings may contribute to the development of novel therapeutic strategies aimed at overcoming multidrug resistance in cancer.

EACR25-2239

CDK12/13 inhibition can counteract Epithelial Ovarian Cancer chemoresistance

*I. Pellarin¹, V. Rossi¹, K. Javad¹, S. D'Andrea¹,
M. Sonego¹, E. Scanziani², M. Schiappacasssi¹,
B. Belletti¹, G. Baldassarre¹*

¹*Centro di Riferimento Oncologico (CRO), IRCCS,
National Cancer Institute, Molecular Oncology, Aviano,
Italy*

²*University of Milan, Veterinary Medicine and Animal
Science, Milan, Italy*

Introduction

Epithelial Ovarian Cancer (EOC) is featured by drug resistant recurrences, especially to platinum (PT) compounds. Alternative Splicing (AS) and transcriptional dysregulations could be ascribed as PT-resistance mechanisms, exerted, among the others, by transcriptional Cyclin Dependent Kinases (CDKs). Here, we identified CDK12 (and the highly homolog CDK13) as possible therapeutic targets in EOC, evaluating their role in AS and DNA damage response (DDR), under the selective pressure of PT-treatment. CDK12 phosphorylates RNA polymerase II, regulating transcriptional elongation at multiple levels. Its depletion impacts on long DDR genes expression, leading to genomic instability.

Material and method

Mutational status of CDK12/13 was assessed using a panel of primary EOC samples and available datasets. CDK12/13 pharmacological inhibition (CDK12i), alone or in combination with chemotherapeutic agents, was addressed in several models, including EOC cell lines and patients-derived primary cultures, both sensitive and resistant to PT. CDK12i-resistant EOC cells were also generated. To explore transcriptional effects on CDK12i, we performed RNA-seq analysis on both sensitive and PT-resistant cells. Finally, we verified CDK12i effects *in vivo* using both syngeneic and PDX models.

Result and discussion

CDK12 is the most and CDK13 the second more frequently mutated and amplified CDK in EOC. CDK12i is effective in a panel of EOC cell lines and patients-derived primary cultures, both sensitive and resistant to PT, as well as in the CRISPR-modified ID8 cells. CDK12i re-sensitizes PT-resistant cells to both PT and PARPi, when used in a sequential treatment schedule, preventing the appearance of PT-resistant clones. The strong antitumor and anti-metastatic activity of the combined regimen was confirmed *in vivo* using both syngeneic and PDX models. Intriguingly, we generated and characterized CDK12i-resistant cells that become extremely sensitive to PT. Mechanistically, CDK12i treatment reduced the expression of the DDR genes ATM, RAD51 and FANCD2 at both mRNA and protein level, likely through AS alteration and/or intronic polyadenylation (IPA) sites usage. Accordingly, RNA-seq revealed that CDK12i modulates mainly Ribosome and Splicing KEGG gene networks expression, impinging on AS patterns. Consistently, we observed a previously undisclosed interaction between CDK12 and the master splicing regulator complex SFPQ/p54nrb, both under PT and CDK12i treatment, suggesting that CDK12 exerts its activity at least in part by regulating SFPQ/p54nrb complex.

Conclusion

We propose that CDK12/13 could represent a valuable actionable therapeutic target alone or in combination therapies, to prevent the onset of PT-resistance or to treat resistant EOC patients, for whom very few therapeutic options are currently available.

Introduction

The rational selection of chemotherapy regimens is crucial to optimize the clinical management of breast cancer (BC), yet it remains a significant challenge. Carboplatin (Cb) has been shown to improve treatment efficacy in many triple negative breast cancer (TNBC)

patients, but not all patients may need this chemotherapy. Additionally, patients with aggressive hormone receptor positive breast cancer (HR+ BC) may also benefit from Cb treatment, but appropriate selection criteria need to be determined. The I-BCT-1 (Improved Breast Cancer Therapy –1; NCT02546232) study aims to investigate biomarkers for patient stratification, identifying high-risk HR+ BC and TNBC that will benefit from extended chemotherapy with Cb, and to discover novel actionable target in patients showing a lack of response to the current treatment modalities.

Material and method

Tumor samples were collected from patients with high risk HER2-negative BC (TNBC, n = 72; HR+, n = 115) before surgery, and after 3 and 12 weeks of treatment. Patients received paclitaxel (80 mg/m², Q1W), either alone or in combination with Cb (AUC6 Q3W), for 12 weeks, followed by four cycles of EC90 (epirubicin 90 mg/m² and cyclophosphamide 600 mg/m²; Q3W). Bulk RNA sequencing (RNAseq) was performed on pre- and on-treatment biopsies to analyze differential gene expression, pathway alterations and infer immune cell subpopulation changes using CIBERSORT.

Result and discussion

Recognizing distinct response mechanisms due to HR expression, patient data were first separated based on HR status. Significant differences in overall gene expression were observed at baseline when comparing good with poor responders. The number of genes with significantly different expression between the responder groups were notably higher in HR+ BC compared to TNBC. Additionally, higher fraction of activated immune cell subsets (including CD8+ T-cells and dendritic cells (DCs)) was associated with favorable response in both HR+ BC and TNBC at baseline. Notably, these differences were more prominent in TNBC than HR+ BC. We are currently analyzing longitudinal samples, to identify mechanisms associated with treatment-induced resistance. The overall aim is to identify potential actionable targets among patients not responding to treatment.

Conclusion

Using results from RNAseq analyses, we have identified transcriptional differences in BC patients with different responses to NAC +/- Cb. Baseline immune infiltration was associated with a favorable treatment response, while the on-treatment immune alterations are currently under investigation.

Introduction

Patients affected by advanced non-small cell lung cancer (NSCLC) with mutant epidermal growth factor receptor (EGFR) are treated with tyrosine kinase inhibitors (TKIs) such as gefitinib and osimertinib, yet most patients develop disease progression due to acquired resistance. Resistance mechanisms include secondary mutations on EGFR and other membrane receptors responsible for cell proliferation and survival, along with epigenetic alterations critical to tumor recurrence. To this end, increasing data on regulation of RNA metabolism by RNA-binding proteins (RBPs) is supporting their pathological relevance. The RBP Hu antigen R (HuR) is an emergent regulator of cancer, currently considered for therapeutic targeting. HuR enhances mRNA stability/translation of key effector genes involved in all cancer traits including sustained cell proliferation, evasion of cell death and drug response. We investigated the impact of gene ablation and pharmacological inhibition of HuR on cell proliferation and survival in EGFR-TKI resistant NSCLC cells.

Material and method

EGFR-TKI-resistant cell lines (HCC827GR/PC9GR/PC9OR/H1975OR) were generated by treating HCC827/PC9/H1975 cells with gefitinib or osimertinib. HuR role was studied using PC9- and H1975-HuR-KO cells generated by CRISPR/Cas9 technology and commercially available HuR inhibitors KH-3 and SRI-42127. Cell proliferation was evaluated by Cell Counting Kit-8 assay. Cell cycle and apoptosis were analyzed by flow cytometry. Protein expression was analysed by immunoblotting.

Result and discussion

In silico analyses of public databases showed significant upregulation of both HuR mRNA and protein levels in primary lung adenocarcinoma tumors compared to normal tissue, with additional increase in samples from patients upon development of EGFR-TKI resistance. Similarly, in vitro generated EGFR-TKI-resistant cell lines showed higher expression of HuR respect to parental cells. Analysis of proliferation of PC9- and H1975-HuR-KO cells indicated that HuR loss significantly reduced cell proliferation with cell cycle arrest in G0/G1 phase associated with p21Cip1/Waf1 upregulation and Cdk2 or Cdk6 downregulation. Pharmacological HuR inhibition by compounds KH-3 and SRI-42127 (2,5 μM, 24 hours) arrested PC9 and PC9GR cells in G1/S phase while in PC9OR, H1975 and H1975OR cells it induced cell accumulation in G2/M phase and modulated the levels of the kinase Aurora A that is a determinant of the acquisition of osimertinib resistance. Regarding cell survival, while HuR gene ablation did not affect cell viability, both HuR inhibitors induced a significant increase of the apoptotic rate in all EGFR-TKI-sensitive and resistant cell lines.

Conclusion

In conclusion, our findings indicate HuR protein as relevant mechanism and potential target in EGFR-TKI

resistant NSCLC given its pro-survival and proliferative functions. Study supporting by AIRC

Introduction

Lung cancer is the leading cause of cancer related deaths worldwide with non-small cell lung cancer (NSCLC) being the most common type (80-85%). While Immune Checkpoint Inhibitors (ICIs) has revolutionized the treatment of NSCLC, their benefits remain limited due to significant resistance and therapeutic failure. The tumor microenvironment (TME) plays a pivotal role in response to immunotherapies, as it enables cancer cells to evade the immune system. However, accessing tumors after the first lines of treatment remains challenging. The development of alternative models to study this resistance is therefore essential.

Material and method

To overcome this limitation, we propose to characterize the influence of the TME on ICIs resistance by developing a complex 3D co-culture model derived from human NSCLC. This model includes patient-derived NSCLC lung tumor cells (ADCA117), human umbilical vein endothelial cells (HUVEC), fibroblasts (HFF-2), as well as monocytes and T lymphocytes isolated from healthy donor blood. We aim to characterize the 3D model at baseline and monitor the influence of TME on response to treatment. To achieve this, we implemented a longitudinal analysis combining multiple approaches, including single cell and spatial transcriptomics (Visium HD), immunohistochemistry, confocal microscopy, and viability assays.

Result and discussion

Confocal microscopy analysis using CD45, CD3, and CD163 markers revealed a homogeneous distribution of immune cells in the 3D complex model throughout the culture. This infiltration was facilitated by the successive addition of PBMCs to the culture medium, to simulate the arrival of new immune cells at the tumor site. This distribution was further confirmed by immunohistochemistry, revealed with CD68 and CD163 staining and highlighting the model's consistent structure. We demonstrated with confocal microscopy that treatments induced DNA damage within the structure, as evidenced by γH2AX staining, along with a decrease in cell proliferation revealed by Ki67. A higher-resolution analysis of the model using spatial transcriptomics with the Visium HD technology revealed distinct layers inside the structure, with a proliferative signature at the periphery

transitioning to an inflammatory and hypoxic signature at the center, indicating the presence of a hypoxic gradient.

Conclusion

The complex human NSCLC derived 3D co-culture model developed is now used to assess treatment effects on both tumor cells and cells from the TME. Combined with an in-depth analysis of treatment responses, this approach will help identify new targets and biomarkers to overcome ICI resistance and improve patient stratification.

Introduction

Colorectal cancer (CRC) is the 2nd leading cause of cancer-related death worldwide. Cetuximab (Ctx) is an Epidermal Growth Factor Receptor (EGFR)-targeted therapy approved for the treatment of metastatic CRC patients (mCRC). However, in many cases patients develop resistance to this therapy, highlighting the need for the development of new therapeutic strategies to overcome Ctx resistance. Recently, it was demonstrated that tumors with high levels of the EGFR effector phospholipase c gamma 1 (PLC γ 1) are resistant to Ctx, while the inhibition of SH2-containing protein tyrosine phosphatase 2 (SHP2) can sensitize these Ctx-resistant cells. With this in mind, our goal is to build a platform for combined EGFR/SHP2-targeted therapy to improve the therapeutic efficacy and overcome resistance in the treatment of mCRC, while reducing systemic toxicity. Towards this goal, we developed an antibody-drug conjugate (ADC) that combines: i) Ctx as a therapeutic anti-EGFR antibody to confer specificity and therapeutic effect; ii) a specific SHP2-inhibitor (SHP099) for cell sensitization; iii) a DOTA chelator for complexation of an imaging radionuclide (67Ga).

Material and method

The synthesis and characterization of an ADC carrying Ctx and SHP099 via maleimide chemistry was performed. Viability studies and western blot analysis were conducted in cell lines with different PLC γ 1 expression (Caco-2 parental and Caco-2 with knocked-down PLC γ 1). DOTA was conjugated to Ctx and to the ADC, and the conjugates radiolabeled with 67Ga. The radiochemical purity (RCP) of the resulting radioconjugates was assessed by ITLC-SG, and their in vitro stability evaluated in PBS. Cellular uptake and internalization of the radioconjugates were studied in SW48 and

Caco-2 CRC cell lines, and blockade and competitive binding assays were performed using Ctx as the “cold” competitor.

Result and discussion

The ADC was obtained with a drug-to-antibody ratio of 3.5. Cell studies show a decrease in viability of cells expressing high levels of PLCg1, while western blot analysis of the same cells demonstrate that the ADC is able to inhibit EGFR and phosphorylated ERK to a higher extent than Ctx. The Ctx and ADC were radiolabeled with 67Ga, leading to radioconjugates with a RCP > 95% that remain stable in PBS up to 48 h. 67Ga-Ctx presents high cellular uptake and internalization. Blocking of EGFR with “cold” Ctx decreases the uptake, indicating that it is receptor mediated. The ability of 67Ga-Ctx in inhibiting EGFR, determined as IC₅₀, was 3.4 nM in Caco-2 cells. Similar studies are underway with the radiolabeled ADC and will also be presented.

Conclusion

We expect to obtain an ADC with improved biological properties for cancer treatment and radiotools to assess EGFR level in tumors. Overall, the proposed dual targeting strategy should promote synergistic therapeutic effects that might overcome resistance to Ctx therapy, enabling a personalized theranostic approach for mCRC.

Targeting PI3K/AKT Pathway

Dysregulation in Triple-Negative Breast Cancer: Overcoming Alpelisib Resistance through Dual Inhibition

G. Colley¹, A. Eustace¹, A. Saques¹, A. White¹

¹Dublin City University, Dublin, Ireland

Introduction

Triple-negative breast cancer (TNBC) is an aggressive breast cancer (BC) subtype lacking hormone receptor (HR) and HER2 expression, making it unresponsive to conventional therapies and necessitating novel targeted strategies. The PI3K/AKT signalling pathway is frequently dysregulated in TNBC, with PIK3CA mutations (~15% of cases) promoting uncontrolled proliferation. Alpelisib, a PI3K/AKT inhibitor, is approved for PIK3CA-mutant, HR-positive BC, but resistance mechanisms remain. We hypothesise that combining alpelisib with approved drugs targeting alternative PI3K/AKT activation mechanisms may benefit a TNBC cohort.

Material and method

Differential expression analyses (DEAs) based on TP53 and PIK3CA mutations were performed on TCGA BC patient RNA-seq data (N=981) using R. The 5-day anti-proliferative effects of targeted drugs, alone and in combination, were assessed using acid phosphatase assays. Reverse-phase protein array (RPPA) and western blotting were performed on lysates from 24-hour-treated cells. Mutant p53-expressing cell lines were transduced with lentivirus to express mutant PIK3CA.

Result and discussion

DEAs showed TP53 contributes to genetic dysregulation in TNBC, with distinct patterns in cases harbouring both TP53 and PIK3CA mutations. TP53 mutations down-

regulate PTEN, a negative regulator of PI3K, leading to aberrant PI3K/AKT activation. We hypothesised that TP53/PIK3CA co-mutations contribute to alpelisib resistance. The TP53/PIK3CA-mutant MFM-223 cell line was less sensitive to alpelisib than PIK3CA-only mutated TNBC cells but more sensitive than TP53-only mutated cells, suggesting PIK3CA mutations improve response while TP53 mutations drive resistance via sustained PI3K/AKT activation. Dual PI3K/AKT targeting could overcome this. Given frequent receptor tyrosine kinase (RTK) dysregulation in TNBC, we tested the approved RTK inhibitor crizotinib with alpelisib, identifying a synergistic effect in TP53/PIK3CA-mutated MFM-223 cells. RPPA analysis revealed dysregulated 4E-BP1 expression in cells treated with this combination, which was validated by western blotting, confirming reduced 4E-BP1 expression and phosphorylation. As a key PI3K target, 4E-BP1 is typically phosphorylated by mTORC1, promoting translation. The alpelisib-crizotinib combination may impair translation regulation, disrupting protein synthesis and proliferation. In MCF10A lines expressing different mutant p53 proteins, alpelisib sensitivity varied by mutation, with western blotting revealing differing PI3K pathway marker expression, suggesting TP53 mutations affect PI3K activation independently of PIK3CA.

Conclusion

TP53/PIK3CA co-mutations drive TNBC dysregulation and may confer PI3K inhibitor resistance. The alpelisib-crizotinib combination may overcome resistance in this TNBC cohort. Future *in vitro* and *in vivo* studies will further investigate therapeutic potential.

Introduction

The clinical management of ovarian cancer has been improved by the introduction of PARP inhibitors (PARPi), such as olaparib, as maintenance therapy after the first-line chemotherapy. PARPi-mediated inhibition of PARP leads to the accumulation of DNA double-strand breaks, which are normally repaired by the homologous recombination (HR) pathway. In HR-deficient tumors (HRD status), PARPi-induced double-strand breaks remain unrepaired, triggering cell apoptosis by a “synthetic lethality” mechanism. Olaparib is therefore indicated for patients with HRD tumors. However, around half of ovarian tumors have a proficient HR pathway (HRP status) and are thus resistant to olaparib. Identifying strategies to sensitize HRP tumors to olaparib constitutes a major challenge for these patients. HDAC inhibitors (HDACi), which modulate gene expression, have been shown to indirectly disrupt the expression and/or function of key components of the HR pathway, thereby impairing its efficiency. In this context, our objective was to evaluate the potential of belinostat, an FDA-approved pan-HDAC inhibitor, to sensitize HRP ovarian cancer cells to olaparib.

Material and method

We assessed the efficacy of the belinostat/olaparib combination in a cohort of a dozen of patient-derived tumoroid models, preclinical models representative of patient tumors. The models included in the study were established from ovarian tumors of different histological subtypes and displayed HRP status.

Result and discussion

Our study showed that belinostat efficiently sensitized half of the tumoroid models to olaparib, highlighting for the first time the efficacy of belinostat/olaparib combination in preclinical ovarian cancer models. This sensitizing effect revealed to persist over the long term and to be associated with apoptosis induction.

Interestingly, analysis of DNA damage using comet assay showed that the combination induced more damage than olaparib in the sensitive tumoroids but not in the resistant ones. This suggests that the sensitizing effect of belinostat may be based on its ability to inhibit the HR pathway. In order to identify predictive biomarkers of response to the combination therapy, a transcriptomic analysis of genes differentially expressed at baseline between sensitive and resistant tumoroids was performed.

Conclusion

Collectively, these results support the use of belinostat as a valuable therapeutic strategy to sensitize HRP ovarian cancers to olaparib, and pave the way for personalized clinical management of HRP patients.

EACR25-2390

Endothelial-Derived CAFs Drive Chemosensitivity via ERCC1-IL-17A Axis: A Novel Therapeutic Target in Tumour Microenvironment

*K. Sobierajska¹, M. Luczak¹, W. Wagner², W. Ciszewski¹
¹Medical University of Lodz, Lodz, Poland*

²Institute of Medical Biology, Polish Academy of Science, Poland

Introduction

Cancer-associated fibroblasts (CAFs) are key regulators of tumour progression and metastasis. By modulating the tumour microenvironment, CAFs enhance cancer cell invasiveness and survival. Additionally, a growing body of evidence indicates that CAFs contribute to tumour drug resistance through the secretion of cytokines and growth factors that alter cancer cell behaviour.

Material and method

We used endothelial-derived CAFs originating from human microvascular endothelial cells (HMEC-1) and human umbilical vein endothelial cells (HUVEC). Furthermore, we employed colorectal cancer cell lines characterized by high (HT29, SW620, HCT116) and low (LS180, LOVO) IL-17A receptor expression. Protein levels were determined using Western blot, while cytokine secretion was analyzed using ELISA assays. The expression of IL-17A and ERCC1 was silenced via interfering RNA. Cell motility of CAFs was tested using the wound healing assay. Endothelium and CAF morphological changes were evaluated by light microscopy.

Result and discussion

Our findings demonstrate that CAFs derived from endothelial cells exhibited resistance to oxaliplatin compared to parental cells. We identified ERCC1 (an essential component of the DNA repair machinery) as a key factor contributing to this phenomenon. Silencing ERCC1 effectively decreased the chemoresistance of CAFs and restored their proliferation to levels similar to those of their endothelial precursors. Furthermore, ERCC1 knockdown partially reversed the mesenchymal phenotype of CAFs, confirmed by decreased levels of mesenchymal markers and increased endothelial ones. Moreover, CAFs with reduced ERCC1 protein level restore endothelial functions. Those changes were associated with the inactivation of the NF-κB signalling pathway and reduction in IL-17A secretion. Since IL-17A provided by CAFs stimulated colon cancer cells and induced chemoresistance, ERCC1 downregulation impaired tumour cell proliferation and increased cancer cells' sensitivity to oxaliplatin or irinotecan chemotherapy.

Conclusion

Our study offers new insights into the molecular mechanisms of CAF-mediated drug resistance, emphasizing the ERCC1-NF-κB-IL-17A axis as a potential therapeutic target to improve the efficacy of colorectal cancer treatment.

⁴Universitätsklinikum, Klinik und Poliklinik für Neurochirurgie, Dresden, Germany

Introduction

Glioblastoma (GB) is the most common and lethal tumor of the central nervous system. Despite the multimodal therapeutic approach, patients' survival remains extremely poor. Sensitivity to therapy varies among patients due to high GB heterogeneity. Tumor Treating Fields (TTFields) represent the only breakthrough of the last decades in increasing life expectancy but are not able to counteract tumor relapses. Tumor recurrence is driven mainly by a subpopulation of cells, the GB stem cells (GSCs), characterized by altered ion channel expression and activity. Unfortunately, most of them cannot be viable therapeutic targets due to their involvement in essential physiological cellular functions. A promising exception is the transmembrane form of Chloride Intracellular Channel 1 (tmCLIC1), upregulated in GB stem-like cells and promotes tumor proliferation. It was recently demonstrated that an inhibitor of tmCLIC1 is the antidiabetic drug metformin. tmCLIC1 could serve as a valuable target for a combined antitumoral therapy alongside TTFields to impair glioblastoma development.

Material and method

We run a genomic and proteomic analysis of surgical material after two biopsies from patients treated or not with TTFields. We developed also an in vitro GB relapse model. GB primary cultures have been treated for up to 12 days with the INOVITRO system. Resistant cells were analyzed using patch clamp, metabolic assays, ROS measurement, and for the expression of stemness marker. Moreover, the combination of metformin and TTFields was tested with growth curve assays.

Result and discussion

TTFields-treated tumors exhibited reduced inter-patient heterogeneity and shared alterations in key cytosolic pathways. In vitro transcriptomic analyses of resistant GB cells confirmed the upregulation of ion channel transcripts, stemness markers, and oxidative stress-related pathways. After 288 hours of continuous TTFields application, glioblastoma cells showed an average depolarization of the resting membrane potential, increasing oxidation and acidification of the cytoplasm. Our data have demonstrated that TTFields combined with metformin resulted in extremely efficient in promoting cancer cell death.

Conclusion

Here, we demonstrate that combining TTFields stimulation with continuous metformin treatment, an inhibitor of tmCLIC1, synergistically suppresses GB growth. These findings highlight a novel therapeutic strategy to overcome treatment resistance and reduce GB recurrence by targeting tmCLIC1 in conjunction with TTFields.

³*Izmir Tinaztepe University Faculty of Medicine, Medical Biology, Izmir, Turkey*

⁴*Izmir Tinaztepe University, Galen Research Center, Izmir, Turkey*

Introduction

Hepatocellular carcinoma (HCC) has one of the highest mortality rates among all cancers, and the most common reasons are metastasis, recurrence, and therapy resistance. As the first multi-kinase inhibitor given in HCC treatment, sorafenib remains the most preferred drug. However, sorafenib resistance develops as a result of prolonged therapy. Although the exact mechanism is yet unknown, non-coding RNA-based mechanisms are thought to be one of the causes of treatment resistance. Previously, we showed that the descending expression of miR-181a-5p causes an aggressive phenotype in HCC. In sorafenib resistance, Caveolin-1 (Cav-1) is overexpressed and enhances the aggressive phenotype. In this study, we wanted to shed light on the mechanism of sorafenib resistance from the perspective of aggressive phenotype triggers that are miR-181a-5p and Cav-1 and their relation.

Material and method

Initially, we examined publicly available transcriptome data of HCC patients treated with SOR/placebo (GEO accession ID: GSE109211) and examined the expressions of MIR181A and CAV1 in patients who are classified as sorafenib responders and non-responders. Then, we generated sorafenib-resistant (SOR-Res) HuH-7, SNU-449 and Mahlavu HCC cell lines, and we determined Cav-1 and miR-181a-5p expression levels compared to their wild-type counterparts. We determined the miR-181a-5p level in SOR-Res cells by overexpressing and silencing miR-181a-5p through transfecting the mimic or inhibitor of miR-181a-5p in biological assays, including MTT, colony formation, stress fiber staining, and motility assays.

Result and discussion

In the patient dataset, MIR181A expression was significantly lower in non-responders compared to responders, whereas CAV1 expression was significantly higher. In SOR-Res cells, Cav-1 expression was increased, and miR-181a-5p expression was decreased; when we overexpressed miR-181a-5p, SOR-Res cells tended to be more sensitized to sorafenib, their colony forming, motility ability and stress fibers were decreased. All the outcomes, including Cav-1 expression, changed to the opposite when we inhibited miR-181a-5p expression.

Conclusion

Since miR-181a-5p and Cav-1 are negatively expressed in SOR-Res cells and patients, miR-181a-5p may be a possible target of Cav-1, and they may contribute to sorafenib-resistance by augmenting the aggressive phenotype in HCC.

EACR25-2458**Overcoming Taxane Resistance Through PRMT5 Inhibition: Targeting Epigenetic Mechanisms**

E. Karyemez¹, B. Cevatemre², I. Bulut³, H. Syed², C. Acilan²

¹Koc University, Graduate School of Health Sciences, İstanbul, Turkey

²Koc University, School of Medicine, İstanbul, Turkey

³Koc University, İstanbul, Turkey

Introduction

Castration-resistant prostate cancer (CRPC) is a lethal form of prostate cancer that no longer responds to androgen deprivation therapy. CRPC treatment primarily relies on chemotherapy, particularly taxanes such as docetaxel (Dtx) and cabazitaxel (Cbz). However, the development of taxane resistance remains a significant clinical challenge. Identifying novel targets to overcome resistance is critical for improving therapeutic efficacy. In this context, PRMT5 has emerged as a potential epigenetic regulator associated with cancer progression and drug resistance.

Material and method

To identify epigenetic regulators of taxane resistance, Dtx- and Cbz-resistant CRPC cell lines were established and an epigenetic drug screen with a library of 150 molecules identified PRMT5 as a re-sensitizing modulator. PRMT5 inhibition was assessed for its role in overcoming taxane resistance using pharmacological inhibitors (CMP5, GSK591, HLCL61) and shRNA knockdown, followed by functional assays including cell viability, clonogenic assay, apoptosis (Annexin V/Caspase-3/7 assays) and cell cycle analysis. Western blot assessed PRMT5 substrates (H3R8me2, H4R3me2) and symmetric dimethylarginine levels. ChIP-seq and RNA-seq analyses identified PRMT5-mediated transcriptional regulation and epigenetic modifications. Patient data, including PRMT5 expression, Gleason scores and clinical outcomes were analyzed from public databases.

Result and discussion

PRMT5 inhibition overcame resistance CRPC and restored taxane sensitivity, as demonstrated by decreased IC₅₀ values and Combefit synergy analysis. CMP5, GSK591 and HLCL61 emerged as the most effective PRMT5 inhibitors, reversing taxane resistance in SRB and clonogenic survival assays. PRMT5 pharmacological inhibition led to a reduction in sDMA levels and histone methylation markers (H3R8me2, H4R3me2), confirming on-target activity. Combination of docetaxel and PRMT5 inhibitor induced G2/M arrest in resistant cells, indicating restored taxane susceptibility. Importantly, PRMT5 inhibition no effects on parental cells, reinforcing its selective role in taxane resistance mechanisms. ChIP-seq analysis revealed differential PRMT5 binding sites between parental and resistant cells, while RNA-seq demonstrated significant downregulation of MYC and E2F target genes. Key regulatory factors, including CCND1, RB1, and ABL1, were identified through the integration of ChIP-seq and RNA-seq data, suggesting their potential relevance in taxane resistance.

Conclusion

Pharmacological inhibition of PRMT5 modulates cell cycle and transcriptional pathways, re-sensitizing

resistant cells to taxane-based chemotherapy, with RNA-ChIP integration revealing key mechanisms related to cell cycle regulation. Given that PRMT5 inhibitors are already being evaluated in clinical trials, our findings further support its potential as a therapeutic target for taxane-refractory patients.

EACR25-2495**Elucidating Topotecan-Resistance Mechanism in Human Breast MCF-7 Cancer Cells and Paclitaxel Cross-Resistance by DNA Damage Signaling Pathway Gene Expression**

S. Marin¹, Y. De Hoyos¹, E. Guerrero²

¹Panama University, Panama, Panama

²Gorgas Memorial Institute for Health Research, Panama, Panama

Introduction

Gene expression profiling and pathway analyses are a detrimental tool to unravel the pharmacological effect of chemotherapeutics on tumor cells. Moreover, gene expression profiling is an important tool to analyze pathways that may confer resistance to chemotherapeutic drugs commonly used in clinical practice for the treatment of several types of cancer. Topotecan is a clinically active anticancer agent, used as a second-line treatment or in combination with other drugs. Topotecan interacts with topoisomerase I and forms DNA double-strand breaks. On the other hand, Paclitaxel is a natural anti-tumor agent that has become the standardized first-line chemotherapy treatment for several types of cancer. Unfortunately, Paclitaxel is associated with the development of drug resistance. At present, studies suggest that Topotecan and Paclitaxel do not exhibit significant cross-resistance, suggesting that tumors resistant to one drug may still be susceptible to the other.

Material and method

Here, we generated an in vitro Topotecan-resistant breast cancer cell line. MCF-7 cells were treated with 50 nM of Topotecan for two weeks with cell culture media changes every 3 to 4 days and Topotecan concentration increased 1.5-fold every two weeks until cells were resistant to 1.2 μM. Resistant cells were treated with 130 nM of paclitaxel for 15 days and then cell pellets were collected for ARN extraction and cDNA synthesis. A real time PCR array that evaluated 26 genes involved in DNA Damage signaling was performed.

Result and discussion

Surprisingly, DNA damage signaling gene expressions were downregulated between -3-to-10-fold change. Down-regulation was significantly reduced after Paclitaxel treatment, however, DNA damage response signaling gene expression was not increased more than 1.5 fold change upregulation.

Conclusion

This findings suggest cross-resistance in HER2 expressing breast cancer cells and that the use of Paclitaxel in combination with topotecan for the treatment of HER2 breast cancer is not an effective line for treatment.

EACR25-2503**Cisplatin resistance hinders the response to CDK4/6 inhibitors in esophageal squamous cell carcinoma cells**

M. Ávalos Moreno¹, A. Vigato¹, F. Moresi¹, L. Schön¹, X. Bisteau¹

¹IRIBHM J.E. Dumont, Université Libre de Bruxelles (ULB), Brussels, Belgium

Introduction

Esophageal squamous cell carcinoma (eSCC) remains one of the deadliest cancers with an overall survival below 20%. The cyclin D-CDK4/6-pRB axis, frequently deregulated in eSCC, was suggested as target for therapy. However, recent clinical trials testing CDK4/6 inhibitors against advanced EC (including eSCC) reported limited clinical activity. Interestingly, all enrolled patients with eSCC tumors had been previously treated with genotoxic drugs. This study aims to investigate how resistance to genotoxic treatment (e.g. cisplatin) may modulate the response to CDK4/6 inhibitors such as palbociclib.

Material and method

Human eSCC cell lines KYSE-140, KYSE-180, KYSE-410 and TE-6 were rendered resistant to cisplatin with two different approaches, pulsatile or continuous. Pulsatile-resistant (RP) cell lines (KYSE-140-RP2, KYSE-180-RP2, KYSE-410-RP2, TE-6-RP2) received high doses of cisplatin in 24h pulses, while continuous-resistant (RC) cell lines (KYSE-140-RC2, KYSE-180-RC2, KYSE-410-RC3, TE-6-RC1) received lower doses continuously over time. Cisplatin resistance was characterized with MTT assay, qPCR and RNA sequencing. Flow cytometry, clonogenic, qPCR and RNA sequencing assays were conducted to characterize differences in response to palbociclib treatment between resistant and parental cell lines.

Result and discussion

All established cell lines decreased their sensitivity to cisplatin and remained stable treatment-free except for KYSE-410-RP2, which progressively lost its resistance. Resistant KYSE-140 cell lines had the most pronounced shift in IC50. Interestingly, clonogenic assays showed KYSE-140-RP2, KYSE-140-RC2, KYSE-180-RP2 and KYSE-410-RC3 cell lines to be significantly less responsive to palbociclib treatment than their parentals. Oppositely, KYSE-410-RP2 didn't alter its response. Similarly, PCA analyses from RNAseq data showed all resistant cell lines to cluster separately from their parental lines (with or without treatment), except for KYSE-410-RP2. qPCR analyses revealed that KYSE-180, KYSE-410 and TE-6 resistant cell lines had a significant upregulation of the multidrug resistance-associated protein MRP2. Unexpectedly, KYSE-140 resistant cell lines had a significant downregulation of this protein, concomitant with the downregulation of CTR1, an influx transporter. These results suggested that divergent resistance mechanisms may influence differently palbociclib response.

Conclusion

These findings indicate that eSCC cells develop different mechanisms of cisplatin resistance, which may lead to a co-acquired resistance to CDK4/6 inhibitors. A further characterization of these mechanisms with phospho-

proteomics will reveal strategies to rescue the sensitivity to CDK4/6 inhibition and suggest novel combinations for eSCC patients.

EACR25-2546**Unraveling tumor intrinsic responses: IFN-gamma predicts clinical immunotherapy efficacy and exclusively triggers apoptosis in solid tumors while sparing hematologic malignancies**

E. Arenas¹

¹Josep Carreras Leukemia Research Institute, Barcelona, Spain

Introduction

Over the past lustrum, tumor intrinsic interferon gamma (IFN γ) has emerged as a pivotal factor in the realm of cancer immunotherapy resistance for solid tumors, being determinant for optimal cancer immunotherapy response to both antigen presentation dependent immunotherapies such as immune checkpoint blockade and T cell redirection therapies like CAR T cells and bispecific antibodies (bsAbs) whose recognition do not rely on the expression of the major histocompatibility complex I (MHC-I). However, the requirement of tumor IFN γ for the efficient killing of CAR T cells and bsAbs in hematologic tumors, which has shown remarkable clinical efficacy, remains uncertain, yielding contradictory results. Furthermore, these studies employed genetically modified knock-out (KO) models with complete absence of the pathway, overlooking its potential role in tumors that acquire resistance through transcriptional down-modulation. In addition, it has been demonstrated distinct molecular mechanisms between complete IFN γ non-responders and partial responders, both of whom exhibit resistance. Furthermore, the tumor antigen's biology, the intrinsic differences between bsAbs and CAR T cells, and the precise antitumor mechanism of action exerted by IFN γ has been disregarded.

Material and method

Hematologic cancer cells naturally expressing CD19 or engineered to express HER2, and solid cancer cells expressing HER2 or engineered to express CD19, and bsAbs and CAR T cells targeting these antigens.

Result and discussion

We demonstrate that a transcriptional impairment of tumor IFN γ signaling employing shRNAs targeting the IFNGR1 gene leads to resistance to bsAbs and CAR T cells exclusively in solid tumors. In addition, we show that IFN γ induces apoptosis in solid but not in hematologic cancer cells, and we show that hematologic cancer cells exhibit a higher basal intrinsic IFN γ signaling which result in a suboptimal response to IFN γ , which can explain their lack of response to the pro-apoptotic effects of IFN γ . Importantly, by analyzing publicly available transcriptomic data from hundreds of cancer cell lines of various origins, we confirmed that hematologic cancers express significantly higher levels of IFN γ -related genes, particularly IRF1, the master regulator of the IFN γ signaling pathway. Furthermore, an analysis of tumor fractions from scRNA-seq datasets of patients treated with various cancer immunotherapies – specifically

immune checkpoint blockade (anti-PD1) for solid tumors and CAR T cells or BsAbs targeting CD19 for leukemia patients – demonstrates that a tumor IFN γ signature predicts clinical efficacy exclusively in solid tumors while sparing leukemia cancers.

Conclusion

These findings underscore the clinical need to develop tailored treatments that are able to activate tumor IFN γ signaling to maximize cancer immunotherapy efficacy specifically in solid tumors, thereby minimizing unnecessary toxicities in hematologic cancers.

EACR25-2550

Signaling Pathways affected by RAGE inhibition in vemurafenib treated melanoma cells

E. Leclerc¹, Y. Alam¹, M. Hasan¹, S. Vetter²

¹*North Dakota State University, Pharmaceutical Sciences, Fargo, United States*

²*North Dakota State University, Pharmaceutical Sciences, United States*

Introduction

The receptor for advanced glycation end products (RAGE) is a pattern recognition receptor that has been shown to participate in melanoma cell proliferation, migration, invasion and tumor growth. Using a subcutaneous xenograft mouse model of melanoma, we previously showed that RAGE also contributes to resistance to the chemotherapeutic drug dacarbazine. Because dacarbazine is not the current standard of care for melanoma anymore, we investigated if RAGE inhibition could enhance the efficacy of vemurafenib, a BRAF mutant inhibitor and a current standard of care for melanoma patients. We also investigated the signaling pathways affected by RAGE inhibition in vemurafenib treated cells.

Material and method

We used two cell lines that express the mutant form of the BRAF kinase. Both cell lines derive from the WM115 human melanoma cell line: the parental WM115 cell line expresses low endogenous levels of RAGE, whereas the engineered WM115-RAGE cell line overexpresses RAGE. The small molecule RAGE inhibitor FPS-ZM1 was used. A synergy assay was performed in vitro and analyzed using the Combenefit software. Signaling pathways related to autophagy and apoptosis were interrogated by Western blot analysis.

Result and discussion

Treatment of WM115 or WM115-RAGE cells with FPS-ZM1 alone did not affect the viability of the melanoma cells. However, when combined with vemurafenib, FPS-ZM1 enhanced the apparent IC₅₀ of vemurafenib by 2- to 3-fold, suggesting that RAGE inhibition enhances the efficacy of vemurafenib in WM115 cells and possibly in other melanoma cells. We are currently investigating the autophagic signaling pathways affected by RAGE inhibition by Western blot analysis.

Conclusion

Our preliminary studies suggest that RAGE inhibition enhances the efficacy of vemurafenib in human melanoma cells. Ongoing studies are currently investigating the signaling pathways affected by RAGE inhibition in melanoma treated cells. Future studies using

a mouse model of melanoma will be performed to determine if the synergistic effect between vemurafenib and the RAGE inhibitor is also observed in vivo.

EACR25-2572

Berberine, a P-glycoprotein inhibitor, shows synergistic anti-cancer effect when combined with Dactolisib in Colorectal Carcinoma HCT116 cell lines

S. Ismailoglu¹, G. Selimoglu², Z. Bolat¹

¹*University of Health Sciences, Istanbul, Turkey*

²*University of Health Sciences, Turkey*

Introduction

Berberine, also known as a P-glycoprotein inhibitor, is an isoquinoline alkaloid that shows low toxicity and anti-cancer activities. P-glycoprotein is an energy dependent drug efflux transporter that can reduce drug accumulation within cells by pumping out therapeutic agents. Berberine shows antiproliferative effect in colorectal carcinoma and induced apoptosis. The phosphatidylinositol 3-kinase (PI3K)/AKT/mTOR pathway, is critical in tumor growth and metastasis. The therapeutic potential of PI3K/AKT/mTOR inhibitors and their combinations have led to their active investigation in preclinical and clinical studies for colorectal carcinoma treatment. Dactolisib, also known as NVP-BEZ235, is a dual PI3K and mTOR kinase inhibitor. The current study investigates the synergistic anti-cancer effect of Berberine and Dactolisib on colorectal carcinoma HCT-116 cell line.

Material and method

Cell viability assay was conducted by resazurine dye and colony forming assay was conducted to determine the cell growth inhibition in HCT-116 cell line when treated with Berberine and Dactolisib. Migration ability of combination treatment of Berberine and Dactolisib was determined by in vitro scratch assay. Cell cycle assay was conducted by staining with propidium iodide to detect the cell distribution of HCT-116 cells. Intracellular uptake of Berberine was detected by fluorescence microscopy. Kinetic analysis and competition assay of both drugs were monitored by Ligand tracer to detect the real-time interaction measurements on live cells.

Results and discussion

Cytotoxicity of Berberine and Dactolisib was observed in a dose and time dependent manner in colorectal carcinoma HCT-116 cell line. Low doses of Dactolisib (0.25 μ M and 0.5 μ M) showed nearly 50% cell viability when combined with 10 μ M Berberine at 48 hours. Co-treatment of Berberine and Dactolisib showed a significant reduction in colony formation and migration ability in HCT-116 cell line. Treatment with Berberine and Dactolisib led to an increase in SubG0 phase of HCT-116 cells, suggesting possible induction in apoptosis. Intracellular uptake of Berberine was higher in combination groups compared to Berberine alone group. Co-treatment of Berberine and Dactolisib reflects the stabilizing effect of Dactolisib on Berberine binding kinetics in HCT-116 cells and ensure prolonged intracellular retention and activity of Berberine. As Berberine a P-glycoprotein inhibitor, this synergistic approach could be a potential combination to overcome drug

resistance. Resistant HCT-116 cell line will be used to further analyze this combination therapy.

Conclusion

These findings suggest a synergistic anti-cancer effect of Berberine and Dactolisib combination on HCT-116 cell line, demonstrating a potential therapy for colorectal carcinoma to overcome drug resistance.

EACR25-2593

Targeting AURKA Overcomes Gemcitabine Resistance in TP53-Mutated Cancers by Disrupting the Replication Stress Response

J. Wang¹, P. Hu¹, W. Wu¹, H. Jin¹

¹Shanghai Jiao Tong University School of Medicine, Shanghai, China

Introduction

Gemcitabine (GEM), a nucleoside analog, has been widely used in the treatment of various cancers. However, its therapeutic efficacy is often compromised by intrinsic or acquired resistance. TP53 mutations have been strongly associated with poor clinicopathological outcomes, reduced survival rates, and significantly enhanced resistance to gemcitabine. Therefore, identifying effective combination strategies to overcome gemcitabine resistance in TP53-mutated cancers is of critical importance.

Material and method

A kinase inhibitor library screen was performed in GEM-resistant TP53-mutated cholangiocarcinoma cells, with synergistic effects assessed using AUC-based scoring. Functional validation was conducted through *in vitro* and *in vivo* studies, including organoid models, patient-derived xenografts (PDX), and clinical dataset analysis. Molecular mechanisms were explored using immunoblotting, immunofluorescence, isolation of proteins on nascent DNA (iPOND), and DNA fiber assays.

Result and discussion

Clinical data analysis revealed that AURKA over-expression correlates with worse survival outcomes in TP53-mutated cancers. Functionally, AURKA inhibition significantly sensitized TP53-mutated cholangiocarcinoma, pancreatic, and colorectal cancer cells to GEM. Mechanistically, AURKA inhibition impaired MRE11-dependent stalled replication fork restart and homologous recombination repair, ultimately compromising S-phase checkpoint activation and inducing mitotic catastrophe in GEM-treated cells. Further investigations demonstrated that AURKA exerts its effects through its kinase activity by regulating PARP1, an upstream modulator of MRE11, thereby promoting replication fork restart and contributing to GEM resistance in TP53-mutated tumors.

Conclusion

Our findings identify AURKA as a key mediator of GEM resistance in TP53-mutated cancers. Targeting AURKA disrupts replication fork restart and DNA repair, thereby enhancing GEM sensitivity. This study provides a strong rationale for the clinical evaluation of AURKA inhibitors in combination with GEM as a promising therapeutic strategy for TP53-mutated cancers.

RASSF1A Methylation and Survival Outcome in Retroperitoneal Leiomyosarcoma

M. Wong¹, M. Openshaw¹, A. Ptasińska¹, M. Tarabichi², U. Krishnakumari³, A. Desai⁴, A. Beggs¹

¹University of Birmingham, Institute of Cancer and Genomic Science, Birmingham, United Kingdom

²IRIBHM, Université libre de Bruxelles, Brussel, Belgium

³University of Leeds, Bioinformatics, Leeds, United Kingdom

⁴Queen Elizabeth University Hospital, Midlands Abdominal Retroperitoneal Sarcoma Unit, Birmingham, United Kingdom

Introduction

The utilisation of liquid biopsy in the detection of methylation status in the cell-free DNA is a new approach in the field of soft tissue sarcoma. We performed a proof-of-concept experiment utilising the cell-free DNA (cfDNA) of retroperitoneal leiomyosarcoma and aimed to investigate the correlation between methylated RASSF1A in leiomyosarcoma with tumour burden and overall survival.

Material and method

Plasma-derived DNA was extracted and eluted in 50 mL of nuclease-free water (NFW). Buffy coat's and tissue sample's DNA were also extracted using the DNeasy® Blood and Tissue Kit. DNA was eluted in 100 mL of Buffer AE. Every sample was subjected to two ddPCR reactions – one with the MSRE and the other without the MSRE. Droplets were generated using the QX200™ Droplet Generator (Bio-Rad). Incubation and thermal cycling were performed using the C1000 Touch Thermal Cycler (Bio-Rad), with the following program. Following PCR, droplets were read and quantified using the QX200 Droplet reader and QuantaSoft™ Software. Methylation ratio {[RASSF1A (Methylated)]: [RASSF1A (Un-methylated)]} was calculated and correlation with tumour burden and survival analysis was made.

Result and discussion

A total of twenty-four patients (8 males and 16 females) were included in the study, with a mean age of 55.33 years. Cell-free DNA (cfDNA) was successfully detected in all 24 samples. Six plasma-derived DNA samples from patients with LMS, confirmed by immunohistochemistry as positive for either desmin, smooth muscle actin, and/or heavy caldesmon were selected, and these include four samples taken pre-operatively and two sets of paired samples (including post-operative samples) were analysed. Methylated RASSF1A was detected across all samples. We did not observe a consistent reduction in percentage of DNA methylation in the post-operative samples. The correlations between methylation ratio and tumour burden (cm^3) ($p = 0.246$) as well as disease-free survival (days) ($p = 0.108$) were positive but not statistically significant.

Conclusion

DNA methylation can be detected using liquid biopsy and ddPCR approach. We optimised the DNA methy-

lation protocol in detecting methylated RASSF1A. A larger sample is required to improve the sensitivity and specificity of the assay.

EACR25-0077

Investigating the influence of copper homeostasis on epigenetic modulation in the tumour microenvironment

J. Rouaen¹, R. Cazzoli¹, T. Shai-Hee¹, A. Salerno¹, O. Vittorio², G. Castrogiovanni¹

¹UNSW, Pathology, Sydney, Australia

²UNSW, Pathology, Sydney, Armenia

Introduction

Neuroblastoma, a pediatric cancer originating in the neural crest (Maris JM, 2010), remains a significant challenge in oncology. It predominantly affects young children (Ward E et al., 2014) and exhibits diverse clinical behaviors, ranging from spontaneous regression to aggressive, treatment-resistant forms (Swift et al., 2018; Tolbert et al., 2018). Emerging evidence highlights the multifaceted role of copper in neuroblastoma (Voli et al., 2020), suggesting its involvement in tumor development, progression, and treatment resistance. Copper ions modulate the activity of various enzymes critical for epigenetic regulation, including histone acetyltransferases, histone deacetylases, and DNA methyltransferases. These modifications can alter gene expression patterns, promoting tumorigenesis. Notably, our most recent study showed that high intratumoral copper levels contribute to immunosuppression by impairing neutrophil function (Rouaen et al., 2024). Understanding how neutrophils contribute to the immune landscape of neuroblastoma is critical for developing targeted therapies.

Material and method

Neuroblastoma cell lines were treated with the copper chelator TEPA to evaluate its impact on epigenetic regulation. Expression levels of epigenetic regulators were analyzed using quantitative PCR and Western blotting. The tumor microenvironment was further investigated using co-culture systems comprising differentiated immune cells and neuroblastoma cells. Neutrophil differentiation and activation were assessed in vitro by treating immortalized neutrophil cell lines with varying concentrations of copper and TEPA. Epigenetic changes in immune cells were assessed by flow cytometry and gene expression analysis.

Result and discussion

Treatment with TEPA resulted in significant down-regulation of epigenetic factors EZH2, UHRF1, and DNMT1 in neuroblastoma cells, suggesting that copper depletion alters the epigenetic landscape of these cells. Furthermore, TEPA treatment induced molecular changes in tumor-infiltrating immune cells, including increased expression of genes associated with anti-tumor immunity. Neutrophils treated with TEPA exhibited shifts in their functional phenotype, including enhanced antitumorigenic activity, as evidenced by increased ROS production and expression of immune-activating markers. These findings suggest that copper homeostasis influences not only the cancer cells but also the neutrophil-mediated immune responses within the tumor microenvironment.

Conclusion

Targeting copper-dependent pathways using chelators like TEPA could disrupt tumor growth while enhancing immune-mediated recognition. These strategies hold promise for the development of combinatorial therapies that exploit copper homeostasis to improve patient outcomes in neuroblastoma.

EACR25-0114

An epigenetic shift of CEMIP drives tumor metastasis and 3D spheroid formation in Androgen-resistant prostate cancer

S. Ali¹, Y. Chi¹, R. Shi¹, R. Na¹

¹The University of Hong Kong, Surgery, HKSAR, Hong Kong, China

Introduction

12.5% of men will receive a prostate cancer diagnosis at some point in their lives, making prostate cancer (PCa) one of the main causes of death and morbidity among men worldwide. Our previous population study based on UK Biobank suggested a significant decreased risk of PCa and PCa deaths. Here, we investigate the possible role of cell migration inducing hyaluronidase 1 (CEMIP) and its epigenetic change as molecular marker that drives tumor metastasis and 3D spheroid formation in androgen-resistant prostate cancer.

Material and method

Our analysis from public database from ChIP-Atlas and UCSC Genome Browser revealed the significance of CEMIP among prostate cancer cell lines. To further investigate, Androgen-insensitive (DU145, PC-3) and androgen-sensitive (LNCaP) human prostate cancer cell lines were knock-downed (si-RNA). Total RNA was extracted from the cells using the Trizol reagents before performing RT-qPCR with different cDNA concentration (25 ng, 50 ng and 100 ng) to confirm a successful knock-down. The results from MTT assay, 3D spheroid formation, migration, invasion and cell cycle analysis furtherly confirmed that the knock-down of CEMIP was more significant in androgen-resistant cell lines with statistical analysis from GraphPadPrism software.

Result and discussion

The results from ChIP-Atlas and UCSC Genome Brower showed that there is significant epigenetic shift of CEMIP at promoter region with Androgen-receptor (AR) binding to it. The results from RT-qPCR confirmed the successful knock-down. The knock-down displayed cytotoxicity effects against cancer cells ($p < 0.05$). Moreover, cancer cells form less aggregation (3D spheroid) after si-CEMIP. The MTT assay, migration, invasion, cell cycle analysis furtherly confirmed that the knock-down effect was more significant in androgen-resistant cell lines ($p < 0.05$). Thus, we confirmed that CEMIP drives tumor metastasis and 3D spheroid formation in Androgen-resistant prostate cancer. Our investigations provide compelling and novel evidence that epigenetic shift of CEMIP is a molecular marker in androgen-resistant prostate cancer and serves as a potential therapeutic target in prostate cancer in the future.

Conclusion

The current study provides novel perspectives into the epigenetic modification of CEMIP in prostate cancer. CEMIP can be a crucial player in prostate cancer as

molecular marker that drives tumor metastasis and 3D spheroid formation. The in vitro and in vivo validation of these results are required to examine whether the promising results are clinically translational. Overall, our outcomes reveal that CEMIP may have potential as a future therapeutic target in prostate cancer.

EACR25-0181

Deciphering the epigenetic de-regulation of the stem cell related HOX signature in glioblastoma

D. Chiesi¹, P. Bady², M. Hegi¹

¹Lausanne University Hospital (CHUV) and University of Lausanne, Clinical Neurosciences, Lausanne, Switzerland

²Lausanne University Hospital (CHUV) and University of Lausanne; Swiss Institute of Bioinformatics (SIB), Translational Data Science & Biomedical Data Science Center, Lausanne, Switzerland

Introduction

Bromodomain and Extra-terminal Tail (BET) proteins are epigenetic transcription regulators and potential therapeutic targets in glioblastoma (GB), the most aggressive primary malignant brain tumor in adults. A differential gene expression analysis of GB-derived sphere (GS) lines demonstrated that the BET inhibitor JQ1 significantly downregulates cancer-relevant gene signatures, including our previously defined HOX signature. HOX genes are crucial for limb segmentation during embryonic development and are associated with treatment resistance in a subset of GB patients characterized by a high-HOX signature. The HOXA gene cluster, located on chromosome 7 (Chr7), is a CpG-rich region and the expression of the HOXA-dominated signature correlates with Chr7 gain and widespread DNA hypermethylation. Previous findings indicated a significant negative correlation between DNA hypermethylation at the alternative HOXA10 promoter and HOX gene expression. This study aims to investigate the oncogenic role of HOXA10 and the epigenetic mechanisms underlying HOXA cluster deregulation in high-HOX GB.

Material and method

To explore these mechanisms, we used various assays: (1) comparative methylation analysis at the HOXA locus in a high-HOX GS line vs original tumor, along with RNA- and ChIP-seq analysis after JQ1 treatment; (2) BETi treatment and modulation of HOXA10/HOXA5 expression using inducible shRNA/ectopic expression systems to examine HOXA gene regulation; (3) functional assays post-HOXA10 modulation to assess cancer-relevant biological impact.

Result and discussion

We confirmed that BETi concertedly decreases HOXA gene expression in high-HOX GS lines. Remarkably, knockdown of HOXA10 in high-HOX GS lines is associated with a concerted downregulation of other HOXA genes; however, ectopic HOXA10 expression suggests that HOXA10 proteins may not be the sole factor contributing to HOX signature expression.

Specificity tests using shHOXA5 models affirmed the unique role of HOXA10, as HOXA5 knockdown did not

alter the expression of other HOXA genes. Functionally, HOXA10 knockdown in high-HOX GS lines results in potently decreased cell proliferation and stemness, accompanied by an emergence of senescence-like traits.

Conclusion

Our results set HOXA10 as a key player of the stem cell-related HOX signature in high-HOX GB, likely enabling tumor progression by its association with proliferative and stem-like features. BETi-mediated downregulation of HOX signature genes presents a promising therapeutic avenue for targeting high-HOX GB. Ongoing research focuses on differential gene expression, aiming to identify HOXA10-regulated genes and reveal its role in BETi-mediated effects. Besides, we are also assessing the potential changes in 3D chromatin architecture and epigenetic landscape around the HOXA cluster that may be involved HOX signature expression.

³IMIBIC - Maimónides Biomedical Research Institute of Córdoba, Department of Cell Biology, Physiology and Immunology -University of Córdoba, Córdoba, Spain

⁴Candiolo Cancer Institute-FPO-IRCCS, NGS Core Facility, Candiolo (TO), Italy

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with poor survival rates due to chemoresistance, clinical heterogeneity, and the absence of reliable early diagnostic markers. A key driver of chemoresistance is the presence of cancer stem cells (CSCs), a small subpopulation with distinct transcriptional profiles regulated by epigenetic and epitranscriptional mechanisms. N6 methyladenosine (m6A), the most abundant RNA modification, plays a crucial role in CSC regulation and cancer progression. Targeting the m6A regulatory machinery presents a promising strategy to enhance treatment efficacy. This study investigates the potential of m6A modulators in reversing epitranscriptomic alterations to promote chemosensitization in patient derived PDAC models.

Material and method

Subtherapeutic concentrations of m6A modulators were tested in circulating tumor cell (CTC)- and patient derived xenograft (PDX)-derived spheroid cultures, both individually and in combination with gemcitabine. m6A immunoprecipitation (Me-RIP) was performed on total RNA, followed by sequencing using the Illumina NovaSeq X Plus platform. Peak calling and transcript identification were conducted using findPeaks tool in HOMER.

Result and discussion

Bioinformatics analysis validated treatment effects, identifying enriched m6A sites and dynamic epitranscriptomic changes. Comparative analyses revealed variability in m6A peak distribution and gene expression, suggesting broad biological impact. Pathway enrichment analysis highlighted significant alterations in proliferation, survival, stress response, and immune regulation. Unique and common m6A peaks, along with differentially expressed genes, indicated both conserved and condition specific regulatory mechanisms.

Conclusion

This study provides preliminary evidence that m6A modifications influence PDAC progression and suggests that targeting m6A could enhance chemotherapy efficacy. Further bioinformatic analysis and GLORI based single base resolution quantification will provide deeper insights into the molecular mechanisms underlying the role of m6A in PDAC.

EACR25-0284

The effectiveness of EZH2 inhibitors in treating human papillomavirus associated cervical cancer and associated pathways

D. Vidalina¹, L. Ghali¹, N. Kassouf¹, X. Wen¹

¹Middlesex University, Natural Sciences, London, United Kingdom

Introduction

High-risk human papillomavirus (HPV) is a major risk factor in the development of several types of epithelial-origin cancers, including cervical and head and neck cancers and is associated with the aggressive and invasive behaviour of cancer cells. Enhancer of zeste homolog 2 (EZH2), a histone methyltransferase, has been found to downregulate expression of tumour suppressor genes and upregulate oncogenes and has also been observed in HPV-associated epithelial cancers, suggesting the possible role of high-risk HPV. Hence, it could promote cancer cell proliferation, invasion and drug resistance. EZH2 inhibitors have been shown to act as epigenetic regulators in cancer treatment, but there is still no consensus on the mechanisms of their action and their effectiveness on HPV-associated cancers.

Epithelial-to-mesenchymal transition (EMT), which induces phenotypic cellular changes, has been implicated in the pathological processes of epithelial cancer progression and metastasis. Epigenetic reprogramming of EMT via EZH2 inhibitors could promote anticancer effects. This study sets up to investigate the expressions of epigenetic changes and EMT markers in HPV-associated cancers cells *in vitro* and to identify whether EZH2 inhibitors (EPZ6438 and ZLD1039) can be effective in suppressing the EMT process and whether this would be associated with HPV oncogene status.

Material and method

EZH2 inhibitors' drug toxicity was evaluated by cell proliferation assay, cell cycle arrest and cell apoptosis assays using flow cytometry analysis on HPV+ and HPV-cervical cancer cells. Following a cell migration-scratch assay, epigenetic, oncogenic and EMT markers have been examined using immunocytochemistry staining, western blotting, flow cytometry and RT-qPCR.

Result and discussion

Both EZH2 inhibitors demonstrated effectiveness in reducing EZH2 expression on both mRNA and protein level, inducing apoptosis and arresting cells in G0/G1 phase. Results also showed a tendency to upregulate expression of epithelial markers at the mRNA and protein levels, which was supported by slower migration observed following the cell migration-scratch assay. This suggests EMT reversal could be initiated through EZH2 inhibition. Oncogene expression was reduced at both mRNA and protein levels following EZH2 inhibitor treatments.

Conclusion

Data from this study suggests that EZH2 inhibitors might be promising therapeutic agents in treating high-risk HPV-associated cervical cancers by downregulating HPV oncogenes and EMT reversal.

²Cancer Research Center of Lyon, Bio-informatic platform, Lyon, France

³Hospices Civils de Lyon, Cancer Research Center of Lyon, Lyon, France

⁴Hospices Civils de Lyon, Cancer Research Center of Lyon, Pierre Benite, France

Introduction

Cancer cell plasticity plays a key role in tumor progression and the acquisition of resistance to targeted and immunotherapy in melanoma. Although the transcriptional programs enabling the switch between differentiated/melanocytic and undifferentiated/invasive phenotypes are characterized, unravelling druggable epigenetic regulators that sustain melanoma cell adaptation and resistance remains crucial. Herein, we identified TRIM24, a bromodomain protein frequently amplified in human melanomas as a crucial regulator of melanoma cell plasticity.

Material and method

TRIM24 expression was analyzed in melanoma patient cohorts under immunotherapy. We then performed shRNA-mediated knock-down in human melanoma cell lines as well as TRIM24-specific degradation using a PROTAC-based approach. We further performed a comprehensive analysis of the transcriptomic and epigenomic reprogramming by RNA-seq, ATAC-seq, and Cut & Tag for histone marks and TRIM24 itself. Finally, *in vivo* experiments in syngeneic mouse models were implemented.

Result and discussion

We demonstrate that TRIM24 expression is increased in metastatic tumors and is associated with relapse under immunotherapy in melanoma patients. Loss-of-function of TRIM24 decreases the migratory capacities and increases the sensitivity to BRAF inhibitors in BRAF-mutated melanoma models. PROTAC-mediated degradation of TRIM24 resensitizes resistant human

melanoma models to targeted therapy. Integrative analysis of the transcriptional profile and the chromatin landscape reveal that TRIM24 knock-down represses undifferentiated/invasive and promotes differentiated/melanocytic transcriptional programs by inducing an epigenome reprogramming in melanoma cells. By delineating TRIM24 binding profile and histone marks affinity, we identify that TRIM24 recognizes a specific histone mark, it directly binds genes controlling an undifferentiated phenotype and alters their chromatin state. We further define a TRIM24 transcriptomic signature, that is found consistently enriched in treatment-resistant undifferentiated/invasive sub-populations in melanoma single-cell RNA-seq datasets. Finally, TRIM24 knock-down in mouse models induces a remodelling of the immune infiltrate and synergizes with immune checkpoint inhibitors.

Conclusion

Overall, our findings spotlight TRIM24 as a novel epigenetic regulator driving melanoma cell dedifferentiation and resistance to therapy. Targeting TRIM24 could offer a promising therapeutic avenue to reverse phenotype switching and restore tumor sensitivity to treatment.

EACR25-0365

Defining the Epigenetic Landscape regulating a Progenitor Signature in Development and, during Tumour Initiation and Progression

M. Bellafante¹, S. Mosole¹, E. Pasquini¹, A. Rinaldi¹, O. Eichhoff², J. Käsler², M. Levesque², L. Cascione¹, F. Bertoni¹, A. Baggioolini¹

¹BIOS+, IOR (Institute of Oncology Research), Bellinzona, Switzerland

²University Hospital Zurich, Department of Dermatology, Zurich, Switzerland

Introduction

This project investigates the epigenetic regulation of cell-state transitions in melanoma, focusing on mechanisms underlying oncogenic competence and drug resistance. While MAPK-targeted therapies initially show high response rates, resistance emerges rapidly, leading to relapse and disease progression. Drug tolerance is closely linked to cell-state transitions and minimal residual disease, with progenitor-like states playing a key role in resistance. Melanoma initiation and progression are influenced by neural crest developmental programs, regulated by epigenetic factors that control cellular plasticity. Among them, ATAD2 and ATAD2B, highly expressed in progenitor cells and frequently altered in melanoma, may drive both normal progenitor state maintenance and drug resistance acquisition.

Material and method

We will use hPSC-derived neural crest cells and melanoblasts with doxycycline-inducible CRISPR/Cas9 knockouts of ATAD2 and ATAD2B to analyze their role in progenitor maintenance and melanoma adaptation. ATAC-seq and Cut&Run will assess chromatin accessibility and transcription factor binding, while RNA-seq and RT-PCR will evaluate transcriptional

changes in drug-treated melanoma cell lines. For in vivo validation, we generated Atad2 lox/lox and Atad2b lox/lox mouse models for inducible knockout during development and tumorigenesis. NSG mice injected with luciferase+ melanoma cells will undergo chronic therapy, with subsets receiving Bay-850 to assess its effect on resistance prevention.

Result and discussion

We expect ATAD2 and ATAD2B to regulate melanoma plasticity by modulating chromatin accessibility and transcriptional programs. Knockout models will clarify their role in progenitor state maintenance and therapy resistance. Single and double knockouts will assess potential compensatory mechanisms in vivo. Bay-850 efficacy will be evaluated in resistant tumours, with alternative inhibitors tested if needed.

Conclusion

This study aims to elucidate the role of ATAD2 and ATAD2B in melanoma plasticity and drug resistance by integrating hPSC models, patient-derived samples, and in vivo systems. By dissecting how these epigenetic regulators influence cellular state transitions, we seek to identify key mechanisms driving tumour adaptation, minimal residual disease, and therapy resistance. Understanding these regulatory networks will provide insights into the interplay between developmental programs and oncogenic transformation. Defining how ATAD2 and ATAD2B contribute to tumour heterogeneity and therapy-induced adaptation could reveal novel vulnerabilities for therapeutic intervention. Ultimately, this research aims to contribute to more effective strategies to overcome drug resistance, improve patient outcomes, and prevent disease relapse in melanoma.

Identification of epigenetic drivers in colorectal cancer from clinical tissue and blood samples

A. Chatterjee¹, P. Stockwell¹, P. Ajithkumar¹, M. Yassi¹, M. Jones¹, B. Knofflock¹, N. Keestra¹, S. VasanthaRajan¹, M. Parry², E. Rodger¹

¹Dunedin School of Medicine, University of Otago, Dunedin, New Zealand, Department of Pathology, Dunedin, New Zealand

²University of Otago, Dunedin, New Zealand, Department of Mathematics and Statistics, Dunedin, New Zealand

Introduction

Colorectal cancer (CRC) presents a major health burden worldwide, and there has been a consistent increase in CRC incidence, particularly in younger people (age <50 years) where the disease is often presented at an advanced stage. Prognosis and survival of CRC patients rely heavily on the stage at diagnosis – the earlier, the better. Epigenetic changes are a universal and hallmark feature of cancer and recent studies from ourselves and others have provided strong evidence that epigenetic drivers play a key role in cancer progression and could be used as early markers. Further, the development of cell-free tumour DNA (ctDNA) methylation analysis represents a major step towards improving the diagnosis and management of cancer.

Material and method

We have streamlined and utilised genome-scale DNA methylation analysis methods (using reduced representation bisulfite sequencing or RRBS) for clinical samples along with RNA-Sequencing analysis for functional epigenomic analysis on tissue samples. In addition, we have streamlined modified RRBS technology to generate ultra-low input DNA methylomes in critical clinical samples such as Formalin Fixed Paraffin Embedded (FFPE) samples and cell-free DNA. Further, we are developing novel machine learning based algorithms to analyse large epigenomic data.

Result and discussion

Our study led to the identification of epigenetic (DNA methylation) drivers for both early and late stages of CRC. These putative methylation driver regions were associated with critical cancer cell pathways and function. Our CRISPR-based DNA methylation editing work indicates that many of these drivers can directly control gene expression without any changes to the underlying DNA sequence. In our cell-free DNA methylome work, we are able to generate robust and reproducible data from a small amount of ctDNA. Our results showed discriminatory methylation differences between malignant and non-malignant conditions and demonstrated high sensitivity and specificity.

Conclusion

We were able to identify epigenetic drivers in both tissue and ctDNA from patient samples. For future clinical application, our research will contribute to the development and application of sensitive and non-invasive methylation-based methods for the detection and monitoring of cancer. This work will potentially identify new epigenetic targets for therapeutic benefits, which will contribute to improved patient outcomes.

EACR25-0613

Multomics 6-base sequencing enhances the performance of early colorectal cancer detection from cell-free DNA

F. Puddo¹, T. Charlesworth², A. Johannsen³

¹biomodal, Research and Development, Cambridge, United Kingdom

²biomodal, Product Marketing, Cambridge, United Kingdom

³biomodal, Bioinformatics, Cambridge, United Kingdom

Introduction

Early detection of colorectal cancer (CRC) has the potential to improve treatment outcomes and survival rates. Liquid biopsy for profiling of cell free DNA (cfDNA) in blood holds huge promise for early CRC detection in otherwise asymptomatic patients.

Material and method

Epigenetic biomarkers have already been shown to significantly contribute to cancer detection in liquid biopsies, but traditional DNA methylation sequencing conflates two cytosine modifications, 5-methylcytosine (5mC) or 5-hydroxymethylcytosine (5hmC), with different and opposing biological functions.

Discrimination of these two states could therefore be crucial for increasing the amount of functional information for CRC detection.

Result and discussion

We therefore employed duet evoC, a biomodal technology that provides the 6-base genome (the complete genetic sequence whilst simultaneously distinguishing 5mC and 5hmC), to cfDNA obtained from a cohort of 32 healthy volunteers and 37 patients with colorectal cancer (CRC) at stages I and IV. Through machine learning approaches, we built classifiers to differentiate between cfDNA from patients with stage I CRC and individuals without cancer using features based 5mC alone, 5hmC alone, both 5mC and 5hmC, or the conflated 5mC/5hmC (modC, as it would be generated by traditional epigenetic technologies).

Conclusion

Our findings reveal that, compared to traditional approaches, 5mC and 5hmC behave synergistically for the detection of early-stage CRC, enhancing diagnostic accuracy (AUC = 0.95). Notably, most regions with an increase in 5hmC in stage I CRC correlate with decreased in 5mC in stage IV CRC, suggesting that 5hmC could be an early marker of demethylation that occurs further down the cancer development trajectory. Applying 6-base sequencing to larger clinical cohorts, and across different indications, will evaluate the potential of 6-base data to improve the earlier detection, diagnosis, and treatment of other diseases.

MicroRNA-Driven Modulation of TACSTD2 (TROP2) in Colorectal Cancer Progression

I. Guercueoglu^{1,2}, K. Huebner^{1,3}, K. Erlenbach-Wuensch², A. Naccarati^{4,5}, B. Pardini⁴, G. Ferrero⁶, R. Schneider-Stock^{1,7,3}

⁴Italian Institute for Genomic Medicine (IIGM), c/o IRCCS Candiolo, Torino, Italy

⁵Department of Clinical and Biological Sciences, University of Torino, Torino, Italy

⁶Erlangen, Germany, Bavarian Cancer Research Center (BZKF)

Introduction

The transmembrane protein TROP2, encoded by TACSTD2, has been identified as a key driver in cancer progression. Interestingly, a significant proportion of colorectal cancer (CRC) tumors are TROP2-negative, suggesting a high degree of plasticity during tumor development. To date, only a few studies have reported on the transcriptional regulation of TACSTD2, either through the transcription factor ATF2 or promoter hypermethylation. MicroRNAs (miRNAs) are small, ~22-nucleotide-long regulatory molecules that bind to the 3' untranslated regions (3'UTRs) of target mRNAs, leading to translational repression or mRNA degradation. The objective of our study was to identify and characterize miRNAs that regulate TACSTD2 (TROP2) expression in CRC.

Material and method

We first conducted an in silico analysis to identify potential miRNA candidates targeting TACSTD2.

Selected miRNAs were then overexpressed in CRC cell

lines using miRNA mimic transfections. Protein and RNA expression levels following miRNA modulation were validated using Western blot and qPCR analyses. A luciferase reporter assay was performed to confirm miRNA binding to the 3'UTR of TACSTD2. Additionally, functional assays were conducted to assess the effects of miRNA modulation in CRC cell lines and human colon tumor organoids.

Result and discussion

For our study, we selected CRC cell lines with high (DLD1, SW480) and low (T84, HCT116) TROP2 expression. We identified miR-376c-3p as a promising candidate for TACSTD2 regulation. Following miR-376c-3p mimic transfection, we observed a time-dependent reduction in TACSTD2 expression in DLD1 and SW480 cells. Furthermore, we confirmed miR-376c-3p binding to the 3'UTR of TACSTD2. Treatment of tumor cells with the DNMT1 inhibitor 5-azacytidine led to an increase in TROP2 expression, which could be attenuated by miR-376c-3p in a context-dependent manner.

Conclusion

Our findings suggest that miR-376c-3p is a novel post-transcriptional regulator of the TACSTD2 oncogene. Altered miRNA expression may contribute to the high intratumoral heterogeneity of TROP2 expression in CRC. Using RNAscope analysis, we will further investigate the inverse correlation between miR-376c-3p and TACSTD2 in the *in vivo* CAM model and patient samples.

EACR25-0720

Correlation with DNA methylation changes and chemoresistance in glioblastoma after mitochondrial transfer

T. Ng¹, K. Kiang¹, G. Leung¹

¹The University of Hong Kong, Department of surgery, School of Clinical Medicine, LKS Faculty of Medicine, Hong Kong, Hong Kong, China

Introduction

Glioblastoma is an aggressive brain tumor with high mortality rate despite treatment with radiotherapy and chemotherapy with temozolomide. This is in part due to the high rate of resistance to temozolomide. It is well known that MGMT methylation is a marker for the prediction of the patients' response to temozolomide. Mitochondrial transfer is recently revealed to cause increased tumorigenicity and chemoresistance in glioblastoma. It is hypothesized that mitochondria transfer may cause increased tumorigenicity and chemoresistance via DNA methylation pathway, which mainly operates via the DNMT proteins.

Material and method

Glioblastoma cells and mitochondria in immortalized normal human astrocytes (NHA) are labelled with fluorescent dye. Cells with or without mitochondrial transfer from NHA are sorted out with a cell sorter after coculture. Methylation specific PCR is performed on bisulfite converted DNA of glioblastoma cells with or without mitochondrial transfer to determine the methylation status of MGMT. Western blotting and qPCR is done to determine the level of MGMT and DNMT in tumor cells with or without transfer. Global methylation

is determined using ELISA methods. Cell viability is assessed on cells with or without mitochondrial transfer after treatment with temozolomide by MTT.

Result and discussion

The glioblastoma cells with mitochondrial transfer show a decrease in global methylation, and global methylation has been shown to be correlated with poor outcome in glioblastoma. The glioblastoma cells with mitochondria transfer is expected to show a decrease in the level of MGMT methylation. The level of DNMT expression is expected to decrease, which may possibly lead to the decreased global methylation and MGMT methylation, and consequently chemoresistance. Cells with mitochondrial transfer is expected to have a higher cell viability after treatment with TMZ when compared to cells without mitochondrial transfer.

Conclusion

Mitochondria transfer in glioblastoma can confer chemoresistance to glioblastoma cells, which may in part be due to MGMT demethylation. Mitochondrial transfer may also contribute to the poor outcomes in glioblastoma by changing the global methylation landscape of the glioblastoma cells.

EACR25-0735

The CTCF - H3K27 methylation axis supports the migration of melanoma cells by regulating cholesterol biosynthesis

D. Babele¹, L. Kaczmarczyk¹, N. Levi¹, G. Gunasekaran¹, M. Salmon-Divon², G. Gerlitz¹

¹Ariel University, Molecular Biology, Ariel, Israel

²Ariel University, Molecular Biology and School of Medicine, Ariel, Israel

Introduction

Cancer cell migration is critical for metastasis formation and depends on heterochromatin levels. Heterochromatin formation characterized by H3K9me3 and H3K27me3 is important for optimizing the transcriptome to support cell migration. Cancer cell migration also depends on the chromatin architectural protein CTCF by a poorly understood mechanism. CTCF acts as a 3D chromatin regulator by controlling cohesin-dependent loop formation as well as a classical transcription factor. Here, we looked for the molecular mechanism by which CTCF supports migration.

Material and method

Melanoma cells with a partial loss of function (pLoF) of CTCF were analyzed for their migration rate and transcriptome changes. Statins were used to manipulate cholesterol levels. Fluorescent microscope analyses were used to measure the formation of migrasomes and focal adhesions. Chromatin binding and 3D chromatin loops were determined by ChIP and 4C-seq techniques, respectively.

Result and discussion

CTCF pLoF inhibited the cellular migration rate while increasing the expression of multiple enzymes in the cholesterol biosynthesis pathway, which was accompanied by an elevation in cellular cholesterol levels. In parallel, we detected changes in membrane dynamics as measured by reduced formation of migrasomes and focal adhesions. Inhibition of cholesterol

synthesis in CTCF pLoF cells restored both the migration rate and the formation of migrasomes and focal adhesions. Conversely, increasing cholesterol levels in wild-type cells inhibited their migration rate. Thus suggesting that CTCF supports cell migration by suppressing cholesterol synthesis. Detailed analysis of the promoter of Hmgcs1, an early enzyme in the cholesterol biosynthesis pathway, revealed that CTCF prevents the formation of a loop between that promoter and another promoter located 200kb away. Additionally, CTCF supports the recruitment of the histone methyl transferase PRC2, leading to H3K27me3 formation at the Hmgcs1 promoter. H3K27me3 at the promoter of Hmgcs1 prevents SREBP2 binding and activation of transcription.

Conclusion

CTCF helps to recruit PRC2 to methylate H3K27 at promoters of cholesterol biosynthesis enzymes to repress SREBP2 binding and transcription. This leads to optimal cholesterol levels for cancer cell migration.

Introduction

Second-generation androgen deprivation therapies (ADT) have provided significant life-extension for patients with metastatic castration resistant prostate cancer (mCRPC); however, tumors eventually progress via therapy resistance as no therapies provide durable response. Approximately between 15-20% of these mCRPC tumors are independent of AR activity via a mechanism termed phenotypic plasticity. The development of phenotypic plasticity is associated with loss of function of the tumor suppressor genes RB1 and/or TP53. These tumors often display altered kinase signaling, chronic inflammation, and multilineage cellular states. Using genetically engineered mouse models (GEMMs) devoid of Pten and

Rb1, it has been previously demonstrated that the chromatin reprogramming factor Enhancer of zeste homolog 2 (EZH2) is an important regulator of alternative transcription programs that promotes phenotypic plasticity. Moreover, the loss of Tristetraprolin (TTP), an RNA binding protein that regulates mRNA stability and increases NF- κ B activation, has been associated with higher rates of aggressive prostate cancer (PCa). Here, our overall goal was to better understand EZH2 role in reprogramming and how this could be exploited therapeutically.

Material and method

To investigate the cell identity control by EZH2, PCa GEMMs were treated with an EZH2 inhibitor. Analysis was performed using a multi-omics approach involving CRISPR/Cas9 functional genomics screen, rapid immunoprecipitation mass spectrometry of endogenous protein (RIME), and snRNASeq. To validate these data, genetic and chemical tools were used with *in vitro* and *in vivo* PCa models.

Result and discussion

We observed that EZH2 regulates alternate transcription programs leading to a multilineage cell states downstream of Rb1 loss that is associated with activation of the mammalian target of rapamycin complex 1 (mTORC1). These data were further supported through RIME and functional genomic analysis validating cross talk between EZH2 and activation of translation. Combined chemical inhibition of EZH2 and PI3K/mTORC1 resulted in superior anti-tumor activity in murine and human phenotypic plastic models and was most significant when this combination was used with castration. Moreover, we elucidated that the regulation of cellular state transition by EZH2 inhibition requires activation of the RNA degrader, TTP.

Conclusion

Together, these data indicate phenotypic plasticity dependence on coordination between EZH2, TTP and mTORC1 signaling that represent novel therapeutic dependencies for this lethal PCa phenotype.

EACR25-0777

Targeting the chromatin remodeler HELLS to Improve Therapeutic Strategies in T-Cell Lymphoma

G. Gambarelli¹, S. Mallia¹, V. Manicardi¹, B. Donati¹, E. Vitale¹, N. Puccio¹, M. Zanelli¹, A. Neri¹, A. Ciarrocchi¹, V. Fragliasso¹
¹*AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy*

Introduction

Chromatin remodelers dynamically modify DNA-nucleosome interactions, playing a crucial role in chromatin structure, accessibility and gene expression. Dysregulation of these proteins is common in cancer and often represents a therapeutic vulnerability. The chromatin remodeler HELLS has emerged as a critical regulator of genome stability and gene expression in aggressive T-cell lymphoma subtypes like ALK- anaplastic large cell lymphoma (ALCL). Selective knock-down of HELLS sensitizes ALCL cells to chemotherapy, suggesting the potential of HELLS as a therapeutic target. This study aimed to explore the role of HELLS in

transcriptional dynamics in ALCL and to assess its therapeutic potential.

Material and method

Formalin-fixed paraffin-embedded sections from diagnostic/relapsed primary lymphoma biopsies were used for retrospective cohort analysis. In vitro experiments combined omics approaches (RNA-seq, ChIP-seq, ATAC-seq and CMap) with functional assays.

Result and discussion

To investigate the transcriptional function of HELLs in ALK- ALCL, we integrated ChIP-seq on the TLBR-2 cell line, the principal model in prior studies elucidating HELLs role in lymphomagenesis, with RNA-seq in HELLs knockdown (HELLs KD) and control cells. We identified 467 deregulated and directly bound by HELLs based on ChIP-seq, termed HELLs-direct genes (HDGs). Their clinical significance was confirmed *in vivo* in a retrospective cohort of 44 ALCL patients (15 ALK⁺ and 29 ALK⁻ ALCL) through the NCounter platform. Merging HDGs with RNAPII-ChIP seq data revealed that about 60% of HDGs showed defects in RNAPII elongation, while 40% exhibited a significant alteration in RNAPII occupancy after HELLs KD. Gene ontology analysis showed that these last HDGs were enriched in T-cell mediated immunity, cytokines signaling and the JAK/STAT pathway, highlighting HELLs' underscored role in immune-related pathways. ATAC-seq analysis showed that HELLs modifies chromatin accessibility mainly at immune-related promoters in T-cell lymphoma cells. This process facilitates RNAP recruitment and transcription factor binding, enhancing transcriptional activity. Immune-related gene promoters were enriched for H3K4me3, further suggesting chromatin structural changes are necessary for their precise gene expression. To assess the therapeutic potential of HELLs, we performed an HDGs-based drug repurposing analysis by interrogating the CMap. We identified PI3K, JAK/STAT, and DNA-PK as top-scored synergistic pathways with HELLs depletion. In vitro experiments confirmed that Ruxolitinib (JAKi) and AZD7648 (DNA-PKi), caused significant synthetic lethality combined with HELLs depletion.

Conclusion

These findings demonstrate the direct role of HELLs in transcriptional regulation and pave the way for the development of targeted and clinically translatable strategies for HELLs inhibition.

Unraveling Inflammation-Related microRNAs in Pleural Mesothelioma: Gene Regulation and Pathway Analysis

G. Tonnini¹, C. Mazziotta¹, J. Rotondo², M. Tramarin¹, G. Badiale¹, M. Oimo¹, C. Cervellera¹, M. Tognon¹, F. Martini¹

¹University of Ferrara, Department of Medical Sciences, Ferrara, Italy

²San Raffaele Roma Open University, Rome, Italy

Introduction

Pleural mesothelioma (PM) is a rare and highly aggressive malignancy originating from the pleural lining. Approximately 80% of cases result from the

inhalation of asbestos fibers. This exposure triggers a chronic inflammatory response in the pleura, leading to tissue damage, uncontrolled cell growth and genetic mutations that promote cancer. There are three main PM histotypes, epithelioid, biphasic, and sarcomatoid. Recent studies highlight the importance of non-coding RNAs in PM, including microRNAs (miRNAs), as potential diagnostic and prognostic cancer biomarkers.

Material and method

Herein, we investigated the differential expression of inflammation-related miRNAs by RT² Profiler PCR Array Human Inflammatory Response (n = 84 miRNAs) in primary mesothelioma cell lines of different histotypes, epithelioid (n = 2), biphasic (n = 2), and sarcomatoid (n = 2), and normal human mesothelial cell lines (n = 2). miRNA expression analysis was analyzed using the 2- $\Delta\Delta Ct$ method. Log₂ fold change <-2>/2 was considered statistically significant. Algorithm, i.e. miRSYSTEM was used for miRNA target genes prediction using the default setting. Gene ontology (GO)/Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses were employed to categorize genes and identify relevant pathway.

Result and discussion

Our results demonstrate distinct miRNA expression profiles in PM compared to control group. A total of 10/84 (12%) miRNAs were differentially expressed when comparing PM to normal cells: of these 6/10 (60%) were upregulated and 4/10 (40%) were downregulated. To determine the potential biological relevance of the differentially expressed miRNAs to PM, we predicted the target spectrum of individual deregulated miRNAs and assessed which biological pathways were enriched with their putative targets. A total of 2,201 targets were predicted for the 4 downregulated miRNAs. GO for biological process showed that regulation of transcription of cell cycle G1/S phase transition were the most enriched processes in PM cell lines. GO for molecular function exhibited that activin receptor activity, protein serine/threonine kinase activity and DNA binding were the most enriched. Moreover, GO indicated that serine/threonine protein kinase complex, activin receptor activity, nucleus and heterochromatin were the most enriched cellular component.

Conclusion

Our investigation highlights that inflammation-related miRNAs are differentially regulated in PM, underscoring their potential as diagnostic biomarkers and therapeutic targets. Future studies will focus on validating these miRNA signatures in a larger panel of cell lines and patient sera, and on elucidating their functional roles in PM pathogenesis.

⁶Portuguese Oncology Institute of Porto (IPO Porto), Cancer Biology and Epigenetics Group (IPO Porto Research Center) and Department of Pathology, Porto, Portugal

⁷ICBAS – School of Medicine and Biomedical Sciences, Department of Pathology and Molecular Immunology, Porto, Portugal

Introduction

Renal Cell Carcinoma (RCC), particularly clear cell RCC (ccRCC), is one of the most lethal among urological cancers, with 25% of cases diagnosed at metastatic stage and 20% of these exhibiting sarcomatoid features, which drive tumor aggressiveness and poor prognosis. Although it is known that altered DNA methylation occurs during ccRCC progression, its contribution to the emergence of sarcomatoid differentiation remains elusive. This study aims to find new DNA methylation biomarkers that accurately identify sarcomatoid features arising in ccRCC.

Material and method

In silico analyses were conducted to assess differentially methylated genes in sarcomatoid ccRCC (sccRCC) using The Cancer Genome Atlas (TCGA), focusing on specific genes linked to normal cellular function, cell stemness, and metabolism. Promoter methylation and expression were validated for the candidate genes in a tissue sample set (54 ccRCC and 34 sccRCC) using Mann-Whitney U test to compare gene methylation and transcript levels between ccRCC and sarcomatoid ccRCC groups and by plotting Receiver Operator Characteristics (ROC) with the respective biomarker performance estimates. Ethics approval was conceded by the Ethics Committee of IPO Porto (CES. 158/023).

Result and discussion

CDHR5 and UPB1 promoter methylation levels were significantly higher in sarcomatoid ccRCC than in ccRCC without sarcomatoid features, while respective transcript levels were significantly diminished in both independent cohorts (TCGA and IPO Porto). When combining CDHR5me and UPB1me levels in a panel, sccRCC was discriminated from ccRCC with 78.7% specificity and 63% sensitivity. Furthermore, increased CDHR5me levels significantly associated with metastatic dissemination at diagnosis in sccRCC patients.

Conclusion

Promoter methylation of CDHR5 and UPB1 is recognized as a possible hallmark to identify sarcomatoid change in ccRCC and may serve as a biomarker to this end. Validation in liquid biopsies could enhance the clinical utility of these findings.

EACR25-0978

Methylation profiles in cervical swabs: challenges in early diagnosis of ovarian cancer

E. Biskup¹, J. Lopacinska-Jørgensen¹, C. Høgdall², E. Høgdall¹

¹Herlev Hospital, Department of Pathology, Herlev, Denmark

²Rigshospitalet, Department of Gynaecology, Copenhagen, Denmark

Introduction

Developing cost-effective and non-invasive methods for the early diagnosis of ovarian cancer remains an unmet medical need, largely due to the disease's unspecific symptoms in its early stages. In this project, we aimed to identify differentially methylated CpG loci in cervical swabs from patients diagnosed with ovarian cancer and benign pelvic masses.

Material and method

Methylation profiles of 77 cervical swabs were analyzed using the Infinium EPICv2 array. The cohort was divided into training and testing sets to develop a diagnostic signature. Multiple statistical approaches were applied to identify CpG sites distinguishing patients with ovarian cancer from patients with benign ovarian diseases.

Result and discussion

None of the statistical methods identified CpG loci capable of diagnosing ovarian cancer with sufficient specificity and sensitivity. Methylation differences associated with clinical conditions appeared masked by variations in cell composition, the primary source of sample heterogeneity.

Conclusion

Diagnostic strategies should not rely solely on methylation patterns in cervical biology but rather focus on detecting tumor-specific DNA sequences transferred from the ovarian cancer site into cervical swabs.

EACR25-0989

Single-Cell Analysis of Epigenetic Landscapes Highlights Recurrent Chromatin Accessibility Alterations in Colorectal Cancer

A. Livanova¹, L. Azzolin¹, A. Raimondi², F. Ghelardi², L. Castagnoli², S. Pupa², F. Palermo², F. Pietrantonio², A. Sottoriva¹

¹Fondazione Human Technopole, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Introduction

Phenotypic variation among cancer cells is shaped not only by genetic heterogeneity but also by distinct epigenetic patterns. Current studies investigating the co-evolution of the genome and epigenome in colorectal cancer (CRC) are largely limited to analyses of bulk samples. Here, we characterise the epigenetic landscape of CRC and adjacent normal tissues at single-cell resolution.

Material and method

Fresh tissue specimens were collected from treatment-naïve CRC cases ($n = 17$) referred for surgery at Fondazione IRCCS Istituto Nazionale dei Tumori (Milan,

Italy). Samples of normal colon tissue ($n = 4$) were obtained as controls to assess epigenetic rewiring in non-malignant cells adjacent to CRC. Bulk whole-genome sequencing was conducted to characterise the genetic landscape of tumours, while single-nucleus 10x multiome assays were performed to assess chromatin accessibility using ATAC-Seq. In the multiome data, cell types were annotated based on canonical cell markers; tumour cells were identified as clusters exhibiting copy number alterations (CNA). Chromatin accessibility peaks in tumour cells were identified for each cancer sample and subsequently compared against a pooled set of normal epithelial cells. Differentially accessible regions ($|LFC| > 1$, $p_{adj} < 0.01$) were annotated, and recurrent somatic chromatin accessibility alterations (SCAAs) in promoters and enhancers were identified and characterised.

Result and discussion

The most recurrent SCAAs affecting promoters and enhancers of cancer-related genes were observed in over 75% of patients, including the activation of promoters for FOXQ1, TOP1, PTCH1, and PLCG1, as well as the inactivation of promoters for TP53, SMAD3, and TSC2. The recurrence of these SCAAs was significantly higher than that of many genetic driver mutations. An analysis of genome-wide chromatin accessibility in tumour cells at transcription factor (TF) binding sites revealed increased accessibility associated with the TCF7/LEF1 family, homeobox TFs (HOX, FOX, SOX families), and SNAI1/2/3 TFs. Distinct epigenetic profiles were observed among CNA clones within the same tumour, although highly recurrent SCAAs were shared across clones. A comparison of normal epithelial cells adjacent to the tumour core with distal normal epithelial cells revealed a subset of SCAAs in cancer-related genes. Intriguingly, some of SCAAs resembled those observed in the tumour cells. Epigenetic footprints affecting extracellular matrix remodelling and antigen presentation were detected in stromal cells adjacent to tumours, compared to stromal elements within normal colon tissue.

Conclusion

A subset of recurrent SCAAs in most CRC samples represents stable, heritable events. Alterations of chromatin accessibility in normal cells adjacent to tumours suggest a spatially dependent epigenetic shift influenced by the tumour microenvironment.

EACR25-1064

IRF2BP2/TRIM28/DNMT1 suppresses transposable elements to maintain AML survival

J. Xu¹, J. Whittle¹, G. Lacaud¹

¹*Cancer Research UK Manchester Institute, Manchester, United Kingdom*

Introduction

Acute myeloid leukemia (AML) is an aggressive hematologic malignancy with poor survival rates, driven by genetic and epigenetic alterations. A promising therapeutic approach involves targeting dysregulated chromatin factors. In this study, we applied Perturb-seq to a primary AML patient sample to identify key chromatin regulators involved in the blockade of AML differentiation. Our analysis revealed interferon

regulatory factor 2 binding protein 2 (IRF2BP2) as a critical genetic dependency. However, its function in AML remains poorly understood. Here, we demonstrate that IRF2BP2 loss impairs AML cell survival by reactivating transposable elements (TEs), leading to the induction of an endogenous immune response signature.

Material and method

To define the role of IRF2BP2, we performed a CRISPR/Cas9-based knockout system in human AML cell lines both *in vitro* and *in vivo*. Furthermore, we conducted RNA sequencing, ChIP sequencing, Rapid Immunoprecipitation Mass Spectrometry of Endogenous Proteins (RIME), and CRISPR interference, to investigate the molecular mechanism by which IRF2BP2 regulate in AML.

Result and discussion

We identified IRF2BP2 as a critical regulator in AML. Its expression is significantly higher in AML patient samples compared to normal hematopoietic cells, suggesting a potential therapeutic window for targeting IRF2BP2 in AML treatment. Our study demonstrated that IRF2BP2 depletion in human AML cell lines induces apoptosis, impairs cell proliferation, and enhances immune response signatures. *In vivo*, loss of IRF2BP2 significantly prolongs survival and reduces leukemia burden in AML models. Mechanistically, we identified TRIM28 and DNMT1 as key interaction partners of IRF2BP2. Both TRIM28 and DNMT1 are well-established master regulators of TEs expression, whose reactivation can trigger innate immune signaling. Our findings reveal that silencing TEs partially rescues the phenotypic effects of IRF2BP2 loss in AML. Overall, IRF2BP2, in conjunction with TRIM28 and DNMT1, functions to suppress TE expression, thereby preventing excessive immune responses in AML.

Conclusion

We demonstrated that IRF2BP2 as a critical dependency in AML via Perturb-seq. We next validated this finding in multiple human AML cell lines both *in vitro* and *in vivo*. Our mechanistic investigations reveal that IRF2BP2, in interaction with TRIM28 and DNMT1, suppresses TEs expression and prevents excessive immune responses. This work lays the foundation for developing novel therapeutic strategies targeting IRF2BP2 and its interaction partners.

Epigenetic changes on the X chromosome in chronic lymphocytic leukaemia

H. Byun¹, E. Willmore², J. Wallis³, H. Marr³,

S. Marshall⁴, G. Strathdee², B. Skinner¹, T. Barrow¹

¹*University of Essex, Colchester, United Kingdom*

²*Newcastle University, Newcastle upon Tyne, United Kingdom*

³*Freeman Hospital, Newcastle upon Tyne, United Kingdom*

⁴*City Hospitals Sunderland, Sunderland, United Kingdom*

Introduction

Chronic lymphocytic leukaemia (CLL) is the most common adult leukaemia. Epigenetic studies have revealed that the CLL epigenome displays widespread

loss of DNA methylation and is shaped by the cell of origin, proliferative history, and selection for gene-specific traits during progression. However, studies performed to date have routinely excluded the X and Y chromosomes, due to challenges in accounting for gender imbalances and X-inactivation in data analysis. Yet, the X chromosome harbours many genes of key relevance to CLL and immune function, including BTK, CD40LG, and chemokine and interleukin receptors. Here, we examined DNA methylation changes on chrX in CLL at diagnosis and during disease progression.

Material and method

DNA methylation at 11,232 loci on chrX were analysed using the Illumina 450k DNA methylation microarray platform. Epigenetic changes present at diagnosis were identified in 115 CLL patients with Stage A disease (78 male, 47 female) compared to CD19+ B-cells from 14 healthy individuals (8 male, 6 female). DNA methylation pre- and post-treatment was analysed in paired samples from 20 patients (12 male, 8 female). Gene expression was examined in 184 CLL patients (105 male, 79 female) and 32 healthy individuals (20 male, 12 female) using the Affymetrix U133 microarray platform.

Result and discussion

We identified 660 differentially methylated loci mapping to chrX ($\Delta\beta > 0.2$, pFDR < 0.05), of which 308 were CLL-specific and not observed during B-cell maturation. These primarily displayed hypomethylation (86%) and were enriched at loci that are biallelically methylated in healthy females. Sex-specific differential methylation was observed, with 137 loci unique to male patients, 68 unique to females, and 103 shared. Highly methylated loci displayed greater variability between male patients in comparison to low and intermediately methylated loci, but not between female patients. Among the differentially methylated genes were the BCL6 corepressor BCOR, pro-survival signalling CD40LG, the growth factor FGF13, the transcription factor KLF8, polycomb group protein SCML1, toll-like receptor TLR7, and the regulator of Wnt signalling ZIC3; we did not observe differential methylation of BTK. Each of these genes was confirmed to be differentially expressed in CLL. In patients undergoing treatment, we observed only moderate changes in DNA methylation ($\Delta\beta > 0.1$) at 110 loci, which were no longer significant following FDR correction.

Conclusion

Targeted analysis of the X chromosome has identified differential methylation and expression of genes with critical relevance to CLL biology, with changes primarily relating to hypomethylation of highly methylated loci. Further work is required to elucidate their impact upon disease progression and patient outcomes.

EACR25-1176

KDM6A Regulates Sex Specific Immune Responses in Melanoma

J. Tiffen¹, C. Tseng¹, S. Alavi¹, G. Sutton²

¹*Centenary Institute, Sydney, Australia*

²*The University of Sydney, Sydney, Australia*

Introduction

KDM6A is a lysine demethylase with well characterised roles in tumour suppression across multiple cancer types.

Interestingly, this X-linked gene fails to undergo inactivation of the second gene copy in females, potentially contributing to enhanced immunity and the female survival advantage observed in many cancers including melanoma.

Material and method

We interrogated datasets of melanoma patients treated with targeted or immune checkpoint inhibitor immunotherapy to determine how KDM6A expression influences treatment outcomes. Functional studies using CRISPR-Cas9 depletion of KDM6A was performed in human melanoma cell lines, followed by growth assays.

Chromatin Immunoprecipitation (ChIP)-seq and RNAseq was used to identify downstream target genes and pathways regulated by KDM6A. A syngeneic mouse melanoma model looked at the effects of Kdm6a knockout on targeted therapy responses in mice.

Result and discussion

KDM6A is more highly expressed in female melanomas and is associated with increased tumour infiltrating lymphocytes, decreased melanoma cell proliferation and better overall survival, compared to males. Melanomas from male patients who have relapsed on BRAF inhibitor treatment show a striking loss of KDM6A compared to females. CRISPR-Cas9 depletion of KDM6A in human melanoma cell lines caused increased cell proliferation and colony formation in vitro, consistent with a tumour suppressive function. In mice fed a normal chow diet, YUMMER1.7 tumours depleted of Kdm6a grew significantly larger than control tumours and were devoid of CD8+ T cells. In mice fed chow containing the Braf inhibitor PLX4720, control tumour growth was relatively constrained, however this effect was abrogated by the loss of Kdm6a. Mechanistically, KDM6A binds to genes associated with immune recognition, particularly those implicated in Major Histocompatibility Complex (MHC) antigen presentation.

Conclusion

Collectively our results support a tumour suppressive role for KDM6A in melanoma, that is particularly prominent in women compared to men and may influence responses to treatment. Understanding these subtleties may improve outcomes for both sexes.

Introduction

Prostate cancer (PCa) is one of the most prevalent cancers in men worldwide. Its aggressiveness is evaluated using the Gleason score, which assesses histological patterns of differentiation. DNA methylation, a key epigenetic mechanism, involves the addition of a methyl group (-CH₃) to cytosine in CpG dinucleotides, particularly in CpG islands at gene promoters, playing a crucial role in gene expression regulation. In prostate cancer, these epigenetic modifications are recognized as critical contributors to tumor progression and treatment resistance. This study aims to evaluate the global DNA methylation of tumor tissue from Mexican patients with PCa.

Material and method

Formalin-fixed paraffin-embedded tumoral tissue and fresh tumoral tissue biopsies from Mexican patients with PCa were collected from Hospital Civil de Culiacán and Pathology and Nephropathology, Diagnosis and Research Center. The Gleason Score for histopathological analysis was assessed by certified pathologists according to ISUP 2019. The global DNA methylation (5-mC) was determined using a colorimetric by an ELISA kit, where the percentage of methylated DNA was proportional to the optical density (OD) intensity. Statistical analyses were performed using GraphPad Prism version 8.0.1.

Result and discussion

A total of 30 PCa samples were collected. The most frequent Gleason Score was 9 (26.66% [8/30]), followed by Gleason Score 7 (4+3) (23.33% [7/30]). Gleason scores 6 and 8 were observed in equal proportions (20% [6/30] each) while the least frequent was Gleason score 7 (3+4) (10% [3/30]). The results showed that global DNA methylation levels were more than twice as high in PCa samples (5.50%) compared to control samples (2.55%). Additionally, a significant difference in global DNA methylation percentages was observed between Gleason score 7 (4+3) and Gleason score 8 (adjusted p-value = 0.0302).

Conclusion

Mexican prostate cancer patients exhibit higher global DNA methylation levels compared to healthy subjects. Additionally, a potential association between the Gleason Score and Global DNA methylation percentage is suggested.

EACR25-1194

Multi-omics Study Identified Novel Oncogenic Roles of DNA-interacting Circular RNA as MLL1 Regulator for Histone H3K4 Methylation in Pancreatic Ductal Adenocarcinoma

C. Wong^{1,2}, J. Peña-Paladines¹, S. Leung¹, K. To³, Y. Chen^{1,2}

¹The Chinese University of Hong Kong, School of Biomedical Sciences, Shatin, Hong Kong, China

²The Chinese University of Hong Kong, Shenzhen Research Institute, Shenzhen, China

³The Chinese University of Hong Kong, Department of Anatomical and Cellular Pathology, Shatin, Hong Kong, China

Introduction

Circular RNAs (circRNAs) play important gene regulatory roles in pancreatic ductal adenocarcinoma (PDAC). Functioning as microRNA sponges is the first identified role of circRNAs. However, emerging evidence suggests that circRNAs may participate in additional gene regulatory mechanisms. We previously identified the dysregulated circRNAs circFOXK2 promoting PDAC growth and liver metastasis. Our current study aimed to uncover the novel and critical gene regulatory mechanisms of circRNAs in PDAC.

Material and method

CircFOXK2-specific pulldown assay with mass spectrometry analysis, and chromatin isolation by RNA purification (ChIRP) with DNA-sequencing, were performed to identify circFOXK2-interacting chromatin complex. Co-immunoprecipitation, electrophoretic mobility shift assay, and three-dimensional structural modeling were performed to study the role of circFOXK2 on peptidylprolyl isomerase E (PPIE)-mixed lineage leukemia protein-1 (MLL1) interaction. Chromatin immunoprecipitation (ChIP) after circFOXK2 knockdown in PDAC cells was performed to investigate the roles of circFOXK2 on histone H3 lysine 4 (H3K4) methylation.

Result and discussion

Mass spectrometry analysis of the circFOXK2-specific pulldown identified circFOXK2-interacting proteins for epigenetics and chromatin remodeling. Particularly, circFOXK2 interacted with PPIE, which is the inhibitor of H3K4 methyltransferase MLL1. Through circRNA-DNA interaction by complementary base pairing, circFOXK2 recognized downstream targets at different genomic locations. At the target genes, circFOXK2 formed a docking pocket by intramolecular base pairing for the N-terminal RNA-recognition motif of PPIE, disrupting the PPIE-MLL1 interaction. This removed the PPIE inhibitory effects on MLL1 for gene-activating H3K4 methylation. Specifically, circFOXK2 promoted thymosin beta 15b (TMSB15B) and brain enriched myelin associated protein 1 (BCAS1) expressions by enhancing H3K4me3 at the promoter. At the gene body, circFOXK2 facilitated transcription elongation of trio rho guanine nucleotide exchange factor (TRIO) and laminin subunit alpha-4 (LAMA4) by intragenic H3K4me3.

At distal intergenic enhancer, circFOXK2 promoted

H3K4me1 of cytochrome p450 family 26 subfamily a member 1 (CYP26A1) and t-complex 11 (TCP11) for gene activation.

Conclusion

The upregulated circFOXK2 promoted oncogenic gene expression through MLL1-mediated H3K4 methylation in cancer. Our study highlighted the importance of circRNAs in gene regulation and the novel mechanism of circRNA-DNA interaction in epigenetics, which may serve as a novel therapeutic target.

⁶Portuguese Oncology Institute of Porto, Urology Clinic & Department of Urology, Porto, Portugal

⁷Josep Carreras Leukemia Research Institute (IJC), Cancer Epigenetics Group, Barcelona, Spain

Introduction

Epigenetic alterations, particularly DNA methylation changes, are key drivers of tumorigenesis and progression in urological cancers. While prostate cancer (PCa) overdiagnosis highlights the need for better biomarkers, bladder cancer (BICa) relies on invasive procedures for diagnosis and follow-up, and kidney cancer (KCa) remains challenging due to its histological heterogeneity and resistance to conventional therapies. DNA methylation profiling holds promise for biomarker discovery and therapeutic targeting. This study aimed to characterize the DNA methylation landscape of PCa, BICa and KCa, integrating findings with The Cancer Genome Atlas (TCGA) datasets to identify shared and cancer-specific DNA methylation signatures with functional relevance.

Material and method

DNA methylation profiles of 72 fresh-frozen tissues (25 PCa, 5 normal prostate, 14 BICa, 5 normal bladder, 17 KCa, and 6 normal kidney) were analyzed using the HumanMethylation450 BeadChip (Illumina). All samples were classified by an expert uropathologist and staged using the AJCC 8th Edition [1]. Differentially methylated CpG sites were identified and integrated with TCGA datasets [RNAseq and DNA methylation (450k)] to

evaluate their impact on gene expression. Gene ontology (GO) analysis was performed to identify affected biological pathways.

Result and discussion

Distinct methylation landscapes were observed across urological cancers. BICa and KCa exhibited genome-wide hypomethylation, whereas PCa was characterized by predominant promoter hypermethylation. Hypermethylation-associated gene silencing was a common feature in PCa and BICa, particularly affecting genes involved in DNA repair, oxidative stress regulation, epithelial-mesenchymal transition (EMT), and immune evasion. Cancer-specific analyses revealed that PCa hypermethylation predominantly impacted metabolic and detoxification pathways, whereas in BICa, it affected genes regulating cell fate and tissue organization, likely contributing to stem-like phenotypes and EMT dysregulation. These findings highlight both shared and unique epigenetic alterations that may drive cancer-specific pathways.

Conclusion

This study provides new insights into the epigenetic heterogeneity of urological cancers, reinforcing the critical role of DNA methylation in tumor-specific biology. The identification of both shared and cancer-specific methylation patterns underscores their potential as biomarkers for early detection and disease monitoring, and therapeutic targeting. These findings support the development of epigenetic therapies and companion biomarkers tailored to the unique vulnerabilities of urological malignancies, highlighting the relevance of precision oncology approaches in these cancers.

Epigallocatechin-3-gallate as a potential epigenetic regulator of ALDH1 expression in colorectal cancer

N. Mojzesova¹, M. Poturnajova¹, Z. Kozovska¹, S. Tyciakova¹, M. Matuskova¹

¹Cancer Research Institute, Biomedical Research Center of the Slovak Academy of Sciences, Department of molecular oncology, Bratislava, Slovakia

Introduction

Aldehyde dehydrogenase 1 (ALDH1) isoforms have recently been identified as crucial molecular markers in colorectal cancer (CRC). Epigallocatechin gallate (EGCG) has been demonstrated as a potential epigenetic-modulating phytochemical agent in cancer prevention and therapy. In this study, we investigated the effect of EGCG on the regulation of the expression of two ALDH1 isoforms, 1A1 and 1A3, in a time- and concentration-dependent manner.

Material and method

We used cell lines with different levels of ALDH1 expression: HT-29, pts80 and LS180 with high expression of ALDH1A1; and FUR, HCT 116, SW480 and LS180 showing high expression of ALDH1A3. After EGCG treatment, the expression of ALDH1 and genes involved in its epigenetic regulation was quantified using RT-qPCR, and protein levels were assessed by Western blot. We employed analyses to monitor DNA methyltransferase (DNMT) activity and pyrosequencing to

detect promoter methylation. Oxidative stress was measured using the CellROX® Orange Reagent.

Result and discussion

After 48 hours, high EGCG concentrations had no significant effect on ALDH1A1 or ALDH1A3 expression. On the other hand, low (2 and 5 µg/ml) concentrations led to a significant ALDH1A3 expression increase at 6 hours, followed by a rapid decline at 12, 24 and 48 hours. ALDH1A1 expression remained unchanged. We also observed that EGCG modulates the expression of Ten-eleven translocation methylcytosine dioxygenase 1 (TET1) and other genes involved in ALDH1A3 expression regulation. These findings suggest that EGCG modulates ALDH1A3 expression through epigenetic mechanisms and may also influence related signalling pathways.

Conclusion

We demonstrated that EGCG selectively affects ALDH1A3 expression, and we suggest that ALDH1A1 and 1A3 are regulated by distinct molecular and epigenetic mechanisms. EGCG influences not only the epigenetic status of ALDH1A3 but also the signalling pathways modulating its expression. Further analyses are required to elucidate the molecular mechanisms underlying EGCG's effect on ALDH1A3 expression.

Introduction

Cooperation between molecular and epigenetic modifications is crucial for colorectal cancer (CRC) carcinogenesis. The main hallmarks in CRC scenario are RAS/BRAF mutations, mismatch repair deficiency (MMRd), microsatellite instability (MSI), and the CpG methylator phenotype (CIMP). Unlike the well-studied aberrant methylation of MLH1 promoter (pMLH1), the role of CIMP and its interaction between the other molecular signature remain not fully understood.

Material and method

To unravel the relationship among these molecular and epigenetic features, we selected a retrospective cohort of 123 CRCs, subdivided in three groups according to their molecular characteristics: 33 cases MMR proficient (MMRp)/BRAF p.V600E mutated (BRAFmut), 46 cases MMRd/BRAFmut, and 44 cases MMRd/BRAF wild type (BRAFwt). We evaluated for the entire cohort the pMLH1 methylation status using pyrosequencing, correlating these data, for 82 sample, with CIMP results assessed with the EpiTect® MethylLight kit.

Result and discussion

The correlation between pMLH1 methylation and MMR protein loss reflected literature data in BRAF mutant CRC, with higher pMLH1 methylation in MMRd/BRAFmut patients compared to MMRp/BRAFmut. Conversely, BRAFwt CRC exhibited mixed pMLH1 methylation status. Overall, our data demonstrated that not always the pMLH1 methylation reflects the widespread genomic methylation. Indeed, only the MMRd/BRAFmut displayed a significantly homo-geneous CIMP-High phenotype (CIMP-H) profile compared to MMRd/BRAFwt and MMRp/BRAFmut groups ($p < 0.0001$), in which this association was not confirmed. In addition, CIMP analysis identified a subgroup of MMRp/BRAFmut patients who exhibited a CIMP-H phenotype without pMLH1 methylation, indicating the presence of alternative pathways linking CIMP and BRAF mutations. Overall, no direct link was established between BRAF mutations and the CIMP phenotype, indicating other mechanisms may influence methylation in CRC.

Conclusion

Our study highlights the heterogeneity of CRC, showing that pMLH1 hypermethylation, MMR deficiency, BRAF mutations, and CIMP do not fully overlap. This aspect warrants further exploration in larger, multi-institutional studies, to better define the correlations among these features and to be able to better exploit them for the clinical management of patients.

Introduction

Breast cancer (BC) is the most common oncological disease affecting women worldwide, which represents approximately 36% of oncological patients. Despite improvement in the survival rate over the past two decades, its incidence continues to rise every year. Among several factors associated with BC risk, metabolic syndrome is involved both in the onset and progression, affecting incidence, prognosis and treatment

response efficacy. Specifically, women with metabolic syndrome show a higher BC-dependent mortality rate. Recently, the repositioning of anti-diabetic drugs for cancer treatment has been investigated with encouraging outcome on cancer prevention especially upon Glucagon-like Peptide-1 Receptor Agonists (GLP-1RAs). Despite the clinical relevance of GLP-1R targeting, its involvement in BC is still poorly investigated. Here, GLP-1R expression regulation in BC will be addressed.

Material and method

GLP-1R contribution in BC tumorigenesis was analyzed in:

- 1) human BC cell line models: MCF-7, MDA-MB-361, SK-BR-3, MDA-MB-231 representing, respectively, the main four BC subtypes;
- 2) human tissue samples derived from biopsy harvested from infiltrating primary tumor of chemotherapy-naïve patients.

Result and discussion

The Cancer Genome Atlas (TCGA) data sets showed an inverse correlation between GLP-1R expression and BC patient life expectancy, highlighting its prognostic value. Interestingly, immunoblotting analysis showed that GLP-1R protein levels are progressively down-modulated in more aggressive BC subtypes associated to worse prognosis. We investigated whether its progressive down-modulation can be attributed to DNA methylation mechanism. First of all, we analyzed global DNA methylation levels in BC subtypes, revealing an increase of 5-methylcytosine (5mC) in more aggressive BC subtypes. To investigate whether DNA methylation increase occurs at GLP-1R promoter regions, we interrogated the Shiny Methylation Analysis Resource Tool (SMART), revealing a higher methylation level of GLP-1R promoter in BC tissue compared to normal one. Specifically, the most methylated CpG islands were found in GLP-1R promoter region of more aggressive BC subgroups. Indeed, the administration of demethylating drugs to BC cell lines was able to restores GLP-1R transcription even in the most aggressive BC subtypes. Interestingly, GLP-1R restoration by gain of function experiments was able to mitigate higher proliferation, migration and invasiveness of aggressive BC.

Conclusion

These findings show that GLP-1R loss could represent one of the molecular players supporting higher aggressiveness in BC, as consequence of a DNA methylation dependent transcriptional regulation. Since GLP-1R restoration counteracts BC aggressiveness, therapeutic approaches preventing its silencing should be developed in a therapeutic perspective.

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers with poor prognosis and therapeutic outcome. Several epidemiological studies show that chronic metabolic diseases, including obesity and type II diabetes, are associated with an increased risk of PDAC incidence and worse clinical outcome. In these conditions, the prolonged exposure to altered metabolism induces aberrant metabolite fluctuations, possibly affecting epigenetic enzyme reactions and consequently modifying the epigenome, thus supporting cancer development. Here, we investigated the correlation between metabolism and epigenetics contributing to PDAC development upon dysmetabolic condition

Material and method

The link between dysmetabolism and PDAC was investigated in pre-invasive pancreatic tumour in *in vivo* and *in vitro* models:

- 1) LSL-KrasG12D; PDX-1- Cre (KC) mice fed with high-fat diet (HFD);
- 2) human pancreatic ductal epithelial cells bearing Kras mutation (HPDE-K-RasG12V) exposed to a combination of free fatty acids and high glucose, to mimic metabolic alterations

Result and discussion

Metabolomics analyses of pancreatic samples highlighted free fatty acid level alteration, higher S-adenosyl methionine (SAM) level and a ratio between α -ketoglutarate (α -KG) and succinate (SA) lower than one during PDAC tumorigenesis in HFD mice. Interestingly, metabolite level alterations were paralleled by ten-eleven dioxygenase 1 (TET1)/ thymine DNA glycosylase (TDG) DNA demethylation complex dissociation and consequent accumulation of iterative cytosine modifications, including 5-formylcytosine (5fC). These findings were validated in the *in vitro* model, revealing a decreased α -KG/SA balance, TET1/TDG complex dissociation, 5fC accumulation, and increased levels of apurinic/aprimidinic site (AP) sites, pointing out TDG function derangement. In this light, we investigated the role of SA on TDG activity modulation by different biochemical analyses, revealing that SA directly binds TDG at residue Arg275, inducing its hyperactivation. To investigate whether dysmetabolism-dependent AP site accumulation is consequence of impaired Base Excision Repair (BER) process, we evaluated the expression of proteins involved in this pathway, revealing decreased levels of ligase 1 (LIG1) and 3 (LIG3) due to higher

methylation levels of their promoter regions in HPDE-K-RasG12V cells exposed to dysmetabolic conditions

Conclusion

Our results show that metabolic alterations affect the DNA methylation/demethylation machinery as consequence of increased intracellular SA levels, leading to TDG hyperactivation, accumulation of iterative cytosine modifications and AP sites, due to BER machinery impairment. These metabolic-epigenetic alterations might support PDAC tumorigenesis and need specific attention for diagnostic and therapeutic purposes

EACR25-1546

EZH2 inhibition: A Key to Unlocking the Notch-Driven Tumor Suppression in Acute Myeloid Leukemia

E. Pace¹, S. Lazzari¹, G. Munzone¹, I. Sclepanti¹, R. Palermo¹

¹*Department of Molecular Medicine, Rome, Italy*

Introduction

The overexpression of the histone H3K27 methyltransferase has been linked to poor prognosis and drug resistance in Acute Myeloid leukemia (AML) by epigenetically regulating critical gene expression, most of which is unknown. Conversely, Notch pathway activity levels are extremely low in the majority of AML samples, consistent with the accumulation of the H3K27me3 repressive histone mark at the loci of its target genes. Of note, enforced Notch signaling activation induces apoptosis of blasts and cell lines of AML and counteracts leukemia in vivo, suggesting Notch-activating strategies as a viable intervention for this hematological cancer. However, the molecular mechanisms influencing Notch repression in AML and its role in the pathogenesis of this disease remain poorly understood and need further exploration.

Material and method

HL-60, NB4, U937 and ME-1 cells; In vitro pharmacological treatment; Gene silencing; Trypan blue exclusion assays; RT-qPCR; Nuclear/cytosol fractionation; Western blotting.

Result and discussion

We hypothesized that EZH2 exerts part of its oncogenic functions in AML through the repression of the Notch signaling pathway. Confirming our hypothesis, EZH2 pharmacological inactivation and/or gene silencing increased Notch receptors, ligands and its target gene HES1 in HL-60, NB4, U937 and ME-1 cell lines, which represent various AML subtypes. Moreover, EZH2 blockage decreased cell proliferation and increased the expression of the differentiating factor CEBP α across the above-mentioned cell lines. Of note, Notch inhibition partially abrogated the antigrowth effects of EZH2-blockage only in acute pro-myelocytic leukemia cells HL-60 and NB4 cells, suggesting that although the interaction between EZH2 and Notch signaling is transversely conserved in AML, Notch activation might have a subtype-specific anti-leukemic effect. In addition, by exploring EZH2/Notch crosstalk in chemoresistance, we observed that EZH2 inhibition synergized with Cisplatin by enhancing its cytotoxic effect in HL-60 cells.

Conclusion

Overall, our findings reveal that EZH2 mediates epigenetic silencing of Notch signaling in AML and suggest the targeting of the EZH2-Notch axis as a viable therapeutic strategy to overcome chemoresistance and enhance the anti-leukemic efficacy of the treatment with Cisplatin in AML.

Introduction

Colitis-associated cancer (CAC), a subtype of colorectal cancer resulting from chronic inflammation in inflammatory bowel disease (IBD), presents a major challenge in identifying high-risk patients. Current biopsy-based surveillance methods are invasive and often insufficient for distinguishing benign inflammation from dysplasia. Consequently, there is a critical need for non-invasive biomarkers to predict CAC progression.

Material and method

In this study, we performed whole-genome bisulphite sequencing (WGBS) on fresh frozen and formalin-fixed paraffin-embedded colonic tissue samples from UC patients at various stages of the disease to explore DNA methylation changes associated with CAC progression. We identified differentially methylated regions (DMRs) and analysed their functional enrichment. Additionally, we assessed copy number alterations (CNAs) to examine genomic changes linked to CAC.

Result and discussion

Our analysis of 10 pilot colonic tissue samples, including cancers, dysplasia, adjacent tissues, inflamed and healthy tissue, revealed significant differences in global methylation patterns across disease stages. Genome-wide CNAs confirmed specific chromosomal alterations in diseased tissues, with losses of chromosomes 22, 4, and 5 in both cancer and dysplastic samples, and gains on chromosome 20. Global methylation analysis indicated significantly lower CpG methylation levels in inflamed and cancer tissues compared to controls, with cancer tissues displaying pronounced CpG hypomethylation. We identified inflammation-associated and cancer-specific DMRs, with cancer samples exhibiting promoter hypermethylation. Importantly, we found differential methylation of approximately 1,000 genes in cancer tissues, including promoters of 25 known driver genes. Promoters hypermethylated specifically in the cancer group were

enriched in pathways related to transcriptional regulation, morphogenesis, and cellular differentiation, underscoring their role in tumorigenesis. Genes involved in DNA binding, transcription factor activity, and chromatin organization were particularly affected, suggesting widespread epigenetic silencing of key regulatory networks.

Conclusion

This study on a pilot set of samples offers critical insights into the epigenetic alterations linked to CAC development and progression. By identifying specific DMRs, we highlight potential targets for early detection. The validation of these findings in a larger cohort, including non-invasive samples like stool and blood, promises to advance effective strategies for CAC surveillance and management, ultimately improving outcomes for patients with IBD.

EACR25-1728

Epigenome-Wide Knockout Screens Reveal Epigenetic Modifiers of Doxorubicin Resistance in Triple-Negative Breast Cancer

E. Güvençer¹, Ö. Yedier-Bayram¹, A. Aksu¹, T. Bağci-Önder¹, T. Önder¹

¹Koç University, Cellular and Molecular Medicine, Istanbul, Turkey

Introduction

Breast cancer is the most frequently diagnosed cancer among women, with triple-negative breast cancer (TNBC) comprising approximately 15% of all cases. It is an aggressive form of breast cancer which is characterized by the absence of estrogen, progesterone, and HER2 receptor expressions. The current treatment for TNBC includes surgical removal of tumor, radiation and conventional chemotherapy which commonly utilizes anthracyclines such as doxorubicin. However, TNBC has a high heterogeneous and aggressive nature which results in development of resistance to chemotherapy and disease relapse. This resistance may emerge from the interplay between genetic and epigenetic mechanisms.

Material and method

This study aimed to investigate the roles of epigenetic modifiers in formation and maintenance of chemo-resistance in TNBC. Epigenetic Knock-Out Library (EPIKOL), a CRISPR-Cas9 based library, is designed to target all chromatin readers, writers, erasers, and associated proteins. This library investigates the function of 779 genes, each targeted by 10 sgRNAs, alongside multiple controls and 35 essential genes to monitor depletion effects.

Result and discussion

To study chemoresistance, doxorubicin-resistant TNBC models were developed by progressively exposing SUM159PT cell line to escalating concentrations of doxorubicin. EPIKOL screens on these resistant models identified SWI/SNF complex members as critical mediators of chemoresistance. RNA sequencing of naïve and chemo-resistant cells revealed key mechanisms implicated in acquired chemoresistance. Our current efforts are directed towards validating the effects of

candidate genes and transcriptome analysis through functional assays.

Conclusion

In conclusion, this study reveals previously unrecognized roles for epigenetic regulators, particularly members of the SWI/SNF complex, in the regulation of chemotherapy resistance, offering a potential foundation for the development of combination therapies targeting these pathways.

EACR25-1754

Multiomics assessment of lung adenocarcinoma subtypes defined through tumor purity-adjusted DNA methylation

D. Nacer¹, E. Arbabian², S. Veerla¹, M. Aine², M. Jönsson², F. Rosengren², A. Karlsson¹, M. Planck², J. Staaf²

¹Lund University, Division of Translational Cancer Research, Department of Laboratory Medicine, Lund, Sweden

²Lund University, Division of Oncology, Department of Clinical Sciences Lund, Lund, Sweden

Introduction

Molecular subtypes of lung adenocarcinoma (LUAD), the most common histological subtype of lung cancer, have been proposed based on one or two-dimensional studies, but none are yet implemented in clinical routine. In this study, we set out to refine LUAD subtyping using a multi-omic approach based primarily on the epigenetic landscape of LUAD from a tumor intrinsic perspective. Epigenetic modifications in cancer cells are independent of sequence variants, directly linked to gene and genome regulation, and provide important information to guide subclassification efforts.

Material and method

DNA methylation profiling (Illumina EPIC v1 beadchips or Illumina Infinium HumanMethylation450 BeadChip array) was performed or obtained from previous studies, on a total of 95 primary LUAD samples from our Swedish cohort. DNA methylation data were adjusted for tumor cell content. Unsupervised clustering using non-negative matrix factorization and accounting for genomic context was used to divide the cohort into epigenetic subgroups/entities. The obtained clusters were then contrasted based on clinicopathological, genomic, transcriptomic, proteomic, and metabolomic data. Findings were validated on LUAD samples from The Cancer Genome Atlas initiative and on a previously published cohort of LUAD cell lines.

Result and discussion

Of the four methylation clusters, two were associated with previously proposed mRNA/protein subtypes, showing similar characteristics to what has been published. As an example, one of the clusters was enriched for older patients, non-smokers, lower tumor cell proliferation, and variants in the EGFR gene. The remaining two clusters, M2 and M3, were a combination of other proposed subtypes. Despite showing a similar mRNA/protein subtype composition to each other, clusters M2 and M3 differed through e.g., higher expression in M3 of a napsin A/surfactant metabolism

metagene, a marker of the LUAD histology. Genes included in this metagene showed lower DNA methylation in M3, despite an aggregate promoter hypermethylation phenotype seen in this cluster. Importantly, M2 and M3 cell lines recapitulated the metagene expression patterns seen in samples from those clusters.

Conclusion

Dissecting LUAD based on combined biological characteristics from multi-omics data results in a deeper understanding of the heterogeneity in this complex disease and can lead to treatment options guided by molecular subtypes as is the case in e.g., breast cancer.

EACR25-1838

Arid1a directs lineage specification in mammary epithelial cells

E. Deby¹, W. Karthaus¹, E. Toska²

¹*EPFL, Lausanne, Switzerland*

²*John Hopkins School of Medicine, Baltimore, United States*

Introduction

Epigenetic regulation is critical to many developmental processes, including mammary gland differentiation. However, the precise epigenetic regulators governing mammary cell fate remain poorly understood. Mutations in the chromatin regulator ARID1A are associated with metastatic disease, therapy resistance, and the maintenance of luminal cell identity in breast cancer.

Material and method

We investigated the impact of Arid1a loss on morphogenesis *in vivo*. Epithelial lineage dynamics were further characterized in organoid-based functional studies. Multiomic single-cell RNA and chromatin accessibility profiling were performed to identify lineage-specific regulators of the Arid1a deficient state. Furthermore, the transcription factors of interest were validated by CRISPR/CAS9-mediated loss-of-function screening.

Result and discussion

Arid1a knockout disrupts key developmental structures such as ductal branching and terminal end buds in mice. Breast organoids derived from these mice exhibit cystic morphology, impaired differentiation, and atypical granularity. Multiomic single-cell RNA and chromatin accessibility profiling further revealed that Arid1a maintains basal, luminal progenitor, and alveolar cell states. Depletion of Arid1a restricts cells to undifferentiated luminal hormonal state diminishes estrogen receptor responsiveness and decreases chromatin accessibility and SWI/SNF targeting at key lineage-defining transcription factors (TF). CRISPR/CAS9-mediated loss-of-function screening identifies Foxa1 and Meis1 as key TFs, whose deletion recapitulates the Arid1a-deficient phenotype. These findings uncover a specific epigenetic mechanism that governs cell-fate specification in the mammary epithelium.

Conclusion

Our work highlights Arid1a and lineage-specific TFs as essential factors for mammary epithelial cell fate specification with important implications for both normal development and breast cancer.

EACR25-1867

LACTB Promotes SHMT2 Degradation, Modulating Glycine Metabolism and DNA Methylation Patterns in Breast Cancer Cells

G. Rodriguez Gomez¹, Z. Kečkéšová¹

¹*Institute of Organic Chemistry and Biochemistry of the CAS, Prague, Czech Republic*

Introduction

β -lactamase-like protein (LACTB) is a recently identified mitochondrial tumor suppressor with broad activity across various tissues. It has been shown to downregulate key pro-survival pathways, including Akt and Wnt/ β -catenin, and to induce cell cycle arrest, apoptosis, differentiation, autophagy, and suppression of epithelial-mesenchymal transition. However, the upstream regulatory mechanisms governing these LACTB-induced effects remain largely unknown.

Material and method

In this study, using proximity biotinylation *in vivo* screening we found that LACTB can interact with another several mitochondrial proteins. Through co-immunoprecipitation and proximity ligation assays we confirm that some of these proteins interact with LACTB in several luminal like and basal like breast cancer cell lines.

Result and discussion

One of the LACTB-interacting proteins found is the serine hydroxymethyl transferase 2 (SHMT2), which catalyzes the conversion of serine to glycine. We found that LACTB can induce a decrease in the expression of SHMT2 protein but not at transcriptional level. Previously, it has been shown that LACTB contain a catalytic domain, so these results suggest that LACTB promotes the degradation of SHMT2 through their interaction. Additionally, we found that the LACTB-induced decrease of SHMT2 promotes a decrease in the levels of intracellular glycine. During the conversion of serine to glycine, SHMT2 generates a byproduct called 5,10 methylenetetrahydrofolate (5,10-MTHF). This byproduct is a methyl donor that can fuel the production of activated methyl groups (S-adenyl methionines), which are essential in the regulation of epigenetic mechanisms, such as DNA methylation. In this way, we found that the decrease in SHMT2 induced by the over-expression of LACTB is able to decrease the global DNA methylation.

Conclusion

Our findings uncover a novel regulatory mechanism in which LACTB modulates SHMT2 protein levels, thereby influencing glycine metabolism and DNA methylation patterns in breast cancer cells. This study provides new insights into the mitochondrial control of tumor suppression and epigenetic regulation.

EACR25-1900

Targeting CBX2 disrupts DNA damage repair and mitosis regulation in glioblastoma – a novel therapeutic opportunity

D. Marsh¹, J. Greenman¹, M. Wade¹

¹*University of Hull, Centre for Biomedicine, Hull, United Kingdom*

Introduction

Glioblastoma (GBM) is the most common and aggressive form of brain tumour. The average length of survival for GBM patients remains low at only 12–18 months following initial diagnosis, partly due to a lack of targeted therapeutics. Identification and validation of novel therapeutic targets is crucial. Chromobox 2 (CBX2), a component of polycomb repressive complex 1 (PRC1), regulates gene expression by altering chromatin accessibility. CBX2 expression is elevated in numerous aggressive cancer types, including GBM. CBX2 has an oncogenic role in other cancers associated with poor prognoses, however, its role in GBM remains largely unexplored. This study aims to determine the functional mechanisms by which CBX2 may promote GBM; thereby determining its potential as a novel therapeutic target.

Material and method

This study uses patient-derived cells (PDCs) and employs a translationally relevant microfluidic perfusion device (“chip”) to maintain micro-dissected GBM patient tissue in a viable state, directly from surgical resection. PDCs and ex vivo maintained GBM tissue were treated with SW2_152F, a selective CBX2 inhibitor. The phenotypic effects of CBX2 inhibition in PDCs were assessed by 5'-bromo-2'-deoxyuridine (BrdU) proliferation assays, flow cytometry, and fluorescence microscopy. Genes and biological pathways differentially regulated following CBX2 inhibition were assessed by RNA-sequencing and Gene Set Enrichment Analysis (GSEA). The molecular and phenotypic effects of CBX2 inhibition in GBM tissue were evaluated by RT-qPCR and immunohistochemical analyses.

Result and discussion

CBX2 inhibition in PDCs caused significant down-regulation of gene signatures associated with G2/M checkpoint signalling, DNA damage repair pathways, and mitosis regulation; concomitant with observations of reduced cellular proliferation, increased double-stranded DNA breaks, and ultimately cell death. Targeting CBX2 induced significant downregulation of the oncogenic transcription factor forkhead box protein M1 (FOXM1) and its target gene polo-like kinase 1 (PLK1). Analysis of patient datasets shows that the expression of both FOXM1 and PLK1 are positively correlated with CBX2 expression in GBM tissue. FOXM1 and PLK1 form a functional axis in regulating mitotic progression and DNA damage repair; overexpression of FOXM1 is linked to tumour growth and chemoresistance in GBM.

Conclusion

We propose that CBX2 inhibition disrupts the FOXM1–PLK1 axis, exploiting the vulnerabilities of GBM by impairing DNA damage repair and checkpoint control, leading to severe mitotic stress and subsequent cell death. Targeting CBX2 may sensitise GBMs to current standard-of-care therapies, offering a promising avenue for novel synergistic treatments.

EACR25-1905

hsa-miR-200c-3p, hsa-miR-25-3p and hsa-miR-301a-3p as potential biomarkers and therapeutic targets for restoration of PTEN expression in clear cell renal cell carcinoma

Á. Alves¹, M. Ferreira¹, M. Eiras², L. Lima²,

R. Medeiros¹, A. Teixeira¹, F. Dias¹

¹*Research Center of Portuguese Oncology Institute of Porto, Molecular Oncology and Viral Pathology Group, Porto, Portugal*

²*Research Center of Portuguese Oncology Institute of Porto, Experimental Pathology and Therapeutics Group, Porto, Portugal*

Introduction

Clear cell renal cell carcinoma (ccRCC) is an aggressive subtype of renal cancer, with 30% of patients who undergo curative surgery experiencing recurrence within five years. Its highly hypoxic tumor microenvironment confers resistance to chemo- and radiotherapy and, although targeted therapies have improved patient survival, resistance remains a common challenge. Thus, there is an urgent need for accurate biomarkers and novel treatments to improve patient management. In recent years, extracellular vesicles (EVs) have emerged as promising diagnostic and therapeutic tools due to their ability to transport microRNAs (miRNAs) that regulate gene expression and tumor progression. A previous study by our group identified an EV-derived miRNA profile (hsa-miR-200c-3p, hsa-miR-25-3p and hsa-miR-301a-3p) as a post-transcriptional silencing mechanism that promotes ccRCC progression by inhibiting phosphatase and tensin homolog (PTEN). Thus, this study aimed to evaluate these miRNAs' biomarker and therapeutic potential in 2D and 3D ccRCC models.

Material and method

EVs from four renal cell lines (HKC-8, 786-O, Caki-2, and Caki-1) were isolated and characterized for size and concentration by nanoparticle tracking analysis, morphology by transmission electron microscopy, and membrane marker presence by ELISA. The selected miRNA profile and PTEN mRNA was quantified by RT-qPCR in cells and EVs derived from renal cell lines in 2D and 3D models. Then, 786-O cells were transfected with miRNA inhibitors using lipofectamine in both cell culture models. Its effect was evaluated by analyzing miRNA and PTEN expression, through RT-qPCR and western blotting, alongside phenotypic changes, including alterations in proliferative and migratory capacity in 2D culture, assessed by WST-1 and wound healing assay, as well as metabolic capacity and spheroid morphology in 3D models.

Result and discussion

The intracellular expression of hsa-miR-25-3p, hsa-miR-200c-3p and hsa-miR-301a-3p was higher in ccRCC cells compared to HKC-8 cells. All miRNAs were excreted in EVs derived from all cells and their expression, intracellularly and in EVs, increased with the aggressiveness of ccRCC cells, while intracellular PTEN mRNA expression decreased. The combined administration of inhibitors targeting these miRNAs significantly increased PTEN expression, leading to reduced proliferation and

migration of ccRCC cells in 2D models, as well as a decrease in spheroid size and metabolic capacity in 3D models.

Conclusion

This study highlights the oncogenic role of these miRNAs and their potential not only as biomarkers for monitoring disease aggressiveness but also as promising therapeutic targets in ccRCC. The combined inhibition of these miRNAs demonstrated the potential to reduce the pro-tumor phenotype, paving the way for a more personalized therapeutic approach for ccRCC patients.

Integrated analysis of longitudinal cell-free DNA and matched tumor profiling data to identify novel breast cancer biomarkers

D. Karabayev^{1,2,3}, R. Rodosthenous¹, iCAN³, A. Ganna^{1,3,4}, E. Pitkänen^{1,2,3}

¹*Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland*

²*Research Programs Unit, Applied Tumor Genomics, Faculty of Medicine, University of Helsinki, Helsinki, Finland*

³*iCAN Digital Precision Cancer Medicine Flagship, Helsinki, Finland*

⁴*Massachusetts General Hospital, Broad Institute of MIT and Harvard, Cambridge, MA, United States*

Introduction

Breast cancer is the most common malignancy and leading cause of cancer-related death in women, accounting for 15.4% of all female cancers. Despite advancements in diagnosis, standard methods such as imaging, tissue biopsy, and blood tests remain invasive, costly, and variable in accuracy. Most cases are diagnosed at an advanced stage, limiting treatment options and reducing survival rates. Cell-free DNA (cfDNA), fragmented DNA released into the bloodstream by normal and tumor cells, has emerged as a promising non-invasive biomarker for early cancer detection. Several initiatives have adopted targeted multi-cancer methylation-based approaches due to their relative simplicity and high performance. However, breast cancer remains particularly challenging to detect, underscoring the need for improved liquid biopsy biomarkers. This study aims to improve the early detection of breast cancer by leveraging cfDNA methylation profiling and matched tumor profiling data to identify more sensitive and specific genomic and epigenetic biomarkers.

Material and method

We analyzed longitudinal plasma samples collected by the Helsinki Biobank, matched to tumor samples available in the iCAN Digital Precision Cancer Medicine Flagship, a large-scale Finnish biobank study integrating deep tumor profiling with longitudinal health data. The cohort included plasma cfDNA from 26 breast cancer patients at stages III and IV, with samples collected both pre-diagnosis (mean 21 months, range 6–47 months before diagnosis) and post-diagnosis (<2 months after diagnosis), totaling 52 samples. Whole-genome enzy-

matic methyl sequencing (EM-seq) was performed, followed by analysis using DRAGEN and Bismark to obtain DNA methylation profiles and genomic variants. Tumor profiling data, including RNA sequencing (RNA-seq) and whole-exome sequencing (WES), is available on the iCAN Discovery Platform, enabling integrative analysis of epigenetic and genomic alterations.

Result and discussion

cfDNA was extracted with a mean yield of 10.9 ng (range: 2.0–64.4 ng). Whole-genome enzymatic methyl sequencing (EM-seq) yielded an average of 88 GB of sequencing data per sample, with a median coverage depth of 6.5× and a 95% alignment rate. Differential methylation analysis is planned to distinguish breast cancer subtypes and identify informative CpG sites for early detection. Copy number profiling and somatic variant analysis will assess genome-wide alterations and determine concordance between cfDNA-derived CNAs and tumor WES data. We will analyze cfDNA fragmentomic landscapes to explore its potential as predictive biomarkers for breast cancer detection and profiling.

Conclusion

The integration of cfDNA methylation, fragmentation, and genomic data holds promise for advancing biomarker discovery, enabling earlier cancer detection and more precise therapeutic strategies.

EACR25-2049

Hypermethylation of extracellular matrix genes in colorectal adenocarcinoma

D. Müller¹, B. Győrffy¹

¹*Semmelweis University, Budapest, Hungary*

Introduction

Abnormal methylation is a long-recognized feature of colorectal adenocarcinoma tissues. Examination of methylation patterns across the genome in large patient populations aids the identification of novel biomarkers for diagnosis, prognosis, and potentially new therapeutic targets. Through the modulation of proliferative signals and the facilitation of invasivity, extracellular matrix (ECM) proteins play a multifaceted role in tumor progression. This study investigates DNA methylation alterations in extracellular matrix (ECM)-related genes using a large-scale, genome-wide DNA methylation dataset.

Material and method

We analyzed genome-wide methylation data from 2,356 tumor and normal samples (19 GEO series and GDC-TCGA), processed using minfi and watermelon in R. Differentially methylated CpG islands (CGIs) were identified via Kruskal-Wallis test and ROC analysis (AUC > 0.91). Hierarchical clustering of CGI methylation was performed, and correlations with gene expression (TCGA-COAD RNA-seq) were evaluated. For data visualization, we used epigenplot.com, a web platform established based on our database.

Result and discussion

Among 20 ECM genes with hypermethylated promoter CGIs (AUC > 0.91), 19 exhibited tumor-specific hypermethylation ($\Delta\beta \geq 0.2$, $p < 0.001$). The most discriminatory CGIs localized to ITGA4 (chr2: 182321761–182323029; $\Delta\beta = 0.37$, AUC = 0.97) and

COL25A1 (chr4: 110222970-110224257; $\Delta\beta = 0.31$, AUC = 0.97), both showing strong inverse correlations with gene expression (ITGA4: R = -0.33, p < 0.001; COL25A1: R = -0.19, p < 0.001). Hierarchical clustering of HM450K data revealed two distinct clusters: 90% normal (cluster 1) and 98% tumor (cluster 2). EPIC platform clustering showed partial overlap (74% normal vs. 79% tumor clusters). The robust separation of tumor/normal samples by ECM CGI methylation underscores its diagnostic potential. The weaker clustering fidelity in EPIC data highlights technical variability between platforms or intrinsic tumor diversity. ITGA4, an integrin critical for cell-ECM adhesion, and COL25A1, a collagen linked to neuronal pathfinding, are epigenetically silenced in tumors, suggesting their dysregulation may promote microenvironment alterations. Notably, the high AUC (>0.91) of top CGIs positions them as candidate biomarkers, though their clinical utility requires validation in independent cohorts. The inverse methylation-expression correlation supports methylation-driven silencing.

Conclusion

Analysis of extracellular matrix (ECM) gene methylation in large colorectal adenocarcinoma cohorts identifies epigenetic drivers of tumor microenvironment remodeling and promising biomarkers.

EACR25-2096

Integrative Multi-Omic Analysis Reveals a Pax8-Driven Gene Network Linking Tumor Stemness to Therapy Response in Ovarian Cancer

J. Santos-Pereira¹, A. Carnero², S. Muñoz-Galván²

¹Instituto de Biomedicina de Sevilla, IBIS, Hospital Universitario Virgen del Rocío, Universidad de Sevilla, Consejo Superior de Investigaciones Científicas, Avda. Manuel Siurot s/n 41013, Seville, Spain, Departamento de Biología Celular, Facultad de Biología, Universidad de Sevilla, 41012 Sevilla, Spain., Spain

²Instituto de Biomedicina de Sevilla, IBIS, Hospital Universitario Virgen del Rocío, Universidad de Sevilla, Consejo Superior de Investigaciones Científicas, Avda. Manuel Siurot s/n 41013, Seville, Spain, CIBERONC, Instituto de Salud Carlos III, Madrid, Spain, Spain

Introduction

Pax8 is a transcription factor essential for the development of the Fallopian tube epithelium and is aberrantly expressed in most ovarian cancers, where it plays a key role in tumorigenesis. It regulates gene networks associated with cell proliferation, survival, and stemness, contributing to therapy resistance and disease progression. Understanding the Pax8-driven regulatory network in ovarian cancer is crucial for identifying potential therapeutic targets and improving patient outcomes.

Material and method

We use public Pax8 chromatin binding data (ChIP-seq, CUT&Tag, CUT&RUN), ATAC-seq and RNA-seq in control and Pax8 knock-out high-grade serous ovarian cancer cells, as well as transcriptomic databases and survival data of ovarian cancer patients, and ovarian cancer cell lines

Result and discussion

We integrated Pax8 chromatin binding, chromatin accessibility, transcriptomic, and patient data to define the core regulatory network driven by Pax8 in ovarian tumors. Despite heterogeneity in Pax8 binding sites across cell lines, we identified a common set of regulated genes. By combining chromatin accessibility, transcription factor footprints, and gene expression changes following Pax8 knockout, we reconstructed a transcriptional network explaining Pax8-regulated genes. Analysis of patient expression data revealed a Pax8-associated gene signature linked to tumor stemness, a key factor in therapy resistance. Notably, this signature predicts disease outcomes and therapy responses in ovarian cancer patients. Finally, we validated experimentally our results from bioinformatic analyses, thus reassuring their robustness.

Conclusion

Our study identifies a Pax8-driven regulatory network that underlies tumor stemness and therapy resistance, highlighting potential targets for precision therapies in ovarian cancer.

EACR25-2159

SUV39H1 regulates cell adhesion of pediatric high-grade gliomas through modulation of β -catenin

A. Klonou¹, A. Giannopoulou¹, C. Adamopoulos¹, D. Kanakoglou², A. Pampalou², P. Sarantis¹, S. Sgouros^{3,4}, P. Korkolopoulou², A. Papavassiliou¹, C. Piperi¹

³Medical School, National and Kapodistrian University of Athens, Department of Neurosurgery, Athens, Greece

⁴IASO Children's Hospital, Department of Pediatric Neurosurgery, Athens, Greece

Introduction

Pediatric high-grade gliomas (pHGGs) are heterogeneous, diffuse, and infiltrative tumors with dismal prognosis. Aberrant post-translational histone modifications with elevated histone 3 lysine trimethylation (H3K9) have been recently implicated in pHGGs pathology. Herein, we investigate the biological role of SUV39H1 methyltransferase in cell proliferation, motility, and gene regulation in pHGG.

Material and method

SUV39H1 mRNA levels were first determined in a public database of pediatric gliomas and protein levels were investigated in a cohort of 24 pHGG, by immunohistochemistry and western immunoblotting. Gene silencing of SUV39H1 was further performed in pHGG cell lines to investigate their functional role in cell proliferation, cell migration and EMT markers.

Result and discussion

SUV39H1 was found enriched in pHGG compared to normal brain and KEGG pathway analysis showed positive correlation with cell adhesion molecules. SUV39H1 protein expression was significantly increased

in pHGG tissues compared to normal brain ($P < 0.001$). Gene silencing of SUV39H1 in pHGG cell lines showed a significant reduction in cell viability ($p < 0.05$) and reduced cell migration ($P < 0.05$) followed by reduced expression of vimentin and β -catenin. Furthermore, SUV39H1 silencing reduced epithelial-mesenchymal transition (EMT) marker genes CDH2, SNAI1 and MARCKS levels.

Conclusion

Our findings demonstrate that increased expression of SUV39H1 in pHGG is involved in regulation of cell adhesion and contributes to epithelial-mesenchymal transition.

EACR25-2204

Functional impact of histone methyltransferase KMT2B in pediatric astrocytomas

A. Giannopoulou¹, A. Klonou¹, P. Korkolopoulou², A. Pambalou², D. Kanakoglou², A. Mitsios³, S. Sgouros³, A. Papavassiliou¹, C. Piperi¹, C. Troungos¹

¹Medical School, National and Kapodistrian University of Athens, Department of Biological Chemistry, Athens, Greece

²Medical School, National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece

³IASO Children's Hospital, National and Kapodistrian University of Athens, Department of Pediatric Neurosurgery, Athens, Greece

Introduction

Histone modifications coordinate gene expression by regulating transcription factor binding. Although the role of the epigenome is clear in a variety of cancers, in pediatric astrocytomas still remains ambiguous. The Mixed Lineage Leukemia 2 (MLL2/KMT2B) protein, responsible for H3K4 trimethylation (H3K4me3), was shown to mediate pro-oncogenic effects in several cancers. Here, we aimed to investigate the functional role of histone KMT2B and KMT2B-regulated signaling pathways in pediatric gliomas.

Material and method

We first performed in silico analysis of a publicly available microarray dataset of 49 pediatric astrocytoma samples using the R2: Genomic Analysis. Then, we evaluated the mRNA and protein expression levels of KMT2B by qRT-PCR, immunohistochemistry, and Western immunoblotting in 38 archival pediatric astrocytoma tissues (Grade 2-4) and normal brain samples. We proceeded to evaluate the functional role of KMT2B silencing (using siRNA) in pediatric glioblastoma cell lines (SJGBM2, CHLA-200) proliferation by XTT, as well as in cell migration by scratch assay.

Result and discussion

In silico analysis revealed that pediatric astrocytomas exhibit significantly increased KMT2B expression levels compared to normal brain tissues, which was further confirmed by qRT-PCR, and Western immunoblotting in tissue samples. Immunohistochemical analysis showed significantly lower KMT2B immunoreactivity in pilocytic astrocytomas compared to grade 3-4 diffusely infiltrating tumors. Accordingly, H3K4me3 protein levels were detected significantly lower in normal brain

compared to astrocytomas grade 1 and grade 2-4. The univariate survival analysis of the entire cohort showed correlation of reduced patient's survival with increased KMT2B expression, indicating a significant clinical impact. To this end, silencing of KMT2B in pediatric astrocytoma cell lines showed a significant reduction in cell proliferation and p53 expression, as well as in cell migration and at mesenchymal marker vimentin levels. Moreover, exposure of these pediatric cell lines to MM-102, a potent inhibitor of the WDR5/MLL interaction, led to a reduction in cell proliferation and migration.

Conclusion

Taken together, our data show a potential oncogenic role of KMT2B in pediatric astrocytomas, correlating to tumor progression and inferior patients' survival that needs further investigation.

EACR25-2261

Methylation-driven epigenetic regulation of the MIR141 core promoter in bladder cancer short-term progression

K. Pilala¹, A. Papadimitriou¹, M. Papadimitriou¹, G. Giagkos², P. Levis², K. Stravodimos², A. Scorilas¹, M. Avgeris^{1,3}

¹Department of Biochemistry and Molecular Biology, Faculty of Biology, National and Kapodistrian University of Athens, Athens, Greece

²First Department of Urology, "Laiko" General Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

³Laboratory of Clinical Biochemistry-Molecular Diagnostics, Second Department of Pediatrics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Introduction

Owing to its markedly heterogenous molecular landscape, bladder cancer (BlCa) is still characterized by non-personalized prognosis and treatment decisions necessitating lifelong post-treatment surveillance. Alterations of DNA methylation are considered to be among the earliest events of bladder carcinogenesis, serving as significant predictors of patient survival and treatment response. Herein, we investigated the methylation profiling and clinical values of MIR141 core promoter in BlCa.

Material and method

DNA and RNA were extracted from 135 bladder tissues. miRNA-seq was conducted in 10 non-muscle invasive (NMIBC; Ta Low Grade: n = 5; T1 High Grade [HG]: n = 5) and 10 muscle invasive (MIBC; T2: n = 5; T3-T4: n = 5) bladder tumors, identifying miR-141-3p as one of the most downregulated miRNAs. Next, in silico analysis was performed to confirm its epigenetic regulation. Genomic DNA underwent bisulfite conversion, followed by PCR amplification of MIR141 core promoter and methylation levels were quantified by pyrosequencing. miR-141 levels were measured by RT-qPCR, following 3'-end polyadenylation of total RNA. Disease progression and patients' death were used as clinical endpoint events. TCGA-BLCA (n = 412) was used as institutionally independent validation cohort for MIR141 gene methylation and transcription.

Result and discussion

miRNA-seq highlighted the loss of miR-141-3p in muscle-invasive tumors (T2-T4), while correlation analysis in TCGA-BLCA (rs: -0.748, p < 0.001) and screening (rs: -0.395, p < 0.001) cohorts unveiled MIR141 core promoter methylation as key regulatory region on miR-141 modulation. In line with miR-141 loss, elevated methylation of MIR141 promoter was associated with aggressive phenotype (muscle-invasive, advanced stages and HG tumors; p < 0.001). Notably, MIR141 promoter hypermethylation was linked to higher risk for short-term progression of superficial (TaT1) to muscle-invasive tumors (p < 0.001), resulting in risk-stratification of the clinically relevant T1HG patient subgroup for post-treatment progression to MIBC (p = 0.035). Multivariate models highlighted MIR141 promoter methylation as an independent marker for short-term progression (HR = 5.828, p = 0.002) compared to established disease markers, displaying superior clinical benefit of MIR141-fitted models in BlCa prognostication.

Conclusion

MIR141 core promoter methylation controls miR-141 levels in bladder tumors and emerged as a robust modern molecular marker to address clinical heterogeneity of disease prognosis, enhance risk stratification beyond conventional clinical markers and support personalized treatment/monitoring decisions for BlCa patients.

EACR25-2323

Exploiting the tumor-suppressive role of the transcriptional repressor SAMD1 in pancreatic ductal adenocarcinoma

L. Jeude¹, R. Liefke^{1,2}, C. Neuhaus¹

¹Philipps University of Marburg, Institute of Molecular Biology and Tumor Research (IMT), Marburg, Germany

²University Hospital Giessen and Marburg, Department of Hematology, Oncology, and Immunology, Marburg, Germany

Introduction

Despite extensive research efforts to better understand pancreatic ductal adenocarcinoma (PDAC) and improve therapeutic outcomes, it remains one of the deadliest cancers with limited treatment options. PDAC is particularly challenging to treat due to its early metastasis, pro-tumorigenic microenvironment, and late diagnosis. Epigenetic mechanisms are important for advancing PDAC therapies, but their impact in complex models like 3D cultures and the tumor microenvironment remains less understood. One class of epigenetic mechanisms is the repression by chromatin regulatory proteins. SAMD1 is a transcriptional repressor that binds to unmethylated CpG islands and interacts with histone demethylase KDM1A and the Polycomb-associated proteins L3MBTL3 and SFMBT1. SAMD1 plays a role in various biological pathways and its loss is embryonically lethal in mice. While high SAMD1 levels are associated with poor survival in some cancers, in PDAC and other cancers, high SAMD1 levels are linked to better survival. PDAC cells lacking SAMD1 show

increased expression of genes related to EMT and inflammation, adopting a more mesenchymal phenotype with accelerated migration rates, partly driven by the SAMD1 target gene CDH2.

Material and method

CRISPR-Cas9 was used to generate SAMD1 KO in PDAC cell lines. PDAC 3D cell cultures were established using ultralow attachment plates and analyzed through microscopy, RNA sequencing, and ChIP. Proximity Extension Assay (PEA) was performed on the supernatants of both 2D and 3D cultures, while extra-cellular vesicles (EVs) from 2D cultures were analyzed by mass spectrometry. Bystander cells were treated with conditioned medium (CM) from PDAC cells, and their gene expression was subsequently analyzed.

Result and discussion

We found that the loss of SAMD1 in PDAC 3D cultures results in a smaller and denser structure, partially mediated by the derepression of CDH2. In addition to the upregulation of EMT marker genes, several genes potentially involved in influencing the tumor microenvironment (TME) were differentially expressed in SAMD1 KO PDAC 3D cultures. Proximity Extension Assay (PEA) of the secretome from both 2D and 3D cultures, along with mass spectrometry analysis of EVs from 2D cultures, revealed differential expression of factors impacting EMT and the TME, correlating with RNAseq data in 2D and 3D models. While in PDAC SAMD1 KO CM WT PDAC cells EMT-promoting genes were upregulated, in macrophages and stellate cells changes in subtype marker gene expression were observed.

Conclusion

Our results suggest that SAMD1 not only regulates EMT in 2D cell culture but may also play a role in 3D models and beyond, influencing the composition of the tumor microenvironment by altering the secretome and EV content of PDAC cells. These findings will help gain a deeper understanding of the role of epigenetic mechanisms in PDAC.

EACR25-2545

Investigating the tumor-suppressive role of the transcriptional co-repressor IRF2BP2 in pancreatic ductal adenocarcinoma

T. Huber¹, R. Liefke¹

¹Philipps-University Marburg, Institute of Molecular Biology and Tumor Research (IMT), Marburg, Germany

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal cancer with limited treatment options. To identify new therapies, it is crucial to further explore its molecular modes of action. Studying epigenetic mechanisms in PDAC will enable the development of targeted therapies to improve patient vitality. Chromatin-regulating proteins play a key role in the epigenetic regulation of gene expression, influencing processes such as tumor growth via inflammation and resistance. One such protein is the transcriptional cofactor IRF2BP2 (Interferon Regulatory Factor 2 Binding Protein 2). Recent studies demonstrated that IRF2BP2 plays a role in multiple biological

processes, such as proliferation and inflammation. In PDAC, higher expression levels of IRF2BP2 correlate with improved patient survival, highlighting its potential importance as a tumor suppressor.

Material and method

CRISPR-Cas9 was used to generate IRF2BP2 knock out (KO) in PDAC cell lines. The KO were analysed by microscopy, biological assays such as proliferation and migration assays, and RNA sequencing. Mass spectrometry (MS/MS) was used to investigate PDAC-specific interaction partners.

Result and discussion

KO of IRF2BP2 in PDAC cell lines resulted in a more elongated cell shape. This phenotype suggested increased motility of the KO cells. We confirmed the increased motility of IRF2BP2 KO cells by analysing cell migration rates through wound healing. Other biological assays such as proliferation assays, adhesion rates and colony formation assays are planned to further investigate the IRF2BP2 KO phenotype. RNA sequence data from PaTu 898t IRF2BP2 KO cells show an increased expression of epithelial-to-mesenchymal transition (EMT) and inflammation-related genes compared to WT cells. The increased expression of EMT-related genes in the KO cells supports the investigated phenotype and the increased migration rate. The increased expression of EMT-related genes in KO cells supports the observed phenotype and the increased migration rate. The increase in inflammation-related genes in the KO cells suggests that IRF2BP2 KO cells are more sensitive to inflammatory stimuli. Therefore, treatment of the cells with cytokines IL1 α and TNF α is planned. The MS/MS data revealed interesting interaction partners like TAF13, KAT6, and CEBPZ, which are still investigated.

Conclusion

The results suggest that IRF2BP2 plays a role in inflammation and EMT in PDAC cells. This may be important for its tumor suppressive role. This study contributes to a better understanding of the role of epigenetic mechanisms in PDAC.

Preventive and Therapeutic Effects of Amaranthus hybridus and Corchorus olitorius on Breast Cancer

E. Iweala¹, O. Dania¹

¹Covenant University, Department of Biochemistry, Ota, Nigeria

Introduction

Considering the projected increase in incidence rates of cancer globally and the burden being higher in Africa, there is a need to find preventive and therapeutic solutions that can be tailored to the African population. Breast cancer is the leading cancer in African females. The willingness to adopt alternative medicine for the

management of diseases is high in Africa. Therefore, this study sought to evaluate the effects of two readily available food plants, Amaranthus hybridus and Corchorus olitorius in preventing and treating breast cancer.

Material and method

Carcinogenesis was induced in laboratory rats by administering a single oral dose of DMBA at 80 mg/Kg body weight. Plant extracts were administered 2 weeks before and 18 weeks after induction of carcinogenesis in the chemopreventive and therapeutic treatments, respectively. RNA was extracted from the mammary tissues at the end of the experimental period, and the expression levels of selected genes including CCND1, APEX1, BAX, and SOD2 associated with anticancer effects were quantified using the RT-qPCR technique.

Result and discussion

No tumor was recorded in the chemopreventive groups. Expression of CCND1 was significantly increased in the groups that developed mammary tumors. APEX1 expression was significantly increased in all the treatment groups that received the plant extracts, while the highest expressions of BAX and SOD2 were recorded in both the chemopreventive and therapeutic groups that received a combination of both plants.

Conclusion

Amaranthus hybridus and Corchorus olitorius leaves contain potent bioactive compounds that prevent tumor development through chemoprevention, and the combination of both leaves possesses better gene amplification effect on the DNA repair gene APEX1, pro-apoptotic gene BAX, and mitochondrial SOD2 gene.

EACR25-0047

Phage display identified claudin 18.2 binding peptide for early pancreatic diagnosis and tumor-target killing

P. Sri Murugan¹, G. Gowri Rangaswamy¹, B. Lee¹

¹Kyungpook National University, Biochemistry and cell biology, Daegu, Korea (Republic of)

Introduction

Pancreatic adenocarcinoma is a lethal condition with a rising incidence, predicted to become the second leading cause of cancer-related deaths worldwide by 2030. One major hurdle in the treatment of this disease is the predominantly elderly patient population and clinically silent and aggressive nature. Early detection of pancreatic neoplasms and novel treatment for highly aggressive and metastatic conditions is of great need in pancreatic tumor therapy. Claudins are crucial components of tight junctions. They are transmembrane proteins and are the keeper of the “fence function”. Claudins in tumor are like the fall of the soldiers entrusted to protect the gate. Claudin 18.2 is a member of the claudin family, commonly expressed in multiple cancers, including Gastric cancer and Pancreatic cancer. Claudin-18.2 expression on cancer cells is increased and exposed on surface of the cells. The development of malignant tumors leads to the disruption of tight junctions, exposing the Claudin 18.2 epitope on the surface of tumor cells as a specific target. Also, claudin 18.2 is transcriptionally upregulated with the binding of cyclic AMP-responsive

element binding protein to the methylated CLDN18.2 promoter region. Claudin 18.2 is considered an early stage marker of pancreatic carcinogenesis. Claudin 18.2 is considered a ‘dark horse’ in anti-tumor therapy. Thus, Claudin 18.2 could be a good “target” for early detection and target-specific treatment of pancreatic tumor.

Material and method

Construction of phage peptide library and bio panning for claudin18.2-binding peptides using claudin18.2 over-expressing cells. Clone selection, Sequence analysis and peptide synthesis. Phage cell-binding ELISA. Immunofluorescence, flow cytometry analysis and pull-down assays of cellular binding of peptides on claudin 18.2 high and low expressing cell lines. In vivo tumor targeting and anti-tumor therapy with claudin18.2-binding peptide conjugated with proapoptotic peptide.

Result and discussion

After five rounds of screening, phage titers that bind to transfected cells were enriched higher-fold compared to phage titers isolated in the first round. 2 phage clones displaying peptides that selectively bound to transfected cells were chosen and sequenced for further study. The two peptides showed selectively binding to claudin 18.2 expressing cells as analyzed by Immunofluorescence. Pull down assay further confirmed selective binding of peptide to claudin 18.2. Bioaccumulation study in vivo showed significant accumulation of peptide in tumor tissue. Treatment of KPC transgenic pancreatic tumor bearing mice with claudin 18.2 peptide conjugated to proapoptotic peptide enhanced the survival of the mice.

Conclusion

Claudin 18.2 peptide can specifically target the tumor cells and conjugation with proapoptotic peptide can induce tumor targeted apoptosis with increased survival in pancreatic tumor bearing mice.

EACR25-0065

Nanobody-PROTACs: Method development towards the use of single-domain antibody proteolysis-targeting chimera constructs (sdAb-PROTACs) to target 'undruggable' proteins for degradation

C. Cope¹, C. Tufarelli¹, R. Britton¹

¹*University of Leicester, Department of Genetics, Genomics and Cancer Sciences, Leicester, United Kingdom*

Introduction

Proteolysis targeting chimeras (PROTACs) are bifunctional molecules that can bring an E3 ligase (e.g. VHL) into close proximity with a protein of interest (POI). The E3 ligase recruits E2 to ubiquitinate the POI, marking it for degradation via a proteasome. Uniquely, PROTACs do not need to inhibit or bind an active site, allowing tailored targeting of the POI, followed by subsequent degradation. This means that PROTACs have the potential to degrade targets previously considered ‘undruggable’, such as the oncogene, KRAS, which is historically difficult to therapeutically target due to lack of deep binding pockets. Typically, PROTACs utilise small molecules to target the POI, however, our work aims to exploit the potential of nanobodies to replace

these small molecules. The gold standard for protein targeting remains monoclonal antibodies, however, nanobodies possess the same antigen binding site specificity, whilst possessing a tertiary structure only a tenth of the size. Our proof of concept work focuses on identifying whether the nanobody-PROTAC has the potential for cellular entry, and thus degradation of its POI.

Material and method

We tagged an anti-GFP nanobody with AZdye647, using the thiol-maleimide Michael addition reaction, SDS-PAGE analysis was used to assess successful conjugation. This conjugate was then used to treat fixed and live cells expressing enhanced green fluorescent protein (EGFP), followed by fluorescent microscopy to confirm cellular entry and POI targeting.

Result and discussion

Initial SDS-PAGE analysis revealed the successful conjugation of AZDye647 to the nanobody. Specific binding within fixed cells was confirmed using fluorescent microscopy, as co-localization of EGFP and the AZdye647-tagged anti-GFP nanobody was revealed. Our data also confirmed that liposomal encapsulation of the AZdye647-tagged anti-GFP nanobody yielded efficient delivery into live EGFP expressing cells.

Conclusion

Together, this data provides confirmation that a nanobody-PROTAC would be capable of passing through the cellular membrane, maintaining its integrity and degrading its POI. Replacement of AZdye647 with an E3 ligase ligand will provide further understanding of whether a nanobody-PROTAC would result in the degradation of ‘undruggable’ oncogenes such as KRAS, *in vitro*, confirming whether this is a viable therapeutic approach to patients with KRAS-mutant cancers.

⁶*University of Algarve, Faculty of Medicine and Biomedical Sciences, Faro, Portugal*

Introduction

Glioblastoma (GBM) is among the most aggressive and lethal cancers, with treatment challenges arising from the complexity and redundancy of its signaling networks. Targeted inhibitors of specific pathways have shown limited success. The nuclear export receptor Chromo-

some Region Maintenance 1 (CRM1) has recently gained attention as a promising therapeutic target, as its inhibition disrupts multiple oncogenic drivers simultaneously. In this study, we investigate whether chromenone derivatives, known for their ability to detect thiol-containing molecules, can act as CRM1 inhibitors.

Material and method

We synthesized various chromenone-based derivatives and demonstrated their ability to inhibit CRM1-mediated nuclear export in a structure- and dose-dependent manner.

Result and discussion

A preliminary structure-activity relationship (SAR) analysis, supported by molecular docking studies, provided insights into selective CRM1 binding. Furthermore, we showed that active chromenone derivatives effectively block the nuclear export of endogenous nuclear export signal (NES)-containing substrates in glioblastoma cells.

Conclusion

Several of these compounds exhibit selective cytotoxicity against glioblastoma cell lines, underscoring their potential as targeted GBM therapies.

EACR25-0084

IQS080 is a novel cytosolic multitargeted kinase inhibitor that simultaneously targets key kinase families, making it a promising candidate for the treatment of pancreatic cancer

²IQS School of Engineering, Universitat Ramon Llull, Grup de Química Farmacéutica, Barcelona, Spain

³Xenopat S.L., Instituto Catalán de Oncología (ICO), Barcelona, Spain

Introduction

Pancreatic ductal adenocarcinoma (PDAC), often called a 'silent cancer,' is one of the most aggressive tumor types, with a poor prognosis and a five-year survival rate of 10–15% after diagnosis. For those patients who present with resectable disease, surgery followed by adjuvant chemotherapy with FOLFIRINOX (fluorouracil, irinotecan, leucovorin, oxaliplatin) or single-agent gemcitabine is the standard treatment. Among such treatments, Erlotinib, a tyrosine kinase inhibitor (TKI) inhibiting EGFR, is used in severe cases. To improve current treatments, we developed a program focused on multitarget TKIs targeting key TK receptors involved in PDAC (EGFR, VEGFR-1, VEGFR-2, PDGFR, and IGFR). We computationally designed, synthesized, and evaluated a series of candidates in vitro against these receptors and in 2D cultures of PANC-1, MiaPaca-2, and BxPC-3 cell lines. Although several compounds exhibited residual activity below 27% for most of the targeted kinases, their IC₅₀ values against PANC-1 ranged between 20 and 50 μM.

Material and method

Surprisingly, during the study, we identified IQS080, a pyrido[2,3-d]pyrimidine with significantly improved metabolic stability (over 85% after 60 minutes of incubation with rat liver microsomes) but presenting almost no interaction with the TKs above but showing the best IC₅₀ against the PDAC cell lines.

Result and discussion

IQS080 shows good inhibitory activities against a group of cytosolic TKs (ERK1, ERK2, JNK1, JNK2, p38alpha, and p38beta). It is remarkable the inhibitory activity against p38alpha, and p38beta with residual activities below 15% both at 5 and 10 μM. Moreover, IQS080 shows IC₅₀ for the inhibition of KRAS wild-type and some of the mutants (G12C, G12V) in the range 17 to 42 μM, revealing a certain degree of interaction with such proteins. The safety profile of IQS080 was tested using the Chick Chorioallantoic Membrane (CAM) assay showing that, even at high doses, does not exhibit significant toxicity or adverse effects on the embryos. Ongoing *in vivo* studies in xenografted subcutaneous PDAC cell lines and Patient-Derived Orthotopic Xenografts (PDOX) are also yielding promising initial results, both as a single agent and in combination therapies.

Conclusion

IQS080 is a novel intracellular multitarget kinase inhibitor that has demonstrated both safety and efficacy as a single agent in preclinical models of PDAC. Its unique mechanism of action could involve the simultaneous inhibition of the three key MAPKs (ERKs, JNKs, and p38s), along with partial inhibition of KRAS (wild-type and major mutant forms). This multitarget approach effectively blocks the activation of compensatory pathways in tumor cells, leading to enhanced antitumor activity. The versatility and favorable safety profile of IQS080 position it as a promising candidate, for further investigation in combination studies with chemotherapy and targeted therapies.

EACR25-0085

Impact of immune checkpoint inhibitors (ICIs) alone or combined with chemotherapy (ICI/chemotherapy) on the prognosis of non-small cell lung cancer (NSCLC) patients with high expression of programmed

G. Chen¹

¹Tongliang District People's Hospital, Department of Oncology and Hematology, Chongqing, China

Introduction

Immune checkpoint inhibitors (ICIs) are the standard therapy for patients with advanced non-small cell lung cancer (NSCLC) exhibiting a programmed death-ligand 1 (PD-L1) tumor proportion score (TPS) of ≥50%. However, the efficacy of ICIs alone or in combination with chemotherapy (ICI/chemotherapy), in patients with NSCLC characterized by high PD-L1 expression and cancer cachexia remains unclear.

Material and method

This retrospective, multicenter cohort study involved 250 advanced NSCLC patients with a PD-L1 tumor proportion score of ≥50%. Patients received either

pembrolizumab monotherapy or pembrolizumab in combination with chemotherapy. Cancer cachexia was defined as weight loss exceeding 5% of total body weight or a body mass index (BMI) of 2% within the 6 months prior to treatment initiation. A total of 50 patients (20%) met the criteria for cancer cachexia.

Result and discussion

The overall survival (OS) and progression-free survival (PFS) of patients with cachexia in both treatment groups were significantly shorter than those of patients without cachexia (OS: 18.8 vs. 37.3 months, $p < 0.001$; DFS: 4.8 vs. 11.3 months, $p = 0.004$). After propensity score matching and stratification by cancer cachexia status, no significant differences in PFS and OS were observed between the pembrolizumab monotherapy group and the combination therapy group, regardless of cancer cachexia status.

Conclusion

For NSCLC patients with high PD-L1 expression and concurrent cancer cachexia, the benefits of ICI/chemotherapy appear limited, suggesting that ICI monotherapy may be the preferable treatment option.

EACR25-0086

Engineering Bacteriophages for Targeted Photodynamic Cancer Therapy

A. Kaltenbrunner¹, P. Costantini¹, M. Nigro¹, L. Pappagallo¹, M. Di Giosia², M. Calvaresi², A. Danielli¹

¹*Alma Mater Studiorum - University of Bologna, Pharmacy and Biotechnology, Bologna, Italy*

²*Alma Mater Studiorum - University of Bologna, Chemistry "Giacomo Ciamician", Bologna, Italy*

Introduction

Conventional cancer therapies often face challenges such as off-target toxicity, resistance and high costs, requiring the development of innovative, precise and affordable therapeutic approaches. Bacteriophages (phages), viruses that infect bacteria, represent a promising platform for precision medicine due to their ability to be genetically engineered and conjugated with therapeutic agents. This study investigates the potential of engineered M13 phages as nanobiotechnological tools for photodynamic cancer therapy (PDT). The phages are modified to target overexpressed cancer markers and conjugated with photosensitisers (PS) that generate reactive oxygen species (ROS) upon light activation, enabling targeted cancer cell death while sparing healthy tissues.

Material and method

The pIII protein of M13 phages was genetically engineered to display a nanobody specific for the epidermal growth factor receptor (EGFR), a marker commonly overexpressed on various cancer cell lines. Photosensitisers, such as Rose Bengal, were conjugated to the major coat protein pVIII for a high payload delivery. These engineered phages were tested in vitro on 2D cell cultures, 3D spheroids and ex vivo on patient-derived ascites samples. After light activation, ROS-mediated cancer cell killing was assessed by cell viability assays, measuring dose-dependent and specific cancer cell eradication.

Result and discussion

The engineered phages demonstrated excellent specificity

for EGFR-overexpressing cancer cells with no effects on negative control cell lines. Conjugation of PS to the phages significantly enhanced PDT efficiency compared to free PS, primarily by increasing local drug accumulation at the tumour site. Each phage delivered hundreds of PS molecules while maintaining structural integrity and stability. In a dose-dependent manner, this platform demonstrates effective eradication of cancer cells. Moreover, ex vivo studies in patient-derived ascites have validated translational potential of the platform. The low cost of phage production also highlights the scalability and accessibility of this platform for cancer therapy in resource-limited settings.

Conclusion

This study establishes engineered M13 bacteriophages as a versatile and precise nanobiotechnology platform for cancer PDT. Their high specificity, robust payload capacity and low production costs position them as a promising alternative to conventional cancer therapies. Ongoing work will focus on overcoming challenges related to phage immunogenicity and macrophage-mediated clearance to improve in vivo efficacy and facilitate clinical translation. These advances have the potential to revolutionise the targeted treatment of cancer and to address global health inequalities.

EACR25-0087

A potential nanocarrier for Androgen-resistant in prostate cancer: Green synthesis of ZnO nanoparticle

S. Ali¹, Y. Chi¹, R. Shi¹, R. Na¹

¹*The University of Hong Kong, Surgery, HKSAR, Hong Kong, China*

Introduction

12.5% of men will receive a prostate cancer diagnosis at some point in their lives, making prostate cancer (PCa) one of the main causes of death and morbidity among men worldwide. Our previous population study based on UK Biobank suggested a significant decreased risk of PCa and PCa deaths. The current study is aim to synthesize ZnO nanoparticle and investigate its underline biological mechanisms of anti-tumor effects in prostate cancer cell lines

Material and method

The preparation of ZnO nanoparticle involves the production and full characterization of EGCG, via gamma rays irradiation, followed by peptide conjugation for subsequent use as an effective template toward the synthesis of tumor cell specific ZnO NPs. Androgen-resistant (DU145, PC-3), androgen-sensitive (LNCaP) human prostate cancer cell lines and BPH-1 control cell line were treated with different concentration of 30 $\mu\text{g/mL}$, 60 $\mu\text{g/mL}$, and 90 $\mu\text{g/mL}$. After 48 hours of treatment, the MTT assay, Migration, Invasion and flow cytometry were performed to confirm the phenomenon

Result and discussion

The ZnO NPs polymeric nanoparticles (86 nm) served multiple roles as reducing and stabilizing agents in the overall template synthesis of tumor cell targeted ZnO NPs. The ZnO NPs capped with EGCG exhibited average Au-core diameter of 20 nm with hydrodynamic diameters of 67 nm, respectively. The ZnO NPs showed optimum in vitro stability in biologically relevant solutions. We

observed a significant suppression of the cell growth in all of the four cell lines at 48 hrs. The results from migration, invasion, cell cycle analysis furtherly confirmed that this suppression effect was more significant in androgen resistance cell lines. The ZnO NPs displayed cytotoxicity effects against cancer cells. Our investigations provide compelling evidence that ZnO NPs functionalized with EGCG is an innovative nano-medicine approach for use in molecular imaging and therapy of GRP receptor positive tumors. The template synthesis of EGCG-ZnO NPs serves as an excellent non-radioactive surrogate for the development of the corresponding NPs theragnostic nanoradio-pharmaceutical for use in cancer diagnosis and therapy.

Conclusion

The current study provides fresh perspectives into the underlying mechanisms of action of ZnO NPs, a plant-derived nanoparticle, in prostate cancer. Future *in vitro* and *in vivo* validation will be conducted to examine whether the promising results are clinically translational.

EACR25-0132

The antihelmintic drug rafloxanide promotes oxidative stress and VDAC1 opening, leading to mitochondrial dysfunction in colorectal cancer cells

L. Tomassini¹, T. Pacifico¹, M. Serra¹, E. Sommella², M. Sambucci³, I. Monteleone⁴, G. Monteleone¹, C. Stolfi¹, F. Laudisi¹

¹*University of Rome Tor Vergata, Systems Medicine, Rome, Italy*

²*University of Salerno, Pharmacy, Salerno, Italy*

³*Santa Lucia Foundation IRCCS, Neuroimmunology Unit, Rome, Italy*

⁴*University of Rome Tor Vergata, Biomedicine and Prevention, Rome, Italy*

Introduction

Functional mitochondria are essential for cancer cells, which rely on oxidative phosphorylation to produce energy and promote tumor growth. Inhibiting this process results in mitochondrial damage and cell death. Therefore, mitochondrial uncouplers, which interfere with oxidative phosphorylation by dissociating ATP synthesis from the electron transport chain, represent a promising class of compounds that can be used as sensitizers in cancer therapy. The halogenated salicylanilide compound rafloxanide (RFX) is an anthelmintic drug that acts as an uncoupler of mitochondria to kill gastrointestinal roundworms. We have recently shown that RFX inhibits cell proliferation and promotes cell death of colorectal cancer (CRC) cells, but the mechanisms underlying these effects remain unclear. We aim to assess whether RFX may influence mitochondrial activity and impact the metabolism of CRC cells.

Material and method

The human CRC cell line HCT116 and DLD1 were treated with RFX at different time points. The oxygen consumption rate (OCR) and the mitochondrial membrane potential (MMP) were assessed using the seahorse XF24 assay and flow cytometry, respectively. Transcriptomic, proteomic and metabolic analysis, as

well as quantification of cytochrome C in the cytosolic fractions, were performed in CRC cells treated with RFX for 24 hours. Oligomerization of the voltage-dependent anion channel (VDAC)-1 was assessed by Western blotting. Reactive oxygen species (ROS) were quantified by fluorescent probe (DCFDA). Balb/c mice received an intraperitoneal (i.p.) injection of azoxymethane (AOM; 10 mg/kg) once every week for 6 weeks. After 20 weeks, mice were treated with RFX (7.5 mg/Kg, i.p.) or vehicle (DMSO) for an additional 8 weeks. Animals were then sacrificed and colonic tumors were collected for proteomic analysis.

Result and discussion

CRC cells treated with RFX showed a significant reduction in basal OCR, ATP production, and maximal respiration, indicating cellular quiescence. Transcriptomic, proteomic, and metabolic analyses revealed a critical impairment in mitochondrial activity following prolonged RFX treatment, along with an increased release of cytochrome C into the cytosol. RFX rapidly enhanced ROS production, promoted the open configuration of VDAC1 - a key regulator of mitochondrial metabolic functions and mitochondrial mediated apoptosis- and induced a progressive decrease in MMP in CRC cells. Treatment with the ROS scavenger N-acetylcysteine significantly limited RFX-dependent VDAC1 opening and mitochondrial membrane depolarization. Proteomic analysis of tumor colonic samples isolated from mice with sporadic CRC revealed a significant mitochondrial dysfunction in those treated with RFX.

Conclusion

Data indicate that RFX-mediated oxidative stress promotes the opening of VDAC1 and mitochondrial dysfunction, leading to the release of cytochrome C and resulting in mitochondria-mediated cell death.

Preclinical Evaluation of RAS(ON) Multi-Selective Inhibitors as a Therapeutic Strategy for KRAS mutant Cholangiocarcinoma

R. Entrialgo-Cardierno¹, K. Morali¹, I. Feliu¹, Y. Wang², M. Yanez-Bartolome³, I. Lopez¹, E. Guruceaga¹, T. Tian³, J. Jiang⁴, S. Vicent¹

¹*CIMA-University of Navarra, Program in Solid Tumors, Pamplona, Spain*

²*Revolution Medicines, Redwood City, United States*

³*VHIO, Upper Gastrointestinal and Endocrine Tumor Preclinical Group, Barcelona, Spain*

⁴*Revolution Medicines, Redwood City, United States*

Introduction

Cholangiocarcinoma (CCA) comprises around 3% of all GI cancers and features a highly dismal prognosis. Therapies predominantly rely on chemotherapy, and treatment advancements have been stagnant for the past decades, underscoring the need for innovative therapies. KRAS is among the most prevalent oncogenes in CCA, highlighting a potential role for novel KRAS inhibitors as treatment options. Here, we present preclinical data on

RAS(ON) multi-selective inhibitors as a potential therapy for CCA with KRAS mutations.

Material and method

Human and murine KRAS mutant cell lines, and immortalized cholangiocytes expressing KRAS wild type and mutant alleles (4B, G12, G13, Q61) were used to study the effect of RAS(ON) multi-selective inhibitors, the investigational agent daraxorrasib (RMC-6236) or the preclinical tool compound RMC-7977, in vitro (2D and 3D) and in vivo (CDX, PDX and CDA). RNA-seq and Western blot were conducted to analyse molecular changes and resistance mechanisms. Pharmacokinetic (PK) and pharmacodynamic (PD) analysis were carried out in KRAS mutant xenografts treated with RMC-7977 to establish the PKPD relationship in vivo. The tumor immune microenvironment was assessed by multiplex flow cytometry. Compound combinations to address resistance were tested in vitro and in vivo. Human and murine cell lines resistant to RMC-7977 were generated and characterized by WES and Western blot.

Result and discussion

KRAS mutant CCA cells were dependent on RAS signalling for growth, like other KRAS-driven cancers such as those from the lung and pancreas. RMC-7977 decreased proliferation and viability of mouse and human CCA cells with KRAS mutations and immortalized cholangiocytes expressing various mutant alleles in vitro. RMC-7977 and RMC-6236 effectively inhibited tumor growth of human and mouse KRAS mutant CCA models in vivo, impairing proliferation and inducing apoptosis. Immune phenotyping of RMC-7977-treated CDAs showed a notable increase in NK, CD8, and CD4 infiltration, and a reduction of PMN-MDSCs, indicative of a less immunosuppressive microenvironment. Consistently, addition of RMC-7977 to the standard of care regimen (Gemcitabine+Cisplatin+antiPD1) exhibited a synergistic antitumor effect, leading to deep regressions in vivo. Early adaptive resistance mechanisms to RMC-7977 were mainly driven by MAPK pathway reactivation, including KRAS upregulation, and RTK and SHP2 overactivation. RMC-7977 plus a SHP2 inhibitor had combinatorial benefits in both treatment-naïve and resistant CCA lines in vitro and in vivo. Lastly, genomic changes in resistant CCA cells involved KRAS, MYC and EGFR amplification, and informed additional drug combinations with RMC-7977.

Conclusion

In summary, our preclinical findings support the clinical testing of RAS(ON) multi-selective inhibitors, either alone or in combination with standard of care regimen or KRAS-pathway inhibitors, as a potential therapeutic strategy for CCA treatment.

EACR25-0194

The synergistic effect of sedanolide and 5-fluorouracil on triggering mitochondria-dependent apoptosis in colorectal cancer cells

R. Tu¹, S. Hsieh², C. Wu¹

¹*Providence University, Department of Food and Nutrition, Taichung, Taiwan*

²*National Kaohsiung University of Science and*

Technology, Department of Seafood Science, Kaohsiung, Taiwan

Introduction

Sedanolide (SN) is a major component found in celery, and it has the potential to act as an anticancer agent by regulating apoptosis. Colorectal cancer (CRC) is the second most common cause of cancer-related death globally, and 5-fluorouracil (5-FU) is one of the most commonly used medications for treating CRC. However, the high doses and long-term use of this medication can lead to significant side effects for colorectal cancer patients.

Material and method

This study aims to investigate the effects of SN combined with 5-FU on inducing apoptosis in human colorectal cancer cells. We analyzed cell viability, apoptosis, and the levels of several key proteins and indicators, including p53, mitochondrial membrane potential (MMP, $\Delta\psi_m$), Bax, Bcl-2, Cytochrome C, Caspase-9, I κ B, voltage-dependent anion channel 1 (VDAC1), and Hexokinase 2 (HK2) after treatment with the combination of SN and 5-FU.

Result and discussion

Our results showed that the combined treatment with both 5-FU and SN reduced the viability of colorectal cancer cells by inducing apoptosis. The combination treatment activated intrinsic apoptotic genes and proteins, including p53, Bax, Cytochrome C, and Caspase-9, while reducing levels of Bcl-2. Furthermore, this study demonstrated that the combination of 5-FU and SN can enhance NF- κ B-DNA binding activity, which decreases the binding of I κ B to VDAC1 and HK2 complexes in the mitochondrial membrane, leading to mitochondrial dysfunction.

Conclusion

In conclusion, the combination of SN and 5-FU enhances mitochondria-dependent apoptosis by regulating intrinsic apoptotic pathways and NF- κ B pathways, resulting in synergistic effects.

⁵*Newcastle University, Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom*

⁶*Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece*

Introduction

Malignant melanoma is an aggressive malignancy with high metastatic burden, and therefore, it is difficult to treat. Alternative treatment approaches are extremely urgent, and this requires a deeper understanding of the molecular mechanisms. Melatonin (MEL) is the hormone of sleep, primarily synthesized in the pineal gland but is also produced in skin. MEL has significant antitumor effects and was suggested as an anticancer agent. However, the mechanisms of action of MEL as an anti-cancer agent remain elusive. One hypothesis is that MEL may inhibit detrimental protein aggregation. Alpha-synuclein (aSyn) is a key player in Parkinson's disease (PD) due to its aggregation in characteristic inclusions in patient's brains. In melanoma, increased aSyn expression is associated with the progression of melanoma through unknown mechanisms. This study evaluated the effect of MEL on melanoma cells and investigated its impact on aSyn expression and associated biomolecular signatures.

Material and method

Melanoma cellular models with varying metastatic status were generated and the cytotoxicity of MEL was assessed. The effect of MEL on the biomolecular signatures of melanoma cells was explored using Raman spectroscopy and machine learning. ELISA was used to explore variations on aSyn protein levels. Molecular docking assessed the interaction and binding affinities of MEL to aSyn.

Result and discussion

MEL displayed stronger cytotoxic effects in non-metastatic compared to metastatic melanoma cells grown as monolayers or spheroids. This effect was associated with biomolecular changes observed within cells upon MEL treatment and modulation of aSyn levels.

Melanoma metastatic cells and spheroids which showed greater resistance to treatment, exhibited elevated levels of secreted aSyn upon MEL treatment. Thus, MEL's impact on aSyn aggregation was assessed. Molecular docking revealed that MEL binds to an aSyn intrinsically disordered C-terminal domain. This binding may inhibit β -sheet oligomer and fibril formation, potentially interfering with melanoma progression. Raman spectral changes in melanoma cells with different metastatic burden, including significant differences in intensity peaks upon MEL treatment, indicated protein conformational changes. Biomolecular signature changes, particularly glycosylation, were also identified, suggesting a role in MEL response to treatment.

Conclusion

MEL demonstrates potential as a potent anticancer agent for melanoma by inducing biomolecular changes that may impact aSyn aggregation. These findings suggest novel therapeutic targets for melanoma treatment.

EACR25-0220

The anti-cancer activity of novel diazo-derived compounds on triple-negative breast cancer

A. Celik¹, O. Tursoy Terzioğlu¹, M. Ozil², Y. Tutar³

¹University of Health Sciences, Molecular Biology and Genetics, Istanbul, Turkey

²Recep Tayyip Erdogan University, Chemistry, Rize, Turkey

³Recep Tayyip Erdogan University, Basic Medical Science, Rize, Turkey

Introduction

Breast cancer is the most common cancer among women and the second leading cause of cancer-related deaths. It is classified into subtypes based on the expression of three key receptors: estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). Triple Negative Breast Cancer (TNBC) accounts for 15–20% of breast cancer cases and is the most aggressive subtype, as it lacks all three hormone receptors. Azo dyes are organic compounds that contain an azo (-N=N-) group and are highly preferred due to their high reactivity and ease of modification. Azo-derived compounds containing different substituted groups have been found to exhibit high antioxidant and anticancer activities. This study aims to evaluate the potential anti-cancer activity of novel diazo-derived compounds on the TNBC cell line MDA-MB-231.

Material and method

The time and dose-dependent cytotoxic effect of the diazo-hydrazone derivative compound 3 was evaluated using the MTT assay in the MDA-MB-231 and the human fibroblast cell line CCD-1072-Sk. Its impact on colony formation and migration was determined through colony formation assay and wound healing assay.

Apoptosis was assessed by analyzing the expression levels of ten apoptosis-related genes: APAF1, BIM, CASP2, CASP7, CASP9, CFLAR, FASLG, NOL3, XIAP, and TP53 using RT-qPCR, alongside Annexin V-FITC analysis performed through flow cytometry. Additionally, nuclear and mitochondrial staining was performed to examine the effects of the compound on cell morphology.

Result and discussion

The IC₅₀ values of compound 3 in MDA-MB-231 and CCD-1072-Sk cells were determined to be 6.67 ± 0.38 and $22.45 \pm 1.94 \mu\text{M}$, respectively, and the Selectivity Index (SI) was calculated to be 3.41 ± 0.06 . The administration of compound 3 was observed to reduce wound healing and the number and size of colonies formed. Both single colony analysis and cell staining revealed the formation of giant multinucleated cells, suggesting that this condition may lead to apoptosis. We observed an increase in the expression of apoptosis-related genes (APAF1, BIM, CASP2, CASP7, CASP9, FASLG, TP53), while there was a decrease in the expression of NOL3, which is known to promote escape from apoptosis in breast cancer. Flow cytometry analysis also revealed that the administration of compound 3 enhanced both early and late-stage apoptosis.

Conclusion

In conclusion, the novel diazo-hydrazone derivative compound 3 was shown to inhibit cell proliferation, colony formation, and migration in MDA-MB-231 cells. It also resulted in the upregulation of apoptosis-initiating and regulatory genes, ultimately inducing apoptosis in cancer cells. The compound may be a good starting template for clinical drug design.

EACR25-0228

Enhanced Efficacy and Targeted Delivery System of a pH-sensitive ARV-825 Nanomedicine for Glioblastoma Treatment

H. Kinoh¹, D. Dung¹, A. Mohamed², X. Liu¹, S. Quader¹, K. Kataoka¹

¹Innovation Center of Nanomedicine, Kataoka-Kinoh Lab, Kawasaki, Japan

²Innovation Center of Nanomedicine, NiShiyama Lab, Kawasaki, Japan

Introduction

Glioblastoma (GBM) is an aggressive brain tumor with limited treatment options due to tumor heterogeneity and the blood-brain tumor barrier (BBTB). Proteolysis-targeting chimeras (PROTACs) offer a novel therapeutic strategy by degrading target proteins. ARV-825, a BET degrader PROTAC, has shown promise against GBM, but faces challenges such as poor solubility, limited BBTB permeability, and potential off-target toxicity. To address these limitations, we developed a pH-sensitive nanomedicine encapsulating ARV-825 for enhanced delivery and efficacy against GBM.

Material and method

We formulated ARV-825 into nanomedicines using PEG-PBLA polymers and pH-sensitive linker via self-assembly and cross-link. The nanomedicine was characterized for size, stability, and drug encapsulation efficiency. In vitro cytotoxicity was assessed in GL-261 glioblastoma cells by measuring the IC-50. In vivo efficacy was evaluated in orthotopic GL-261-luc glioblastoma models in C57BL/6 mice. We monitored tumor growth using in vivo imaging and assessed treatment efficacy by analyzing survival rates.

Result and discussion

pH-sensitive ARV-825-loaded nanomedicines exhibited enhanced drug potency with an in vitro IC-50 of 0.013 μM compared to 0.1 μM for free ARV-825. In vivo imaging revealed significant tumor growth inhibition in mice treated with ARV-825 nanomedicines. Furthermore, the nanomedicine significantly prolonged survival time and improved survival rates compared to controls.

Conclusion

This study demonstrates that PROTAC-based nanomedicine represents a promising approach for treating glioblastoma. Our ARV-825-loaded pH-sensitive PBLA-PEG micelles enhanced drug potency, improved tumor targeting, and extended survival in preclinical GBM models. This nanomedicine approach warrants further investigation for clinical translation. Future research should focus on detailed mechanistic studies, safety evaluations, and strategies to further enhance tumor-specific delivery and minimize off-target effects.

EACR25-0295

Development and Validation of a Novel Multi-Functional Iron Oxide Nanoparticle for the Targeted Induction of Ferroptosis in Cancer

D. McPhail¹, J. Cronin², R. Wurelly², R. Beadman², J. Crane³, M. Davies¹, D. Tripathy⁴, R. Yuxiong Su⁴,

⁴Hong Kong University, Division of Oral and Maxillofacial Surgery, Hong Kong, China

Introduction

Ferroptosis is a recently discovered form of iron-driven cell death, wherein intracellular ferrous iron results in lipid peroxidation (LPO) and oxidative stress. Due to the inherent iron-dependency of cancer, ferroptosis may be an exploitable mode of cell death in the treatment of cancers which are resistant to conventional chemotherapeutics.

Material and method

We have developed a novel iron oxide nanoparticle (IONP) for the targeted induction of ferroptosis in cancer. IONPs were coated in FDA-approved PEGylated phospholipids and MC3-DLin-DMA. MC3-DLin-DMA (used in clinically-approved lipid nanoparticles (LNPs)) provides two polyunsaturated fatty acid (PUFA) chains to initiate ferroptosis. These PUFA-rich, PEGylated, phospholipid-stabilised Fe₃O₄-filled micelles were characterised by size, shape, and charge. Uniquely, the pro-fertopto activity of this IONP is initiated by spontaneous homolysis of hydroperoxides and the reaction of H₂O₂ with Fe(II) ions within the micelles. The IONP self-generates hydroxyl and alkoxyl radicals that ultimately cause LPO in cells.

Result and discussion

The efficacy of IONPs in inducing ferroptosis was measured in vitro by viability and LPO assays. The potency of IONPs could be enhanced with the use of RNA interference for a key ferroptosis defence gene (AIFM2). In vivo studies demonstrated that IONPs administered by subcutaneous injection or transdermal delivery using fast-dissolving microneedle patches provide high efficacy in the reduction of tumour volume at low doses.

Conclusion

This study has developed and validated an effective and innovative cancer drug which uses a multi-functional approach to induce ferroptosis. It is intended for this drug to progress to further pre-clinical trials and be evaluated in combination with pro-fertopto drugs.

EACR25-0301

Innovative Cyclic Peptide Disrupts IL-17RB/MLK4 Interaction for Targeted Pancreatic Cancer Therapy

C. Hu¹, S. Tien¹, Y. Lo¹, C. Huang¹, Y. Ko¹, D. Wu¹

¹Academia Sinica, Genomics Research Center, Taipei, Taiwan

Introduction

The IL-17B/IL-17RB signaling axis promotes pancreatic cancer progression by interacting with mixed-lineage kinase 4 (MLK4). This interaction activates downstream oncogenic signaling pathways contributing to tumor growth and metastasis. Disrupting the IL-17RB/MLK4 interaction is a promising pancreatic cancer therapeutic

strategy. We previously developed a linear peptide, TAT-IL17RB403-416, designed to interfere with this interaction. In this study, we aimed to improve the therapeutic efficacy of this peptide by converting it into a cyclic form.

Material and method

A cyclic analog of TAT-IL17RB403-416 was designed based on the conserved IL-17RB loop region and synthesized using solid-phase peptide synthesis with disulfide bond cyclization. In vitro experiments, including cellular uptake, soft agar colony formation, and spheroid formation assays, were performed using the CFPAC1 human pancreatic cancer cell line. An orthotopic mouse model was used to assess in vivo efficacy. The IL-17RB/MLK4 interaction was analyzed by co-immunoprecipitation and biolayer interferometry. Computational modeling and docking predicted the cyclic peptide's binding mode to MLK4. Site-directed mutagenesis and co-immunoprecipitation experiments assessed the role of key residues in IL-17RB and MLK4.

Result and discussion

Novel cyclic peptide significantly enhanced cellular uptake and stability compared to the linear form. This improved uptake and stability translated to superior inhibition of pancreatic cancer cell growth in vitro. Furthermore, treatment with the cyclic peptide significantly reduced tumor growth and metastasis in an orthotopic mouse model. Mechanistically, we identified key residues mediating the IL-17RB/MLK4 interaction, including cysteine 408 in IL-17RB and arginine 216 in the MLK4 kinase domain, which are critical for the cyclic peptide's activity. Additionally, we found that lysine 410 in IL-17RB is essential for maintaining the structural integrity and function of the cyclic peptide as a protein-protein interaction disruptor. These findings highlight the therapeutic potential of cyclic peptides targeting the IL-17RB/MLK4 interaction in pancreatic cancer and provide a deeper understanding of the molecular basis of this interaction.

Conclusion

This study highlights the potential of cyclic peptides as effective protein-protein interaction disruptors in pancreatic cancer. The enhanced efficacy observed with the cyclic peptide analog emphasizes the importance of rational design and optimization in peptide drug development. This promising therapeutic approach warrants further investigation for the treatment of pancreatic cancer.

⁴*Centro de Investigación Biomédica en Red de Enfermedades Raras, (CIBERER), Madrid, Spain*

⁵*University Hospital Zurich (USZ), and University of Zurich (UZH), Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland*

Introduction

Surgery is the first-line and only curative treatment for localized paragangliomas (PPGLs). However, in metastatic cases, surgical intervention is rarely feasible, and effective therapeutic options remain limited, resulting in a poor prognosis for patients with aggressive or metastatic (m)PPGL. This underscores the urgent need to identify novel treatment strategies. In this study, we investigate the antitumor potential of targeting two key dysregulated pathways in PPGL: PI3K signaling and cell cycle regulation.

Material and method

We assessed the efficacy of buparlisib, a PI3K α inhibitor (PI3Ki), and ribociclib, a CDK4/6 inhibitor (CDK4/6i), as monotherapies and in combination, using functional assays in representative in vitro models of PPGL. These models included two rodent cell lines (MPC and PC12) as well as rat- and patient-derived primary PPGL cells. The combination therapy was further evaluated in vivo in PC12-derived mouse xenografts. Transcriptomic analysis of treated PC12 cells identified a mitotic gene signature uniquely dysregulated by combination treatment, which was validated in PPGL cells through qRT-PCR and functional assays assessing mitotic spindle defects. Additionally, RNA-Seq analysis of human PPGLs revealed an upregulation of this gene signature in mPPGLs compared to non-metastatic cases, a finding further confirmed by qRT-PCR in independent patient samples.

Result and discussion

Dual inhibition of PI3K and CDK4/6 resulted in superior suppression of cell proliferation and invasion compared to monotherapies, while also inducing apoptosis in both 2D and 3D organotypic cultures of PPGL cell lines. Synergistic effects were observed in primary organotypic cultures derived from both rat and patient PPGLs, as well as in PC12-derived xenografts, where tumor growth was significantly reduced, even at lower drug doses. RNA-Seq analysis identified key mediators of the combination treatment response, including mitotic spindle pathways and FOXM1 signaling, both of which were experimentally validated. Bioinformatics analyses further confirmed the activation of the mitotic gene network in human mPPGLs.

Conclusion

Combined inhibition of PI3K and CDK4/6 targets mitotic spindle regulation and exerts potent antitumor effects in PPGL models. Given the upregulation of mitosis-associated genes in mPPGL, this combination therapy holds promise as a novel approach for treating aggressive forms of these tumors.

EACR25-0375

Rationally designed cholesterol-coated peptide nanospikes as a novel therapeutic strategy in the management

of Adrenocortical Carcinoma

⁸The University of Kansas Medical Center, Department of Cancer Biology, Kansas City, KS, United States

⁹University of Galway, Discipline of Pharmacology and Therapeutics, Ireland

Introduction

Management of adrenocortical carcinoma (ACC) is challenging, with diagnosis often occurring at advanced stage. Surgical resection of localized disease offers potential cure, but recurrence is high (75-85%). Mitotane is the only approved drug for advanced ACC, but has a narrow therapeutic window, is poorly tolerated, and effective in less than 30% of cases. Nanotheranostics rationally designs nanomaterials for simultaneous diagnosis, drug-delivery, and treatment. Most FDA-approved nanomedicines rely on the enhanced permeability and retention (EPR), where nanoparticles passively accumulate in tumors. This improves drug delivery while reducing adverse effects but is subject to variability between patients and tumor types, which can be improved by specific nanoparticle-targeting to tumors. ACC cells rely on cholesterol, for steroid hormone synthesis, as a key component of cell membranes, and as fuel. Exploiting this, we designed tri-maleimide peptide-based nanospikes (NS) functionalized with two cholesterol molecules and a fluorescent tag (Rhodamine B). These rationally designed NS were tested for uptake and cytotoxicity on three ACC cell lines: H295R (chemotherapy-sensitive), HAC-15 (chemoresistant), MUC-1 (chemoresistant).

Material and method

Cell death was assessed using SYTOX Blue, and the role of SR-B1 in NS uptake was evaluated using BLT-1. Caspase-dependent/independent cytotoxicity was investigated using z-VAD (pan-caspase inhibitor), and measuring markers of apoptosis, ER stress and autophagy (Caspase 3 & 8, CHOP, LC3). LC-MS/MS was used to measure steroidogenesis.

Result and discussion

NS were rapidly taken up by all ACC cell lines, with significant cell death observed within 2 hours in the H295R cell line at the physiological concentration of 20 μ g/ml ($p < 0.01$), at 50 μ g/ml in HAC-15 ($p < 0.01$) and at 100 μ g/ml in MUC-1 ($p < 0.5$). NS uptake was not prevented by the Scavenger Receptor-B1 (SR-B1) inhibitor BLT-1, suggesting direct-membrane or LDL-R

mediated uptake. Confocal microscopy and TEM revealed that NS accumulated in mitochondria. ACC cell death occurred through a caspase-independent pathway: (i) cleaved caspase-3 protein was not upregulated (ii) zVAD-fmk had no significant effect on NS-induced cytotoxicity, while (iii) autophagy-related markers (LC3II/LC3I ratio) were upregulated. Forskolin-stimulated cortisol production was also reduced in H295R cells after NS treatment.

Conclusion

Rationally designed cholesterol-functionalized nanospikes (NS) demonstrate rapid uptake and potent cytotoxicity in ACC, inducing caspase-independent cell death and disrupting steroidogenesis. These findings highlight the potential of NS as a novel theranostic approach for ACC, offering targeted drug delivery with reduced toxicity and improved efficacy compared to conventional therapies. Future studies will load NS with lipid-soluble cytotoxic drugs e.g. mitotane.

PI3K-dependent GAB1/Erk phosphorylation renders head and neck squamous cell carcinoma sensitive to PI3K α inhibitors

X. Zhang¹, J. Xu², X. Wang³, L. Xu¹, S. Jiang⁴, Y. Zhang⁵, J. Ding⁴, C. Qing², L. Meng¹

¹Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Division of Anti-tumor Pharmacology, State Key Laboratory of Chemical Biology, Shanghai, China

²Kunming Medical University, School of Pharmaceutical Sciences & Yunnan Key Laboratory of Pharmacology for Natural Products, Kunming, China

³ShanghaiTech University, School of Life Science and Technology, Shanghai, China

⁴Shanghai, China

⁵Shanghai, Chile

Introduction

Phosphatidylinositol 3-kinase alpha (PI3K α) inhibitors are currently evaluated for the therapy of head and neck squamous cell carcinoma (HNSCC). CYH33 is a novel PI3K α -selective inhibitor discovered by our group, which is currently in clinical trials for the treatment of advanced solid tumors including HNSCC. However, there is an urgent need to elucidate its mechanism of action and improve its efficacy against HNSCC.

Material and method

Tandem-Mass-Tag (TMT) phosphoproteomics was performed to reveal the comprehensive regulation of kinase by CYH33. Cell proliferation was evaluated by Sulforhodamine B (SRB) assay. Western blotting was employed to detect protein levels. Xenografts derived from HN4 or SUNE-1 cells were utilized to evaluate the therapeutic efficacy *in vivo*.

Result and discussion

We found CYH33 displayed promising but variable therapeutic activity against HNSCC. Inhibition of PI3K/Akt pathway by CYH33 was not sufficient for its activity against HNSCC. Tandem-Mass-Tag (TMT) proteomics and phosphoproteomics were performed to reveal comprehensive regulation of kinase by CYH33. Among them, phosphorylation of MAPK1/Erk at

activation sites (T185/Y187) were significantly attenuated by CYH33 in sensitive HNSCC cells. CYH33 significantly suppressed phosphorylation of Erk in sensitive but not resistant cells. Further inhibition of Erk phosphorylation enhanced the activity of CYH33 against HNSCC. Signaling network of differentially phosphorylated proteins illustrated that phosphorylation at multiple sites (Y659, Y406, S651, S648) of the adaptor protein GAB1, which integrates the signaling from PI3K and receptor tyrosine kinases, were significantly down-regulated upon CYH33 treatment. CYH33 dose-dependently suppressed the phosphorylation of GAB1 at Y659 in sensitive HNSCC cells, whereas it had little effect in resistant cells. We found that CYH33 attenuated the membrane localization and phosphorylation of GAB1, resulting in reduced Erk phosphorylation and ultimately inhibiting the proliferation of sensitive cells. Meanwhile, activation of EGFR induced GAB1 phosphorylation independent of PI3K in HNSCC. Concurrent inhibition of EGFR synergistically potentiated the activity of CYH33 against HNSCC.

Conclusion

In conclusion, we found that PI3K α -selective inhibitor CYH33 displayed potent activity against HNSCC, which was associated with inhibition of Akt signaling as well as attenuation of PI3K-dependent GAB1/Erk phosphorylation. Simultaneous inhibition of GAB1 phosphorylation independent of PI3K potentiated the anti-HNSCC activity of CYH33. These findings revealed the insight mechanism of CYH33 against HNSCC and provided rational combination regimen for HNSCC.

EACR25-0411

Targeting Estrogen-Related Receptor Gamma (ERR γ) in Ovarian Carcinoma: Therapeutic Potential of DN200434 and MK2206 Combination in-vitro and in-vivo

D. Gulwani¹, R. Goel¹, P. Upadhyay¹, T. Singh¹

¹All India Institute of Medical Sciences, Medical Oncology, New Delhi, India

Introduction

Ovarian carcinoma (OC) is a leading cause of cancer-related mortality in females, necessitating the development of novel therapeutic strategies. Estrogen-related receptor gamma (ERR γ), an orphan nuclear receptor, has been implicated in cancer progression; however, its precise role in OC remains to be elucidated. This study evaluated the effects of DN200434, an ERR γ inverse agonist, alone and in combination with the Akt inhibitor MK2206 in OC models. By investigating ERR γ modulation in vitro and in vivo, this study aims to provide insights into its role in OC progression and resistance, offering a foundation for novel targeted therapies.

Material and method

ERR γ expression in ovarian cancer (OC) cell lines (SKOV3, OVCAR3, IGROV, and PA-1) was analyzed using western blotting. The effects of DN200434 on cell proliferation, apoptosis, and cell cycle arrest were examined in SKOV3 and OVCAR3 cells. For combination treatment, the half-maximal inhibitory

concentration (IC50) values of DN200434 and MK2206 were determined using a CCK assay following a 24-hour treatment. OC cells were treated with either drug alone or in combination to evaluate the inhibitory effects on apoptosis, cell cycle progression, colony formation, migration, and spheroid formation. The expression of key molecular markers associated with these processes was validated using western blot analysis. Calcein-AM staining was performed on the spheroids to assess the impact of the drug combinations. To evaluate the in vivo therapeutic efficacy, SKOV3 tumor-bearing xenografts were established, and apoptosis within the excised tumor tissues was assessed using TUNEL staining.

Result and discussion

ERR γ was overexpressed in ovarian cancer (OC) cells, and DN200434 treatment effectively reduced its expression. DN200434 inhibited OC cell proliferation in a dose-dependent manner by inducing cell cycle arrest, followed by apoptosis. Furthermore, DN200434 in combination with MK-2206 exhibited a synergistic cytotoxic effect, significantly enhancing OC cell death. Combination treatment (DN200434/MK-2206) suppressed cell proliferation through cell cycle arrest and apoptosis, while also markedly reducing colony formation efficiency, migratory capacity, and spheroid formation. Additionally, combination therapy diminished the stemness of OC cell-derived spheroids. The antitumor efficacy of DN200434/MK-2206 was further validated in an in vivo OC model, where ex vivo TUNEL staining of tumor tissues confirmed a significant increase in apoptosis in the combination-treated mice.

Conclusion

Our findings indicate that ERR γ acts as a positive regulator of ovarian cancer (OC) progression and is a promising therapeutic target. The combination of DN200434 and MK-2206 significantly inhibited cancer cell growth. This dual therapy holds substantial potential for further investigation and progression to clinical trials.

EACR25-0414

Oxyresveratrol inhibits the tumorigenesis and metastasis of human HCC cells by targeting the CCDC19/PLK1/CCNB1 pathways

H. Chiou¹, Y. Chen², Y. Hsieh²

¹Chung Shan Medical University, Department of Medical Laboratory and Biotechnology, Taichung, Taiwan

²Chung Shan Medical University, Institute of Medicine, Taichung, Taiwan

Introduction

Oxyresveratrol (OxyR), a natural polyphenolic phytoalexin found in grape skins, mulberries, peanuts, and red wine, has been reported to exhibit various biological activities, including anticancer, antioxidant, anti-inflammatory, free radical scavenging, and neuroprotective effects. However, its role and molecular mechanisms in hepatocellular carcinoma (HCC) remain unclear.

Material and method

Cell viability, colony formation and in vitro migration and invasion assays were performed to assess the effects

of OxyR on HCC cell proliferation and metastatic potential. RNA sequencing (RNA-Seq) was conducted to identify differentially expressed pathways. The protein and mRNA expression levels of CCDC19, PLK1, and CCNB1 were validated using qRT-PCR and western blotting. Additionally, the expression levels of CCDC19, PLK1, and CCNB1, along with overall survival analysis, were examined by the GEPPIA database and Kaplan-Meier (KM) plot. To further investigate the anti-invasive role of CCDC19 and PLK1 in OxyR-treated HCC cells, siRNA-CCDC19 knockdown and PLK inhibition were employed.

Result and discussion

Our results demonstrated that OxyR treatment inhibited the proliferation, migration, and invasion of HCC cells. RNA-Seq analysis revealed that OxyR downregulated the expression of CCDC19, PLK1, and CCNB1 in HCC cells, which was further confirmed by qRT-PCR and western blotting. Additionally, we found that CCDC19, PLK1, and CCNB1 were significantly upregulated in HCC tissues, and their expression was associated with tumor stage and poor survival outcomes in HCC patients. Silencing CCDC19 or treatment with a PLK1 kinase inhibitor in combination with OxyR significantly suppressed cell migration and invasion. Furthermore, we found that OxyR reduced the expression of the transcription factor FoxO4 in HCC cells.

Conclusion

Our study provides new insights into the anti-tumor effects of OxyR by targeting the CCDC19, PLK1, and CCNB1 expression. These findings suggest that OxyR may serve as a promising anticancer agent for HCC treatment.

EACR25-0450

Integrative Pharmacogenomics in RCC Tumoroids Uncovers Biomarker-Driven Combination Therapies

T. Chen¹, J. Jia¹, X. Pu¹, Z. Liu¹, Y. Yu¹, Q. Zhang², J. Xu³, J. Zheng¹, W. Zhai¹

¹*Renji Hospital, Shanghai Jiao Tong University School of Medicine, Department of Urology, Shanghai, China*

²*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, National Research Center for Translational Medicine (Shanghai), State Key Laboratory of Medical Genomics, Shanghai, China*

³*Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Department of Urology, Hangzhou, China*

Introduction

Effective treatment for renal cell carcinoma (RCC) remains critical for improving survival outcomes, as conventional therapeutic approaches exhibit limited response rates ranging from 30% to 60%. Personalized RCC therapy requires models capturing tumor heterogeneity and drug resistance mechanisms. This study aimed to identify novel anticancer drugs and synergistic drug combinations for RCC through ex vivo pharmacogenomic profiling of patient-derived tumoroids.

Material and method

All patients' samples were obtained from Renji Hospital, with written informed consent and Research Ethics Board approval in accordance with the Declaration of Helsinki. Primary RCC tumoroids were generated from fresh

surgical specimens using a scaffold-free 3D culture system. Histopathological validation was performed through hematoxylin-eosin (H&E) staining and immunohistochemical (IHC) analysis of lineage-specific biomarkers. Whole exome sequencing and RNA-seq were used to characterize the mutation profile, copy number variation and gene expression. Validated tumoroids underwent high-throughput screening against 81 anti-cancer drugs at serial dilutions. Dose-response curves were modeled via the R package GRmetrics to calculate area under the curve (AUC), half-maximal inhibitory concentration (IC50), and maximal efficacy (Emax). Drug-gene associations were assessed through Spearman correlation coefficients between log2-transformed gene expression values and AUC-derived sensitivity metrics (Benjamini-Hochberg adjusted $p < 0.05$). Synergy quantification was performed via SynergyFinder.

Result and discussion

52 RCC tumoroids were successfully cultured and screened from 75 surgical specimens (69.3% success rate). Histopathological and biomarker analyses confirmed retention of parental tumor architecture and pathological types. Molecular concordance was observed between tumoroids and matched primary tissues in mutational landscapes and transcriptomic profiles. Pharmacotyping revealed 15 agents with high potency ($AUC < 0.8$ in $\geq 70\%$ samples), including proteasome inhibitors and HDAC inhibitors, alongside 33 compounds demonstrating heterogeneous responses. Transcriptome-drug sensitivity integration identified 400 significant associations, notably linking elevated INSR expression to resistance against proteasome inhibitors. Combinatorial testing in INSR-high tumoroids revealed synergistic interaction between Ixazomib and the dual IGF-1R/INSR inhibitor BMS-754807.

Conclusion

Scaffold-free tumoroids faithfully recapitulate inter-patient heterogeneity in RCC, serving as robust platforms for drug discovery. Our pharmacogenomic framework identifies actionable therapeutic vulnerabilities and predictive biomarkers, providing a rationale for personalized combination therapies.

Introduction

Conventional cancer therapies induce severe side effects and have limited therapeutic windows. Nanoparticles emerged as a potential solution to overcome some of these limitations. However, the most widely applied carriers are synthetic and often show low biocompatibility and biological barrier crossing. On the other hand, extracellular vesicles (EVs) are phospholipid bound spherical structures that mediate cell to cell communication allowing engineering and loading with therapeutic cargoes. While EVs are promising, they may need to be engineered with target ligands to accumulate into the target tissues at clinically relevant numbers. We investigated the tumor targeting peptide p28 as an EV targeting moiety. p28 is derived from the bacterial protein azurin, and both the full protein and its derived peptide demonstrated selective uptake by cancer cells. In fact, in two phase I clinical trials, p28 showed safety and anti-tumor activity, suggesting a favorable therapeutic index.

Material and method

EVs were isolated from clinically relevant sources, mesenchymal stromal cells (MSCs, a promising therapeutic EV source) and human platelet lysate (hPL, derived from clinically expired platelet concentrates), through a scalable and good manufacturing practice (GMP) compatible method, comprising tangential flow filtration (TFF) for MSC-EVs and size exclusion chromatography (SEC). A characterization using nanoparticle tracking analysis (NTA), total protein quantification, western blotting (WB), and transmission electron microscopy (TEM) was performed.

Result and discussion

The EVs were isolated with a particle-to-protein ratio (PPR) of $(7.8 \pm 0.3) \times 10^9$ and $(5.7 \pm 5.1) \times 10^{10}$ particles/ μg protein for MSC-EVs and hPL-EVs respectively, demonstrating their high purity. These particles showed the expression of EV markers (CD63 and CD9), the classic morphology in TEM, and an average size of 131 nm (for MSC-EVs and hPL-EVs). Concerning particle numbers, MSC and hPL yielded $(2.5 \pm 2.6) \times 10^{10}$ and $(1.1 \pm 0.9) \times 10^{11}$ particles/mL of concentrated starting material, respectively. Both EVs were successfully functionalized with the tumor targeting peptide p28 (p28-EVs). Flow cytometry analysis demonstrated an enhanced uptake of p28-EVs into metastatic triple negative breast cancer MDA-MB-231 cells compared to non-functionalized EVs. MSC-EV uptake increased 1.6 ± 0.7 ($n = 3$), whereas hPL-EV uptake increased 2.2 ± 0.6 ($n = 3$) fold, highlighting the promise of p28 to boost EV penetration in tumor cells.

Conclusion

We demonstrated that p28, when attached to the EV surface, functions as a targeting moiety for cancer cells. We envision the use of this system in targeted cancer therapy with fewer side effects. Acknowledgments: AventaCell Biomed Corp. for providing hPL.

³Instituto Nacional de Cancerología E.S.E, Biología del cáncer, Colombia

⁴Universidad Nacional de Colombia, Farmacia, Colombia

⁵Universidad Nacional de Colombia, Patología, Colombia

Introduction

Glioblastoma multiforme (GBM) is the most aggressive primary brain tumor, with poor prognosis and limited treatment options. Resistance to standard therapies, such as temozolamide and radiotherapy, remains a major challenge, necessitating novel therapeutic strategies. Emerging evidence suggests that targeting mitochondrial dysfunction and non-canonical cannabinoid receptors could help overcome resistance in GBM and other cancer subtypes. This study investigates the potential of cannabichromene (CBC), cannabigerol (CBG), and piperine in modulating PINK1 and GPR55, key regulators of mitochondrial homeostasis and tumor progression, as a strategy to enhance treatment efficacy

Material and method

In silico molecular docking was performed to evaluate the binding affinity of CBC, CBG, piperine, and related compounds to PINK1 and GPR55. In vitro assays included cell viability (MTT), lactate dehydrogenase (LDH) release, Western blot (WB), PCR analysis, mitochondrial potential assays, and experiments using both established glioblastoma cell lines (U87MG, T98G) and a primary culture derived from a glioblastoma patient. The expression profiles of PINK1 and GPR55 were also analyzed using a database of 6,010 glioblastoma cases in Colombia spanning the last 10 years. From this database, 20 samples were recovered for immunohistochemical (IHC) analysis and compared against normal cortical tissue, and public transcriptomic datasets were also examined.

Result and discussion

CBC and CBG exhibited high binding affinity to GPR55 and PINK1. Cytotoxicity assays showed that both compounds, along with piperine, reduced glioblastoma cell viability in a dose-dependent manner, with IC₅₀ values comparable to or lower than temozolamide. WB and PCR analyses confirmed that cannabinoid treatment modulated PINK1 and GPR55 expression, suggesting a role in mitochondrial homeostasis and tumor progression. In some cases, cell death was linked to mitochondrial potential alterations, an indirect measure of PINK1 modulation. These findings align with IHC data from patient samples and transcriptomic datasets, indicating

differential biomarker expression in GBM vs. normal tissue.

Conclusion

CBC and CBG exhibit anticancer potential through PINK1 and GPR55 modulation, highlighting novel therapeutic targets for glioblastoma. Their influence on mitochondrial dynamics and oncogenic signaling suggests a role in overcoming therapy resistance in GBM and other cancers. Moreover, PINK1 emerges as a key molecular target given its differential expression in glioblastoma samples and correlation with survival outcomes in Kaplan-Meier analysis. The agreement between in silico predictions and in vitro validation reinforces these findings and underscores the value of integrating computational and laboratory approaches in drug discovery. Further studies are needed to elucidate their mechanisms and enhance their translational applicability.

¹⁰BBMRI-ERIC, Director General, Graz, Austria

Introduction

canSERV is a €15 Mio. project offering cutting-edge research services, enabling innovative R&D projects and fostering precision medicine for patients benefit.

CanSERV involves 18 leading organizations across Europe including Research Infrastructures, key organisations and oncology experts.

Material and method

canSERV's main objectives are:

- (i) offer at least 200 different unique Personalised Oncology relevant and valuable cutting-edge services;
- (ii) establish a single, unified, transnational access platform to request services and trainings;
- (iii) ensure oncology-related data provided will be fully compliant with FAIR principles and complement and synergise with other EU initiatives and
- (iv) ensure long-term sustainability beyond project duration. Furthermore, canSERV establishes the European Molecular Tumour Board Network (EMTNB) that is open for anyone to join. The EMTNB develops Molecular Tumour Board (MTB) consensus guidelines, an MTB outcome registry, and provides advice to scientists, clinicians, and MTBs.

Result and discussion

canSERV offers a series of open and challenge calls for access to services in the amount of ~€9 Mio. The calls are designed to support researchers to develop innovative research projects that explore cutting-edge methodologies and target critical gaps in cancer research and care by providing funding to services. Over the past two years, canSERV launched 3 open calls and 4 challenge calls that resulted in 336 research proposals submissions from 41 countries worldwide. These proposals address a diverse array of important frontiers in cancer research, including biomarker discovery and validation, novel therapeutics, advanced diagnostics, understanding cancer biology, cutting-edge AI/ML models for oncology and the advancement of precision medicine.

Conclusion

canSERV presents an unparalleled opportunity to accelerate cancer research, drive innovation, and improve patient outcomes.

canSERV is granted by the EU Horizon programme under #101058620.

Repurposing the antifungal piroctone olamine as a targeted treatment for pancreatic ductal adenocarcinoma

S. Prince¹, K. Serala¹, S. Mdletshe¹, J. Bai¹,

A. Abrahams¹, O. Gayet², L. Moubré², N. Dusetti²

¹University of Cape Town, Human Biology, Cape Town, South Africa

²Inserm, Cancer Research Centre of Marseille, Marseille, France

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is an intractable disease and its incidence is continuously rising in underdeveloped and developing countries including in South Africa where 84% of patients diagnosed die from the disease. This highlights an urgent need for cheap and effective therapeutic agents to reduce the burden of PDAC. We hypothesise that repurposing commercially available non-cancer drugs that inhibit key drivers of PDAC may facilitate the rapid identification of cost-effective drugs. In PDAC the expression of the homologous TBX2 and TBX3 transcription factors correlates with distant metastasis and poor patient survival. Here, we investigated whether TBX2 and TBX3 can serve as targets for piroctone olamine, an antifungal previously shown to inhibit TBX2 and TBX3 in TBX2/3-dependant melanoma and rhabdomyosarcoma cells, for treating PDAC.

Material and method

Human PDAC cell lines (BxPC-3, CFPAC-1, PANC-1, and SW1990) were used in this study. To investigate the role of TBX3 in PDAC as well as the anti-cancer effects and mechanisms of action of piroctone olamine numerous assays were performed in 2D and 3D spheroid and organoid PDAC cell culture models. These included, MTT and clonogenic assays, SA-β-galactosidase activity, Annexin-V/Propidium Iodide staining, immunocytochemistry, western blotting, scratch motility and transwell invasion assays, as well as 3D spheroid formation and invasion assays. The CellTiter-Glo® 3D Cell Viability kit was used to assess the effect of

piroctone olamine in a panel of PDAC patient-derived organoids.

Result and discussion

When TBX3 was stably knocked down in PDAC cells, they underwent senescence and had reduced proliferative ability and spheroid growth. Interestingly, TBX2 levels increased in the TBX3-knocked down PDAC cells, and depleting TBX2 in these cells inhibited their migration and invasion. These results thus demonstrated that TBX2 and TBX3 have distinct oncogenic functions in PDAC and that any effective anti-PDAC drug will need to inhibit them both. Using a high throughput drug repurposing screen we identified piroctone olamine to inhibit TBX2 and TBX3 levels and we show that it is a promising drug candidate to be repurposed for the treatment of TBX2/3-dependant PDAC. Indeed, treatment with piroctone olamine inhibited the levels of both TBX2 and TBX3 and recapitulated the phenotypes observed when TBX2 and TBX3 were knocked down in 2D and 3D PDAC cell culture models. Impressively, treatment with piroctone olamine significantly reduced the size and viability of PDAC patient-derived organoids.

Conclusion

Together, our data suggest that piroctone olamine has great potential to be repurposed for the targeted treatment of TBX2/3-dependant pancreatic cancer.

EACR25-0539

Targeting PDGFRA in Pediatric High-Grade Gliomas: Insights from Brazilian Preclinical Models

M. Baroni¹, L. Tshikawa¹, A. Martin¹, T. Duarte¹, F. Escremin², G. Teixeira³, B. Mançano⁴, C. Junior⁴, S. Teixeira¹, R. Reis^{1,5}

²Barretos Cancer Hospital, Department of Molecular Diagnosis, Barretos, Brazil

³Barretos Cancer Hospital, Department of Pathology, Barretos, Brazil

⁴Barretos Cancer Hospital, Department of Pediatric Oncology, Barretos, Brazil

⁵University of Minho, Institute of Life and Health Sciences Research (ICVS) - School of Medicine, Braga, Portugal

Introduction

Pediatric high-grade gliomas (pHGG) are highly aggressive brain tumors associated with poor prognosis. The development of reliable preclinical models to advance personalized therapeutic strategies is essential. The PDGFRA gene plays a critical role in gliomagenesis, with alterations linked to tumor progression and resistance mechanisms. In this study, we established and characterized patient-derived primary cultures and xenografts (PDX and PDOX) from Brazilian pediatric HGG cases with PDGFRA alterations, aiming to evaluate their biological features and responses to targeted therapies. Two pHGG models were derived from pediatric patients. Case 1 harbored PDGFRA (c.1977C>G) and TP53 (c.637C>T) variants, leading to the generation of HCB570 primary culture, PDX, and PDOX OXP9. Case 2, associated with CMMRD syndrome and

an MSH6 germline mutation, exhibited PDGFRA amplification, resulting in the establishment of HCB589, PDX, and PDOX OXP22.

Material and method

Cell characterization included xCELLigence proliferation assays, doubling time assessment, colony formation, and determination of temozolomide (TMZ) IC50. Patient and the PDX models underwent histopathological and EPIC methylation profiling to classify their molecular subtypes. Targeted sequencing (SOPHiA Solid Tumor and RNA Fusion Panels) was also performed to identify genomic alterations. In vitro drug treatment with Dasatinib, Imatinib, and Regorafenib was performed to assess therapeutic vulnerabilities. Dasatinib was further evaluated in vivo using PDX models.

Result and discussion

Both primary cultures demonstrated colony-forming capability and TMZ resistance with IC50 approximately 750 μM. The PDX models closely resembled patient tumors in histopathological and molecular profiles, confirming their classification as pHGGs IDH wild-type H3 wild-type. Importantly, PDGFRA alterations were detected in both cases, with one harboring a point mutation (c.1977C>G) and the other showing an amplification. Targeted drug treatment indicated that all three PDGFR inhibitors (Dasatinib, Imatinib, and Regorafenib) reduced cell viability in vitro. Dasatinib, selected for further validation in vivo, significantly inhibited tumor growth in the PDX models, reinforcing PDGFRA as a key therapeutic target in pediatric gliomas.

Conclusion

The successful establishment of pediatric pHGG preclinical models with PDGFRA alterations provides valuable tools for understanding glioma biology and testing targeted therapies in the admixture Brazilian population. Our pre-clinical findings highlight Dasatinib as a potential treatment for PDGFRA-driven pHGG, supporting the further clinical trials. Furthermore, including rare genetic backgrounds, such as CMMRD, contributes to diversifying glioma research models and expanding translational oncology efforts.

²Fundación Vithas, Grupo de Hospitales Vithas, Brain Tumor Laboratory, Spain

³Spain,

⁴Hospital Universitario Puerta de Hierro, Neurosurgery, Madrid, Spain

⁵Hospital Universitario Quironsalud, Neurosurgery, Madrid, Spain

Introduction

Gliomas are the most common primary brain malignancies in adults, classified by aggressiveness into low-grade gliomas (LGG, grades II–III) and high-grade gliomas (HGG, grade IV). Glioblastoma (GBM), a grade IV IDH1 wild-type astrocytoma, is the most prevalent and aggressive form, with an incidence of 3.22 cases per 100,000 people. GBM's high inter- and intra-tumoral heterogeneity contributes to its poor prognosis, with a median overall survival of 15 months and a 5-year survival rate of ~5%. Despite this, the standard of care (SOC) – maximal surgical resection, radiotherapy, and temozolomide (TMZ) chemotherapy – has seen little advancement. LGG research faces challenges due to low proliferation rates and tumor heterogeneity, limiting conventional preclinical models. In this context, patient derived *in vitro* models like organoids provide a promising platform for personalized medicine.

Material and method

In this study, we generated patient-derived organoids from over 50 glioma patients, characterized them based on histology, microstructure, expression patterns, and growth, and evaluated their response to SOC therapies. Subsequently, RNA-seq data was used for de novo drug discovery via the DiSCoVER platform, with candidate compounds validated *in vitro*.

Result and discussion

Organoid establishment was successful in most cases, with a higher success rate for GBM-derived organoids compared to LGG. Organoids proliferated and mimicked parental tissue in histology, microstructure, and expression patterns. However, biobanking proved unsatisfactory. Screening of common chemotherapeutic compounds revealed that SOC TMZ and other commonly used treatments had little effect on viability, whereas gefitinib showed a notable impact. Our de novo *in silico* approach identified alectinib, ruxolitinib, and dabrafenib as promising candidates, which were confirmed to significantly reduce viability, impair migration, and alter key molecular pathways.

Conclusion

In conclusion, while patient-derived glioma organoids present limitations in proliferative capacities and biobanking efficiency that must be addressed for clinical implementation, they remain an invaluable preclinical tool. As demonstrated in this work, the combination of organoids with bioinformatics tools like DiSCoVER establishes a potent platform for testing novel therapeutic strategies in the context of untreatable cancers such as gliomas.

EACR25-0559

Combining *in silico* and *in vitro* approaches to repurpose candidate drugs for oral squamous cell carcinoma

Zaria, Nigeria

⁴State University of Feira de Santana, Department of Technology, Feira de Santana, Brazil

⁵Barretos Cancer Hospital, Molecular Oncology Research Center, Barretos, Brazil

Introduction

Oral Squamous Cell Carcinoma (OSCC) remains a significant public health concern. Despite advances in treatments, including surgery, and chemotherapy, choices remain limited, underscoring the need for innovative therapeutic strategies. Developing new drugs is both costly and time-intensive. Drug repurposing offers a compelling solution by leveraging existing, well-characterized medications that are already approved and toxicologically safe. In this context, aiming to identify promising candidates for repositioning in OSCC, we combined integrated *in silico* analyses tools based on molecular and genetic insights with *in vitro* cytotoxicity screening based on bi- (2D) and three-dimensional (3D) models.

Material and method

A total of 237 drug candidates were retrieved from DrugBank to identify druggable targets. Ranking was based on cancer-related pathways and protein-protein interaction centrality. The *in vitro* cytotoxicity of selected compounds was evaluated in OSCC cell lines (HSC-3, H357) following the National Cancer Institute (NCI) Developmental Therapeutics Program (DTP) guidelines, with CellTiter-Glo® as the viability assay. Homotypic OSCC spheroids were generated using optimized magnetic 3D bioprinting. After ranking, 21 compounds were selected and underwent single-dose screening (10 µM). H357 cells were more sensitive than HSC3, showing lower viability across multiple compounds. Three most promising candidates (Daunorubicin, Erlotinib, and Romidepsin), which displayed growth inhibition properties (at least a 35% reduction), advanced to five-dose screening assays in both 2D and 3D models. In 2D cultures, Romidepsin exhibited the strongest cytotoxic effect, with the lowest IC50 values in both cell lines. In 3D assays, all three drugs demonstrated cytotoxic activity, with Romidepsin once again emerging as the most potent compound.

Result and discussion

The ranking strategy accelerated candidate selection and increased the chances of success by focusing on targets that exert greater influence on pathways relevant to OSCC. HSC-3 cells, known for higher tumorigenic potential, exhibited greater drug resistance than H357. Different mechanisms of action that maximize the therapeutic applications of the selected drugs were found. They include epidermal growth factor receptor (EGFR) inhibition, topoisomerase II inhibition, and a potent class I histone deacetylase (HDAC) blocker. Differences in 2D and 3D responses highlight the need for physiologically relevant models to improve translational relevance.

Conclusion

These findings reinforce the value of drug repurposing as an efficient strategy for expanding OSCC treatment options. By integrating computational approaches with physiologically relevant 3D models, this approach paves the way for more precise and personalized cancer therapies.

EACR25-0618**Discovery of DAC-1522, a novel Trop2-targeting degrader-antibody conjugate for precision oncology**

⁴DaCure Therapeutics, Shanghai,

Introduction

Antibody-drug conjugates (ADCs) have revolutionized cancer therapies by enabling the targeted delivery of cytotoxic payloads to tumor cells. However, their efficacy and safety are constrained by the limited repertoire of payloads. Notably, all FDA-approved Trop2-targeting ADCs currently rely on topoisomerase inhibitors as payloads, which may lead to both intrinsic and acquired drug resistance. Degrader-antibody conjugates (DACs) have emerged as a next-generation approach, combining the precision targeting of ADCs with the diverse options of protein degraders to overcome these challenges. Our study aimed to develop a Trop-2 targeting DAC with the potential to surpass the limitations of traditional ADCs.

Material and method

We screened a library of BET degraders using MDA-MB-231 and BT-474 cell lines using the CCK8 assay and confirmed their degradation efficacy via Western blot analysis. The selected payload candidates were subsequently converted into linker-drug conjugates and attached to antibodies to generate DACs. The drug-to-antibody ratio (DAR) and aggregation levels were characterized using reversed-phase liquid chromatography (RPLC) and size-exclusion chromatography (SEC). The in vitro potency and selectivity of representative DACs were assessed across a panel of cancer cell lines, including MDA-MB-231, JIMT-1, BXPC-3, KP-4, and NCI-N87. Additionally, their in vivo anticancer efficacy was investigated in JIMT-1, MIA PaCa-2, and BXPC-3 cell-derived xenograft (CDX) models.

Result and discussion

Several BET degraders demonstrated significantly enhanced cytotoxicity and degradation efficacy. The corresponding DACs achieved the designated DAR without aggregation. In vitro studies showed that DAC-1522 exhibits potent antiproliferative activity against multiple human cancer cell lines. Its efficacy is strongly correlated with Trop2 expression, ensuring selective cytotoxicity in Trop2-positive cells while sparing Trop2-negative cells, thereby offering a favorable therapeutic window. Notably, DAC-1522 retains uncompromised antiproliferative activity in an ADC-induced acquired drug resistance model, underscoring its potential to overcome resistance following ADC treatments. In vivo, a single intravenous injection of DAC-1522 achieves complete tumor regression in a human pancreatic cancer

BXPC-3 xenograft model, significantly outperforming Trodelyv® in efficacy. No obvious safety concerns were observed.

Conclusion

Our findings strongly support the further development of DAC-1522 as a highly promising therapeutic candidate for Trop2-expressing cancers.

EACR25-0622**Punicalagin-mediated suppression of oncogenic properties in ovarian epithelial adenocarcinoma cells**

Z. Bhutta¹, K. Choi¹

¹Chungbuk National University, Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Cheongju, Korea (Republic of)

Introduction

Ovarian cancer ranks among the most prevalent cancers in women, presenting considerable obstacles to effective treatment. Chemotherapy, frequently employed as adjunct post-surgery or as neoadjuvant therapy, is fundamental in the fight against the disease. Phytochemicals may serve as prospective chemo-therapeutic drugs to alleviate these limitations. Punicalagin, a polyphenolic molecule in pomegranates, has attracted interest in its significant therapeutic capabilities, especially its anticancer effects. This study aims to investigate the anti-proliferative and anti-migratory effects of Punicalagin on ovarian cancer utilizing the OVCAR-3 and SKOV-3 cells.

Material and method

Cell proliferation was measured by six distinct concentrations of punicalagin (6.25, 12.5, 25, 50, 100, and 200 µM) during 24-, 48-, and 72-hour incubation durations. Furthermore, a colony formation experiment was conducted to assess the capacity of cells to establish colonies following treatment with punicalagin. Moreover, wound healing and transwell migration experiments were performed to evaluate the migratory capacity of ovarian cancer cells. The MitoSOXTM assay was employed to identify mitochondrial reactive oxygen species (ROS). The rate of apoptosis was determined using the flow cytometry (Annexin V/PI staining), while the autophagy was confirmed using the acridine orange staining. Western blot assay was used to verify the findings obtained.

Result and discussion

Our findings demonstrated a substantial suppression of tumor cell proliferation and colony formation capacity in a dose- and time-dependent manner. Wound healing and transwell migration experiments indicated that Punicalagin inhibits the migratory capacity of ovarian cancer cells. Additionally, the MitoSOXTM assay demonstrated the involvement of reactive oxygen species in the effectiveness of Punicalagin in ovarian cancer cells. Acridine orange staining demonstrated autophagy in OVCAR-3 cells only, while flow cytometry analysis confirmed apoptosis in both cell lines. An increase in the E-cadherin, BAX, and a decrease in N-cadherin were confirmed in both cell lines. At the same time, the conversion of LC3-I to LC3-II was noted in the OVCAR-3 cells.

Conclusion

Punicalagin exhibits promising anticancer properties and may be a valuable chemotherapeutic agent in treating ovarian adenocarcinoma.

EACR25-0623

Anti-cancer effects of Amiodarone via cell cycle arrest, mitochondrial dysfunction, excessive autophagy, and increased apoptosis in thyroid cancer cells

S. Ahn¹, K. Choi¹

¹*Chungbuk National University, Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Cheongju, Korea (Republic of)*

Introduction

Amiodarone (AMD), an antiarrhythmic drug approved by the World Health Organization in 2005, inhibits various ion channels, including sodium, potassium, and calcium channels. These ion channels play a crucial role not only in normal cells but also in cancer cells. Recent studies have suggested the potential anticancer effects of AMD due to its pharmacological properties. This study aims to confirm the anticancer effect of AMD and its underlying mechanism in thyroid cancer cells.

Material and method

In this study, the thyroid cancer SNU-790 cells were used. WST assay was performed to determine whether AMD affects cell viability in SNU-790 cells.

Subsequently, a trans-well migration assay was conducted to evaluate the migratory effects of AMD. A cell cycle arrest assay using PI staining and an Annexin V/PI staining assay were performed to evaluate the proliferative ability and apoptotic cell population rate. MitoSOX™ staining and 2',7'-dichlorodihydrofluorescein diacetate (DCF-DA) staining assay were used to measure mitochondrial and cytosolic ROS levels, respectively. The change in mitochondrial membrane potential (MMP) was detected by JC-10 staining assay. Additionally, acridine orange (A/O) staining was performed to investigate whether AMD may induce autophagy.

Result and discussion

WST assay revealed a decrease in cell viability with increasing AMD concentrations. Subsequent experiments were conducted using concentrations based on IC₅₀ value (12 µM). Trans-well migration assay demonstrated that higher AMD concentrations inhibited cell migration. MitoSOX™ and DCF-DA staining assay indicated that AMD treatment led to increased mitochondrial and cytosolic ROS levels. Similarly, JC-10 staining assay was able to depict a concentration-dependent decrease in MMP, indicating mitochondrial dysfunction in SNU-790 cells. Furthermore, Annexin V/PI staining revealed an increase in the rate of apoptosis with increasing AMD concentrations. Additionally, since AMD is widely recognized as an autophagy inducer, A/O staining was performed to assess autophagy induction in thyroid cancer cells. The results demonstrated that autophagy activation increased with higher AMD concentrations.

Conclusion

Amiodarone induces cell cycle arrest, mitochondrial dysfunction, excessive autophagy, and increased

apoptosis in SNU-790 thyroid cancer cells by increasing cytosolic and mitochondrial ROS levels.

EACR25-0627

UD-086 overcomes trastuzumab deruxtecan-resistance and has a best-in-class therapeutic index in MMAE-based antibody drug conjugates

N. Oishi¹, S. Nonouchi¹, Y. Karatsu¹, T. Matsushita¹, K. Ito¹, H. Sunamoto¹, T. Kashiwagi¹, K. Onuma¹, R. Iwamura¹, Y. Aga¹

¹*Ube Corporation, Pharmaceutical Research Laboratory, Ube, Japan*

Introduction

Although many antibody drug conjugates (ADCs) have been currently approved, they still face the problem of difficulty in having sufficient therapeutic index due to off-target toxicity caused by linker instability. To solve this problem, we developed a novel UBE's versatile hydrophilic (UVH) linker and auristatin E (AE) prodrugs. UVH linker contains a novel, highly hydrophilic amino acid derivative enables high stability in the blood with the maximum drug to antibody ratio (DAR) of 16. This linker is cleaved by Cathepsin B. AE prodrug is significantly less toxic than AE due to its lower cell membrane permeability. On the other hand, AE prodrugs released from ADCs taken up by cancer cells are converted to AE in the cancer cells and exhibit potent cytotoxic activity. Using this state-of-the-art linker and prodrug, we generated UD-086, a next generation HER2-directed ADC consisting of trastuzumab, UVH linker, and AE prodrugs with a DAR of eight and evaluated in vitro and in vivo efficacy and the safety profile.

Material and method

The drug-linkers were conjugated to trastuzumab via their maleimide groups to prepare UD-086. Linker stability of UD-086 in human serum was evaluated for up to 168 h of incubation. The amounts of released payloads were measured by LC-MS/MS. In vitro cytotoxicity of AE prodrug and AE was tested in NCI-N87 cells. In vitro bystander killing effect of UD-086 was evaluated in a co-culture system of NCI-N87 (HER2-positive) and MDA-MB-231 (HER2-negative). The pharmacokinetic (PK) profile of UD-086 was determined in BALB/c mice. In vivo efficacy of UD-086 was evaluated in NCI-N87, DXd-resistant NCI-N87 and JIMT-1 cells xenograft mouse models. Toxicity study of UD-086 was conducted in cynomolgus monkeys.

Result and discussion

UD-086 showed much higher linker stability in human serum in vitro than trastuzumab deruxtecan (DS-8201a). AE prodrug was stable in human serum, and it was approximately 300 times less toxic than AE in NCI-N87 cells. UD-086 indicated in vitro bystander killing effect as well as DS-8201a. UD-086 demonstrated a comparable total antibody PK profile to trastuzumab. In NCI-N87 xenograft model, UD-086 showed three to 10-fold potent efficacy than DS-8201a and 10-fold potent efficacy than disitamab vedotin, respectively. In NCI-N87 xenograft model, the minimum effective dose of UD-086 was 1 mg/kg. In DXd-resistant NCI-N87 and JIMT-1 xenograft models, DS-8201a resistance was

exhibited, and UD-086 showed more than 30-fold potent efficacy than DS-8201a. The maximum tolerated dose of UD-086 was 6 mg/kg in cynomolgus monkey (Q3W×3, non-GLP).

Conclusion

The therapeutic index of UD-086 is six. UD-086 shows strong efficacy in the DS-8201a resistance tumor models. Despite the conjugating AE with DAR of eight, UD-086 shows very high blood stability and has a significantly improved best in class therapeutic index compared to previous MMAE-based ADCs.

EACR25-0640

Risk and benefit for basket clinical trials in oncology: a systematic review with meta-analysis

K. Klas¹, K. Strzebonska¹, L. Zaborowska¹, T. Krawczyk¹, A. Włodarczyk¹, U. Bak-Kuchejda¹, M. Polak¹, S. Van Wambeke², M. Waligora¹

¹Jagiellonian University Medical College, Department of Bioethics, Krakow, Poland

²ZNA, Department of Oncology, Antwerp, Belgium

Introduction

Basket clinical trials (BCTs) are human research studies commonly used in precision medicine. BCT simultaneously test a therapeutic intervention for multiple malignancy types under the same study protocol. Patients with different cancers recruited to BCT share specific molecular characteristics which are predictive of clinical benefit from the experimental treatment. Our aim was to evaluate risks and benefits in cancer BCTs.

Material and method

The study protocol was prospectively registered in PROSPERO [1]. We systematically searched Embase, PubMed, and ClinicalTrials.gov for interventional cancer BCTs published between 1 January 2001, and 14 June 2023. We included targeted therapy and/or immunotherapy studies of all cancer types. We measured risk using drug-related grade 3 or higher adverse events (AEs), and benefit by objective response rate (ORR), progression-free survival, and overall survival.

Result and discussion

We identified 126 arms of 75 BCTs (7,659 patients) that met our eligibility criteria. The overall fatal treatment-related AE rate (grade 5) was 0.7% (95% confidence interval [CI] 0.4–1.0), and 30.4% (95% CI 24.2–36.7) of patients experienced grade 3–4 drug-related toxicity. The overall drug-related grades 3–5 rate was higher for targeted therapies than immunotherapies: 31.7% (95% CI 25.6–37.8) vs 7.9% (95% CI 0.0–23.1), $p = 0.004$. The pooled overall ORR was 18.0% (95% CI 14.8–21.1) and was lower in solid tumors, 17.5% (95% CI 14.3–20.8), compared with hematological malignancies, 63.6% (95% CI 36.3–90.9); $p = 0.004$. The median progression-free survival was 3.1 months (95% CI 2.6–3.9), and the median overall survival was 8.9 months (95% CI 6.7–10.2).

Conclusion

Cancer patients should be properly informed about the benefits and risks in BCTs. Our data suggest that nearly four out of five participants did not respond to treatment, one in 135 died because of drug toxicity, and nearly one

third experienced grade 3–4 treatment-related AEs. While we acknowledge that our systematic analyses do not cover all aspects related to benefits and risks in cancer BCTs, we note that efforts should be made to improve the data reporting that allows for such assessments.

Exploring the Cytotoxic Potential of Calcite on MCF-7 Cells: A Promising Approach for Breast Cancer Treatment

A. Kothidar¹, S. Mitra¹, D. Ankaiah¹, O. Weiss¹, D. Baranes¹

¹Ariel University, Department of Molecular Biology, Ariel, Israel

Introduction

Breast cancer is the most common malignancy in women and a leading cause of cancer-related mortality worldwide. Despite therapeutic advancements such as chemotherapy, radiation, and biological medications, challenges like recurrence and metastasis remain, highlighting the need for novel treatment strategies. While calcium carbonate has been shown to inhibit the progression of lung cancer and induce oxidative damage in HeLa cells, its effects on breast cancer cells remain inadequately studied. This research demonstrates cytotoxic impact of calcite, the most abundant crystalline form of calcium carbonate, on MCF-7 human breast adenocarcinoma cells *in vitro*.

Material and method

Cellular metabolic activity was evaluated using an MTT assay, and live-dead cell viability was determined by Hoechst-Propidium Iodide (PI) staining. The interaction between calcite and cells was visualized via Scanning Electron Microscopy (SEM). Cell proliferation was assessed using Ki-67 immunofluorescence. Additionally, clonogenic assay evaluated the ability of MCF-7 cells to form colonies. Scratch wound assays were performed to assess cell migration, while apoptosis was analyzed through AO-EtBr staining and cell cycle progression was examined by flow cytometry.

Result and discussion

The cytotoxic effects of calcite on MCF-7 cells were assessed across various concentrations (0.01–1 mg/ml) and time points. MTT assay results showed a significant, dose- and time-dependent decrease in cell viability. At day 3, 0.1 mg/ml calcite resulted in a 21% reduction in viability, while 1 mg/ml caused a 60% inhibition, indicating calcite's potent effect on cell viability. Calcite also reduced cell proliferation. At 0.1 mg/ml, Ki-67 expression was decreased by 59%, and at 1 mg/ml, by 36%, compared to the control (61.75%). This correlated with a reduction in colony formation, where calcite-treated cells showed a 31% and 83% reduction at 0.1 mg/ml and 1 mg/ml, respectively, highlighting calcite's potential to inhibit proliferation and colony formation. The effect on migration showed significant inhibition, with a 41% reduction at 0.1 mg/ml and 80% at 1 mg/ml, suggesting calcite interferes with cell motility. Apoptosis analysis revealed a 13-fold increase in necrotic cells at 1 mg/ml and 8-fold at 0.1 mg/ml compared to controls, indicating calcite induces cell death through necrosis,

particularly at higher concentrations. Additionally, calcite treatment caused dose-dependent G0/G1 phase arrest, reducing cells in S and G2/M phase suggesting that this cell cycle arrest may contribute to observed reductions in proliferation and migration.

Conclusion

In summary, calcite effectively inhibits MCF-7 cell growth by decreasing viability, limiting proliferation and migration, and inducing necrosis and cell cycle arrest. These results support further investigation into calcite as a potential therapeutic agent in the treatment of breast cancer.

EACR25-0653

Selective degradation of MLK3 by novel CEP1347-VHL-02 PROTAC compound limits oncogenic potential of TNBC

K. Karpinska¹, D. Mehlich^{1,2}, V. Sabbasani³, M. Łomiak¹, P. Torres-Ayuso⁴, K. Wróbel¹, R. Serwa¹, R. Swenson³, J. Brognard⁵, A. Marusiak¹

⁴*Temple University, Department of Cancer and Cellular Biology, Lewis Katz School of Medicine, Philadelphia, United States*

⁵*National Institutes of Health, Laboratory of Cell and Developmental Signaling, National Cancer Institute, Frederick, United States*

Introduction

Triple-negative breast cancer (TNBC) accounts for 20% of all breast cancer (BC) cases and is associated with the worst prognosis because of the lack of effective therapies. Mixed-lineage protein kinase 3 (MLK3, MAP3K11) is a member of the MLK family of serine/threonine kinases, which belongs to mitogen-activated protein kinase kinase kinases (MAP3Ks). MLK3 expression is significantly elevated in TNBC cell lines compared with epithelial non-tumorigenic breast cell lines and other BC subtypes and involved in the high tumorigenic potential of TNBC cells. Proteolysis-targeting chimeras (PROTACs) represent a major targeted protein degradation technology that allow for the selective targeting of protein of interest (POI) in cancer cells. PROTACs are chemically synthesized heterobifunctional compounds consisting of three elements: a ligand for the POI that we want to degrade, ligand for recruiting an E3 ligase and an appropriately designed linker between those two ligands. PROTAC molecules simultaneous bind the POI and E3 ligase together forming a ternary complex, and due to proximity of target protein to E3 ligase complex, a lysine residues within the POI are ubiquitinated and protein is targeted to proteasomal degradation.

Material and method

Here, we present a novel, potent, and selective MLK3 degrader, CEP1347-VHL-02, based on the pan-MLK inhibitor CEP1347 and ligand for E3 ligase von Hippel-

Lindau (VHL), by employing proteolysis-targeting chimera (PROTAC) technology.

Result and discussion

Our synthesized compound effectively targeted MLK3 for degradation via the ubiquitin-proteasome system in several cell line models but did not degrade other members of the MLK family. Furthermore, we showed that CEP1347-VHL-02 robustly degraded MLK3 and inhibited its oncogenic activity in TNBC, measured as a reduction of clonogenic and migratory potential, cell cycle arrest, and the induction of apoptosis in MDA-MB-468 cells.

Conclusion

In conclusion, we present first-in-class PROTAC that induces the rapid and selective degradation of MLK3 in cancer cell lines. Our study provides new opportunities for the selective targeting of MLK3 in cancer and paves the way for the development of next-generation degraders against MLK3 and related kinases. Notably, MLK3 degradation by CEP1347-VHL-02 significantly reduced the oncogenic potential of TNBC cells, suggesting that the targeted degradation of this kinase may be a feasible treatment strategy for this subtype of breast cancer.

⁴*State Key Laboratory of Drug Research, Department of Medicinal Chemistry, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China*

Introduction

Cyclin-dependent kinase 9 (CDK9) plays a pivotal role in regulating transcriptional elongation, and has emerged as a promising target in cancer therapy. However, our previous research has demonstrated that CDK9 inhibitors induce abnormal upregulation of H3K27me3 in diffuse large B-cell lymphoma (DLBCL) cell lines, impairing the inhibitory effect on tumor cells proliferation. Interestingly, EZH2 inhibitors can reverse the upregulation of H3K27me3, leading to synergistic antitumor effects.

Material and method

Based on this observation, we designed and synthesized a series of dual inhibitors targeting both CDK9 and EZH2 through fusion based strategies to achieve enhanced antitumor activity.

Result and discussion

Among the compounds developed, the potent CDK9/EZH2 dual inhibitor D16 exhibited impressive and balanced inhibitory properties of both targets, with IC50 values of 67 nM for CDK9 and 84 nM for EZH2.

Notably, compound D16 induced greater DNA damage and exhibited stronger inhibitory effects on DLBCL proliferation compared to the single-target inhibitor SNS-032 or C24. In addition, D16 showed potent anti-proliferative activities in various solid tumor cell lines, which may provide an innovative strategy for the treatment of cancer.

Conclusion

All these findings highlight the potential of dual CDK9/EZH2 inhibitors as a novel approach for cancer therapy.

EACR25-0667

EZH2 inhibitors dramatically sensitize breast cancers to HER2 kinase inhibitors through cooperative effects on YAP and pro-apoptotic regulators

N. Perurena¹, M. Watanabe¹, A. Schade¹, W. Brown², E. Luo², K. Cichowski¹

¹*Brigham and Women's Hospital and Harvard Medical School, Medicine, Boston, United States*

²*Brigham and Women's Hospital, Medicine, Boston, United States*

Introduction

The receptor tyrosine kinase HER2 is overexpressed and/or amplified in around 20% of breast cancers and functions as an oncogenic driver. While HER2 inhibitors have dramatically improved the clinical outcome of HER2+ breast cancer, metastatic disease remains incurable due to intrinsic and acquired resistance. Therefore, there is an urgent need to develop more effective therapeutic strategies that will induce deeper initial responses and delay or prevent relapse. To this aim, we sought to identify additional oncogenic targets that when inhibited, potentiate the effects of HER2 inhibitors. We considered the epigenetic regulator EZH2, which represses transcription by depositing trimethyl marks at H3K27, as such co-target since 1) it is over-expressed in 84% of HER2+ breast cancers, including stage III and stage IV tumors, and 2) has been shown to contribute to breast cancer development and metastasis.

Material and method

We investigated the therapeutic effects of combined EZH2 and HER2 inhibitors in multiple human HER2+ breast cancer cell lines in vitro and in xenograft models in vivo. To identify the molecular mechanism by which these agents cooperate we performed RNA-seq and ChIP-qPCR experiments. The molecular mediators identified were further validated with genetic knockdown or chemical inhibition experiments.

Result and discussion

We have found that EZH2 inhibitors shift the epigenetic state of HER2+ tumors, dramatically enhancing baseline responses to HER2 kinase inhibitors and re-sensitizing drug resistant tumors in vitro and in vivo. Specifically, we report that EZH2 normally silences the pro-apoptotic gene, BMF, by methylating H3K27 at the BMF locus. EZH2 inhibitors promote the release of H3K27me3, but this stimulates the binding of repressive YAP/TEAD complexes which still restrict its expression. However, in the presence of EZH2 inhibitors, HER2 kinase inhibitors trigger the dissociation of repressive YAP/TEAD

complexes, potently upregulate BMF, and kill resistant cells. Accordingly, EZH2 inhibitors similarly cooperate with genetic or chemical inhibitors of YAP/TEAD, which also induce BMF expression and trigger apoptosis.

Conclusion

Together these studies show how EZH2 and YAP coordinately insulate the BMF locus and demonstrate that EZH2 inhibitors can be used to reprogram HER2+ tumors, resulting in a dramatic sensitization to HER2 kinase inhibitors and enhanced killing of residual disease.

³*University of Newcastle, School of Medicine and Public Health, Newcastle, Australia*

⁴*University of Technology Sydney, School of Life Sciences, Faculty of Science, Sydney, Australia*

Introduction

The receptor tyrosine kinase-like orphan receptor 1 (ROR1) has been identified as an attractive target for ovarian and endometrial cancer therapy. Using the pipeline established from a large collaborative drug repurposing project, we identified Ivacaftor, an FDA-approved cystic fibrosis medication, as a candidate predicted to interact with ROR1. This study aimed to provide preclinical evidence supporting the potential repurposing of Ivacaftor for HGSOC and endometrial cancer treatment using 2D preclinical models as well as 3D patient-derived organoid models in vitro.

Material and method

Dose response analysis was undertaken in ROR1 expressing HGSOC cell lines OVCAR4, KURAMOCHI, COV362 and COV318 as well as endometrial cancer cell lines Ishikawa and ARK1 using a serial dilution of eight concentrations of Ivacaftor (3.9 μM to 100 μM). Cell viability was assessed at 72 hours post drug treatment using the MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) assay. Cells were treated with 15uM ivacaftor and 30uM carboplatin for 24, 48, and 72 hrs for flow cytometry analysis using Apoptosis, DNA Damage and Cell Proliferation Kit (BD Biosciences) which stained for fluorophores against cleaved PARP, H2Ax, and BrdU. Additionally, ROR1-expressing HGSOC and molecularly classified endometrial cancer patient-derived organoids (n = 3 for HGSOC and n = 6 for endometrial cancer) underwent dose-response analysis, with CellTiter Glo-based viability measurements determined at 72 hours post-treatment. Finally, the mechanisms associated with Ivacaftor treatment were

explored in the cell lines and organoids through Western blotting, flow cytometry and real-time Annexin V assays.

Result and discussion

The IC₅₀ for Ivacaftor ranged from 6.5 to 13.2 μM in 2D HGSOC cell lines cultured in 2D and 0.004 to 1.5 μM in endometrial cancer cell lines. In organoid models, IC₅₀ values ranged from 11.6 to 15.1 μM for HGSOC and from 0.4 to 18.6 μM for endometrial cancer. Notably, mismatch repair deficient (MMRd) endometrial cancer models exhibited the highest sensitivity, with IC₅₀ values lower than 1 μM, in contrast to p53 wildtype and p53 abnormal models. Ivacaftor treatment induces cell apoptosis similar to carboplatin treatment, but does not increase DNA damage in the cells, as opposed to carboplatin treatment. Ivacaftor treatment does not cause an increase in cells stalling in S phase. In addition, Ivacaftor treatment suppressed tumour stemness and modulated ROR1 signaling associated oncogenic pathways including the PI3K/AKT pathway and epithelial to mesenchymal transition (EMT).

Conclusion

In conclusion, Ivacaftor demonstrated significant single agent anti-tumour potential in preclinical HGSOC and endometrial cancer models, supporting its further investigation as a repurposed therapy for ROR1-expressing ovarian and endometrial cancers.

³University Of Balamand, Faculty of health sciences, beirut, Lebanon

⁴Lebanese University, Faculty Of Health Sciences, Tripoli, Lebanon

⁵American University of Beirut, Faculty of Medicine, Beirut, Lebanon

Introduction

Colorectal cancer (CRC) remains a major global health burden, driving the need for novel, less toxic therapeutic strategies. This study evaluated the potential of bioactive compounds from the Mediterranean red coral seaweed, *Jania rubens*, as adjuvants to standard chemotherapies (Doxorubicin, Capecitabine, and Irinotecan) in CRC treatment.

Material and method

MTT and colony formation assays were used to assess CRC cell viability following treatment with *J. rubens* extracts, alone and in combination with chemotherapeutic agents. Cell cycle analysis and reactive oxygen species (ROS) measurements were performed to determine mechanisms of cytotoxicity. Wound healing and zymography assays were conducted to evaluate cell migration and metastatic potential, respectively. Epithelial-mesenchymal transition (EMT) was assessed by analyzing the expression of N-cadherin, Twist, and Snail

Result and discussion

Our findings demonstrate a synergistic anticancer effect. *J. rubens* extracts, when combined with chemotherapeutic agents, significantly reduced CRC cell viability, as evidenced by MTT and colony formation assays. This enhanced cytotoxicity was associated with the induction of G0/G1 cell cycle arrest and a marked increase in intracellular ROS production. Furthermore, wound healing and zymography assays revealed a dose-dependent reduction in CRC cell migration and metastatic potential, demonstrated by decreased MMP-2 and MMP-9 enzymatic activities. Importantly, the extracts effectively suppressed EMT, as indicated by the downregulation of N-cadherin, Twist, and Snail

Conclusion

These results underline the significant potential of *J. rubens* bioactives as adjuvants to conventional CRC chemotherapy and provide a strong rationale for further preclinical investigations to explore the therapeutic potential of *J. rubens* extracts in CRC management

⁵"G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy, Department of Neurosciences, Imaging and Clinical Sciences, ch, Italy

⁶"G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy, Center for Advanced Studies and Technology (CAST), c, Italy

Introduction

LGALS3BP is a hyperglycosylated secreted protein overexpressed in various human malignancies. Recently, it has been identified as one of the most abundant proteins in extracellular vesicles secreted by cancer cells. Furthermore, studies of biological fluids such as blood, urine, and saliva highlight LGALS3BP as a promising biomarker and therapeutic target. Our group has developed a specific antibody-drug conjugate (ADC) targeting LGALS3BP, named 1959-sss/DM4, demonstrating potent antitumor activity across multiple models, including glioblastoma. In this study, we explored its potential as both a biomarker and therapeutic target using an orthotopic patient-derived glioblastoma model.

Material and method

Orthotopic glioblastoma (GBM) models were established using both commercially available LUC-U87MG cells

and patient-derived cell lines. Tumor tissues were analyzed by IHC and IF to assess antibody penetration into the brain and evaluate ADC anti-tumor efficacy. Circulating tumor-derived LGALS3BP in mice plasma samples was quantified using a sandwich ELISA with the therapeutic 1959 antibody. Additionally, PE-conjugated 1959 therapeutic antibody was used in flow cytometry to specifically detect LGALS3BP-positive extracellular vesicles (EVs) in patients' blood samples.

Result and discussion

We first established an orthotopic GBM preclinical model using U87MG-LUC cells and observed a significant reduction of tumor mass in treated animals, as revealed by LMI signals. Interestingly, an ELISA assay on serum from tumor-bearing mice quantified human circulating LGALS3BP protein, suggesting its potential as biomarker for the disease in this model. We then transitioned to a patient-derived orthotopic model and, in an initial study, we confirmed by immunofluorescence staining that 1959 antibody successfully reached the brain lesion and accumulated within the tumor 72 hours post-injection. Furthermore, we observed that ADC treatment induced mitotic catastrophe in GBM tissues and enhanced tumoral immune infiltration, particularly by B lymphocytes and macrophages. Next, we employed liquid biopsy to detect brain tumors in injected mice in order to design a mouse trial experiment. Indeed, following brain tumor detection via liquid biopsy, mice were treated with either PBS or 1959-sss/DM4 (10 mg/kg). Two weeks after the final treatment, we observed a significant reduction in tumor mass and the complete absence of circulating LGALS3BP, as confirmed by ELISA analysis of plasma samples. Finally, we developed a polychromatic flow cytometry method based on the use of 1959-PE antibody able to identify and count LGALS3BP + circulating EVs in GBM patients' blood samples.

Conclusion

Our findings strongly suggest that circulating LGALS3BP plays a critical role in GBM as both a potential biomarker and therapeutic target, warranting further preclinical and clinical validation.

EACR25-0718

Investigating the Antitumour Potential of Fucoidan with Everolimus: An *in vitro* and *in vivo* Study Focusing on ER α /Akt/mTOR Pathway Suppression

A. Elsafy¹, H. Elgohary², M. Khattab³, M. Abdollah⁴

¹National Food Safety Authority, Cairo, Egypt

²Faculty of Pharmacy, The British University in Egypt, Drug Research and Development Group, Cairo, Egypt

³Faculty of Pharmacy, Cairo University, Department of Pharmacology and Toxicology, Cairo, Egypt

⁴Faculty of Pharmacy, The British University in Egypt, Department of Pharmacology and Biochemistry, Cairo, Egypt

Introduction

Breast cancer (BC) remains one of the most prevalent cancers worldwide, with resistance and relapse posing significant challenges despite advances in therapy. This

study explores the chemomodulatory effect of fucoidan, a sulfated polysaccharide abundant in edible seaweeds, in combination with everolimus, a clinically approved mammalian target of rapamycin (mTOR) inhibitor.

Material and method

MCF-7 human BC cell line was used *in vitro*. MTT cell viability assay was used to calculate the IC₅₀ of the drugs while the scratch wound assay assessed the effect of the drug combinations on cancer cell motility. Flow cytometry was used for cell cycle analysis and Annexin V/PI apoptosis assays. *In vivo*, forty female Swiss Albino mice (23 ± 2 g) were injected intramuscularly with Ehrlich Ascites Carcinoma (EAC) cells into the hind limb. After tumour development, mice were randomly divided into four equal groups ($n = 10$): untreated control, fucoidan, everolimus, or their combination (E+F). After sacrifice, ELISA was used to evaluate various markers in the tumour tissues [1].

Result and discussion

In vitro, fucoidan synergistically reduced the IC₅₀ of everolimus from >500 nM to 76.6 nM. The scratch wound assay showed significantly lower percentage wound closure in the combination group (19.07%) compared to everolimus alone (28.13%) and control (75.65%) by day 3 ($p < 0.05$). Cell cycle analysis revealed that E+F treated cells had a significantly higher percentage of S-phase arrest (77%) and a lower percentage in G2/M (19.4%) compared to the control ($p \leq 0.0001$). The Annexin V/PI apoptosis assay showed a significant reduction in viable cells (95.56% in control versus 87.7% in E+F). Furthermore, the percentage of late apoptotic and necrotic cells were significantly higher in E+F group compared to the control group (2.8% versus 1.9% and 9.15% versus 1.97%, respectively). *In vivo*, the combination therapy significantly reduced tumour progression. Hematoxylin and eosin staining of control tumours showed extensive sheets of pleomorphic viable cells, whereas the E+F group exhibited large necrotic masses with abundant fragmented and pyknotic cancer cells. No significant weight loss was observed, indicating minimal toxicity from the given therapies. ELISA analysis of tumour tissues revealed a significant reduction in survivin, ER α , VEGF, and the downstream oncoproteins p-mTOR and p-AKT in the E+F group.

Conclusion

This study provides the first preclinical evidence supporting the efficacy of fucoidan with everolimus in BC. The promising anticancer effects appear to be mediated, at least in part, by fucoidan-induced suppression of the ER α /Akt/mTOR axis. Further investigations are required to validate these findings.

[1] All animal experimental procedures were approved by the research ethics committee of the Faculty of Pharmacy, Cairo University, in compliance with EU Directive 2010/EU/63.

EACR25-0741

Bufalin Targets Protein Translation and Cell Metabolism to Overcome Therapy Resistance in Melanoma

A. Genbauffe¹, L. Soumoy², Z. De Le Court¹, C. Salamone¹, L. Mukeba-Harchies³, J. Colet¹, F. Journé¹

¹University of Mons, Human Biology and Toxicology, Mons, Belgium

²Gustave Roussy Institute, Villejuif, France

³University of Mons, Mons, Belgium

Introduction

Melanoma is an aggressive skin cancer with frequent resistance to targeted therapies against the mutant BRAF pathway, limiting treatment options. Persister cells, an intermediate state between sensitivity and resistance, contribute to therapy escape through translation re-programming and metabolic adaptation. Bufalin, a cardiotonic steroid, has shown anti-cancer properties in melanoma by targeting the Na⁺/K⁺ ATPase α-subunit (ATP1A1). Our study investigates Bufalin effects on translation (c-MYC/eIF4A loop) and metabolism (β-oxidation, phospholipid remodeling, mitochondrial function) to evaluate its therapeutic potential.

Material and method

Bufalin effects were assessed on a panel of melanoma cell lines representing key genetic backgrounds (BRAF-sensitive and resistant to targeted therapies, NRAS, and WT). Cell viability was measured using Crystal Violet staining. ¹H-NMR spectroscopy was used to analyse global metabolic alterations, with a focus on phospholipid and amino acid metabolism. Polysome profiling was performed to evaluate translation dynamics, particularly the regulation of the c-MYC/eIF4A loop. Finally, RT-qPCR and Western Blot were used to assess the expression of β-oxidation enzymes and lipid transporters.

Result and discussion

Bufalin significantly reduced the viability of all tested melanoma cell lines. ¹H-NMR spectroscopy revealed major metabolic alterations, including amino acid depletion (alanine, glycine, asparagine, leucine), phospholipid remodeling, and mitochondrial stress. Notably, we observed a 4-fold increase in glycerophosphocholine (GPC) level and a depletion of phosphocholine and choline, suggesting a disruption in membrane homeostasis and choline metabolism. This correlated with differential expression of GPD5 and GPD6, two key regulators of the phospholipid turnover. Polysome profiling showed that Bufalin induces a global reduction in translation, driven by c-MYC down-regulation (RT-qPCR, Western Blot) and decreased eIF4A transcription (RT-qPCR), impacting the eIF4F complex. Consequently, translation of CREBBP, a key eIF4F target, was also reduced. Bufalin further inhibited β-oxidation by downregulating key enzymes (CPT1A, ACADS, ACOX) and the lipid transporter CD36. Mitochondrial function was significantly altered, as indicated by a complete depletion of pantothenate (a precursor of Coenzyme A, CoA) and a reduction in spare respiratory capacity (Seahorse analysis), suggesting a loss of metabolic flexibility and impaired energy production.

Conclusion

Buflin disrupts translation and metabolic adaptability, two key mechanisms of therapy resistance. By inhibiting c-MYC/eIF4A, it reduces protein synthesis, while its effects on phospholipid homeostasis, β-oxidation, and mitochondrial metabolism impair metabolic flexibility. These findings suggest Buflin could limit persister cell survival and help counteract resistance mechanisms in melanoma.

EACR25-0762

Novel Tamoxifen Derivatives Suppress Breast Cancer Growth and Alter Cancer-Related Gene Expression

I. S. Canitez¹, E. Aydin¹, M. Christodoulou², I. Durmaz Sahin^{1,3}

¹Koc University, Research Center for Translational Medicine (KUTTAM), Istanbul, Turkey

²University of Milan, Department of Food, Environmental and Nutritional Sciences (DeFENS), Milan, Italy

³Koc University, School of Medicine, Istanbul, Turkey

Introduction

Breast cancer (BC) is the most commonly diagnosed cancer and the leading cause of cancer-related mortality among women worldwide. In 2022, approximately 2.3 million new cases were reported, resulting in 665,684 deaths and accounting for 15.4% of all cancer-related deaths in women. Tamoxifen, a selective estrogen receptor modulator (SERM), is a cornerstone in the treatment of hormone receptor-positive (HR+) BC. However, its therapeutic efficacy is often compromised by resistance and adverse effects. Structural modifications, such as the introduction of novel functional groups, have the potential to enhance its anti-cancer properties. This study investigates the cytotoxic and anti-cancer effects of newly synthesized tamoxifen derivatives on breast cancer cells, aiming to improve therapeutic strategies for BC treatment.

Material and method

We synthesized six novel tamoxifen derivatives and assessed their cytotoxicity using the sulforhodamine B (SRB) assay in four human breast cancer cell lines (MCF-7, T47-D, SK-BR-3, MDA-MB-231) and two non-tumorigenic human breast epithelial cell lines (MCF-10A, MCF-12A). The most potent compound, identified through preliminary screening, underwent further in vitro characterization to elucidate its mechanism of action. This included cell cycle analysis via propidium iodide (PI) staining, apoptosis evaluation through Annexin V/7-AAD staining, and quantitative PCR (qPCR) analysis of key cancer-related genes.

Result and discussion

Cytotoxicity screening identified GG009 as the most potent tamoxifen derivative, exhibiting significant anti-proliferative activity in all four breast cancer cell lines, particularly MCF-7 and T47-D, while demonstrating lower cytotoxicity in normal breast epithelial cells. Further mechanistic studies revealed that GG009 induced cell cycle alterations and increased apoptotic cell populations in MCF-7 and T47-D cells. Additionally, qPCR analysis of nearly 90 genes associated with cancer progression showed that GG009 treatment downregulated several oncogenic genes linked to aggressive cancer phenotypes and poor prognosis in breast cancer.

Conclusion

Our findings highlight the promising anti-cancer role of the novel tamoxifen derivative GG009 against breast cancer cells. Gene expression analysis also suggests that GG009 may modulate key cancer-related pathways, demonstrating the need for further investigation into its mechanism of action to enhance breast cancer therapy.

EACR25-0771**Targeting Copper Availability to Enhance Thymoquinone's Cytotoxicity in Colorectal Cancer***D. Ismail¹, H. Muhtasib¹*¹*Faculty of Arts and Sciences, American University of Beirut, Biology, Beirut, Lebanon***Introduction**

Cancerous tumors have been shown to display higher levels of copper (Cu) than normal tissues. Previous studies have demonstrated that Cu can transform thymoquinone (TQ), an antioxidant phytochemical exhibiting a safe profile and remarkable antineoplastic effects against many types of cancer, into a prooxidant agent, generating reactive oxygen species (ROS) and promoting cellular death. However, the mechanism by which Cu improves the sensitivity of cancer cells to TQ remains unclear. In particular, this mechanism has not yet been elucidated in colorectal cancer.

Material and method

In this project, we investigated TQ's effect on HT-29 and HCT-116 colorectal cancer cell lines enriched with Cu to mimic in vivo conditions. We have performed MTT viability assays, Cell-cycle analysis, Apoptosis assay, Intracellular ROS measurement, and in vivo studies in NOD-SCID mice to examine the effect of TQ on Cu-associated cancer progression.

Result and discussion

In this project, we investigated TQ's effect on HT-29 and HCT-116 colorectal cancer cell lines enriched with Cu to mimic in vivo conditions. Our findings indicate that Cu sensitized HT-29 cells to TQ by enhancing its inhibitory actions leading to an improved reduction in cell viability compared to Cu-free conditions. After 24 hours of treatment, the IC₅₀ of TQ in Cu-free HT-29 cells was 111 µM which decreased significantly to 42.8 µM in their Cu-treated counterparts. In addition, under Cu-treated conditions, TQ treatment led to an enhanced G2/M arrest, a significant increase in intracellular ROS levels at 40 and 80 µM, and a higher percentage of HT-29 cells undergoing late-stage apoptosis at 40 µM, compared to Cu-free conditions. TQ also induced a time and dose-dependent inhibitory effect on HCT-116 cells, yet no difference was observed between Cu-free cells and those enriched with Cu. For that, we further aim to study the role of Cu in HCT-116 cells treated with TQ in the presence of the Cu chelator TTM. Notably, in non-cancerous FHs74Int cells, Cu supplementation did not enhance TQ cytotoxicity, suggesting a cancer-selective effect. To gain deeper insights into the Cu-TQ interaction, we will examine the impact of TQ on Cu uptake machinery and downstream signaling pathways by assessing DNA damage and evaluating the induction of apoptosis and oxidative stress. Additionally, ongoing in-vivo experiments using NOD-SCID mice aim to examine the effect of TQ on Cu-associated cancer progression.

Conclusion

Our findings demonstrate that Cu supplementation will enhance the cytotoxic effects of TQ on colorectal cancer, thereby increasing their sensitivity to this natural product. In conclusion, our study could provide an innovative therapeutic approach against colorectal cancer where we

can use the increased level of Cu to target cancer cells while sparing the normal ones.

EACR25-0779**FAM46C expression sensitizes multiple myeloma cells to PF-543-induced cytotoxicity***F. De Grossi¹, A. Miluzio², M. Mancino², S. Biffo¹, N. Manfrini¹*¹*Università degli studi di Milano, Milan, Italy*²*Istituto Nazionale Genetica Molecolare, Milan, Italy***Introduction**

FAM46C is a tumor suppressor protein initially identified in multiple myeloma (MM) and increasingly recognized for its role in other cancers. Despite its importance, research on FAM46C therapeutic potential in combination with targeted treatments remains limited. Sphingosine kinases (SPHK1 and SPHK2) are key regulators of sphingolipid signaling, a crucial pathway for maintaining cell structure and function, which is frequently deregulated in tumors. Recent evidence from our lab suggested that FAM46C expression synergized with treatment with SK1-I, a pan-SphK inhibitor. Here, we concentrated on SPHK1, the sphingosine kinase primarily associated to cancer, and explored the synergistic impact of induced FAM46C expression alongside treatment with PF-543, a specific SPHK1 inhibitor.

Material and method

We first conducted data mining in the DepMap database to determine a potential correlation between FAM46C expression and sensitivity to PF-543 in multiple myeloma (MM) cell lines. Upon identifying a correlation, we validated our findings *in vitro* by assessing cells' sensitivity to PF-543 in presence or absence of functional FAM46C expression. The results we obtained were further validated in an *in vivo* xenograft model established by injecting NOD scid gamma with OPM2 cells harbouring either wt FAM46C or the loss-of-function D90G variant in presence or absence of PF-543 administration.

Result and discussion

We found a correlation between expression of a functional FAM46C and cell sensitivity to PF-543. *In vitro*, MM cells re-expressing functional FAM46C exhibited greater sensitivity to PF-543 compared to cells expressing the loss-of-function D90G variant.

Conversely, down-modulation of FAM46C lead to a reduction of the cytotoxic efficacy of PF-543 in MM cell lines. Using our *in vivo* xenograft model we found that FAM46C-expressing MM tumors were sensitive to PF-543 while tumors harboring the D90G loss-of-function variant of FAM46C were not. Our results indicate that expression of a functional FAM46C can indeed sensitize cells to PF-543 treatment. Future studies should explore whether wt FAM46C synergizes with other SphK1 inhibitors or combination therapies, as well as the precise molecular mechanisms underlying this effect.

Conclusion

Overall, our findings indicate that FAM46C plays a crucial role in drug response, enhancing sensitivity to PF-543 in both *in vitro* and *in vivo* settings. Our results

reveal a novel synergistic interaction between FAM46C expression and SPHK1 inhibition, presenting a promising therapeutic approach for MM treatment.

EACR25-0795

An intracellular cytidine deaminase biodegrader to overcome cancer chemoresistance

M. Sorbara¹, M. Cristol¹, C. Lopez¹, M. Vienne¹, A. Faith¹, L. Ligat¹, A. Stella², O. Schiltz², P. Cordelier¹, N. Bery¹

¹Cancer Research Center of Toulouse, INSERM, Toulouse, France

²The Institute of Pharmacology and Structural Biology, CNRS, Toulouse, France

Introduction

Cytidine deaminase (CDA) is an enzyme that catalyzes the deamination of (deoxy)cytidine into (deoxy)uridine, thereby maintaining intracellular pyrimidine homeostasis. Through its enzymatic activity, CDA contributes to the resistance of cancer cells to deoxycytidine (dC) analogue-based chemotherapies, such as gemcitabine and cytarabine, in pancreatic ductal adenocarcinoma (PDAC), lung cancer, and acute myeloid leukemia (AML). While catalytic inhibitors of CDA have been developed, they exhibit off-target effects and have failed in clinical trials. Thus, alternative therapeutic strategies to inhibit CDA and overcome resistance to dC-based chemotherapies are needed. Here, we leverage the specificity of intracellular antibodies (i.e., antibodies expressed within cells) to develop an innovative approach for targeted CDA degradation.

Material and method

We designed intracellular antibody-based degraders (also known as biodegraders or bioPROTACs) to induce targeted protein degradation via the proteasome. Upon transfection or transduction, the expressed biodegrader selectively depletes its intracellular target. To develop these biodegraders, we performed a phage display selection to isolate antibodies binding to CDA, followed by a cell-based screening assay using flow cytometry to identify potent CDA biodegraders. Two lead candidates were further characterized for their efficacy, specificity, and affinity using mass spectrometry, Western blot, and surface plasmon resonance.

Result and discussion

The selected CDA biodegraders efficiently depleted endogenous CDA protein in multiple PDAC, lung cancer, and AML cell lines. Functionally, CDA biodegrader sensitized cancer cells to gemcitabine and cytarabine, reducing their IC₅₀ values and inhibiting cell proliferation through increased apoptosis. In vivo, using a cell-derived xenograft (CDX) mouse model, we demonstrated that the combination of CDA biodegrader and gemcitabine significantly inhibited pancreatic and lung tumour growth. Remarkably, we have begun developing an intracellular delivery approach for this CDA biodegrader and have demonstrated its successful in vitro delivery, effectively sensitizing PDAC and lung cancer cells to gemcitabine.

Conclusion

CDA biodegrader represents a promising and innovative strategy to overcome chemoresistance in dC analogue-

based cancer therapies. Future work will focus on optimizing the intratumoral delivery of CDA biodegrader in experimental PDAC and lung cancer models *in vivo*, with the ultimate goal of advancing these therapeutic protein towards clinical application.

EACR25-0823

dTAG-based degradation of CDK5 as a therapeutic strategy in colorectal cancer

F. Grau-Leal¹, M. Costa¹, A. Bernat-Peguera¹, I. María García-Pérez², C. Mayor-Ruiz², C. Galdeano³, V. Ruiz de Porras¹, C. Vendrell-Ayats¹, C. Queralt⁴, E. Martínez-Balibrea⁴

¹Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain

²Institute for Research in Biomedicine (IRB), Barcelona, Spain

³Institute of Biomedicine (IBUB), University of Barcelona, Barcelona, Spain

⁴Catalan Institute of Oncology (ICO), Badalona, Spain

Introduction

Colorectal cancer (CRC) remains a critical challenge due to limited therapeutic options. CDK5 has emerged as a potential target; however, its structural similarity to other CDKs complicates direct inhibition. Targeted protein degradation (TPD), which utilizes the ubiquitin-proteasome system, offers a novel approach. The dTAG system, based on PROTACs, enables specific protein degradation for functional studies *in vitro* and *in vivo*. Our aim was to lay the foundation to generate a PROTAC drug against CDK5 as a novel treatment for CRC.

Material and method

HT-29 and LoVo CRC cell lines were knocked out of endogenous CDK5 using CRISPR-cas9. FKBP12F36V-tagged CDK5 was reintroduced using lentiviral vectors. Degradation via dTAGv-1 was validated by western blot (WB) (D1F7M, Cell Signaling). Degradation of CDK5 *in vivo* was measured in subcutaneous (SC) HT-29_Nluc_CDK5dTAG and WT mock cells in BALB/c (nu/nu) ($n = 3/\text{group}$). Tumours were treated with vehicle (5% DMSO in 20% solutol/saline) or dTAGv-1 via intraperitoneal (IP) (40 or 80 mg/kg), SC (40 mg/kg), or intratumoral (IT) (40 mg/kg) administration for 3 days. Tumours were harvested on day 4, snap-frozen, and analysed for protein degradation via WB. To assess liver metastasis, HT-29_Nluc_CDK5dTAG cells were injected into the spleen of BALB/c (nu/nu) ($n = 10/\text{group}$), and metastases were tracked via bioluminescence imaging over 4 weeks (IVIS Illumina II). Mice were treated daily with 40 mg/kg dTAGv-1 or vehicle intraperitoneally. At endpoint, ex vivo fluorescence was measured, and liver samples were paraffin-embedded. Statistical analysis used was one-way ANOVA with Tukey's multiple comparison for SC and bioluminescence data, and Mann-Whitney U test for fluorescence.

Result and discussion

CRISPR/Cas9 efficiently knocked out CDK5, and FKBP12F36V-tagged CDK5 was successfully reintroduced in both cell lines. From 500 nM down to 10 nM of dTAGv-1 induced a dose-dependent degradation of CDK5, confirmed by WB. In vivo, IT administration achieved the highest degradation (5.27% \pm 2.58%, $p <$

0.01), outperforming IP and SC routes. Degradation rates for IP (40 mg/kg: 59.46% \pm 10.36%; 80 mg/kg: 40.23% \pm 8.4%) and SC (48.15% \pm 20.37%) routes showed no significant differences. All treatment groups exhibited significant protein degradation compared to vehicle ($p < 0.001$) (mean \pm SD). Metastases were significantly reduced in dTAGv-1-treated mice vs. vehicle controls as measured by bioluminescence ($3.73 \times 10^7 \pm 1.13 \times 10^7$ vs. $3.65 \times 10^8 \pm 1.15 \times 10^8$; p/s/cm²/sr, mean \pm SEM; $p < 0.05$) and fluorescence [$4.45 \times 10^8 \pm 1.59 \times 10^8$ vs. $3.68 \times 10^9 \pm 2.67 \times 10^9$; (p/s/cm²/sr)/(μ W/cm²) mean \pm SEM; $p < 0.01$], respectively.

Conclusion

The dTAG system effectively degraded CDK5 in vitro and in vivo, reducing tumour burden and metastases without observed toxicities. These findings highlight CDK5 TPD's potential as a therapeutic strategy in CRC.

Introduction

In lung cancer patients (LCPs), patient-derived organoids (PDOs) offer a valuable platform for predicting treatment responses (1). However, the successful establishment of PDO cultures, their multiomic profiling, and high-throughput drug-testing remain challenging due to the difficulty in obtaining pure tumor organoids, highlighting the need for further optimization (2).

Material and method

In this study, PDOs were generated from both primary lung cancer tissues and matched non-neoplastic tissues derived from 22 LCPs. Pathological and multiomic profiling, including methylomic analysis with Epic Array technology, was performed to assess the concordance of genetic and epigenetic landscapes, as well as histopathological features, between primary tissues and PDOs. To improve the success rate of PDO establishment, we evaluated the effects of Nutlin-3a and pan-ERBB inhibitors in eliminating outgrowing normal organoids while selectively enriching specific mutant PDOs. Furthermore, potential therapeutic vulnerabilities and resistances of PDOs were assessed through high-

throughput drug screening using a panel of 142 compounds.

Result and discussion

We generated 12 pairs of lung cancer organoids (LCOs) and matched healthy lung organoids, each validated through histopathological and molecular analyses and exhibiting diverse mutational landscapes. Histopathological and epigenetic profiling demonstrated a strong concordance between LCOs and their corresponding primary tumors. Copy number variation analysis confirmed high concordance of major mutational patterns in PDOs with primary tumors. Deconvolution of latent methylation components revealed tumor-specific epigenetic states for individual patients, which were recapitulated in the LCOs. Furthermore, epigenomic profiling allowed clear discrimination between healthy and tumor organoids, reinforcing genomic findings. Optimization with Nutlin-3a and pan-ERBB inhibitors improved the selection of mutant PDOs. High-throughput drug-screening proved feasible and led to the identification of novel therapeutic targets.

Conclusion

This study demonstrates for the first time that LCOs recapitulate the distinct epigenomic landscapes of primary tumors in addition to genomic features. By refining PDO selection and integrating multiomic analyses with high-throughput drug screening, our approach enhances the utility of LCOs as a robust platform for advancing personalized therapy in precision oncology.

EACR25-0867

Sesquiterpene Lactones Cynaropicrin and Ludartin as Potential Therapeutic Agents in Ovarian Cancer

A. Akdag¹, İ. Durmaz Şahin¹

¹Koç University, İstanbul, Turkey

Introduction

Ovarian cancer is a heterogeneous malignancy responsible for over 200,000 deaths worldwide annually. Among its subtypes, high-grade serous carcinoma (HGSC) is the most common epithelial ovarian cancer, often diagnosed at advanced stages. While platinum-based chemotherapy initially achieves high response rates, approximately 75% of patients develop resistance within five years, highlighting the urgent need for novel therapeutic strategies. This study investigates the cytotoxic potential of two natural sesquiterpene lactones, cynaropicrin and ludartin, in ovarian cancer cell lines, including chemoresistant models. We aim to evaluate their efficacy and elucidate their mechanisms of action to overcome chemoresistance.

Material and method

To identify potent natural compounds, we performed an NCI-SRB assay on ovarian and breast cancer cell lines. Cynaropicrin and ludartin were selected based on their significant cytotoxic effects. Their mechanisms of action were further explored using PI staining for cell cycle analysis, MUSE Annexin-V staining for apoptosis detection, and Western blotting for protein expression analysis.

Result and discussion

The NCI-SRB assay identified cynaropicrin and ludartin as highly effective against ovarian cancer cell lines, exhibiting low IC₅₀ values. Further analyses demonstrated that both compounds induced cell death and affected cell cycle progression.

Conclusion

Our findings suggest that cynaropicrin and ludartin promote cell death and alter cell cycle dynamics in ovarian cancer cells. Further studies are needed to elucidate their precise molecular mechanisms and therapeutic potential. These results support their development as promising candidates for ovarian cancer treatment.

Introduction

Platelets are small anucleated blood cells derived from the cytoplasmatic fragmentation of megakaryocytes in the bone marrow. Platelets play a crucial role in various physiological and pathological processes, such as hemostasis, thrombosis, tumor progression, and metastasis. Platelets and other cells have been considered attractive

drug delivery systems for cancer therapy mainly due to their superior biocompatibility, better natural targeting, high drug-loading capacity, lower immunogenicity, and good ability to cross biological barriers. Dysregulation of the NF-κB pathway is common in hematological cancers. The inhibition of this pathway by parthenolide (PRT) has shown great potential, however, its low solubility and lipophilicity have prevented its further approval for cancer treatment. This study aimed to evaluate the potential use of platelets as a drug delivery system of PRT for the treatment of B-cell malignancies in vitro.

Material and method

We used six different cell lines: 697 [B-acute lymphoblastic leukemia (B-ALL)], HG-3 [chronic lymphocytic leukemia (CLL)], Raji [Burkitt lymphoma (BL)], Farage [diffuse large B-cell lymphoma (DLBCL)], H929 and U-266 [multiple myeloma (MM)]. Fresh leuko-reduced human platelets were obtained from health volunteers at a local hospital after obtaining informed consent. PRT and doxorubicin (DOX) loading into platelets was achieved after 1 h incubation with agitation. Drug incorporation was confirmed by HPLC and immunofluorescence (IF) assays. Metabolic activity was evaluated using resazurin assay. Cell death was assessed by flow cytometry (FC) using Annexin V/7AAD double staining. Statistical significance was considered when $p < 0.05$.

Result and discussion

Our results showed that all B-cell malignancy cell lines are sensitive to PRT alone, in a time-, dose- and cell line-dependent manner, with Farage being the most sensitive ($IC_{50} = 1.5 \mu M$) and U-266 the least ($IC_{50} = 22.1 \mu M$). Additionally, PRT induced cell death by apoptosis through oxidative stress and decreased mitochondrial membrane potential. After drug incorporation, platelets were CD61+ (platelet marker), CD45- (leukocyte marker), and CD62P- (P-selectin, platelet activation marker). IF and CF proved the internalization of DOX and HPLC the internalization of PRT. Cell lines were then incubated with DOX- and PRT-loaded platelets in a 1:100 ratio for 48 h. Non-loaded platelets did not reduce the metabolic activity of cells. DOX- and PRT-loaded platelets reduced metabolic activity depending on the cell line. Specifically, PRT-loaded platelets induced more significant metabolic activity reduction in H929 cell line ($71.6\% \pm 8.4\%$, $p = 0.03$).

Conclusion

Our study showed that platelet loading might provide a new therapeutic strategy for PRT delivery, specifically to B-cell malignancies. However, more studies are needed to better understand the relevance of PRT-loaded platelets in hematological cancers.

EACR25-0889

Designer proteins to drive the targeted degradation of tankyrase

H. Kok¹, P. Rowling¹, L. Itzhaki¹

¹*University of Cambridge, Department of Pharmacology, Cambridge, United Kingdom*

Introduction

The poly(ADP-ribose) polymerases (PARPs) Tankyrase 1 (TNKS1) and Tankyrase 2 (TNKS2) (TNKS1/2) are key regulators of Wnt/β-catenin signalling and a promising drug target in cancers with hyperactive Wnt/β-

catenin signalling. TNKS1/2 contain five ankyrin-repeat clusters (ARCs) (four of which mediate substrate binding), a sterile alpha motif (SAM) domain to allow polymerisation and a catalytic PARP domain. TNKS1/2 promote Wnt/β-catenin signalling via their polymerisation and PARP activities. The consensus-designed tetratricopeptide repeat (CTPR) protein is an ultra-stable modular scaffold protein onto which new functions can be engineered by peptide ‘grafting’. Previously, a CTPR protein was functionalised by grafting a tankyrase-binding peptide (TBP) onto a loop between two CTPR units (1TBP-CTPR2). Then, a series of nTBP-CTPR2n proteins with increasing numbers of TBP loops and CTPR units (nTBP-CTPR2n) were generated. As small-molecule TNKS1/2 inhibitors and other therapeutic strategies to inhibit Wnt/β-catenin signalling have met with limited success to date, we aim to design chimeric proteins containing nTBP-CTPR2n to drive the targeted degradation of TNKS1/2 in cancer cells with hyperactive Wnt/β-catenin signalling.

Material and method

Competition fluorescence polarisation (FP) assays were carried out to measure the binding of His6-tagged nTBP-CTPR2n proteins to TNKS1 (ARC2-3) and TNKS2 (ARC4) in the presence of a fluorescently labelled TBP. Our E3 chimeras were designed with the aid of AlphaFold2 and generated by molecular cloning. HiBiT-TNKS2 and each of the E3 chimeras were transiently expressed in HEK293T cells for 24 hours before the levels of HiBiT-TNKS2 in cells were quantified using the Nano-Glo® HiBiT Lytic Detection System.

Result and discussion

His6-tagged nTBP-CTPR2n proteins are shown to bind TNKS1 (ARC2-3) and TNKS2 (ARC4), and the binding affinity increases as the number of TBPs increases. Following this, a series of E3 chimeras is created by fusing nTBP-CTPR2n to (a) speckle-type POZ protein (SPOP) which lacks its natural substrate binding domain and (b) the RING domain of tripartite motif-containing protein 21 (TRIM21). Transient expression of these E3 chimeras proved that the constructs are not cytotoxic. Co-transfection experiments demonstrated that the level of HiBiT-TNKS2 in HEK293T cells decreased by approximately 50% in the presence 2TBP-CTPR4-SPOP and TRIM21 RING-1TBP-CTPR2.

Conclusion

Chimeric E3 proteins containing nTBP-CTPR2n induce the reduction of HiBiT-TNKS2 in cells, suggesting degradation.

EACR25-0915

Use of the Novel Molecular Glue, MRT-2359 for Targeting MYC-dependent Breast Cancer

M. Tang¹, J. Crown², M. J. Duffy¹

¹*UCD School of Medicine, Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland*

²*Department of Medical Oncology, St Vincent's University Hospital, Dublin, Ireland*

Introduction

Brain cancer is a leading cause of cancer-related mortality in children, with medulloblastoma (MB) being the most common malignant type. Surgery, radio- and chemotherapy are the current standard of care (SoC); however, 30% of patients relapse or develop secondary tumors, and survivors present debilitating neurocognitive impairments from SoC. To address this existing unmet

Since MYC is one of the most frequently altered driver genes in cancer formation, it is a highly attractive target for new anti-cancer therapies. Historically, however, MYC has proved difficult to target due to the absence of a suitable crevice for binding of potential low molecular weight drugs. A promising strategy for targeting “difficult to drug” cancer targets is the use of protein degraders such as PROTACs or molecular glues. A molecular glue currently being evaluated in a clinical trial is the GSPT1 degrader, MRT-2359. Here, we show that MRT-2359 also degraded MYC and inhibited the growth of breast cancer cells in culture.

Material and method

Cell viability was determined with the MTT assay using 14 breast cancer cell lines. Induction of apoptosis was analyzed by flow cytometry using annexin V and propidium iodide (PI) staining.

Result and discussion

Using 3 breast cancer cell lines, MRT-2359 was found to degrade MYC in a concentration-dependent manner. Consistent with its ability to degrade MYC, MRT-2359 was found to inhibit the proliferation of breast cancer cell lines with IC₅₀ (half maximal inhibitory concentration) values ranging from 36.7 nM to 2 μM. Similar inhibition of cell growth was found irrespective of whether the cells were HER2-positive, estrogen receptor-positive or triple-negative. IC₅₀ values for MRT-2359 were significantly lower than those for 2 previously described MYC-MAX antagonists (for MYCi975, p < 0.0001; for MYCMI-6, p < 0.0002), i.e., MRT-2359 was a more potent inhibitor of breast cancer cell growth than either MYCi975 or MYCMI-6. In addition to the inhibition of cell growth, MRT-2359 was found to induce apoptosis in a time and concentration-dependent manner.

Conclusion

Our results suggest that MRT-2359 is a potential treatment for MYC-dependent breast cancer. Furthermore, our data provide a rationale for extending the ongoing clinical trial with MRT-2359 to breast cancer.

³*Peptomyc S.L., Barcelona, Spain*

⁴*Vall d'Hebron Institute of Oncology, Spain*

⁵*Vall d'Hebron Institute of Oncology and Peptomyc S.L., Barcelona, Spain*

Introduction

Brain cancer is a leading cause of cancer-related mortality in children, with medulloblastoma (MB) being the most common malignant type. Surgery, radio- and chemotherapy are the current standard of care (SoC); however, 30% of patients relapse or develop secondary tumors, and survivors present debilitating neurocognitive impairments from SoC. To address this existing unmet

medical need, we must develop novel therapeutic approaches. MYC is a master regulator of cellular processes and one of the most dysregulated proteins in cancer, including MB. When overactivated, it drives tumorigenesis and tumor maintenance, and until recently, MYC has been considered undruggable.

Material and method

Omomyc is a MYC dominant negative inhibitor, currently in clinical trials for adults with advanced solid tumors as an Omomyc-based mini-protein (OMO-103). With this project, we investigate the use of Omomyc as a potential therapy for pediatric MB. We examine the effect of Omomyc on inhibiting proliferation and self-renewal in vitro in patient-derived MB cells and neural stem cells, and investigate its effects on extending overall survival in vivo. In addition, we perform RNA-sequencing on Omomyc-treated MB cells to further investigate the mechanism of action, and we explore MB patient samples transcriptomic datasets to identify combinatorial treatment strategies.

Result and discussion

We show that Omomyc selectively targets MB brain tumor initiating cells by impairing proliferation and self-renewal, while sparing the human neural stem cells. Omomyc treatment induces downregulation of MYC regulated genes, cell cycle pathways, and other oncogenic pathways specific to MB. Moreover, the half-maximal inhibitory concentration was maintained between primary and matched SoC-recurrent samples. We further observed a significant survival advantage in our MB patient-derived orthotopic xenograft murine model. Lastly, we identify a suitable synergistic target for combinatorial treatment strategies.

Conclusion

Overall, our work discovers that Omomyc may be a promising therapy for a subset of MB patients with high-MYC expression, particularly at recurrence. Moreover, we have identified a combinatorial treatment strategy with synergistic effect in vitro, and next steps include its validation in vivo.

COI: LS is CEO and employee of Peptomyc, a company developing MYC inhibitory peptides. JW and LS are shareholders in Peptomyc.

EACR25-0930

A novel ribosome biogenesis inhibitor, PMR-116, displays broad spectrum efficacy in preclinical tumour models

R. Ferreira¹, K. Panov², A. Huglo³, R. Rebello³, E. Kusnadi³, M. Haddach⁴, D. Drygin⁴, R. Hannan¹, N. Hein¹, L. Furic³

¹ANU, Canberra, Australia

²Queen's University, Belfast, United Kingdom

³Peter MacCallum Cancer Centre, Melbourne, Australia

⁴Pimera Inc, San Diego, United States

Introduction

Inhibition of RNA Polymerase I, the enzyme responsible for the synthesis of ribosomal RNAs, the nucleic scaffold of ribosomes, has been proven as a novel therapeutic target as most cancer cells are “addicted” to ribosome biogenesis.

Material and method

In collaboration with Pimera Inc, we developed and tested the efficacy of a second generation RNA

polymerase I inhibitor, PMR-116, in various pre-clinical cancer models. On-target activity of PMR-116 was confirmed in peripheral blood cells isolated from patients with solid tumours enrolled in a phase I trial of PMR-116.

Result and discussion

PMR-116 potently inhibits Pol I transcription with ~200 fold higher selectivity towards Pol I compared to Pol II transcription. PMR-116 inhibits rRNA synthesis by stalling the Pol I complex at the rDNA promoter preventing promoter escape and consequently elongation. PMR-116 anti-cancer activity was evaluated against a panel of over 100 cancer cell lines representative of 20 major types of solid and haematological malignancies. This new Pol I inhibitor exhibited broad anti-proliferative and cytotoxic activity with an IC₅₀ ranging from 32–4500 nM and a median IC₅₀ of 300 nM. In contrast, cells derived from normal tissues were significantly less sensitive (IC₅₀ ranging from 6–33 μM). In vivo, PMR-116 significantly improved survival and reduce tumour burden in several preclinical models such as V_k*MYC transgenic model of indolent multiple myeloma, CT26 xenograft model of colorectal cancer, MMTV-PyMT transgenic model of metastatic breast cancer, mixed-lineage leukemia (MLL)-eleven nineteen leukemia (ENL)+Nras acute myeloid leukemia (+/-p53 mutation) and patient-derived xenografts of prostate cancer and AML. In a phase I trial of PMR-116, on-target activity of PMR-116 was observed in cells derived from the peripheral blood.

Conclusion

PMR-116 significantly reduced cancer growth in a wide range of tumor models, including GEMM, syngeneic and PDX models. PMR-116 is undergoing clinical testing in phase I in solid tumors with the objective to determine maximum tolerated dose and identify a phase II dose.

EACR25-0967

Inhibition of Translesion Synthesis (TLS) activity enhances cell death and prevents tumor growth

P. Ayiku¹, N. Barda¹, D. Tobi¹, T. Listovsky¹

¹Ariel University, Molecular Biology, Ariel, Israel

Introduction

DNA-damaging chemotherapy agents such as cisplatin have been a first line approach in cancer treatment for decades; however, their long-term success is often reduced by intrinsic and acquired drug resistance. Although the mechanisms causing drug resistance are quite distinct, they are directly connected to mutagenic translesion synthesis (TLS). The TLS pathway promotes DNA damage tolerance by supporting replication opposite to a lesion and inaccurate single strand gap filling. It has been shown that inhibiting TLS enhances cell death, reduces cisplatin resistance and the appearance of secondary tumors. Therefore, small molecule inhibition of the TLS pathway is a new promising strategy for improving cancer treatment. We recently discovered a small molecule named C#3*. C#3 directly binds to the TLS protein - MAD2L2, and inhibits TLS activity by blocking the binding site of Rev1. Therefore, the active TLS complex composed of MAD2L2-Rev1 cannot be formed.

Material and method

To evaluate c#3 synergistic activity, we used both non-transformed cell lines and cancer lines such as lung and melanoma. All cells were co-treated with cisplatin and c#3, and cell survival, DNA damage levels and TLS complex formation were evaluated. We also used purified GST-MAD2L to determine the binding affinity between MAD2L2 and c#3. Finally, we validated c#3's synergistic activity using two syngeneic mice models.

Result and discussion

In cell-based experiments, we found that co-treatment with cisplatin and c#3 sensitized various cancer cell lines, reducing cisplatin's IC₅₀ by twofold or more. Co-treatment caused a significant elevation in DNA damage levels, explaining the sensitization effect. Using diverse biochemical methods, we demonstrated that c#3 directly binds to MAD2L2 and prevents the formation of the TLS complex. Importantly, c#3 is not cytotoxic when administered alone. Using a syngeneic mouse model, we demonstrated that combined treatment of cisplatin and c#3 significantly prevented tumor growth and prevented lung metastasis.

Conclusion

Therefore, c#3's activity underlines its potential as a lead compound for developing novel TLS inhibitors for improving chemotherapy treatment, reducing the appearance of metastasis, and alleviating patients' side effects.

Optimizing Gemcitabine Delivery: HPMA Copolymer Conjugates with Controlled Drug Release and Immunomodulatory Activity

K. Běhalová¹, N. Klusová¹, M. Ivančík¹, M. Širová¹, R. Polář², T. Etrych², M. Kovář¹

¹*Institute of Microbiology of the Czech Academy of Sciences, Laboratory of Tumor Immunology, Prague, Czech Republic*

²*Institute of Macromolecular Chemistry of the Czech Academy of Sciences, Department of Biomedicinal Polymers, Prague, Czech Republic*

Introduction

Gemcitabine (Gem) is a nucleoside analogue widely used in clinical practice for treating various malignancies, including breast, lung, pancreatic, and ovarian cancers. However, its therapeutic efficacy is limited by its rapid metabolism in the bloodstream, which leads to a short half-life. To address this, we developed N-(2-Hydroxypropyl)methacrylamide (HPMA) copolymer-based Gem nanotherapeutics (P-Gem1–4) designed to protect Gem from degradation, prolong its circulation time, and enable controlled drug release. The nature of the spacer between Gem and the HPMA backbone dictates the drug release kinetics, which significantly influences the anticancer efficacy.

Material and method

We synthesized four P-Gem conjugates with different spacers: P-Gem1 (tetrapeptide GFLG), P-Gem2 (β -alanine), P-Gem3 (valeric acid), and P-Gem4 (amino-caproic acid). To evaluate their in vitro antitumor

activity, we performed [³H]-thymidine incorporation assay, Annexin V assay and Caspase-3 assay. The in vitro studies were conducted on 4T1, LL2, Panc02, Panc1, and MiaPaca2 cell lines. Furthermore, we analyzed changes in gene expression related to apoptosis, cell cycle regulation, proliferation, angiogenesis, metastasis, and immune response in 4T1 tumors using TaqMan qPCR arrays. To further investigate immune modulation, we studied the impact of treatment on immune cell populations in the spleen and tumors of Balb/c mice bearing 4T1 tumors.

Result and discussion

Our in vitro assays revealed a correlation between cytostatic and cytotoxic effect and drug release kinetics, with IC₅₀ values increasing as the drug release rate decreased. These findings confirm that the drug release rate decreases from P-Gem1 to P-Gem4. Ex vivo qPCR analysis of 4T1 tumors treated with P-Gem conjugates showed upregulation of pro-apoptotic and cyclin-dependent kinase inhibitor genes, along with down-regulation of immune-suppressive molecules. Notably, the most significant gene expression changes were observed in tumors treated with P-Gem4. Furthermore, in the spleens of treated mice, we detected a decrease in the levels of MDSC and Treg cells, particularly in those treated with the slow-releasing conjugates P-Gem3 and P-Gem4. These findings indicate that slow-release P-Gem conjugates exhibit superior anticancer activity compared to free Gem and the fast-releasing conjugates P-Gem1 and P-Gem2.

Conclusion

P-Gem conjugates demonstrated drug release kinetics-dependent cytostatic and immunomodulatory activity in vitro and ex vivo. Our results suggest that slow-release P-Gem conjugates have the potential to improve the therapeutic effectiveness of Gem, especially in hard-to-treat malignancies such as triple-negative breast cancer and pancreatic cancer.

Introduction

Multiple drugs have been approved for the treatment of hepatocellular carcinoma (HCC) in recent years. However, the clinical benefit is far from optimal, extending the survival of patients for a few months only. This is due to the complex, heterogeneous nature of different HCC patients, in which cancer cells harbor a mix of driver and passenger mutations. Understanding the characteristics of driver-specific liver cancers is fundamental in the development of effective therapeutics in the era of precision medicine. Therefore, we aim to establish a platform to overcome the current limitation of cell lines and animal models, which the effects of individual driver mutations cannot be studied in detail in the absence of passenger mutations.

Material and method

We utilized HCC tumors generated by the hydrodynamic tail vein injection (HTVI) of proto-oncogene combinations in mice together with the tumor organoid platform to study the characteristics of HCC driven by different driver mutations. Paired tissues and tumor organoids were characterised by whole exome sequencing, transcriptome sequencing, phosphoproteomics and ATAC-seq. Tumor organoids established were tested against an FDA approved anti-cancer drug library comprising over 600 drugs to identify drugs that are effective in killing HCC driven by specific driver mutation.

Result and discussion

We successfully established HCC tumor organoids with specific driver mutations (loss of TP53, Axin1, and PTEN, and CTNNB1 activating mutation in the background of MYC overexpression) and validated their gene mutations at both genomic and proteomic levels. Using a high-throughput screening approach for drug repurposing, we identified ERBB family inhibitors as potential therapeutic targets for CTNNB1 mutation-driven HCC ($\Delta 90$ CTNNB1/MYC). Multi-omics analysis through chromatin accessibility, transcriptomics, and phosphoproteomics revealed activation of the ERBB signaling pathway in CTNNB1 mutation-driven HCC via increase transcription of related genes, Egf and Tgfa, driven by transcription factor Foxa2. Activation of ERBB signaling pathway in HCC patients with CTNNB1 activating mutation was further confirmed with clinical data extracted from publicly available phosphoproteom data. Finally, using a preclinical animal model, we validated the sensitivity of CTNNB1 mutation-driven HCC towards ERBB family inhibitors.

Conclusion

In conclusion, we successfully established an HCC organoid platform that allows the study of driver-specific liver cancers in the absence of passenger mutations. We discovered ERBB family inhibitors as novel therapeutics for CTNNB1 mutation-driven HCC and elucidated the distinct pathways that potentially drive the sensitivity towards ERBB family inhibitors in CTNNB1 mutation-driven HCC. Our findings provide the foundation for future repurposing of FDA-approved drugs for the treatment of HCC patients with CTNNB1 mutation.

Nanobiotechnological engineering of M13 bacteriophage for EGFR-targeted theranostics

P. Costantini¹, M. Nigro¹, E. Turrini², R. Saparetti³, M. Di Giosia³, L. Ulfo¹, M. Sollazzo¹, A. Porcelli¹, M. Calvaresi³, A. Danielli¹

¹*Università di Bologna, Department of Pharmacy and Biotechnology, bologna, Italy*

²*Università di Bologna, Department for Life Quality Studies, Bologna, Italy*

³*Università di Bologna, Department of Chemistry G. Ciamician, bologna, Italy*

Introduction

Bacteriophages, especially the M13 filamentous phage, are gaining attention as nanomedicine platforms due to their low immunogenicity, efficient penetration of biological barriers, safety profile and targeting capabilities. Here, we present the development of a novel theranostic platform using the M13 phage.

Material and method

The acquired tropism of M13D12 was demonstrated through single and co-culture experiments using EGFR-positive and EGFR-negative cell lines. The targeting specificity of the engineered phage was assessed by fluorescence microscopy and flow cytometry. To functionalize the phage for photodynamic therapy (PDT), photosensitizers (Rose Bengal - RB) or fluorescent dyes (CF594) were chemically conjugated onto the pVIII proteins of M13D12. Conjugation efficiency was confirmed via spectrophotometric analysis, SDS-PAGE, and fluorescence spectroscopy. The biological activity of M13D12-RB was evaluated in both 2D and 3D cell culture models. The cytotoxic effect following light irradiation was assessed using standard viability assays. Tumor penetration and cell viability after PDT was evaluated also on ex-vivo sample derived from patient with ovarian cancer. For in vivo validation, EGFR-positive tumor-bearing mice were injected intratumorally with M13D12-RB, followed by laser irradiation and tumor regression was monitored over time.

Result and discussion

Chemical conjugation of photosensitizers and fluorescent dyes onto the pVIII proteins of M13D12 was successfully achieved without altering the phage's targeting properties. In single and co-culture experiments, the engineered phage demonstrated selective binding and internalization in EGFR-overexpressing cells, confirming its acquired tropism. Upon irradiation, M13D12-RB exhibited potent photodynamic killing activity in both 2D and 3D cell cultures, effectively eliminating EGFR-positive cells at picomolar concentrations of nanovector. In 3D tumor spheroids, the phage successfully penetrated the core and induced complete disaggregation of the cytoarchitecture upon light exposure. Ex vivo tumor models further confirmed the deep penetration and selective cytotoxicity of M13D12-RB. In vivo studies demonstrated significant tumor regression following laser irradiation, validating the therapeutic potential of the phage-based PDT approach.

Conclusion

This study demonstrates the potential of engineered M13 bacteriophages as precise and versatile platforms for

targeted cancer therapy, addressing key limitations of PDT through enhanced tumor targeting. While the system was specifically developed for EGFR-overexpressing cancers, its modular design allows for adaptation to other tumor markers, offering a powerful and customizable solution to overcome side effects and drug solubility challenges, enabling the targeted treatment of diverse cancer variants.

CircRNA-mediated inhibition of miRNA-454 as a novel therapeutic strategy in prostate cancer

H. Borchardt¹, R. Kudchi¹, S. Hüttelmaier², O. Rossbach³, A. Aigner^{1,4}

¹Leipzig University, Rudolf-Boehm-Institute for Pharmacology and Toxicology, Clinical Pharmacology, Leipzig, Germany

²Martin Luther University Halle, Institute of Molecular Medicine (IMM), Halle, Germany

⁴Comprehensive Cancer Center Germany (CCCG), Site Leipzig, Leipzig, Germany

Introduction

Prostate cancer is one of the most common cancers, causing high mortality rates in men. Since existing drugs are associated with side effects and often do not show long-term efficacy, there is an eminent need for novel therapeutic approaches. Certain miRNAs have been shown to be aberrantly up- or downregulated in tumors and to exert oncogenic or tumor suppressive functions. This may provide a basis for therapeutic intervention, by aiming at miRNA inhibition or miRNA replacement. The role of miR-454 in prostate cancer has been described ambivalently so far, with both, tumor suppressive and promoting functions.

Material and method

Our study aimed to comprehensively explore the role of miRNA-454 in prostate cancer. Two approaches were investigated: miR-454 replacement through reintroduction of miR-454 mimics, and miR-454 inhibition by using circRNAs as miR-454 sponge.

Result and discussion

Especially miR-454 inhibition by introducing a miR-454-specific circ-RNA led to a significant induction of cell death and reduced proliferation in different 2D and 3D models. Moreover, colony formation assays (CFA) revealed substantial effects on the cells' ability to form colonies, indicating decreased tumorigenic potential. In some cases, miR-454 replacement exerted tumor cell-inhibitory effects as well. In an *in vivo* therapy study in prostate xenograft-bearing mice, the therapeutic application of miR-454-specific circRNAs formulated in polymeric nanoparticles for RNA delivery led to tumor inhibitory effects.

Conclusion

These results demonstrate the functional relevance of miRNA-454 and establish miR-454 as a promising potential target in prostate cancer. The dual approach of either replacing or inhibiting miRNA-454 provides flexibility in treatment design and may offer personalized

options based on individual patient profiles. Finally, the circ-RNA mediated miR-454 sponging was identified as the more powerful strategy for miRNA inhibition and treatment of prostate cancer cell *in vitro* and *in vivo*.

KA103, a novel targeted toxin for Head and Neck Cancer

S. Castaneda-Zegarra¹, I. Kristine-Aukrust¹, K. Berg¹, A. Longva¹, A. Weyergang¹

¹Institute for Cancer Research, Norwegian Radium Hospital, Oslo University Hospital, Department of Radiation Biology, Oslo, Norway

Introduction

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer in the world, with over 878,000 new cases diagnosed and over 440,000 deaths in 2020. Despite the heterogeneity of HNSCCs, it has been found that the transmembrane protein epidermal growth factor receptor (EGFR) is overexpressed in nearly 90% of cases, making it a potential therapeutic target. The EGFR monoclonal antibody cetuximab is the only targeting drug approved for this indication. However, intrinsic and acquired resistances provide considerable limitations for treatment efficacy.

Material and method

The anticancer properties of targeting molecules can be enhanced by linking them to a toxin, generating a targeting toxin (TT). Moreover, we have designed and recombinantly produced KA103, a novel EGFR-targeted fusion protein based on EGF and gelonin, a ribosome inactivation protein toxin (RIP).

Result and discussion

Here, we show that KA103 has similar efficacy as gelonin in a cell-free reticulocyte system but exerts targeted cytotoxicity, as shown in EGFR-positive and negative cell lines. Moreover, KA103 is highly effective against EGFR-expressing HSCC *in vitro*, especially against cetuximab-resistant SCC040 cells, indicating KA103 to overcome cetuximab resistance. In addition, *in vivo* data depicts that KA103 induces SCC040 tumor growth delay without detecting severe toxicity. Furthermore, we have established that fluorescently labeled KA103 can be used to evaluate *in vivo* biodistribution, showing the highest labeled KA103 uptake retention at the tumor.

Conclusion

In conclusion, our findings show that KA103 production is highly reproducible and induces EGFR-targeted toxicity in HNSCC cell lines. In addition, KA103 promotes tumor growth delay in HNSCC models without general toxicity and with high KA103 uptake at the tumor. The presented results warrant further preclinical evaluation of KA103.

Introduction

Prostate cancer (PCa) remains one of the most diagnosed and life-threatening malignancies in men, despite advances in therapy. High recurrence rates and drug resistance in PCa have been attributed to a subpopulation of slowly dividing and dormant cancer cells known as PCa stem cells (PCSCs). Consequently, developing novel therapeutic strategies to target PCSCs and improve PCa management is a critical priority. Imipridones are a class of structurally related compounds with demonstrated anticancer activity across various solid and hematological cancers in preclinical models and clinical trials (phase I–III). Among these, ONC201, the first-in-class imipridone, has shown promising in vitro and in vivo efficacy and progressed to a phase I clinical trial for PCa. However, the anticancer potential of its derivatives, ONC206 and ONC212, remains unexplored in the context of PCa. Thus, this study investigates the antitumor effects of ONC206 and ONC212 at the functional and molecular levels using two-dimensional (2D) and three-dimensional (3D) in vitro PCa models. Furthermore, it evaluates the potential synergistic effects of imipridones with conventional PCa therapies, focusing on patient-derived organoids (PDOs) for clinically relevant insights.

Material and method

The effects of ONC206 and ONC212, relative to ONC201, were assessed using 2D in vitro assays for cell proliferation, viability, and migration on two human PCa cell lines, DU145 and PC3, representing different disease stages. Moreover, the 3D sphere formation and propagation assays were employed to evaluate the potency of these imipridone derivatives in targeting PCSCs.

Result and discussion

ONC212 was the most potent imipridone in inhibiting 2D PCa cell growth, viability, and migration. Notably, ONC212 more effectively targeted PCSCs in 3D assays compared to ONC201.

Conclusion

This study highlights ONC212 as a promising therapeutic candidate for targeting PCSCs, potentially improving PCa management by overcoming tumor resistance and recurrence.

EACR25-1056

Incorporation of disulfide bond into interleukin-2 for enhancing stability, solubility and therapeutic efficacy

W. Chuang¹, M. Shih¹, Y. Chang²

¹NCKU, Biochemistry and Molecular Biology, Tainan, Taiwan

²Biochemistry and Molecular Biology, Tainan, Taiwan

Introduction

Interleukin-2 (IL-2) is a prototypically pleiotropic cytokine that promotes T-cell proliferation, survival and differentiation. It plays a crucial role in regulating immune responses and maintaining immune homeostasis and regulates natural killer (NK) cell natural lethality. In this study, we showed that the introduction of disulfide

bonds and human serum albumin (HSA) into IL-2 can significantly improve its receptor specificity, thermal stability, and solubility.

Material and method

IL-2 mutants and variants were expressed in Pichia pastoris and CHO systems and purified to homogeneity. CTL-L2 cell proliferation and CIK assays used to study their activities. DSC was used to determine the thermostability of IL-2 and its variants. X-ray crystallography was used to determine 3D structures of IL-2 mutants.

Result and discussion

We showed that the incorporation of disulfide bond into IL-2 exhibited 2.2-fold increase in activity, and HSA-cytokines expressed in ExpiCHO exhibited higher activity than that expressed in Pichia pastoris. Differential scanning calorimetry was used to analyze the thermostability of IL-2 and its C125S, C125A, C125L, C125S/K43C/T111C, C125A/K43C/T111C, and C125L/K43C/T111C mutants, and their Tm values were 57.12, 48.36, 49.39, 64.64, 60.61, 66.47 and 82.24 oC. The results showed that the C125S and C125A mutations caused the decrease in their thermostability. In contrast, the incorporation of the K43C/T111C disulfide bond into C125S, C125A, C125L mutants increased the Tm values of 12.25, 17.08, and 17.60 oC, leading to higher stability. To confirm the formation of disulfide bond, 3D structure of the C125S/K43C/T111C mutant was determined by X-ray crystallography. The analysis showed that two disulfide bonds (C43-C111 and C58-C105) were formed. IL-2 mutant was found to be effective in inducing the cytotoxicity effect of PBMCs against HepG2-GFP cell line.

Conclusion

In summary, we have successfully engineered IL-2 by the introduction of disulfide bond, mutation and HSA fusion protein. We anticipate that IL-2 variants from this study can be used for autoimmunity and cancer therapies.

EACR25-1060

In vivo delivery of gemcitabine through HPMA copolymer conjugates: slow drug release kinetics is crucial for potent antitumor activity

K. Behalova¹, N. Klusova¹, M. Ivancik¹, M. Sirova¹, R. Pola², T. Etrych², M. Kovar¹

¹Institute of Microbiology of the Czech Academy of Sciences, Laboratory of Tumor Immunology, Prague, Czech Republic

²Institute of Macromolecular Chemistry of the Czech Academy of Sciences, Department of Biomedicinal Polymers, Prague, Czech Republic

Introduction

Gemcitabine (Gem) is the anticancer drug with potent cytostatic activity causing inhibition of DNA synthesis through so called masked chain termination. Gem is used alone or in combination with paclitaxel bound to albumin nanoparticles for the first-line treatment of pancreatic carcinoma, for the treatment of metastatic or inoperable breast carcinoma (in combo with paclitaxel), advanced or metastatic non-small cell lung carcinoma (in combo with cisplatin), ovarian carcinoma (in combo with carboplatin) and advanced or metastatic bladder cancer (in combo

with cisplatin). The most unfavorable pharmacological features of Gem are very extremely short half-life and possible metabolic inactivation via cytidine and deoxy-cytidine deaminases.

Material and method

We have designed, synthesized and characterized a set of linear N-(2-hydroxypropyl)methacrylamide (HPMA) copolymer conjugates (Mw ~40–45 kDa, D <1.1, HD ~8 nm) bearing Gem (12–15 wt%) covalently linked through amide bond using primary amine group of Gem to extend its half-life in circulation and protect it from cytidine and deoxycytidine deaminases degradation. Four conjugates with different spacers between the HPMA copolymer backbone and Gem were prepared with the aim to study the effect of Gem release kinetics on the in vivo drug half-life and antitumor activity in several mouse tumor models.

Result and discussion

Our HPMA copolymer-gemcitabine conjugates showed different rate of Gem release: P-Gem1 > P-Gem2 > P-Gem3 > P-Gem4 in PBS and in mouse sera, though the release rate was generally faster in sera comparing to PBS. The cytostatic activity in vitro correlated with drug release kinetics, i.e. the faster release the lower IC₅₀. P-Gem conjugates provided also much longer half-life in the circulation upon i.v. administration. Maximum tolerated dose in mice perfectly correlated with Gem release kinetics with fastest conjugate being the most toxic one. Particularly P-Gem3 and 4 showed superior antitumor activity in mouse 4T1 breast, LL2 lung and MiaPaca2 pancreatic carcinoma models in comparison to Gem.

Conclusion

P-Gem conjugates extensively prolonged the half-life of the Gem in the circulation. Our in vivo results suggest that slow-release P-Gem conjugates have the potential to improve the therapeutic efficacy of the Gem in several hard-to-treat carcinomas.

Zebrafish Avatar-test predicts tumor response to chemotherapy in Breast Cancer: A co-clinical study for personalized medicine

R. Mendes¹, J. Ribeiro², H. Gouveia³, C. Rebelo de Almeida¹, M. Castillo-Martin¹, M. José Brito⁴, E. Batista³, M. João Cardoso³, F. Cardoso³, R. Fiori¹

¹*Champalimaud Centre for the Unknown, Experimental Clinical Research, Lisbon, Portugal*

²*Gustave Roussy, Département de Médecine Oncologique, Paris, France*

³*Champalimaud Clinical Center, Breast Unit, Lisbon, Portugal*

⁴*Champalimaud Clinical Center, Service of Pathology, Lisbon, Portugal*

Introduction

Breast cancer (BC) is highly heterogeneous at clinical, histological, and molecular levels. Tumors are classified

into subtypes based on receptor status (ER, PR, HER2), along with stage and grade, guiding targeted treatments and improving outcomes. Despite these advances, chemotherapy remains the mainstay for high-risk early BC and metastatic disease. However, with multiple equivalent options available, treatment efficacy varies, and no test exists to determine the most effective therapy for an individual. As a result, treatment selection relies on physician experience, toxicity, and patient preference rather than direct tumor sensitivity, potentially leading to unnecessary toxicities and ineffective treatment.

Material and method

We developed a fast in-vivo BC therapy screening test using the zebrafish patient-derived xenograft model (zAvatars), where in-vivo results can be obtained in just 10 days. This assay relies on the injection of fluorescently labeled tumor cells from core needle biopsies, surgical specimens, pleural effusions and ascites into zebrafish embryos. Tumor behavior, and therapy response are then assessed after 2–4 days of treatment. To determine the predictive value of the BC zAvatars we performed a pre-clinical study, where zAvatars were treated with the same therapy as the donor-patient and their response to therapy was compared.

Result and discussion

We successfully established zAvatars across all five molecular BC subtypes, at different disease stages, and with varying tumor aggressiveness. Notably, zAvatars derived from ER-positive tumors retained ER expression and key BC biomarkers such as ER, PR, and Gata3, while preserving the tumor microenvironment. Our data show a 100% concordance (18/18 cases) between zAvatar-test and the corresponding patient's clinical response to treatment. Additionally, we observed that the majority of zAvatars derived from patients with early-stage BC did not form micrometastases, whereas all zAvatars from advanced-stage BC displayed micro-metastases. This suggests that zAvatar metastatic potential reflects donor tumor stage. However, given the small sample size and the long latency of BC recurrence, further studies are needed to determine whether the zAvatar model can reliably predict metastasis risk. If validated, this model could significantly enhance BC treatment management by refining risk stratification. The presence of micrometastases in zAvatars may help identify patients requiring more intensive adjuvant therapy and closer surveillance, whereas their absence could suggest a lower risk of recurrence.

Conclusion

The zAvatar model accurately predicted patient treatment responses across diverse therapeutic regimens (single-agent and combination therapies), disease stages and BC subtypes. These findings highlight its potential as a powerful, versatile and personalized in-vivo assay for optimizing BC treatment strategies.

EACR25-1110

Effect of RID-A proteins in cachexia and tumor metabolism

M. Fornaro¹, A. Brossa¹, F. Antico², M. Cedrino³, C. Riganti⁴, B. Bussolati¹

¹Department of molecular biotechnology and Health Sciences, Molecular Biotechnology Center, University of Turin, Turin, Italy, Turin, Italy

²Molecular Biotechnology Center, University of Turin, Turin, Italy, Turin, Italy

³i3T Scarl University of Turin, Via Nizza 52, Turin, Italy, Turin, Italy

⁴Department of Oncology, University of Turin, Turin, Italy

Introduction

RID-A proteins play an important role in tumor metabolism and cachexia, which is a complex multi-factorial syndrome characterized by a progressive decrease in muscle mass in cancer patients. In particular, these proteins exhibit unique enzymatic properties related to amino acid metabolism and play a vital role in accelerating the hydrolysis of amines and imines. One of the important functions of RID-A is to neutralize the highly reactive metabolite 2-aminoacrylate, which has the potential to disrupt various metabolic pathways, and hydrolyze it into pyruvate. Additionally, alterations in tumor metabolism significantly contribute to the progression and severity of cachexia. Therefore, understanding the detoxifying power of RID-A proteins may offer insights into modulating tumor metabolism and alleviating cachexia symptoms.

Material and method

We used an *in vivo* cachexia model in BALB/c mice using a subcutaneous injection of C26 murine colon carcinoma cells. Mice were treated once a week for two weeks with 2.5 mg/kg of UK114 protein, belonging to RID-A family, synthesized from mouse (MS UK) sequences. Mice were sacrificed at >10% weight loss. At the time of sacrifice, tumors and organs were weighed. The gastrocnemius was analyzed for muscle fibers area. Further analysis was carried out for the expression of atrogens (atrogin-1, musa-1, murf-1, overexpressed in case of cachexia). Furthermore, an analysis of tumor metabolism was carried out, quantifying the levels of pyruvate and lactate on tumor specimens. A trichrome staining was performed to assess tumor angiogenesis, and the expression of vascular endothelial growth factor (VEGF) was evaluated through real-time PCR.

Result and discussion

UK114 treatment induced a slowdown in tumor growth and an improvement in cachectic symptoms, with less weight loss. Furthermore, an improvement in the cachectic state was observed at the level of the muscle fibers as well as at the molecular level. Pyruvate levels were increased and could possibly be implicated in the inhibition of HDAC, whose levels slightly decreased. In parallel, lactate levels decreased. A reduction in the number of intratumoral vessels was also observed, which was confirmed at the molecular level by the reduced VEGF levels.

Conclusion

Our study evaluated the detoxifying effect of UK114 on neoplastic cachexia and demonstrated how UK114 induces a reduction of tumor volume, angiogenesis and an amelioration of muscle fibers. Further studies will better assess the effect on tumor metabolism.

EACR25-1112

Targeting BCKDK to Overcome Paclitaxel Resistance in Breast Cancer: A Novel Therapeutic Approach

G. Mohamed¹, A. Richardson²

¹Mid Yorkshire Trust, General medicine, Wakefield, United Kingdom

²Keele University, School of pharmacy, Stoke-On-Trent, United Kingdom

Introduction

Breast cancer is one of the most common malignancies globally, with chemotherapy, including paclitaxel, being a cornerstone of treatment. However, paclitaxel resistance is a major clinical challenge, limiting treatment success and leading to relapse. Branched-chain keto-acid dehydrogenase kinase (BCKDK), a key regulator of branched-chain amino acid metabolism, was identified in siRNA screens as a potential contributor to paclitaxel resistance. This study evaluates BCKDK as a novel therapeutic target to overcome chemotherapy resistance in breast cancer.

Material and method

Paclitaxel-resistant MCF7 breast cancer cells were cultured under standard conditions and treated with paclitaxel alone or in combination with experimental BCKDK inhibitors, CMVA and DCBC. These inhibitors were identified through prior siRNA screening and chemical design to specifically target BCKDK activity. Protein extraction was performed using RIPA buffer, followed by quantification using the BCA assay. Western blotting was used to confirm BCKDK overexpression in resistant cells. For functional evaluation, BCKDK protein was purified using His-tag affinity chromatography, followed by ion-exchange chromatography, and characterized via HTRF kinase assays to assess enzymatic activity and inhibitor potency. HTRF assays measured the ability of CMVA and DCBC to block ATP binding to BCKDK. Cell viability was assessed using the SRB assay and CellTiter-Glo, comparing paclitaxel monotherapy versus combination treatments. Statistical analysis was performed to evaluate synergy using Combination Index (CI) calculations.

Result and discussion

BCKDK was overexpressed in paclitaxel-resistant MCF7 cells compared to sensitive cells. Combining paclitaxel with BCKDK inhibitors significantly reduced cell viability compared to either treatment alone. HTRF assays confirmed potent inhibition of BCKDK kinase activity by novel inhibitors, interfering with ATP binding. The data suggest that BCKDK promotes survival mechanisms that contribute to chemoresistance. By blocking BCKDK, cells become more susceptible to paclitaxel-induced apoptosis, indicating a synergistic therapeutic potential.

Conclusion

BCKDK is a promising therapeutic target in paclitaxel-resistant breast cancer. Dual targeting of BCKDK and microtubule dynamics via paclitaxel offers a novel strategy to overcome chemotherapy resistance. This approach could improve treatment outcomes for patients with resistant breast cancer.

EACR25-1129**Preclinical Evaluation of T-DXd and AZD1390 in HER2-Low, Triple-Negative Breast Cancer Models**

L. Bless¹, H. Wischmann¹, J. Crown², D. Collins¹, N. Conlon¹

¹Dublin City University, Dublin, Ireland

²St Vincents Univeristy Hospital, Dublin, Ireland

Introduction

Triple-negative breast cancer (TNBC) is defined by its deficiency of oestrogen-, progesterone-, and HER2 receptors; Antibody-drug conjugates (ADCs) provide a novel treatment strategy. Trastuzumab deruxtecan (T-DXd), a HER2-directed ADC with a topoisomerase I-inhibiting payload, is approved in both HER2-amplified and HER2-low (HER2 IHC1+ and IHC2+, without amplification) breast cancer. 30–40% of TNBC tumours show HER2-low status and may benefit from T-DXd. Additionally, disruption of the DNA damage response pathway is a promising approach. Ataxia-telangiectasia mutated (ATM) kinase is a major player in double-strand break repair response (DSB). Inhibitors of ATM kinase enhance the effect of DSB inducers, like topoisomerase inhibitors, resulting in DNA damage accumulation. Therefore, there is strong rationale for investigating T-DXd plus ATM inhibition in TNBC.

Material and method

We investigated T-DXd plus the ATM inhibitor AZD1390 in eight TNBC cell lines with HER2-low expression. Target expression patterns of the TNBC panel were examined via Western Blotting. Proliferation was assessed by 5-day matrix based acid phosphatase assay in 2D conditions. Synergy scores were calculated with Combenefit Software. 3D cell culture models were created with the RASTRUM Bioprinter. Cell viability was assessed after 7-day drug treatments in 3D cell models via CellTiter-Glo® 3D Cell Viability Assay. Synergistic combinations were further characterised by investigation of Caspase 3/7 apoptosis induction via live-cell imaging and assessment of DNA damage induction via high-resolution fluorescence microscopy.

Result and discussion

All tested cell lines were sensitive to T-DXd and AZD1390 single agents (SA) below the achievable peak plasma concentration. Both drugs were combined across clinically relevant concentrations. No antagonism was observed. Moreover, strong synergy was observed across concentrations in the entire cell line panel. Three cell lines were chosen for further investigation, MDA-MB-468, MDA-MB-231, and HCC1937, which all showed high responsivity to the combination treatment. 3D-cell models of these cells were created using the RASTRUM Bioprinter. T-DXd [5 µg/ml] and AZD1390 [2.5 µM] were given as SA or in combination over a 7-day treatment. T-DXd plus AZD1390 synergistically reduced cell growth in 3D models, and cell viability was significantly reduced in combinations compared to single-agent ADC ($p \leq 0.05$). Response to treatment in 3D culture conditions mirrored 2D cultures, with no difference in drug sensitivity. Live-cell imaging revealed that combination treatment synergistically increased apoptotic

cell death compared to SA (T-DXd [5 µg/ml], AZD1390 [2.5 µM]).

Conclusion

T-DXd plus AZD1390 shows significant synergy in growth reduction of cancer cells in 2D and 3D culture conditions, even at low nanomolar concentrations. This combination shows promising results to enhance target therapies for TNBC patients.

EACR25-1144**Datopotamab deruxtecan plus PARP inhibition is highly synergistic in 2D and 3D ovarian cancer models**

L. Stockmann¹, Y. Li¹, L. Tschirner¹, E. Moehrle¹, J. Crown², N. Conlon¹

¹Life Sciences Institute, Dublin City University, Dublin, Ireland

²Department of Medical Oncology, St Vincent's University Hospital, Dublin, Ireland

Introduction

Ovarian cancer (OC) is the 5th leading cause of cancer deaths in women worldwide. Datopotamab deruxtecan (Dato-DXd) is a novel TROP2-directed antibody-drug conjugate (ADC) with a topoisomerase I inhibitor payload that is FDA approved for the treatment of hormone receptor-positive, HER2-negative breast cancer that has been previously treated with systemic therapy. TROP2 is commonly overexpressed in OC, making it an attractive therapeutic target. PARP inhibitors (PARPi) target the DNA damage response (DDR) and are used to treat different cancer types, especially cancers with DDR deficiency. Olaparib is a PARPi approved for the treatment of several different cancer types. Saruparib (AZD5305) is a PARP1-selective inhibitor in clinical development. This preclinical study examines the efficacy of Dato-DXd alone and in combination with PARPi olaparib and saruparib in OC cell lines in 2D and 3D culture conditions.

Material and method

This study utilised a panel of six OC cell lines with different BRCA2 mutation and HR deficiency status. The anti-proliferative effects of Dato-DXd and olaparib/saruparib were determined using a 5-day acid phosphatase assay. Synergism was assessed using Combenefit software with the Loewe additivity model. Induction of caspase 3/7 activation, a marker of apoptosis, was tested with single agents and combinations using kinetic, fluorescent microscopy with the Incucyte S3 imaging system. Internalisation rates of Dato-DXd were monitored using the Incucyte. Single agent and combination anti-proliferative effects were assessed in 3D bioprinted culture conditions utilising the RASTRUM platform. Comparison of image-based analysis and metabolic readout with Cell Titer Glo 3D was carried out.

Result and discussion

The combinations of Dato-DXd + olaparib/saruparib were highly synergistic in the TROP2-high cell line models tested with no antagonism observed (concentration range 0.008–5 µg/mL and 0.625–10 µM, respectively). Lower levels of synergy were still observed in TROP2-low cell lines. Treatment response of PEO1 and PEO4 cells was further functionally characterised.

Dato-DXd in combination with PARPi synergistically induced apoptosis. Combinations were effective in 3D models of cancer growth with comparable efficacy to 2D models. Dato-DXd is internalised in a time- and concentration-dependent manner in TROP2 expressing cells. Internalisation assays revealed increased levels of Dato-DXd internalisation when combined with olaparib.

Conclusion

This study provides a preclinical rationale for the clinical investigation of Dato-DXd in combination with PARPi olaparib or saruparib in OC.

EACR25-1165

Reactivating the crosstalk between natural killer and tumour cells in non-small cell lung cancer (NSCLC) patients with no actionable mutations

E. Cavassi¹, M. Bedeschi¹, V. Vouret-Craviari^{2,3}, A. Ciarrocchi⁴, B. Donati⁴, N. Marino¹, A. Tesei¹

¹Biosciences Laboratory, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

²Université Côte d'Azur, CNRS, INSERM, IRCAN, Nice, France

³IHU RespirERA, Nice, France

⁴Laboratory of Translational Research, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

Introduction

Significant progress has been made in treating non-small cell lung cancer (NSCLC) over the past two decades, with the discovery of oncogenic driver mutations facilitating personalized targeted therapies. However, managing advanced NSCLC without targetable drivers remains a clinical challenge and, for most patients, chemotherapy is still the standard of care. Advanced-stage tumours seem to have lost the crosstalk with the immune system, leading to poor responses to therapies. Natural killer (NK) cells act as a first line of defence against tumours and recent studies have shown that chemotherapy can enhance the innate immune system activity. Moreover, it is known that NK infiltrating solid tumours can improve patients' survival. Notably, NK cells expressing the P2X7 receptor (P2X7R) within the hypoxic tumour core exhibit an anergic state, which is hypothesized to be reversible through modulation of P2X7R expression. Our study investigates the potential of antimetabolite drugs to reactivate the NK-mediated immune response in NSCLC, focusing also on the combination of standard chemotherapy with P2X7R antagonists.

Material and method

A549 and NK-92 cell lines were acquired from ATCC and maintained following manufacturer's protocol, either for 2D and 3D experiments. Cytotoxicity and apoptosis were investigated through MTS assay (CellTiter 96® AQueous One Solution Cell Proliferation Assay, Promega) and Annexin V assay (Annexin V-FITC Apoptosis Detection Kit). Gene expression profile was determined by qRT-PCR (Applied Biosystems™ 7500 Real-Time PCR System) and Droplet Digital PCR (QX600 Biorad). NKs infiltration was evaluated on 3D tumour spheroids using confocal microscopy. Digital

Spatial Profiling (GeoMx®, Nanostring) was performed on FFPE tissues to study the immune microenvironment.

Result and discussion

We set up a co-culture model with A549 and NK cells to study the crosstalk after treatment with gemcitabine, pemetrexed and cisplatin. In addition we combined the antimetabolite drugs with AZ10606120, a P2X7R antagonist. Our results showed that gemcitabine and pemetrexed enhance NK-mediated cytotoxicity against A549 cells: we observed augmented apoptosis rate and increased expression of NK activating ligands, suggesting a significant NKs activation. Concerning the P2X7R role in modulating NKs activity, we observed an increased NK cell infiltration into 3D tumour spheroids treated with AZ10606120. Moreover, the combination of AZ10606120 with gemcitabine and pemetrexed demonstrated enhanced cell killing efficacy compared to chemotherapeutics alone. Finally, the combination resulted also in the activation of NK receptors, which was not observed with the drugs alone.

Conclusion

Our findings suggest that standard chemotherapy may indirectly enhance anti-tumour immunity by reactivating NK cells, also in combination with P2X7R antagonists, providing a potential avenue for improving therapeutic outcomes in NSCLC.

EACR25-1173

Harnessing the impacts of a G-quadruplex ligand in liposarcoma: Implications for MDM2 oncogene targeting and DNA damage-mediated immunomodulatory effects

E. Naghshineh¹, B. Tosoni², S. Pasquali¹, N. Zaffaroni¹, S. Neidle³, S. Richter², M. Folin¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Department of Experimental Oncology, Milan, Italy

²University of Padova, Department of Molecular Medicine, Padova, Italy

³University College London, School of Pharmacy, London, United Kingdom

Introduction

Well-differentiated (WD)/dedifferentiated (DD) liposarcomas (LPS), which account for ~60% of all liposarcomas, are characterized by the amplification of the 12q13–q15 region, with consequent aberrant expression of MDM2. Patients have limited therapeutic options, particularly in advanced disease, and their outcomes remain largely unsatisfactory. Hence, there is an unmet need to identify and validate WD/DDLPS-specific actionable targets for developing novel biology-driven therapies. G-quadruplexes (G4s), non-canonical secondary structures that can form in G-rich nucleic acid sequences, have recently been identified and characterized within the inducible MDM2 P2 promoter. In addition, G4 ligand-induced DNA damage can lead to the formation of cytoplasmic micronuclei (MN). Spontaneous rupture of the MN envelope allows its recognition by receptor cyclic GMP-AMP synthase (cGAS), initiating the cGAS-STING-Interferon axis downstream of DNA damage. Therefore, we explored the

potential of inhibiting MDM2 expression by targeting its G-quadruplex structures with small-molecule G4 ligands while also assessing the immunomodulatory effects of the G4 ligand in DDLPS cell lines.

Material and method

We used in-house developed patient-derived LPS cell lines and normal pre-adipocytes. CUT&Tag and RNA-seq were performed to analyze the abundance of G4s in the different cell lines. Cell viability, RT-PCR and Western blot assays, siRNA inhibition and nascent transcript analysis were used to assess the effects of QN-302 treatment on different patient-derived DDLPS cell lines.

Result and discussion

A G4 ligand, QN-302, significantly impaired the growth of DDLPS cells in a dose-dependent manner. We found that DDLPS cell lines showed enhanced G4 formation and that QN-302 activity strikingly paralleled cell-specific G4 abundance. QN-302-mediated MDM2 G4 stabilization at the P2 inducible promoter prevented polymerase progression from the constitutive P1 promoter in DDLPS cells, thereby inhibiting the formation of full-length MDM2 transcripts. This resulted in the accumulation of the tumor suppressor protein p53. In addition, QN-302 induced DNA damage in DDLPS cells and increased MN, with a significant fraction marked by γ -H2AX. Concomitantly, exposure to QN-302 led to the upregulation of a subset of interferon-stimulated genes (ISGs), including IFI27, IFI44L, IFI6, ISG15, and MX2, along with an increased release of certain cytokines, particularly IL-6.

Conclusion

We have identified a novel therapeutic strategy to inhibit MDM2 expression and promote p53 reactivation in DDLPS. Additionally, QN-302-induced DNA damage may activate the cGAS-STING pathway in DDLPS cell lines. The G4 multiple-target modality holds potential for further development through the rational design of drug combinations with standard chemotherapy, targeted therapies, and immunotherapy.

EACR25-1186

Targeted Treatment of Solid Tumors with BRAF Fusions

J. Samuel¹, S. Verma², E. Winquist², S. Climans³, C. Cacciotti⁴, G. Boldt², J. Raphael²

¹*Western University, Medicine, London, Canada*

²*Western University, Medical Oncology, London, Canada*

³*Western University, Neurology, London, Canada*

⁴*Western University, Pediatrics, London, Canada*

Introduction

BRAF fusions are uncommon driver alterations in a range of cancers. While the BRAF V600E mutation is a recognized target for the BRAF inhibitors, BRAF fusions have not yet been investigated as potential targets for treatment in most cancers, and there is limited literature available to help guide treatment for patients with these fusions with targeted therapies, including direct BRAF inhibitors and downstream MEK inhibitors. This systematic review aims to summarize the available literature on the targeted treatment of solid tumors harboring a BRAF fusion.

Material and method

We conducted a systematic review to delineate the reported efficacy, response rates and survival outcomes, of targeted treatment in patients with a solid cancer harboring a BRAF fusion. PubMed, Embase, and Cochrane CENTRAL were searched between 2014 and 2024. Data were extracted to assess the details of efficacy.

Result and discussion

A total of 37 studies involving 113 patients with BRAF fusion-positive cancer who underwent targeted therapies were included. Most of these studies were case reports and case series ($n = 31$, 84%), with four clinical trials (11%) that were either phase I or phase II. The review included various cancer types, with central nervous system (CNS) cancers, including gliomas and pilocytic astrocytomas, being the most common ($n = 66$, 58%), followed by melanoma ($n = 20$, 18%) and non-small cell lung cancer (NSCLC) ($n = 9$, 8%). Other cancers ($n = 18$, 16%) included sarcoma ($n = 7$), genitourinary ($n = 2$) and colorectal ($n = 1$). Among the BRAF fusion gene partners, KIAA1549 was the most frequent ($n = 62$, 55%), followed by SND1 ($n = 6$, 5%) and AGK ($n = 4$, 4%). The targeted therapies used were varied, with MEK inhibitors being used in most patients, selumetinib ($n = 36$, 32%), followed by trametinib ($n = 34$, 30%), as well as, binimetinib and cobimetinib. BRAF and pan-RAF inhibitors used included dabrafenib, vemurafenib, tovotafenib and belvarafenib. The response rates were reported for 103 patients, with 2% achieving a complete response ($n = 2$), 46% showing a partial response ($n = 47$), and 22% exhibiting stable disease ($n = 23$). Objective response rate in NSCLC, sarcoma, melanoma and CNS tumors was 88%, 57%, 52% and 41% respectively. Data on survival outcomes was limited.

Conclusion

In conclusion, there is limited data on the efficacy of targeted therapy in solid tumors with a BRAF fusion, with most evidence coming from case reports/series, alongside a few phase I/II trials. While BRAF fusion-positive cancers show varying yet promising responses to BRAF and/or MEK inhibitors, the effectiveness may vary with histology. Given the rarity of these fusions, there is a clear need for international collaboration and innovative trial designs, such as basket and platform trials, to assess targeted treatment strategies more effectively and improve outcomes for these patients.

EACR25-1193

Synthetic Danshen Compound Inhibits Adipogenesis, Promotes Adipocyte Browning, and Induces G1 Cell Cycle Arrest While Suppressing Tumor Cell Migration and Invasion in Prostate Cancer Cells

E. Cheng¹, H. Ku², C. Cheng²

¹*Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Department of Medical Education, New Taipei City, Taiwan*

²*Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical*

Foundation, Department of Pediatrics, New Taipei City, Taiwan

Introduction

Prostate cancer (PCa) is the most prevalent cancer among men in developed countries, with its increasing incidence strongly linked to the rising prevalence of obesity and metabolic syndrome. Our previous studies have shown that the synthetic Danshen compound (SDC) can enhance ATF3 expression, inhibit adipogenesis and lipogenesis, and promote adipocyte browning. While both native and synthetic Danshen compounds have been observed to influence the growth and metastasis of PCa cells, the precise mechanisms underlying their actions remain unclear.

Material and method

This study aimed to investigate whether SDC affects the growth, migration, and invasion of PCa cells by modulating cell cycle and epithelial-to-mesenchymal transition (EMT)-related pathways. Androgen-dependent LNCaP cells and androgen-independent DU-145 and PC-3 cells were used as PCa models. We assessed the effects of SDC on these processes.

Result and discussion

Our findings revealed that SDC significantly reduced cell proliferation in all three PCa cell lines in a dose-dependent manner, as measured by the BrdU assay. The colony formation assay demonstrated a dramatic decrease in colony numbers following SDC treatment, further indicating its anti-tumor effects on PCa cells.

Mechanistically, SDC induced G1 cell cycle arrest by inhibiting the expression of key regulators, including CDK4/CDK6, Cyclin D1/Cyclin D3, and Myc. Moreover, SDC suppressed cell migration and invasion and reduced matrix metalloproteinase (MMP) activity in PCa cells. These effects were associated with the inhibition of AKT/S6 signaling and a reduction in N-cadherin protein expression, highlighting its impact on EMT-related pathways.

Conclusion

In conclusion, this study demonstrates that SDC exhibits potent anti-tumor activity by targeting multiple pathways involved in cell cycle regulation, migration, and invasion. In addition, SDC can promote periprostatic adipose tissue browning via suppressing the microenvironment of cancer progression. These combined effects thus suggest that SDC could serve as a promising therapeutic agent for the treatment of prostate cancer.

Introduction

Current approaches to precision oncology have been dominated so far by genomics. However, studies have generally shown that cancer patients who receive genomic testing do not always benefit from a genomic precision medicine strategy. This revealed the interest to explore additional approaches, such as functional precision medicine, a strategy by which living patient tumor cells, represented in patient-derived tumor-derived model, are exposed to therapies and response is measured to predict clinical response. In this context, the recent advent of Patient-Derived Tumor Organoids (PDTO) offers promising opportunities to facilitate personalized treatment strategies. Here we studied the feasibility of performing PDTO-based functional assays in ovarian and Head and Neck Squamous Cell Carcinoma (HNSCC) patients to evaluate their predictive potential for clinical purposes.

Material and method

We established a panel of 37 long-term PDTO models from ovarian cancer patients and 24 long-term PDTO from HNSCC patients. Histological and molecular profiles of PDTO were compared to patient tumor using immunohistochemical analyses and global approaches (CGH array and transcriptomic profiling). PDTO models were exposed to standard treatments for ovarian cancer and HNSCC, and response was assessed using viability assay. To further define the Homologous Recombination (HR) status of ovarian PDTO, we performed a functional assay evaluating the ability of PDTO to initiate HR (RECAP test) using automated histo-imaging quantitative analysis of RAD51 foci, as well as an NGS analysis based on the sequencing of an HR-related genes panel to obtain a genome instability score (GIS).

Result and discussion

We demonstrated that PDTO mimicked histological and expression of tumor markers of paired tumors. Moreover, non-negative matrix factorization approach revealed that PDTO recapitulated the transcriptomic profile of the cancer component from their sample of origin. Exposure of PDTO to the different treatments showed that PDTO exhibit heterogeneous responses. Interestingly, response of PDTO to cisplatin was correlated to prognosis of HNSCC patients while response of PDTO from high-grade serous ovarian carcinoma to carboplatin recapitulated patient response to first-line treatment. Additionally, the detection of HRD phenotype of PDTO using functional assay was associated with the results of the HRD test Genomic Instability Scar (GIScar).

Conclusion

These results provide further evidence of the potential interest of PDTO as relevant models for preclinical research as well as for functional precision medicine.

EACR25-1242**Assay development for addressing drug resistance mediated by fibroblasts in ER+ breast cancer***E. Rodriguez-Tomás¹, F. Massai², M. Vallin², A. Östman¹*¹*Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden*²*Karolinska Institutet, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden***Introduction**

Identifying new drug targets to overcome therapy resistance in ER+ breast cancer is essential for enhancing patient survival and quality of life. Cancer-associated fibroblasts have been suggested as therapeutic targets for overcoming treatment resistance in ER+ breast cancer, given their ability to influence cancer cells via the secretion of signaling molecules, matrix proteins, and immune evasion mechanisms. Here, we establish a co-cultured-based high-throughput screen format to identify drug candidates that either inhibit the pro-tumoral effects of fibroblasts or overcome fibroblast-mediated treatment resistance.

Material and method

This assay utilizes a co-culture format incorporating MCF-7 and BJhTERT cell lines to effectively model ER+ breast cancer cells and human immortalized fibroblasts, respectively. Both cell lines were transfected with lentiviruses to express fluorescent proteins – mCherry in MCF-7 cells and GFP in BJhTERT cells. The cells were cultured in DMEM and seeded at different densities and ratios in mono- and co-culture into 384-well plates using a Multidrop liquid dispenser. At 5, 16, and 24 hours post-seeding, some plates were fixed with 4% PFA and stained with Hoechst nuclear dye, while others were treated with a selective estrogen receptor modulator (SERM) or left untreated as controls. Twenty-four hours after treatment, the plates were fixed, imaged, and analyzed using an Operetta CLS high-content analysis system. The analyses were conducted by quantifying MCF-7 and BJhTERT cell numbers based on Hoechst, GFP, and mCherry signals.

Result and discussion

Optimal cell densities and ratios in 384-well plates were identified as 500 MCF-7 cells and 1000 BJhTERT cells per well in both mono- and co-culture. Sixteen hours post-seeding was found to be the most suitable time to initiate treatment and observe fibroblast-driven growth effects. During this period, MCF-7 cells in monoculture exhibited a fold change of 1.3, indicating a 30% increase in cell numbers relative to the initial count. In co-culture with fibroblasts, the fold change was 1.9, reflecting a 90% increase and significantly greater cell growth than in monoculture, highlighting the growth-promoting effect of fibroblasts on MCF-7 cells. Tamoxifen administration at a concentration of 20 µM led to a significant reduction in MCF-7 cell numbers, with a 63% decrease in monoculture compared to 38% in co-culture. This indicates that the drug was more effective at inducing cell death in MCF-7 cells grown alone than in those co-cultured with fibroblasts, demonstrating the protective influence of fibroblasts.

Conclusion

Our co-culture-based assay format is well-suited to reveal the influence of fibroblasts on drug resistance in ER+ breast cancer cells. Furthermore, this model system will enable us to identify new fibroblast-related drug targets through high-throughput screening.

EACR25-1246**Anisomelic Acid Suppresses HPV-Driven Tumor Growth with Potential TEAD2 Targeting: Evidence from a Xenograft Model and Proteomics***N. Delshad¹, P. Paul¹, J. Rantala², J. Eriksson¹*¹*Åbo Akademi University and Turku Bioscience Centre, Cell Biology, Turku, Finland*²*Misvik Biology, Turku, Finland***Introduction**

Despite widespread vaccination programs, human papillomavirus (HPV) remains one of the leading causes of cancers, with a rising incidence of head and neck squamous cell carcinoma, emphasizing the need for new approaches. In our previous studies, we have shown that treatment of HPV-positive cells with Anisomelic Acid (AA) led to the degradation of the E6 and E7 onco-proteins of HPV16, the primary drivers of HPV-mediated oncogenicity. In the current study, we aimed to evaluate the in vivo efficacy of AA and identify its targets.

Material and method

We evaluated the efficacy and safety of AA in a murine xenograft model using HPV16-positive SiHa cells inoculated in Hsd Nude Foxn1nu mice. Following tumor establishment, mice received daily subcutaneous AA injections or placebo for 10 days. Tumor size was measured weekly during the study and ex vivo, and toxicity was assessed through body weight monitoring, histopathological analysis of liver, kidneys and spleen, complemented by blood biochemical analysis. To identify potential AA targets, we conducted a proteome integral solubility alteration (PISA) assay coupled with multiplexed quantitative proteomics via tandem mass spectrometry (MS/MS) on AA treated SiHA cells. Additionally, we performed computational docking simulations (Schrödinger, Glide) to explore AA's potential binding modes within target proteins. We also treated hippo pathway-dependent cell lines, (NCI-N87 and NCI-H23) with AA, and analyzed their dose-response curves.

Result and discussion

AA treatment inhibited tumor growth compared to the placebo group, without any observable toxicity. Body and organ weights remained within normal range, and histological analyses of the liver, kidneys, and spleen revealed no pathological changes despite minimal changes in alkaline phosphatase (ALP) and Globulin. Quantitative proteomic analysis identified TEAD2 as a potential target of AA. In addition, computational docking simulations on potential targets suggested that AA binds to TEAD2 with a docking score comparable to existing TEAD inhibitors. The binding appears to be stabilized by a salt bridge between AA carboxylate group and LYS389, along with a hydrogen bond involving ASN405. The dose-response curves for NCI-N87 and

NCI-H23 cell lines treated with AA yielded IC₅₀ values of 5.8 μM and 3 μM, respectively, showing the effectiveness of AA and providing more evidence supporting its TEAD inhibitory effects.

Conclusion

Anisomelic Acid (AA) effectively inhibited tumor growth in an HPV positive xenograft model without observable toxicity. Proteomics, computational analyses and in vitro screening suggest TEAD2 as a potential target. Further validation of AA's mechanism of action, particularly its role in TEAD inhibition and E6 and E7 degradation, is necessary. Future studies should explore AA's efficacy, alongside existing TEAD inhibitors in additional HPV positive models to strengthen its potential for clinical translation.

³Erasmus University Rotterdam, Experimental Oncology, Rotterdam, Netherlands

⁴University Hospital Wales, ECMC Cardiff, Cardiff, United Kingdom

⁵Cardiff University, School of Pharmacy and Pharmaceutical Sciences, Cardiff, United Kingdom

Introduction

Metastatic prostate cancer (mPC) remains the leading cause of mortality among prostate cancer patients, largely due to resistance to conventional treatments, including androgen/AR-targeted therapy (ARTT). The NF-κB signalling pathway is frequently up-regulated in PC/mPC, but current inhibitors face tolerability issues. As a key NF-κB regulator, BCL3 represents a promising therapeutic target. Our well-tolerated BCL3 inhibitor (BCL3i), TNAT-101, has shown potential in modulating NF-κB signalling, making BCL3 a strong candidate for novel therapeutic interventions. This study aims to investigate the role of BCL3 in tumour progression/ARTT-resistance and assess the therapeutic potential of TNAT-101.

Material and method

To examine BCL3 in prostate homeostasis and tumorigenesis, we employed genetically engineered mouse models (GEMMs) using both functional genetic (Bcl3 deletion) and pharmacological (BCL3i) approaches in high-risk/locally advanced PC (hrlPC) GEMMs. To assess the impact of BCL3 loss on ARTT sensitivity, we utilised a panel of human hrlPC/mPC cell lines (AR+/AR-/ARmut/ARamp) and GEMM-derived organoids with varying degrees of enzalutamide sensitivity.

Functional assays and molecular characterisation were performed to determine BCL3's role in ARTT response. Additionally, TNAT-101 efficacy was evaluated in multiple mPC patient-derived xenografts (PDX), and RNA-Sequencing was conducted to elucidate BCL3i

mechanisms and identify potential biomarkers of treatment sensitivity.

Result and discussion

Our findings show that BCL3 is dispensable for normal prostate homeostasis in vivo, yet its involvement in NF-κB signalling correlates positively with tumour progression in PC GEMMs, reinforcing its potential as a therapeutic target. TNAT-101 significantly reduced tumour burden in two castration-resistant mPC PDX models (CU-PC01 and PC2400), whereas PC-3 xenografts remained resistant. Molecular characterisation of PC2400 and CU-PC01 tumours, including RNA-Sequencing, revealed significant transcriptional alterations, including changes in WNT-related signalling genes. Additionally, TNAT-101 treatment in PTEN-deficient hrlPC GEMM-derived organoids ex vivo reduced proliferation and increased apoptosis, supporting its therapeutic potential in early-stage hrlPC. So far, BCL3i or BCL3 knockdown in our panel of cell lines revealed no impact on proliferation or viability but significantly affected stem cell function.

Conclusion

These results indicate that BCL3 drives PC/mPC growth and highlight BCL3-targeted therapy as a promising treatment for advanced PC. Ongoing investigations are exploring the role of BCL3 in prostate homeostasis, tumorigenesis and ARTT resistance to determine when TNAT-101 treatment would be the most effective, ultimately aiming to improve survival outcomes and patient care.

EACR25-1302

PTPN2/PTPN1 inhibition induces tumor eradication in ALK-positive lymphoma by triggering a combination of ALK-induced oncogenic stress and immune responses

M. Rubin¹, M. Maccagno¹, M. Maggiore¹, A. Pistone¹, A. Macioce¹, R. Tagliero¹, G. Arena¹, M. Russo¹, C. Voena¹, R. Chiarle¹

¹University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy

Introduction

Oncogenic fusions of the anaplastic lymphoma kinase (ALK) gene drive a subtype of anaplastic large cell lymphoma (ALCL), leading to the constitutive activation of ALK that triggers downstream oncogenic pathways such as MAPK/ERK, JAK/STAT, PI3K/AKT to promote cellular proliferation and survival. We recently discovered PTPN2 and PTPN1 phosphatases as two direct regulators of ALK phosphorylation, that is crucial to provide an optimal signaling in lymphoma cells: any alteration of ALK activation may reduce the cellular fitness. In this context, PTPN2 and PTPN1 are dependence genes in ALK+ ALCL with a mechanism that is not fully elucidated yet.

Material and method

ALK+ and ALK- ALCL cell lines were treated in vitro with the ALK inhibitor crizotinib (TKI) or the PTPN2/PTPN1 phosphatase inhibitor ABBV-CLS-484 (AC484) with increasing concentrations at various time points. Viability and cell cycle were analyzed by flow cytometry and CellTiter-Glo. ALK and downstream oncogenic signaling activation were assessed by Western Blotting.

In vivo studies were performed by injecting murine ALK+ ALCL cells into syngeneic BALB/c mice or by engrafting human ALK+ ALCL cell lines or patient-derived xenografts (PDXs) in NSG immunodeficient mice. Mice were treated with TKI or AC484. Tumor growth was evaluated by caliper or imaging, and residual tumor cells were assessed by histology and immunohistochemistry. Anti-ALK CD8+ T cell immune responses were measured by flow cytometry.

Result and discussion

AC484 induced a rapid hyperphosphorylation of ALK and its downstream mediators in all murine or human ALK+ ALCL cell lines, an effect that is opposite to the blockade of ALK and downstream signaling obtained with ALK TKIs. AC484 promoted apoptotic and DNA damage responses, although with kinetics delayed compared to TKI. ALK- ALCL and PTPN1/PTPN2 knock-out ALK+ lymphoma cells were insensitive to AC484, highlighting the specificity of AC484 for ALK and PTPN1/PTPN2. AC484 induced apoptosis in ALK+ ALCL cells that became resistant to TKI, suggesting its use as a therapeutic option for untreatable TKI-resistant ALCL. In vivo, AC484 promoted a marked reduction of tumor growth in human ALK+ ALCL grafted into NSG mice. Remarkably, AC484 induced a complete eradication of ALK+ lymphoma cells injected s.c. or i.v. in immunocompetent mice, concomitant to a potent increase of the anti-ALK CD8+ T cell immune response.

Conclusion

We propose AC484 as one of the first drugs that exploits oncogenic signaling amplification, instead of blockade, as a novel therapeutic approach. AC484 markedly amplifies ALK signaling resulting in oncogenic stress and anti-tumor activity selectively in ALK+ ALCL even if resistant to ALK TKI. In addition, AC484 strongly boosts anti-ALK immune responses suggesting that the immune modulating activity of AC484 could contribute to its curative potential.

EACR25-1318

The Superior Therapeutic Potential of Curcumin-Loaded Zinc Oxide Nanoparticles Against Bladder Cancer

Z. Salhab¹, R. El Kurdi¹, A. Yehya^{2,3}, F. Ghalmouche³, D. Patra¹, W. Abou-Kheir³

¹American University of Beirut, Chemistry, Beirut, Lebanon

²University of Montpellier, Institute of Human Genetics, Montpellier, France

³American University of Beirut, Anatomy, Cell Biology, and Physiological Sciences, Beirut, Lebanon

Introduction

Bladder cancer (BC) is one of the most common cancers globally, and while cystectomy remains the gold standard for treatment, it significantly impairs patients' quality of life. Bladder-preserving therapies like chemotherapy, immunotherapy, and novel agents are promising but are limited by severe side effects and high recurrence rates. The latter are mainly encountered due to the non-selective targeting of conventional treatments and tumor heterogeneity. Turmeric curcumin has been proven to have strong anticancer activity, but its clinical efficiency

is hindered by poor bioavailability. Nanotechnology in zinc oxide nanoparticles (ZnO-NPs) has shown to be a great approach to enhance drug delivery and therapeutic efficiency. This study aims to emphasize the possible application of zinc metal oxide in conjugation with curcumin in the eradication of BC cells.

Material and method

The study aims to synthesize and optimize ZnO-NPs with curcumin for improved therapeutic activity against BC. Anticancer activity of ZnO-NPs, curcumin, and their conjugates will be compared *in vitro* by utilizing 2D and 3D BC cell models including human bladder transitional cell carcinoma cell lines UC3 and T24, immortalized uroepithelial cell line SV-HUC-1, and BC patient-derived organoids. Cytotoxicity will be assessed by MTT and Trypan Blue assays, while migration, invasion, and oxidative stress effect will be assessed by wound healing, transwell invasion, and nitroblue tetrazolium assays. Apoptosis and cell cycle distribution will be monitored by flow cytometry. Additionally, cancer stemness will be explored by sphere formation assays, while immunofluorescence, qRT-PCR, and Western blot analysis will reveal important molecular alterations.

Result and discussion

ZnO-NPs were synthesized using the co-precipitation process and the formation was confirmed using X-ray diffraction. Scanning electron microscopy revealed aggregation of nanoparticles, and Energy-dispersive X-ray showed the presence of Zn and O. Additionally, we succeeded in establishing BC patient-derived organoids indicating their feasibility for use in future cancer research.

Conclusion

This study suggests that ZnO may enhance the anticancer activity of curcumin, potentially improving therapeutic outcomes in BC patients.

EACR25-1321

The RUVBL1/2 Complex: An Actionable Molecular Target in Bladder Cancer

B. Akdemir¹, S. Eriş¹, N. Kaygusuz¹, E. Çakiroğlu¹, G. Karakülah², S. Şentürk¹

¹Izmir International Biomedicine and Genome Center, Genomics and Molecular Biotechnology, Izmir, Turkey

²Izmir International Biomedicine and Genome Center, Biomedicine And Health Technologies, Izmir, Turkey

Introduction

Bladder cancer is a common malignancy in urology, marked by a high recurrence rate and limited treatment strategies. This highlights the need for novel biomarkers and therapeutic targets. The RUVBL1/2 complex, consisting of RUVBL1 and RUVBL2 and functioning as a AAA+ ATPase, plays a crucial role in various cellular mechanisms. Dysregulation of RUVBL1/2 has been implicated in cancer, with studies showing that both genetic and pharmacological inhibition can suppress tumorigenic properties. However, the specific contribution of the RUVBL1/2 complex to bladder cancer remains largely unexplored.

Material and method

A genome-wide CRISPR/Cas9 screening using the Brunello library in J82 and RT4 cell lines identified

RUVBL1 and RUVBL2 as druggable vulnerabilities in bladder cancer. To investigate the role of the RUVBL1/2 complex in tumor progression, CRISPR/Cas9-mediated depletion and pharmacological inhibition were employed. Functional analyses included proliferation, BrdU incorporation, cell cycle and apoptosis, 2D clonogenic and 3D soft agar anchorage-independent growth assays, migration and invasion, and DNA Damage and Replication Stress assays. Additionally, the effects of pharmacological inhibition were assessed across these assays, emphasizing its therapeutic potential.

Result and discussion

Genetic depletion or pharmacological inhibition of the RUVBL1/2 complex using the selective inhibitor CB-6644 significantly impaired cell proliferation, survival, and 3D anchorage-independent growth, leading to cell cycle arrest and increased apoptosis. Mechanistically, these effects were accompanied by a reduction in migration and invasion capacities, supported by elevated DNA damage, replication stress, and alterations in key molecular markers, further highlighting the therapeutic potential of targeting RUVBL1/2 in bladder cancer.

Conclusion

Our findings indicate a significant reliance of bladder cancer on the RUVBL1/2 complex, emphasizing its potential as both a biomarker and a therapeutic target. The functional and mechanistic roles of RUVBL1/2 in tumor progression warrant further investigation, particularly in the context of its cellular and molecular interactions. Future studies exploring these pathways will provide deeper insights into the contribution of RUVBL1/2 to bladder cancer pathogenesis and may aid in the development of targeted therapeutic strategies.

Cold-pressed lingonberry (*Vaccinium Vitis-idaea*) extract inhibits proliferation, invasion and glycolysis of oral carcinoma cells

T. Onali¹, K. Korelin¹, A. Al-Samadi¹, A. Kivimäki², A. Halahlah³, W. Wahbi¹, O. Eriksson-Rosenberg⁴, R. Korpeala², T. Salo¹

¹Helsinki University, Department of Oral and Maxillofacial diseases, Helsinki, Finland

²Helsinki University, Department of Pharmacology, Helsinki, Finland

³Helsinki University, Department of Food and Nutrition, Helsinki, Finland

⁴Helsinki University, Department of Biochemistry and Developmental Biology, Helsinki, Finland

Introduction

Berry phytochemicals, such as polyphenols, show anti-cancer effects and may prevent or inhibit progression of oral cavity carcinoma. Our aim was to investigate the anticancer activity of cold-pressed lingonberry extract (LBE) on oral cancer.

Material and method

Four different cell lines were tested for proliferation and energy metabolism: primary oral tongue carcinoma (SCC25), lymph node metastatic oral tongue carcinoma (HSC-3), HPV-16 transfected, dysplastic oral keratinocytes (DOK) and normal gingival fibroblasts (NGF). Cell

cultures were treated with lingonberry extract (LBE, 0.1%, 1% and 2%) in culture media, with and without pH-adjustment. Cell proliferation was measured after 72 hours with CyQuant direct assay. Cellular energy metabolism, including glycolysis (extracellular acidification rate) and mitochondrial respiration (oxygen consumption rate), were measured after 48 hours of LBE treatment. Additionally, proliferation and apoptosis of the malignant cell lines were investigated over 48 hours with live cell imaging assays. Invasion length and area were measured over 72 hours in a spheroid model of the metastatic HSC-3 cell line.

Result and discussion

LBE inhibited proliferation of malignant and dysplastic cells, but not NGF. Similarly, LBE inhibited glycolysis in the malignant and dysplastic cell lines but had no effect on NGF. The pH-adjusted LBE inhibited cellular proliferation of oral carcinoma cells (SCC25 and HSC-3) but did not affect proliferation of NGF or DOK. LBE increased mitochondrial respiration in SCC-25 and HSC-3 but decreased it in the non-malignant cells. LBE and pH-adjusted LBE inhibited similarly the invasion of metastatic HSC-3, but LBE had a pronounced effect on proliferation compared to the pH-adjusted extract.

Conclusion

Cold-pressed lingonberry extract inhibited proliferation and invasion of oral carcinoma, possibly by targeting cellular energy metabolism.

Introduction

Pancreatic cancer (PanC) remains one of the most lethal malignancies, with a 5-year survival rate of only 5%, highlighting the urgent need for novel treatment strategies. The introduction of epoxide and oxime functions in the steroid backbone has been shown to have increased cytotoxicity in several types of cancer cell lines. Given the significant burden of PanC, we aimed to assess the anticancer potential of newly synthesised steroid derivatives with oxime and epoxide groups in several PanC cell lines.

Material and method

The compounds OX1, EP2OX and OX4, along with their corresponding parent compounds P1, OX2 and P4 were designed, synthesised and evaluated for their cytotoxicity in three PanC cell lines, MIA PaCa-2, PANC-1, and Hs 766T through the SRB assay, 48h after treatment with the compounds (1 to 75 μ M). Additionally, cell viability, cell death profile, cell cycle alterations and mitochondrial membrane potential were evaluated by flow cytometry.

Result and discussion

The compounds were successfully synthesised following known methodologies for the synthesis of oximes and epoxides. In general, all steroid derivatives decreased MIA PaCa-2, PANC-1 and Hs 766T cancer cells proliferation in a dose-dependent manner. The most sensitive cell line to the three compounds was MIA PaCa-2 with IC₅₀ values of 7.70 μ M (OX1), 2.36 μ M (EP2OX) and 15.01 μ M (OX4). In contrast, in general, the parent compounds exhibited significantly lower cytotoxicity in all the PanC cell lines studied, compared to their corresponding derivatives. Such fact proves that the introduction of epoxide and/or oxime functions increased the cytotoxic potential of these compounds. Additional flow cytometry studies with EP2OX (the most active compound) revealed that it was able to decrease MIA PaCa-2 cancer cell viability, causing cell death by necrosis at higher doses. This was accompanied by a cell cycle blockage at phase G2/M and mitochondrial membrane dysfunction.

Conclusion

EP2OX exhibited a cytotoxic effect driven by necrotic cell death. These findings highlight the need for further investigation into its mechanism of action and selectivity, paving the way for the development of novel therapeutic candidates for PanC treatment.

Unveiling the Therapeutic Potential of Tick Salivary microRNAs in Cancer Treatment

J. Peña-Martín¹, J. Medina-Muñoz¹, C. Grinán-Lisón¹, P. Graván¹, C. del Val¹, H. Boulaiz¹, M. Kotsyfakis², M. Hackenberg¹, J. Marchal¹

¹University of Granada, Granada, Spain

Introduction

MicroRNAs (miRNAs) are key regulators of gene expression, influencing diverse cellular processes including tumorigenesis. While endogenous miRNAs have been extensively studied in cancer, exogenous miRNAs from non-human sources remain largely unexplored. Recent findings suggest that tick salivary miRNAs possess regulatory potential in host cells, with possible implications in cancer therapy. Here, we investigate the impact of a set of tick-derived miRNAs (designated miR-X, miR-Y, miR-Z, and miR-W) on melanoma and pancreatic cancer models, aiming to elucidate their functional role and therapeutic potential.

Material and method

Synthetic miRNA mimics were transfected into A-375 (melanoma), BxPC-3, and MIA PaCa-2 (pancreatic cancer) cells. RNA sequencing (RNA-Seq) and small RNA sequencing (small-RNASeq) were performed in A-375 assessing miRNA stability and differential gene expression. In silico target prediction and gene enrichment analysis identified miRNA targets and affected pathways. Functional assays, including viability (alamarBlue™), apoptosis (Annexin V/PI staining), and cell cycle analysis (PI staining by flow cytometry), RT-qPCR, and Western Blotting were performed in all three cell lines.

Result and discussion

Small-RNASeq confirmed successful miRNA delivery, with stable expression over 24 hours. RNA-Seq identified over 7,000 DEGs, with 81.4% of stable downregulated DEGs corresponding to predicted miRNA targets. Functional enrichment analysis highlighted pathways related to MAPK signaling, apoptosis, and cell cycle regulation. Both A-375 and BxPC-3 (BRAF-mutated) showed moderate metabolic inhibition, while MIA PaCa-2 (KRAS-mutated) exhibited the strongest response, with miR-Y reducing metabolic activity by 90% and increasing apoptosis by 1.83-fold. Cell membrane damage observed via electron microscopy suggested a non-classical cell death mechanism. Molecular validation confirmed Rcc-1, a nuclear factor linked to cell cycle regulation, as a direct miR-Y target, with 93.4% transcript and 16.4% protein reduction.

Conclusion

Our findings demonstrate that tick salivary miRNAs exert regulatory effects on cancer cells, impairing tumor cell survival through modulation of oncogenic pathways. The strong cytotoxicity of miR-Y in KRAS-mutated MIA PaCa-2 cells, along with the moderate metabolic inhibition observed in BRAF-mutated A-375 and BxPC-3 cells, suggests a potential interaction with the MAPK signaling pathway, a key regulator of proliferation and survival in many cancers. These results position exogenous miRNAs as promising candidates for innovative cancer therapies, warranting further exploration in preclinical models.

Boronated derivatives with a carborane cage, sulfamido group, and Gd-DOTA for B/Gd-NCT with Carbonic Anhydrase IX inhibition

S. Rakhsan¹, A. Lanfranco¹, D. Alberti¹, P. Renzi¹, A. Zarechian¹, N. Protti², S. Altieri², S. Geninatti Crich¹, A. Deagostino¹

¹University of Turin, Torino, Italy

²University of Pavia, Pavia, Italy

Introduction

Mesothelioma is a malignant neoplasm of mesothelial cells primarily caused by asbestos exposure and is highly aggressive. A multi-therapeutic approach is essential to improve treatment outcomes and prevent recurrence. Boron/Gadolinium Neutron Capture Therapy (B/Gd-NCT), combined with Carbonic Anhydrase IX (CA)

inhibition, offers a promising strategy. NCT is a binary radiotherapy using thermal neutron capture by nuclides (mainly 10B and 157Gd) to target malignant tumors, aiming to destroy cancer cells while sparing nearby healthy tissue. Moreover, the use of Gd containing compounds enhances treatment by allowing monitoring through MRI.

Material and method

2 types of compounds were synthesized and evaluated as 10B and 157Gd delivery agents to perform at the same time NCT and CA inhibition: 1-Boronated derivatives (CA-USF) containing a carborane cage conjugated with sulfamido and ureido groups. 2- Boronated derivatives (Gd-CA-SF) conjugated with sulfamido and a Gadolinium complex. BNCT and B/Gd-NCT experiments conducted on AB22 murine mesothelioma cells. Phantom imaging and uptake assessments were performed by incubating AB22 and Met-5A (normal mesothelium cell line) with Gd-CA-SF. In vivo experiments were then carried out using CA-USFs.

Result and discussion

In vitro studies demonstrated that CA-USFs exhibited stronger CA inhibition than Acetazolamide. BNCT experiments on AB22 cells incubated with CA-USFs showed significant proliferation inhibition, with a complete suppression observed 20 days post-neutron irradiation. In vivo experiments showed a significant tumor reduction in mice treated with 10B-CA-USFs, especially with BNCT and CA IX inhibition. The uptake of Gd-CA-SF by AB22 cells was higher than that of Met-5A cells, consistently with the results of phantom imaging, thus demonstrating the selectivity of the system. In vitro B/Gd-NCT results showed that combining the effects of 157Gd and 10B with CA-SF, followed by irradiation, achieved the lowest proliferation rate in AB22 cells.

Conclusion

This study highlights the potential of combining BNCT with CA inhibition for mesothelioma treatment. CA-USFs showed strong CA inhibition, enhancing BNCT efficacy and completely suppressing AB22 cell proliferation in vitro while significantly reducing tumors in vivo. The selective uptake of Gd-CA-SF by AB22 cells, confirmed by phantom imaging, underscores the precision of this approach. The synergy of 157Gd, 10B, and CA inhibition achieved the lowest proliferation rates, demonstrating its therapeutic promise.

⁶*Belgrade, Serbia*

Introduction

Apigenin is an aglycone of many natural glycosides and is known chemically as 4,5,7-trihydroxyflavone.¹ The biological and pharmacological activities of apigenin are diverse, which include anti-inflammatory, antioxidant, anticancer, anti-proliferative and anti-spasmodic.² The chemistry of oxorhenium(V) complexes is receiving increasing attention because of the potential application in medical and chemistry.

Material and method

Three rhenium complexes with apigenin and its derivatives were synthesized (Complex 1: C₃₇H₂₉Cl₂O₉PRe, Complex 2: C₃₇H₃₇Cl₂O₉PReSi₂, Complex 3: C₃₄H₂₉Cl₂O₇PRe and acetylated C₁₉H₁₄O₇ and silylated apigenin C₂₇H₃₈O₄Si₂), fully characterized and used for biological studies. Cytotoxicity assessments were conducted using the resazurin reduction assay across multiple cancer cell lines, including HT29 (colon-rectal adenocarcinoma), Jurkat (T-cell leukemia), LNCaP (prostate cancer), and MCF7 (breast cancer). Cisplatin was used as a standard of care for this experiment.

Result and discussion

All three complexes showed significant cytotoxic potential toward Jurkat cell line and moderate activity against other cell lines. Furthermore, IC₅₀ values of all complexes were less than 5 μM, and demonstrated enhanced cytotoxic activity compared to the parent ligands in most cases, particularly in leukemia cells (Jurkat), while solid tumor cell lines showed more variable responses. Additionally, two Re compounds were selected for further investigation in dedicated anti-migration and anti-invasion assays.

Conclusion

Taking everything into consideration, rhenium plays a crucial role in disrupting leukemia cell biology. On the other hand, isolated ligands have milder effects, suggesting the complexes' bioactivity is enhanced by rhenium coordination. These findings will elucidate the molecular mechanisms and identify potential biomarkers. This comprehensive assessment of their physicochemical properties and cytotoxicity has provided valuable data to support the continued development of rhenium compounds as potential anti-cancer agents.

Biological Basis for the Development of CPL410005 as an Antibody-Drug Conjugate

F. Mitula¹, D. Popiel¹, T. Kornatowski¹, M. Mroczkiewicz², W. Pyra¹, J. Hucz-Kalitowska¹, O. Abramczyk¹, M. Marczak¹, M. Wieczorek³, J. Pieczykolan¹

¹*Celon Pharma S.A., Preclinical Development Department, Kazuń Nowy, Poland*

²*Celon Pharma S.A., Medicinal Chemistry Department, Kazuń Nowy, Poland*

³Celon Pharma S.A., Pre- and Clinical Development Department, Kazuń Nowy, Poland

Introduction

CPL410005 is a potent UBA1 inhibitor with strong anti-cancer activity in vitro. However, its systemic toxicity and poor tumor selectivity limit its therapeutic potential as a standalone small-molecule drug. To overcome these limitations, this study explores the conjugation of CPL410005 to an anti-HER2 antibody to enhance tumor specificity and reduce off-target effects. Targeting the Ubiquitin-Proteasome System (UPS) with Antibody-Drug Conjugate (ADC) for directed UBA1 inhibition represents a promising strategy for cancer therapy.

Material and method

CPL410005 cytotoxicity was assessed across a broad panel of cancer cell lines. Its pharmacokinetic properties, including solubility, metabolic stability, and hepatotoxicity, were evaluated in vitro. To improve tumor-specific targeting, CPL410005 was conjugated to an anti-HER2 antibody via a selectively cleavable linker. ADCs were characterized in vitro for stability, HER2 binding affinity (SPR), and cytotoxic effects in HER2-positive and HER2-negative cell lines.

Result and discussion

CPL410005 exhibited potent in vitro cytotoxicity on a panel of 130 cell lines, with IC₅₀ values of 15.3 nM in U937 and 22.7 nM in HCT116 cell lines. However, systemic administration in xenograft models resulted in dose-limiting toxicity at 10 mg/kg. ADC conjugation significantly improved tumor-specific uptake, with conjugation yields above 85%, as confirmed by RP-HPLC. HER2-ADC conjugates retained high HER2 binding affinity (KD = 1.2 nM) and displayed selective cytotoxicity in HER2-overexpressing SK-OV-3 and SK-BR-3 cells, with IC₅₀ values of 1.8 nM and 2.5 nM, respectively. No significant cytotoxicity was observed in HER2-negative HEK293 cells at concentrations up to 1 μM. Pharmacokinetic studies showed prolonged plasma half-life (*t*_{1/2} = 18.2 h) compared to free CPL410005 (*t*_{1/2} = 2.9 h), while linker cleavage-dependent drug release ensured selective cytotoxicity in target cells.

Conclusion

CPL410005's potent UBA1 inhibition utilized in the form of ADC technology enhances tumor selectivity and reduces systemic toxicity. These findings support further preclinical development of HER2-targeted UBA1 inhibitors as a novel therapeutic strategy for HER2-positive cancers.

Arginine deprivation, mTOR signalling and DNA repair response in models of ovarian cancer

L. Evangelista¹, F. McKinney¹, A. Prabhakaran¹, C. An¹, C. Balcells Nadal¹, A. Gruevska², A. Nijhuis¹, Z. Hall², I. McNeish¹, H. Keun¹

¹Imperial College London, Surgery and Cancer, London, United Kingdom

²Imperial College London, Metabolism, Digestion and Reproduction, London, United Kingdom

Introduction

High-grade serous carcinoma (HGSC) is the most frequently diagnosed and aggressive form of ovarian cancer that presents with poor clinical outcomes long-term. Despite the initial success of current treatments, such as platinum-based chemotherapies and poly (ADP-ribose) polymerase (PARP) inhibitors, patients often relapse, highlighting the need for more effective maintenance therapies. Arginine deprivation therapies, such as administration of the enzymatic drug ADI-PEG20, target tumour metabolism by removing extracellular sources of arginine that cancer cells rely on for growth and proliferation and has been shown to be especially effective in cells deficient in the rate-limiting enzyme of arginine biosynthesis, argininosuccinate synthase (ASS1).

Material and method

Analyses were performed on CRISPR/Cas9-edited ID8 murine ovarian epithelial models with TP53-loss, PTEN-loss and ASS1-deficiency. The bulk metabolomes of ADI-PEG20-treated or arginine-starved ID8 lines/ omental tumours were analysed by liquid chromatography-mass spectrometry (LC-MS). Treatment-related growth inhibition was assayed using SRB and compared between PTEN-wild type/loss models. The effects of arginine starvation on mTOR signalling and DNA repair response proteins were measured by western blotting analysis.

Result and discussion

Arginine deprivation via ADI-PEG20 treatment or medium starvation induces global metabolic changes impacting several pathways including polyamine biosynthesis, one-carbon metabolism, choline metabolism and glutamine metabolism. Arginine starvation induced suppression of mTOR signalling and DNA repair response factors, suggesting mechanisms by which arginine deprivation may inhibit tumour growth and induce cell death differentially according to PTEN status when combined with the PARP inhibitor Olaparib.

Conclusion

These findings highlight the potential for arginine deprivation therapies in treating genetically defined subsets of ovarian carcinoma, particularly in combination with clinically approved agents that interfere with DNA repair such as PARP inhibitors.

EACR25-1359

Co-targeting of EGFR and Sp1 to inhibit TKIs resistance and improve immune response in NSCLC tumors

C. De Rosa¹, A. Ariano¹, L. Amato¹, D. Omodei², R. Camerlingo³, G. Roviello², C. Della Corte¹, V. De Rosa², F. Iommelli²

¹University of Campania Luigi Vanvitelli, Department of Precision Medicine, Naples, Italy

²National Research Council, Institute of Biostructures and Bioimaging, Naples, Italy

³Istituto Nazionale Tumori - IRCCS - Fondazione G. Pascale, Department of Cell Biology and Biotherapy, Naples, Italy

Introduction

Hindering resistance to EGFR tyrosine kinase inhibitors (TKIs) is a major challenge in oncology. Many NSCLC

patients show high sensitivity to EGFR TKIs but under drug pressure, drug-resistant clones emerge, and new therapeutic strategies are needed to avoid treatment failure. Sp1 is a well-recognized transcription factor implicated in cancer progression and here we want to demonstrate that concurrent inhibition of EGFR kinase domain and Sp1 may hinder proliferation of cancer stem cells (CSCs), impair cell migration, improve immune response and enhance cell toxicity in NSCLCs.

Material and method

We used H1975, HCC827, PC9 and PC9 osimertinib resistant (PC9/OR) cell lines growth in adhesion or as tumor-spheres (TS). Cells were screened for Sp1 levels before and after 1 μM osimertinib treatment. Cell toxicity assay was performed using osimertinib (0.1–1 μM) alone or in combination with Sp1 inhibitor Mithramycin A (Mit A). We integrated our data with cBioPortal analysis for SP1 gene CNV expression in lung tumors and with computational studies to identify new Sp1 inhibitors. In silico methods along with HDOCK software were used to identify new compounds that show lower toxicity than Mit A but with similar ability to impair DNA binding activity of Sp1. Wound healing and TS assays were also conducted to detect cell migration ability and stem-like cells survival after 72h treatment. Furthermore, modulation of the immunosuppressive receptor CD47 in treated and untreated cells were also assessed along with screening of PDL-1 levels in exosomes isolated from sensitive and OR cells.

Result and discussion

Treatment with osimertinib 1 μM for 72h was able to strongly reduce cell viability and increase cell death markers in NSCLC cells. However, concomitant increase of Sp1 levels was also observed in treated cells along with activation of EMT, CSC signaling and CD47 expression. Similar results were obtained by western blot analysis of nuclear extracts and protein content of exosomes released from PC9 and PC9/OR cells. We found the highest Sp1 nuclear localization along with the highest PDL-1 exosomes levels in resistant cells. Bioinformatic analysis of SP1 gene CNVs revealed a lower overall survival (OS) in tumors with SP1 amplification. Interestingly, combined treatment using osimertinib along with Mit A was able to improve cell toxicity, reduce cell migration and inhibit the TS formation. We also found that drugs combination caused a reduction of CD47 levels on NSCLC cells surface. In addition, our computational studies showed that Hedera-saponin B, similar to Mit A, binds to the GGGCGG DNA box with high affinity thus representing a new potential inhibitor of Sp1 activity and reported to be a well-tolerated compound.

Conclusion

Co-targeting of EGFR and Sp1 may inhibit migration and survival of resistant cells with stem-like phenotype. In addition, such therapeutic strategy may hinder immune evasion and may be a tool for preventing treatment failure in NSCLC patients.

EACR25-1363

Characterisation of bicyclic drug conjugate tool molecules using complementary 2D and 3D cellular

models in vitro

J. Bré¹, L. Mascheroni¹, M. Harman¹, L. Urbonas¹,

A. Hilser¹, H. Scott¹, M. Masiero¹, M. Bell¹, I. Rioja¹

¹Bicycle Therapeutics, Cambridge, United Kingdom

Introduction

Bicycle Therapeutics is developing a chemically synthesised bicyclic peptide (Bicycle®) class of medicines characterised by their high affinity and selectivity, small size enabling fast tissue penetration, modularity for conjugation and favourable pharmacokinetics. Bicycle molecules are currently being explored in the clinic as Bicycle® Drug Conjugates (BDCs™) for targeted delivery of cytotoxic payloads into tumours.

Material and method

A panel of cell lines with a range of target cell surface expression levels were used to characterise tool BDC molecules designed to target membrane type 1 matrix metalloproteinase (MT1-MMP). Cell binding and internalization were determined by flow cytometry and confocal microscopy, respectively, using fluorescently labelled peptides. Cytotoxicity assays were performed in 2D and 3D cellular models with Bicycle Drug Conjugates (BDCs).

Result and discussion

Assays have been developed to demonstrate that cell binding correlates with target expression. Additionally, target mediated gradual internalisation was observed within a 6-hour period for binder molecules. By contrast, no cell binding or internalisation was observed with non-binder molecules. Target-mediated cell killing can also be characterised in 2D and 3D with the BDC molecules.

Conclusion

Complementary use of 2D and 3D cellular models for pharmacological characterisation represents the most complete approach to study Bicycle molecules in vitro. As 3D cell models closer mimic the 3D structure and cell-to-cell interaction, these assays may be used to support the translation to *in vivo* models.

EACR25-1373

Diphyllin, a SPP1/DKK1 inhibitor, restricts hepatocellular carcinoma growth by modulating sugar and bile acid metabolism

J. Zhang¹, Z. Li¹, Z. Chen¹, A. Lyu¹, C. Wang²

¹Hong Kong Baptist University, Hong Kong, Hong Kong, China

²Guangdong Pharmaceutical University, Guangdong, China

Introduction

Hepatocellular carcinoma (HCC) is a prevalent solid tumor with high global incidence and mortality rates. The overexpression of tumor-derived SPP1 and DKK1 is implicated in the malignant progression of HCC, poor prognosis and resistance to chemotherapy. Inhibitors targeting tumor-derived SPP1 and DKK1 thus represents a promising strategy for cancer therapy.

Material and method

Molecular docking was used to screen out the inhibitors of SPP1/DKK1 from herbal databases. *In vitro* and *in vivo* experiments were performed to determine the anticancer effect of diphyllin on HCC. To further

elucidate the underlying mechanism of Diphyllin against HCC, RNA-Sequencing and metabolomics were performed to analyse the alteration of genes and metabolic pathways.

Result and discussion

We discovered a natural molecule, Diphyllin, can suppress the expression of both SPP1 and DKK1. Diphyllin was found to induce apoptosis in HepG2 and Hepa1-6 while suppressing cell proliferation, migration, and invasion. Mechanistically, Diphyllin appears to reprogram sugar metabolism and inhibit bile acid synthesis by regulating the HIF-1 pathway in liver cancer cells, leading to the enhancement of the cellular stress response. These mechanisms collectively promote apoptotic cell death and reduce cell proliferation. Furthermore, the combination of Diphyllin with sorafenib demonstrated significant synergistic anti-tumor activity *in vitro*.

Conclusion

In summary, our findings highlight Diphyllin as a promising natural inhibitor of SPP1/DKK1, effectuating robust anti-tumor effects potentially through the inhibition of bile acid synthesis and the reprogramming sugar metabolism, which enhances the cellular stress response and promotes apoptotic cell death, leading to the suppression of growth on HCC.

EACR25-1374

HSPGs targeting and multimeric cytotoxic conjugates as a novel PDC strategy against pancreatic cancer

K. Ciura¹, A. Chorążewska¹, N. Porębska¹, L. Opaliński¹

¹*University of Wrocław, Department of Medical Biotechnology, Wrocław, Poland*

Introduction

Heparan sulfate proteoglycans (HSPGs) are membrane-bound and extracellular matrix glycoproteins playing critical role in cell physiology. Together with fibroblast growth factors (FGFs) and their receptors (FGFRs), HSPGs form ternary signaling complexes regulating numerous cellular processes e.g., differentiation, migration and proliferation. Moreover, HSPGs have been identified as a potential cancer-related biomarkers, overexpressed in several cancer types, especially in pancreatic cancer, underlining the importance of discovery of new drug delivery agents targeting HSPGs.

Material and method

We confirmed successful production of GFPp_FGF1_HS and CC3_FGF1_HS using SDS-PAGE and Western-Blot. Different oligomeric states of GFPp_FGF1_HS were isolated using FPLC. Later, using Native-PAGE, calibrated SEC column and DLS we confirmed the designed oligomeric state of produced MLAs. BLI and FPLC elution profile analyses were performed for estimation of GFPp_FGF1_HS and CC3_FGF1_HS affinity for heparans. We analyzed and compared endocytosis of different oligomeric states of MLAs using fluorescent microscopy. Sortase E-mediated ligation was performed for attachment of cytotoxic drug – mono-methyl auristatin E (MMAE), to GFPp_3x_FGF1_HS and CC3_FGF1_HS, confirmed with Western Blot and mass spectrometry. Finally, we estimated EC50 of

multimeric cytotoxic conjugates using cytotoxic assays with healthy and pancreatic cancer cell lines.

Result and discussion

Here, we designed and tested multimeric ligand assemblies (MLAs) based on engineered FGF1 variant with abolished recognition of FGFRs, selectively interacting with HSPGs. We used two different oligomerization scaffolds – coiled coil (CC) motifs and GFPpolygons (GFPp) for controlled oligomerization of FGF1. Importantly, BLI and FPLC elution profile analyses showed that oligomerization increases MLAs affinity for heparans in comparison to its monomeric form. In addition, fluorescent microscopy revealed that oligomerization of FGF1 increases its endocytosis via HSPGs due to multivalency-dependent clustering of HSPGs on the cell surface, demonstrating the remarkable potential of the studied MLAs as an effective targeting moiety. Finally, we conjugated designed MLAs with monomethyl auristatin E (MMAE), generating HSPG-specific protein drug conjugates (PDCs). Synthesized GFPp-based and CC-based multimeric cytotoxic conjugates showed high cytotoxicity against panel of pancreatic cancer cell lines with EC50 ranging from 4.15 nM to 6.83 nM.

Conclusion

Conclusively, this data suggests that targeting HSPGs with multimeric PDCs is an effective strategy for selective and precise drug delivery into pancreatic cancer cells.

EACR25-1376

Teaching cells the drug uptake – rational modulation of endocytosis for precise delivery of novel HSPGs targeting conjugate into pancreatic cancer cells

A. Chorążewska¹, K. Ciura¹, N. Porębska¹, L. Opaliński¹

¹*University of Wrocław, Department of Medical Biotechnology, Wrocław, Poland*

Introduction

Pancreatic cancer has the highest mortality rate of any major cancer. Heparan sulfate proteoglycans (HSPGs) are cell surface glycoproteins involved in the regulation of cell-to-cell communication and modulation of cell signaling. HSPGs are overexpressed in pancreatic cancer, making them an attractive molecular target in precision medicine approaches. The natural ligands for HSPGs are fibroblast growth factors (FGFs) that together with the fibroblast growth factor receptors (FGFRs) transduce signals across the plasma membrane. Here we constructed an FGF1-based HSPG-specific oligomeric ligand, TriFHS, by uncoupling FGF1 from FGFRs and increasing its valency by controllable oligomerisation. We have successfully attached a cytotoxic drug MMAE to TriFHS and proved cytotoxicity of the conjugate against pancreatic cancer cells. Since effective endocytosis is key to the action of PDCs (protein drug conjugates), our goal was also to increase the selectivity and efficiency of delivery of TriFHS-vcMMAE to cancer cells. We decided to do so by manipulating cellular signaling, which ultimately controls endocytosis.

Material and method

Using confocal microscopy and immunofluorescence staining, we showed co-localisation of TriF with a molecular target (proteoglycan) and with endosomes. To find signaling cascades that inhibit internalization of TriFHS-vcMMAE into healthy cells, and at the same time promote endocytosis into pancreatic cancer cells, we employed high content screening (HCS) microscopy using the Opera Phenix Plus high-throughput confocal microscopy platform and the library of kinase inhibitors (2653 compounds). Finally, by studying different cell lines (physiological and pancreatic cancer cells) and selected in the HCS assay chemical compounds, using confocal microscopy, we showed differences in the cytotoxicity of TriFHS-vcMMAE.

Result and discussion

Initially, with HCS we identified kinase inhibitors that reduce the efficiency of TriFHS-vcMMAE endocytosis into healthy pancreatic cells. Based on this, we performed another HCS to study the effect of selected inhibitors on pancreatic cancer cells, and identified nine compounds that can block endocytosis into healthy cells and not affect or promote internalization into tumor cells. With the results gathered in this screen, we are now rationally modulating endocytosis to increase the selectivity and efficiency of cytotoxic drug penetration into pancreatic cells.

Conclusion

We show for the first time that it is possible to teach healthy and cancer cells specific behaviors and thus improve selectivity of ADC uptake, which can help to revolutionize the ADC (Antibody Drug Conjugate) approach.

Apoptotic Effects of a Flavone Combination on Brain Metastatic Triple-Negative Breast Cancer Cells

M. Losada-Echeberria¹, P. de Juan-Maciá¹, M. Herranz-López¹, V. Micol¹, E. Barrajón-Catalán¹

¹*Instituto de Investigación, Desarrollo e Innovación en Biotecnología Sanitaria de Elche (IDIIBE), Elche, Spain*

Introduction

Breast cancer (BC) is the most common malignancy in women, with approximately two million new cases diagnosed annually worldwide. Triple-negative breast cancer (TNBC) is particularly aggressive and lacks molecular targets, limiting treatment options and worsening prognosis. A major challenge in TNBC is its high tendency to metastasize to the brain, where therapeutic options are further restricted due to the blood-brain barrier and the limited efficacy of conventional treatments. Polyphenols have emerged as promising candidates for cancer therapy due to their ability to regulate key cellular processes such as proliferation, apoptosis, and metastasis. Previous studies identified diosmetin, apigenin, and luteolin as the primary flavones responsible for the antiproliferative effects of olive leaf extracts. This study evaluates the cytotoxic and cytostatic effects of a flavone combination (DAL511), composed of diosmetin, apigenin, and luteolin, in the brain metastatic TNBC cell line MDA-MB-231-BR. Human astrocytes

served as a non-tumoral control to assess treatment selectivity. Additionally, we analyzed apoptotic markers and key signaling pathways involved in TNBC progression.

Material and method

Cell models: MDA-MB-231-BR (TNBC, brain metastasis variant) and human astrocytes (non-cancerous control). Clonogenic assays were performed using crystal violet staining. Cell migration and invasion were assessed through wound healing and Matrigel GFR-based assays. Cell cycle, mitochondrial membrane potential and apoptosis analysis were performed using a Muse Cell Analyzer (Millipore) and their respective kits. ROS generation was analyzed using dichlorofluorescein diacetate staining. Western blotting investigated apoptotic markers and related signaling pathways.

Result and discussion

DAL511 had a stronger antiproliferative effect on MDA-MB-231-BR cells than on human astrocytes. Treatment significantly reduced clonogenic survival, migration, and invasion. Cell cycle assays showed an increase in the subG0 cell population, indicating cytotoxic activity correlated with enhanced apoptosis and mitochondrial membrane depolarization. ROS levels also increased after DAL511 treatment. Western blot analysis confirmed activation of apoptotic markers, including cleaved caspase-3 and PARP, along with alterations in key signaling pathways such as MAPK and PI3K/AKT.

Conclusion

The flavone combination DAL511 induces apoptosis in MDA-MB-231-BR breast cancer cells by disrupting mitochondrial function and increasing ROS production. Additionally, it modifies apoptosis-related protein expression and signaling pathways, supporting its potential as a therapeutic candidate for TNBC.

⁷*Navinci Diagnostics, Uppsala, Sweden*

Introduction

The PD-1/PD-L1 axis is a critical regulator of immune checkpoints and a primary target for immune checkpoint inhibitors (ICIs) in solid tumor treatment. However, despite its promise, PD-1/PD-L1 blockade has limited efficacy, with only 20–30% of bladder cancer patients responding to therapy. Currently, patients receive ICIs based solely on PD-L1 status, overlooking the spatial

complexity of tumor-immune interactions. We propose that direct measurement of PD-1/PD-L1 interactions between immune and tumor cells provides a more accurate predictor of treatment response. The *in-situ* Proximity Ligation Assay (isPLA), commercialized by Navinci Diagnostics, enables the visualization of protein-protein interactions between cells by using paired antibodies. If the target proteins are within 40 nm of each other, a rolling circle amplification signal is generated and detected via fluorescence microscopy. When combined with multiplex immunofluorescence, this method can further distinguish interactions among specific cell populations, such as tumor and immune cells, while providing insights into the tumor microenvironment. By integrating isPLA with multiplexed immunofluorescence, we aim to refine patient stratification and improve the predictive accuracy of immunotherapy, contributing to the development of more personalized cancer treatments.

Material and method

FFPE tissue samples from a retrospective cohort of bladder cancer patients were stained using the Naveni® protocol on a Leica Bond RX system, followed by multiplexed immunofluorescence with Akoya Bioscience's PhenoCycler technology. isPLA detection oligos were incorporated to visualize PD-1/PD-L1 interactions alongside a 14-plex antibody panel.

Result and discussion

We successfully established an automated isPLA workflow on the PhenoCycler Fusion imaging platform, enabling precise detection of PD-1/PD-L1 interactions while simultaneously profiling single and co-expressed markers across immune, stromal, and tumor cells. Preliminary data from a proof-of-concept cohort of 13 patients revealed a significantly higher number of PD-1/PD-L1 interactions in complete responders compared to non-responders, suggesting that the frequency of these interactions may serve as a potential predictor of response to ICI treatment. Building on this, we have implemented the interaction assay with a 40-plex panel to achieve deeper spatial profiling, allowing for more comprehensive characterization of the tumor microenvironment in patient samples.

Conclusion

In conclusion, we have created a method that enables simultaneous detection of PD-1/PD-L1 interactions while spatially profiling the tumor microenvironment. Our findings suggest that differences in the frequency of isPLA spots correlate with response to ICI treatment. This approach provides a valuable framework for refining patient stratification and improving predictive biomarkers for immunotherapy response.

Introduction

Inhibitors of Apoptosis Proteins (IAPs) are oncological targets whose over-expression enhances cell survival and resistance to anticancer agents. IAPs regulate NF-κB pathway acting as E3 ligases; furthermore, they sequester caspases to prevent apoptosis. Such IAPs functions are mediated by type I and II BIR (Baculovirus IAP repeat) domains, respectively. Type II BIRs are validated targets for cancer therapy. The biophysical and structural analysis (crystallography, SAXS) of a specific cavity on type II BIRs allowed the rational design of Smac-mimetics, which we patented as potent anti-cancer agents; however, chemoresistance events depending on type I BIRs have been reported.

Material and method

We, thus, virtually screened libraries of commercial compounds (Chembank, DrugBank, LOPAC) targeting type I BIRs, identifying candidates with promising in vitro profiles, both on isolated proteins and in cell-based assays. In particular, one candidate modulated NF-κB activation in TNBC (Triple Negative Breast Cancer) models, inducing cell death, both as single agent and in combination with Smac-mimetics. Integrating cell-viability assays, virtual docking, NMR and techniques to determine drugs affinities towards the target proteins a library of 50 derivatives has been characterized and a selection of derivatives has been further investigated in cell-based and protein-based assays.

Result and discussion

The selection of derivatives demonstrated to reduce cell viability in TNBC and in NSCLC (Non-Small Cell Lung Cancer, NCI-H1299, cell line smac-mimetics-resistant). Further investigations revealed that the cytotoxic effect of these derivatives perturbs the NF-κB pathway and induces caspase-mediated cell death, increasing ROS production. The effect of drug candidates has been evaluated also on target proteins, including single BIR domains and full length IAPs. In fact, the selected candidates present low micromolar affinities for the protein targets and produce thermal shifts of the proteins tested.

Conclusion

The hypothesis of IAPs-engagement in the function of this new class of derivatives is now under investigation and further studies on different cellular models and on pro-apoptotic pathways is ongoing. The objective is to propose a candidate for *in vivo* tests. The modulation of pro-survival complexes regulating the NF-κB pathway, as the ones mediated by IAPs, can be the strategy to overcome cases of resistance to current IAPs-targeting chemotherapics, but also to better define IAPs roles/functioning and find accurate/selective therapies.

⁷Yale Cancer Center, Department of Internal Medicine, New York, United States

Introduction

High-risk neuroblastoma (NB) is an aggressive pediatric malignancy with poor prognosis, as the 5-year disease-free survival rate remains below 50% despite intensive therapy. Developing novel combination treatments is crucial to improving outcomes. Isotretinoin (13cRA), a key agent in post-consolidation NB therapy, exhibits anti-proliferative and pro-differentiative effects. To identify compounds that enhance its efficacy, we screened a library of 169 natural polyphenols and found that isorhamnetin (ISR) synergizes with 13cRA, reducing cell viability by 80%. Mechanistically, this effect correlates with upregulation of the adrenergic receptor α 1B (ADRA1B), a member of the catecholamine receptor superfamily. This study investigates ADRA1B's role in mediating the synergistic effects of 13cRA and ISR, as well as the broader impact of adrenergic receptor modulation on NB growth in combination with 13cRA.

Material and method

We generated ADRA1B-knockout (KO) NB cell lines using CHP134 (13cRA-sensitive) and SK-N-AS (13cRA-resistant) cells. Cellular responses to 13cRA and isorhamnetin, alone or in combination, were assessed via metabolic assays, apoptosis assays, differentiation markers, and gene expression analysis. Additionally, a high-throughput screen using an adrenergic receptor ligand library evaluated cell viability upon co-administration with 13cRA. Finally, the combinatorial approach was tested *in vivo* using NB xenograft models.

Result and discussion

CHP134 ADRA1B-KO cells treated with 13cRA showed reduced viability and increased Caspase-3/7 activation, comparable to wild-type cells treated with the combination of 13cRA and ISR. Furthermore, 13cRA exposure in CHP134 KO cells induced neurite outgrowth and upregulation of neural differentiation. In contrast, SK-N-AS cells (WT or ADRA1B-KO) showed no changes in viability or differentiation marker expression following 13cRA treatment. Pharmacological inhibition of α 1B-AR and 13cRA administration to the cells, mirrored the genetic KO results. Treating a panel of 11 NB cell lines with α 1/ α 1B-AR antagonists revealed that the presence of MYCN-amplification is essential to observe the sensitization over the cell viability reduction and neural differentiation induced by 13cRA, thus mimicking the ISR activity. As expected, the addition of α 1/ α 1B-AR agonists led to opposite effects. *In vivo*, co-treatment with 13cRA and the FDA-approved α 1 AR antagonist doxazosin significantly slowed tumor progression in NB xenograft models.

Conclusion

Our findings suggest that α 1-AR antagonism sensitizes NB cells to 13cRA by facilitating the pro-differentiative and pro-apoptotic effects, potentially disrupting an auto-

crine catecholamine-driven pro-survival circuit. Given the druggable nature of ARs, α 1-AR inhibition emerges as new a promising pharmacological therapeutic strategy for neuroblastoma treatment.

⁴University of Bern, Institut für Gewebemedizin und Pathologie, Bern, Switzerland

⁵University Hospital-Inselspital, Department of Urology, Bern, Switzerland

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is associated with rapid progression, therapy resistance, and a highly complex tumor microenvironment (TME). Our research focuses on developing patient-derived models to test investigational drug compounds' effects and elucidate the interplay between epithelial cells and TME elements in PDAC therapy response and resistance. To this end, we established a PDAC patient-derived xenograft (PDX) model, along with PDX-derived organoids (PDXO) and ex vivo tissue slice models, to enable personalized drug testing and therapeutic optimization.

Material and method

The PDAC-PDX was established by subcutaneous implantation of metastatic PDAC tissue in immunocompromised SCID mice. Bulk RNA sequencing of the PDX tissue was analyzed using a drug prediction algorithm (Darwin OncoTarget™/OncoTreat™) PDXOs were generated in an extracellular matrix gel, while ex vivo tissue slices from PDX tumors were cultured at the liquid-air interface in a transwell system for four days. Drug testing was performed on the PDXOs, with viability assessment post-treatment using an ATP-based viability assay. Additionally, selected therapeutic agents are applied to ex vivo PDX slices to evaluate drug effects in a more complex setup where tissue architecture and stroma components are partially preserved.

Result and discussion

The established PDAC-PDX model preserves key genomic characteristics of its original patient-derived tissue while maintaining consistent histological features of PDAC across *in vivo* passages. PDXOs retained molecular and phenotypical features of the PDX tissue, as confirmed by IF and genomic analysis. Transcriptomic analysis of PDX tissue identified both FDA-approved and investigational drug candidates. PDXO drug treatment experiments determined the efficiency of PDAC standard-of-care combinations gemcitabine & nab-paclitaxel and folfirinox. Additionally, predicted compounds showed reduced organoid viability, such as AT9283, plicamycin, belinostat, lapatinib, trametinib,

olaparib, or bosutinib. These compounds are being evaluated in an ex vivo tissue slice model, to better capture PDAC complexity and evaluate the effect also on TME elements.

Conclusion

Drug resistance remains a major challenge in PDAC treatment, demonstrating the need for new therapies. Our findings highlight organoids as a robust model for testing tumor epithelial cell-targeting compounds, offering a key advantage in personalized drug screening due to in vitro expansion potential. Using a newly developed PDX model and derived PDXOs, we demonstrated the feasibility of testing SOC drugs and therapies predicted from transcriptomic data. We are extending this approach to a larger cohort of patient-matched tissue and organoids.

Remodeling the Tumor Microenvironment through TSP-1/CD47 Antagonization: Non-Clinical Characterization of the TAX2 drug candidate

A. Moniot¹, M. Etiennot¹, A. Henry¹, M. Ghoula¹, S. Poli², S. Dedieu^{3,1}, A. Jeanne¹

¹*Apmonia Therapeutics, Reims, France*

²*Poli Consulting, Onex, Switzerland*

³*Université de Reims Champagne-Ardenne, MR 7369*

MEDyC, CNRS, Reims, France

Introduction

Thrombospondin-1 (TSP-1) is a matricellular glycoprotein overexpressed in a wide range of cancers and a poor prognosis marker. Among its receptors, CD47 is mainly implicated in tumor angiogenesis and immune evasion. While most efforts focused up to now on disrupting CD47 binding to its macrophage counter-receptor SIRPa (“don’t eat me signal”), the TSP-1/CD47 axis is emerging as promising target for treating solid tumors. We have developed TAX2, a 12 aa cyclic peptide acting as an orthosteric antagonist for TSP-1/CD47 interaction.

Material and method

The binding properties of TAX2 peptide to TSP-1 from various species were characterized in vitro while the anti-cancer activity and biodistribution of TAX2 were evaluated in tumor-bearing mice. The stability of TAX2 was tested in plasma and whole blood from different species before pharmacokinetic (PK) profiling following a single intravenous (IV) administration. The potential impact of TAX2 on CD47/SIRPa interaction was investigated using molecular modeling and a cell-based reporting assay. Potential off-target interactions were assessed across a panel of 44 targets, while potential unintended immunogenicity of TAX2 was evaluated in cytokine release assays. Toxicology studies were conducted in rats and dogs to characterize the toxicity profile of TAX2 after IV injection. Last, PK data obtained in rodents and dogs were used for prediction of Human PK parameters using allometric scaling.

Result and discussion

In silico and in vitro studies showed that TAX2 binds selectively to human, rat, mouse and dog TSP-1, and

disrupts the TSP-1/CD47 interaction without affecting CD47’s interaction with SIRPa. The pharmacologically active dose (PAD) of TAX2 in mice was determined at 30 mg/kg based on efficacy studies in several cancer models. In a highly aggressive ovarian cancer model, TAX2 demonstrated its efficacy by improving mouse survival, while offering clinically relevant combination potential with PARP inhibitors. TAX2 PK profile determined in rodents and dogs showed rapid plasma clearance over 1 to 4 hours, while exposure increases proportionally with the dose. Biodistribution studies revealed preferential accumulation in tumors and TSP-1-expressing tissues. TAX2 peptide showed no significant off-target interaction or functional effect across a panel of 44 human targets and did not induce uncontrolled cytokine release in human whole blood, supporting a favorable safety profile. Toxicology studies indicated that TAX2 was well tolerated with NOAEL (No Observable Adverse Effect Level) values of 400 mg/kg in rats and 100 mg/kg dogs. According to PK predictions, the PAD in humans ranges between 9 and 33 mg/kg.

Conclusion

TAX2 peptide, a first-in-class TSP-1/CD47 antagonist, is being developed as an injectable product for the treatment of cancers. These non-clinical data support this concept and TAX2 is now expected to enter in Phase 1/2a clinical trial in advanced solid tumors.

¹*Axxam SpA, Cell Biology, Assay development, Milan, Italy*

²*Sinea Therapeutics Inc, Boston, United States*

Introduction

Cancer is driven by genetic alterations that disrupt normal cellular regulation, leading to uncontrolled proliferation and evasion of apoptosis. One crucial mechanism in tumor development is oncogene addiction, where malignant cells become highly dependent on a single oncogene for survival. Additionally, synthetic lethality – where the simultaneous loss of two genes results in cell death, while the loss of a gene alone is tolerated – is a common feature in cancer pathology. Targeting either the key oncogene or its synthetic lethal partner can induce tumor regression when cancer-specific mutations are identified. In solid tumors, BCL-xL, an anti-apoptotic BCL-2 family member, is often over-expressed, promoting survival and resistance. The small molecule BCL-2 inhibitor, venetoclax, was approved for the treatment of hematopoietic tumors, highlighting the therapeutic potential of targeting BCL family in cancer. Targeted protein degradation, including BCL-xL degraders, has emerged as a promising strategy to restore apoptosis in cancer cells. A cell-based assay was developed to assess BCL-xL protein degradation, offering a sensitive and reliable tool for studying protein

turnover dynamics and to evaluate the potency of BCL-xL degraders in cancer cells.

Material and method

To enable precise tracking of BCL-xL degradation, a gene editing approach was applied to introduce a HiBiT sequence into the endogenous BCL-xL gene expressed in a relevant cancer cell line. This modification allows for the direct detection of BCL-xL protein levels through a luminescent signal. In the presence of LgBiT, the reconstituted NanoLuc luciferase produces a luminescent signal directly proportional to protein levels, enabling accurate quantification of degradation. The assay was developed in 384-well plate format, allowing for high-throughput screening and scalability.

Result and discussion

The assay was validated using DT2216, a well-characterized BCL-xL degrader, which effectively diminished the luminescent signal by promoting target degradation. After optimization for high-throughput screening, the assay demonstrated robust performance in evaluating candidate degraders acting on HiBiT-tagged proteins. Further validation through western blot analysis in cancer cells confirmed that the assay faithfully represents the behavior of the native, untagged protein, underscoring its suitability for extensive screening campaigns.

Conclusion

This study introduces a robust cell-based assay for monitoring targeted protein degradation in cancer cells. The method streamlines the screening process for novel degraders and can be adapted to other oncogenic targets. Ultimately, this approach holds great promise for the development of targeted cancer therapies that selectively eradicate tumor cells while minimizing collateral damage to normal tissues.

Muscle-invasive bladder cancer organoids as a functional system to address therapy response: Perspective in advancing precision medicine

H. Yue¹, C. Macedo-Silva¹, M. Radic¹, P. Chouvardas¹, D. Hanhart¹, M. de Menna^{1,2}, G. N. Thalmann³, M. Kruithof-de Julio^{1,3,2}, B. Kiss³

¹*University of Bern, Urology Research Laboratory, Department for BioMedical Research, Bern, Switzerland*

²*University of Bern, Translational Organoid Resource, Department for BioMedical Research, Bern, Switzerland*

³*Inselspital, Bern University Hospital, Department of Urology, Bern, Switzerland*

Introduction

Muscle-invasive bladder cancer (MIBC) exhibits high inter-patient heterogeneity, driving recurrence, treatment failure, and poor prognosis, underscoring the need for precision oncology. Patient-derived organoids (PDOs) are robust preclinical models that preserve parental tumors' (PT) molecular and cellular complexity. This study developed a PDO-based drug screening platform to improve therapeutic precision.

Material and method

MIBC PDOs were derived from resected tumors (44 samples) and expanded under optimized 3D culture.

PDOs were treated for 48h with the reported human Cmax values of both standard-of-care (SOC) chemotherapy and selected FDA-approved compounds, including Tyrosine kinase inhibitors (TKIs), mTOR inhibitors, PARP inhibitor, and other non-SOC drugs. Cell viability was assessed using Cell Titer-Glo® luminescent assay. Differences between treatment groups and the respective controls were analyzed using ordinary one-way ANOVA. Morphology alterations were observed before and after treatment using CQ1 confocal imaging cytometer.

Result and discussion

Our study confirms that PDOs retain most of the characteristic markers of PT. The success rate of PDO establishment was around 84% within 6–14 days of culture. MIBC PDOs exhibited two distinct morphological types: mixed (65%) and solid (35%). SOC chemotherapy – cisplatin/gemcitabine (78%, 25/32) and MVAC (88%, 14/16) – showed strong efficacy, significantly reducing PDO-cell viability, aligning with widely observed clinical response of patients, which reinforced the model's predictive reliability. Notably, in some non-SOC compounds like daunorubicin (50%, 10/20) and epirubicin (84%, 16/19), the cytotoxic effect was equal to or even better than SOC. Nonetheless, lapatinib (30%, 6/20) and olaparib (31%, 5/16), dual TKIs (EGFR/HER2) and PARP inhibitor, respectively, also showed to be promising for MIBC treatment. We unexpectedly discovered a highly aggressive MIBC during the process, exhibiting a cell line-like growth pattern with rapid, sustained proliferation and morphological stability after multiple passages. It provides a novel model for studying aggressive MIBC. Ongoing research is in progress to explore therapeutic vulnerabilities.

Conclusion

In this study, we established a valuable MIBC biobank for drug discovery and validation. Inter-sample drug variability reflects MIBC heterogeneity, emphasizing the need for molecular profiling and *in vitro* screening to guide personalized treatment and informed clinical decisions.

Novel Titanocene-derived complex with high albumin affinity: Evaluation of antitumor activity in ovarian cancer cells

V. Pérez-Garrido¹, I. Martínez-Argudo², M. Guadarrama², S. Gómez-López², L. López-Sanz², A. Maldonado², M. Ruiz², R. Calero², R. Serrano²

¹*University of Castilla la Mancha, Faculty of Environmental Sciences and Biochemistry, Toledo, Spain*

²*University of Castilla la Mancha, Toledo, Spain*

Introduction

Chemotherapy resistance in ovarian cancer remains a current issue. Ti(IV)-derivatives represent a new alternative for platinum-resistant tumour treatment. They have demonstrated low toxicity and high efficacy *in vitro* and *in vivo*. However, their low stability and solubility in biological media have impeded its clinical application. Therefore, we have developed Ole-Ti, a new titanium complex with an oleic-like aliphatic chain, improving stability and solubility through non-covalent binding with

serum albumin. In this study, we report some results about in vitro and in vivo effects of Ole-Ti.

Material and method

Ole-Ti cytotoxicity was tested on A2780 and A2780Cis (cisplatin resistant) ovarian tumour cells lines by MTT assays. Intracellular Ti(IV) accumulation was quantified by TXRF. DNA interaction was studied by electro-phoretic mobility assays. Apoptosis and oxidative stress were evaluated by flow cytometry with AnnexinV and DCFH-DA cell staining. Moreover, Caspase-3 protein level was assessed by western blot. PCR and qPCR were used to analysed the expression of endoplasmic reticulum stress mediators. For in vivo studies, A2780 cells were subcutaneously injected into nude-Foxn1 mice model. Mice were treated with Ole-Ti for two weeks and tumors volume were measured daily.

Result and discussion

Ole-Ti showed greater cytotoxic activity than its precursor (TiCp2Cl₂) on A2780 and A2780Cis cells. Based on IC₅₀ and resistance factor values, we determined that Ole-Ti had high potency on A2780Cis cells. This seems to be related to elevated Ole-Ti uptake into cells. Thus, apoptotic cells increased significantly after Ole-Ti treatment. As well, some molecular mechanisms proposed for other titanium derivatives were evaluated with Ole-Ti. DNA does not seem to be the main target of Ole-Ti since no conformational change was observed in the electrophoretic mobility assay. In addition, we inspected Ole-Ti ability to induce cellular stress. The endoplasmic reticulum stress pathway was not activated in tumour cell lines after Ole-Ti treatment for 48 hours. Although Ti(IV) is a non-redox metal, oxidative stress production was significant in Ole-Ti treated cells. Taking in further, the addition of N-acetyl-L-cysteine significantly decreased the cytotoxic activity of Ole-Ti, suggesting that ROS could be responsible for cell death. Finally, the in vivo Ole-Ti potential was demonstrated as treatment with Ole-Ti reduced tumour size more effectively and earlier compared to cisplatin, leading to an increase in the mice survival.

Conclusion

Overall, Ole-Ti displays strong antitumor activity in ovarian cancer cells both in vitro and in vivo. Nevertheless, the cellular mechanism of Ole-Ti is still uncertain. We anticipated that oleic-like aliphatic chain might play a key role in Ole-Ti molecular activity. Hence, further research is required to identify additional pathways and molecular targets.

EACR25-1450

Mesoporous Silica Nanoparticles for the Selective Delivery of Doxorubicin to Folate Receptor-Expressing Cancer Cells

C. Morelli¹, C. Longobucco¹, M. Fava¹, E. Ricci¹, M. De Santo¹, P. Cavallaro¹, R. Marinaro¹, D. Sisci¹, L. Pasqua², A. Leggio¹

¹University of Calabria, Department of Pharmacy, Health and Nutritional Sciences, RENDE (CS), Italy

²University of Calabria, Department of Environmental Engineering, RENDE (CS), Italy

Introduction

Cancer is a significant global health issue, responsible for nearly 20% of deaths in 2021. One of the major challenges in cancer treatment is the development of therapeutic strategies that selectively target tumor cells while minimizing harm to normal tissues. Localized drug delivery can help achieve this goal. A mesoporous silica-based nanodevice, designed to carry the chemotherapy drug doxorubicin (DOXO), was developed. This device, referred to as FOL-MSN-DOXO, releases the drug in response to the acidic environment of tumors and incorporates folic acid (FOL) for targeting purposes. The effectiveness of FOL-MSN-DOXO was tested in vitro against folate receptor-expressing (FR+) cancer cells, as well as against folate receptor-negative (FR-) normal (healthy) cells.

Material and method

The endocytosis of mesoporous silica nanoparticles (MSNs) was monitored through transmission electron microscopy (TEM). The efficacy of FOL-MSN-DOXO was evaluated using growth experiments, Annexin V and TUNEL assays, reactive oxygen species (ROS) measurements, Western Blot analysis, and immuno-staining on rat Dorsal Root Ganglion (DRG) cells.

Result and discussion

FOL-MSN-DOXO effectively killed FR+ cancer cells while sparing FR- normal cells. In contrast, free DOXO was toxic to all cell lines, regardless of FR expression. The uptake of MSNs occurred exclusively in FR+ cells via FR-mediated endocytosis, with no uptake observed in FR- cells. Both FOL-MSN-DOXO and free DOXO significantly increased ROS production, leading to apoptosis. However, only free DOXO induced ROS and triggered apoptosis in FR- normal cells. Importantly, the vehicle alone (FOL-MSN) showed no toxicity in any tested cell lines, and immunostaining on DRG cells demonstrated significantly lower neuronal toxicity for FOL-MSN-DOXO compared to free DOXO

Conclusion

The FOL-MSN-DOXO nanosystem specifically targets cancer cells that express FR, offering enhanced safety and comparable effectiveness against tumors when compared to conventional doxorubicin formulations. As a result, it presents a promising strategy for the targeted and safe delivery of chemotherapy in the treatment of cancers that express folate receptors.

EACR25-1458

Targeting UBE2N with Novel Non-Covalent Inhibitors: A Drug Discovery Approach to Combat PARPi Resistance in Ovarian Cancer

S. Khan¹, C. Ghadi², L. Ibazizene¹, F. Schwaben³, C. Kieffer³, J. de Oliveira Santos³, A. Voisin-Chiret³, L. Weiswald⁴, M. Meryet-Figuière⁴

¹Université de Caen Normandie, INSERM U1086 ANTICIPE (Interdisciplinary Research Unit for Cancers Prevention and Treatment), BioTICLA laboratory (Precision medicine for ovarian cancers), Caen, France

³Normandie University, UNICAEN, CERMN, Caen,

France, France

⁴UNICANCER, Comprehensive Cancer Center François Baclesse, France

Introduction

Ovarian cancer poses a major global health challenge, resulting in approximately 200,000 deaths annually. While Poly ADP-ribose polymerase inhibitors (PARPi) offer a promising treatment strategy, their effectiveness is primarily limited to patients with deficiencies in the homologous recombination (HR) pathway, affecting only about half of the patient population. This highlights a critical need for novel approaches to enhance PARPi efficacy and broaden its applicability in ovarian cancer. UBE2N, an E2 ubiquitin ligase, emerges as a promising target to improve the efficacy of PARPi therapy. This enzyme plays a crucial role in the HR pathway, a vital mechanism for DNA repair. By inhibiting UBE2N and disrupting the HR pathway, we aim to render ovarian cancer cells sensitive to PARPi treatment, allowing it to potentially benefit a wider range of patients. Our lab research demonstrated how UBE2N inhibition enhances ovarian cancer cell sensitivity to DNA-targeting drugs, particularly PARPi. While research on UBE2N inhibitors is in its early stages, there are promising options of covalent inhibitors like NSC697923 and BAY 11-7082 and non-covalent inhibitors like ML307 as well as Variabine B. However, none of these molecules have the necessary properties for preclinical or clinical development. This research aimed to develop novel, noncovalent UBE2N inhibitors to enhance PARPi effectiveness in ovarian cancer.

Material and method

To identify potential UBE2N inhibitors, we utilized a combined structure- and ligand-based virtual screening approach, targeting the 19,000-compound CERMN Chemolibrary. The screening was based on three available UBE2N structures (PDB codes: 4ONM, 6UMP, and 3HCU), which capture distinct conformations of the flexible 114–124 loop. This loop, located near the active site residue Cys87, is critical for defining the shape and volume of the active site cavity. Conformational changes within the loop can therefore directly impact binding and potentially modulate the UBE2N activity. From the virtual screen, 22 compounds were selected based on interaction energy calculations and assessments of the stability of the compound-UBE2N complexes. These compounds, all targeting the UBE2N active site, underwent *in vitro* evaluation using SKOV3 ovarian cancer cells.

Result and discussion

Preliminarily, cytotoxicity assays demonstrated that 5 compounds significantly reduced cell viability. Further investigation using PARPi sensitization assays and clonogenic assays for colony formation identified 2 novel non-covalent UBE2N inhibitors that exhibited significantly higher potency than the known inhibitor ML307, particularly when combined with the PARPi Olaparib.

Conclusion

This study demonstrates, for the first time, successful PARPi sensitization using non-covalent UBE2N inhibitors, highlighting their potential to broaden PARPi therapy eligibility in ovarian cancer by enhancing tumor cell sensitivity to Olaparib.

EACR25-1465

Lysosomal Stress as an Off-target Effect of UNC0642 in Pancreatic Cancer Cells

A. Juan-Albuquerque¹, M. Lee¹, G. Grimes¹, N. Jiménez-Moreno¹, S. Wilkinson¹

¹University of Edinburgh, The Institute of Genetics and Cancer, Edinburgh, United Kingdom

Introduction

Many emerging and established anticancer therapies accumulate in lysosomes due to their physicochemical properties, independent of their intended targets. However, the relevance to anticancer activity remains understudied. Here, we use UNC0642, a G9a/GLP inhibitor, as a tool compound to investigate the impact of chronic lysosomal accumulation of a therapeutic molecule in pancreatic ductal adenocarcinoma (PDAC) cells.

Material and method

We generated a transient G9a/GLP double knockout (DKO) in a murine PDAC cell line using CRISPR-Cas9 and validated the loss of protein expression and enzymatic activity via Western blot. This DKO cell line was used to differentiate the on-target versus off-target effects of UNC0642. Immunofluorescence was performed to assess the expression of lysosome-associated proteins. Additionally, RNA-Seq followed by quantitative real-time PCR was used to examine transcriptional changes induced by lysosomal-damaging agents.

Result and discussion

UNC0642 was originally designed as a catalytic inhibitor of the methyltransferase G9a and its paralog GLP. However, using a G9a/GLP DKO PDAC cell line, we demonstrate that its primary anti-proliferative effect is mediated predominantly by an off-target mechanism. Lysotracker co-staining confirmed UNC0642 accumulation in lysosomes, leading to lysosomal swelling, as evidenced by increased LAMP-1 puncta and altered lysosomal morphology. Furthermore, UNC0642 induced chronic lysosomal damage, as demonstrated by increased galectin-3 puncta, a well-established marker of lysosomal membrane damage. Notably, UNC0642 triggered lysosomal damage to a similar extent as L-Leucyl-L-Leucine methyl ester (LLOMe), a known lysosomal detergent. Chronic lysosomal damage induced by UNC0642 and LLOMe correlated with reduced PDAC cell viability. Additionally, RNA-Seq revealed a novel transcriptional signature indicative of lysosomal damage, including upregulation of Serpinb9 family members, Car6, and Rgs1.

Conclusion

Our findings suggest that chronic lysosomal damage is a significant off-target effect that can create vulnerabilities in PDAC cells for targeted therapeutic treatment. These effects should be considered when evaluating the mechanisms of action of current and emerging anticancer therapies.

EACR25-1466

Multimodal targeting of Ephrin A2 in solid tumors using bi-cyclic drug conjugates

L. Diaz-Gil¹, A. Regupathy¹, J. Riedl¹, L. Mascheroni¹, M. Harman¹, L. Chen¹, K. Van Rietschoten¹, G. Mudd¹,

G. Bennett¹, M. Skynner¹

¹Bicycle Therapeutics, Cambridge, United Kingdom

Introduction

Bicycle® molecules are short linear peptides stabilized into a bi-cyclic conformation by a chemical scaffold. They are characterized by high affinity, selectivity, and small size, enabling fast tumor penetration and favourable pharmacokinetic. Bicycle® molecules can be readily conjugated to a variety of payloads, or to other Bicycle® molecules providing a toolkit of building blocks to create novel precision guided medicines. Ephrin A2 (EphA2) is a member of the Ephrin superfamily of receptor tyrosine kinases, which regulates cell migration, adhesion, proliferation and differentiation during development. It is highly expressed in different solid tumors while relatively low in healthy tissue but its targeting by antibody-drug conjugates has been unsuccessful.

Material and method

EphA2-specific binders were identified using phage display, and structure guided chemical optimization led to the development of a molecule with improved affinity, physicochemical properties and metabolic stability. This molecule was then used as the targeting moiety for the development of a set of three EphA2-specific therapeutic agents characterized by different mechanism of action: 1) a Bicycle® Drug Conjugate (BDC™) composed by the EphA2-targeting molecule, a valine-citrulline cleavable linker, and a monomethyl auristatin E (MMAE) cytotoxin payload (BT5528). 2) A Bicycle® Radionuclide Conjugate (BRC®) obtained by radiolabelling the EphA2-targeting molecule with 68Ga, for imaging purposes and with 177Lu, as a therapeutic agent. 3) A Bicycle® tumor-targeted immune cell agonist (TICA®) designed as a heterodimer composed of an EphA2- and CD137-targeting molecules (BT7455). Preclinical characterization of these molecules was evaluated in a variety of assays across both in vitro and in vivo settings.

Result and discussion

BT5528 demonstrated EphA2-dependant robust anti-tumor activity in preclinical models, including both cell- and patient-derived xenografts that are resistant to current treatments. In addition, imaging studies performed with an EphA2-targeting BRC, showed high tumor uptake and renal-mediated clearance, with minimal systemic exposure. Finally, BT7455 exhibited highly potent EphA2-dependent stimulation of CD137 and robust in vivo anti-tumor activity against EphA2-expressing tumors in preclinical models.

Conclusion

The Bicycle Platform enables the development of a multimodal therapeutic approach for solid tumor treatment, including the targeting of previously intractable proteins for other agents such as ADCs, therefore offering the opportunity to develop both best and first in class therapies. This approach is exemplified herein with EphA2 targeting Bicycle® containing molecules, with BT5528 currently in Phase 1/2 clinical trials

EACR25-1474

Tackling Hepatocellular Carcinoma with novel PROTAC Degraders of eIF6

G. Tempra¹, E. Fassi¹, A. Colleoni¹, G. Deroma², A. Miluzio², M. De Amici¹, G. Grazioso¹, S. Biffi², C. Matera¹

¹University of Milan, Department of Pharmaceutical Sciences, Milan, Italy

²National Institute of Molecular Genetics, Milan, Italy

Introduction

eIF6, a translation initiation factor that operates downstream of the insulin pathway, has recently emerged as a potential drug target. eIF6 levels have been shown to increase throughout the progression from Non-Alcoholic Fatty Liver Disease (NAFLD) to hepatocellular carcinoma (HCC), a major cause of cancer-related mortality worldwide. Furthermore, depletion of eIF6 has been observed to reduce tumorigenesis in Myc-induced lymphomagenesis and to decrease white fat accumulation in the liver. On these premises, modulating eIF6 activity could represent an effective strategy to prevent the pathological progression of NAFLD to HCC, as well as to target existing HCC. To this end, we are leveraging the PROTAC (Proteolysis Targeting Chimera) technology, which exploits the ubiquitin-proteasome system for targeted protein degradation.

Material and method

To explore the feasibility of targeting eIF6 for degradation, we are developing selective eIF6 PROTAC degraders based on previously identified eIF6 binders, along with new hits obtained through a virtual screening campaign. A computational study was conducted on a set of eIF6 degraders, utilizing molecular docking, molecular dynamics simulations (MDs), and ligand binding free energy calculations (MM-GBSA) to identify the most promising binders. These compounds are currently under investigation in biophysical and cellular assays to evaluate binding affinity and degradation efficiency.

Result and discussion

Several putative eIF6 binders were identified through computational studies, and biophysical assays confirmed their ability to bind the translation factor. The lead PROTAC candidates exhibited strong binding interactions in docking and MD simulations, supporting their potential to induce eIF6 degradation. These results suggest that selected compounds could serve as effective degraders. Further experimental validation is ongoing to assess their efficacy in cellular models.

Conclusion

The top-scoring eIF6 degrader candidates are currently under study. Preliminary findings support the potential of the PROTAC technology in targeting eIF6 for the treatment of HCC. The design, synthesis, and characterization of novel eIF6 PROTACs will be presented and discussed.

⁷Institute of Nanoscience, Nanotechnology, and Molecular Materials (INAMOL), Spain

Introduction

Coordination compounds are among the main chemotherapeutic treatments used for several cancer types. Although widely used, platinum-based therapies have limitations such as low selectivity, leading to side effects, reduced efficacy, and drug-resistance. Titanium (Ti) coordination compounds have emerged as promising agents in the treatment of cisplatin (CP)-resistant tumors. To solve some instability and solubility problems of these compounds, we synthesized a new titanocene-derived complex, $[\text{TiCp}_2(\text{OOC})_2\text{py-O-myrr}]$ (Myr-Ti), with improved stability and high albumin affinity. We explore the antitumor activity of Myr-Ti in CP-resistant models both *in vitro* and *in vivo*.

Material and method

Cytotoxicity of Myr-Ti in A2780CIS and COR-L23CPR (both CP-resistant tumor cells) and their sensitive variants was assessed by MTT assays. Intracellular Ti accumulation was measured by ICP-MS. Apoptosis and cell cycle progression were analyzed by flow cytometry with Annexin-V and PI staining. ROS production was evaluated using the DCFHDA probe by flow cytometry. Interaction of Myr-Ti with DNA was assessed by spectroscopic studies and DNA mobility assays. Proteins involved in ER stress were analyzed by western blot and PCR. For *in vivo* studies, nude-Foxn1 mice were subcutaneously xenografted with A2780CIS cells. Mice were treated for three weeks with Myr-Ti, and tumor volumes were measured daily.

Result and discussion

Myr-Ti was more cytotoxic than its precursor titanocene dichloride in all cell lines tested. IC₅₀ and resistance factor values pointed that this greater cytotoxicity is maintained in CP-resistant cells and correlated with increased Myr-Ti uptake. In addition, Myr-Ti led to an increase of apoptotic population and G2/M cell cycle arrest, which was not accompanied by an increase in ROS levels. Myr-Ti does not appear to interact with DNA, as no conformational changes were observed in electrophoretic mobility or by spectroscopic techniques. Furthermore, ER stress pathways were not activated in cells after Myr-Ti treatment, indicating that the

mechanism of action of Myr-Ti differs from those proposed for other Ti-derivatives. Finally, CP-resistant tumor-bearing mice treated with Myr-Ti showed greater tumor volume reduction and increased overall survival. Histological and Ki67 staining confirmed that Myr-Ti caused cell death in tumor tissue with minimal damage to other primary organs.

Conclusion

Together, these data support that Myr-Ti has significant antitumor activity in CP-resistance models both *in vitro* and *in vivo*. The underlying mechanisms seem to differ from those proposed for other coordination compounds, although further research is required. Myr-Ti showed improved therapeutic efficacy for overcoming CP-resistance, with limited adverse systemic side effects, highlighting its potential for further studies and clinical translation.

EACR25-1518

Targeting CITK in high-grade brain tumors: a comparison of polypharmacological and specific inhibitors

A. Ferraro¹, G. Pallavicini¹, G. Iegiani¹, R. Parolisi¹, M. Gai², C. Mercurio³, M. Varasi³, F. Di Cunto¹

¹Neuroscience Institute Cavalieri Ottolenghi, University of Turin, Department of Neurosciences, Orbassano, Turin, Italy

²University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy

³Experimental Therapeutics Program, FIRC Institute of Molecular Oncology Foundation IFOM, Milan, Italy

Introduction

Medulloblastoma (MB) and glioblastoma (GBM) are the most frequent high-grade brain tumors (HGBT) in children and adulthood, respectively. Despite the improvements in patient survival, many patients still die and those who survive suffer from neurological and endocrine disorders. Therefore, more effective therapies are needed. Citron Kinase (CITK), the primary product of the CIT gene, mutations of which are responsible for the MCPH17 primary microcephaly syndrome, is essential during neurodevelopment for proper cytokinesis and genomic stability in normal neural progenitor cells. CITK is validated as target for MB treatment as its depletion leads to cytokinesis failure and DNA double strand breaks (DSBs) accumulation in MB cells. Moreover, loss of CITK induces apoptosis and reduces tumor growth *in vivo*.

Material and method

After discovering that Lestaurtinib is an inhibitor of CITK, we tested it on different MB and GBM patient derived cell lines and *in vivo* injecting the drug in MBs arising in SmoA1 transgenic mice. In parallel, we conducted a Hit Discovery Program, which resulted in the identification of specific molecules targeting citron, which we subsequently tested on GBM patient-derived cell lines.

Result and discussion

Similar to CITK knockdown, treatment with Lestaurtinib leads to cytokinesis failure, accumulation of DNA double strand breaks, impairs cell proliferation and increases cell

death in MB and GBM cells. Also, Lestaurtinib treatment reduces tumor growth and increases mice survival. The Hit Discovery Program resulted in the identification of molecules that inhibit CITK in the low-nanomolar range. When tested on GBM cells, some of these molecules produced phenotypes characteristic of CITK loss, although their effects were weaker compared to the polypharmacological compound Lestaurtinib.

Conclusion

Compared to a polypharmacological inhibitor, more specific CITK catalytic inhibitors may recapitulate the effects of protein knockdown, but to a lesser extent and in a cell line-dependent manner. Given that the data on different cell lines show a varied response to CITK inhibition, we have begun to explore the genes and pathways that make a cell line sensitive to CITK, with the aim of predicting in the future which lines would be more responsive to treatment.

EACR25-1520

Development of Lipid-Based Gene Delivery Systems for CART Cell Therapy

M. Guerreiro¹, I. Pinto¹, D. Farinha¹, A. Sarmento-Ribeiro², H. Faneca¹

¹*Center for Neuroscience and Cell Biology (CNC), University of Coimbra; Centre for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra, Coimbra, Portugal*

²*Laboratory of Oncobiology and Hematology (LOH) and University Clinic of Hematology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal*

Introduction

Chimeric Antigen Receptor (CAR) T cell therapy has revolutionised cancer treatment by engineering T cells to recognise and eliminate tumour cells. While viral vectors are the standard method for gene delivery in CAR T cell production, they present challenges, including high costs and safety concerns. Lipid-based vectors, particularly liposomes, have emerged as a promising alternative due to their biocompatibility, and ability to protect and efficiently deliver genetic material. Taking advantage of these characteristics, this study aims to develop and characterise liposome formulations to overcome current limitations in gene delivery and improve CAR T cell production.

Material and method

Five formulations (F1-F5), with different molar ratios of selected lipids, were prepared using the thin-film hydration method followed by extrusion. Lipid quantification was performed using the Liebermann-Burchard method for formulations F1, F2 and F5 and Fiske-Subbarow for F3 and F4. Lipoplexes were formed by mixing the liposomes with a DNA plasmid, encoding the green fluorescent protein, at different (+/-) charge ratios (1/1; 2/1; 4/1; 8/1). Dynamic light scattering characterised the lipoplexes for size, polydispersity index and zeta potential. Transfection efficiency and cytotoxicity were evaluated 48h post-transfection by flow cytometry.

Result and discussion

Prepared liposomes were large unilamellar vesicles (98.3-152.7 nm) with positive surface charges (34.2-47.8

mV), confirming their cationic nature, which can facilitate plasmid DNA complexation. Electrostatic interactions, established between the positive charges of liposomes and negative charges of DNA, induced the formation of liposome/DNA complexes, also called lipoplexes, as indicated by size and zeta potential shifts. Lipoplexes prepared at lower charge ratios (1/1; 2/1) displayed larger particle sizes, suggesting less DNA complexation, while higher ratios (4/1; 8/1) resulted in smaller, more stable complexes. Lipoplexes prepared at the charge ratio 1/1 revealed a negative surface charge, while the remaining formulations (2/1; 4/1; 8/1) exhibited a positive surface charge. Lipoplexes prepared with liposomes F4, at the charge ratio of 4/1, achieved the highest transfection efficiency likely due to the balance between particle size, surface charge and lipid composition, potentially enhancing membrane interaction and endosomal escape. Lipoplexes prepared at the charge ratio 8/1 promoted an increase in cytotoxicity, suggesting that while higher charge ratios may stabilise lipoplexes, they can also compromise cell viability.

Conclusion

Although liposomes show promise as a safer, more effective alternative for CAR T cell obtention, further optimisation, such as incorporating targeting ligands to improve lipoplexes internalisation, is needed to enhance transfection efficiency.

EACR25-1553

Development of GD2-Targeted Herpes simplex vectors for OncoVirotherapy

A. Napolano¹, M. Fenech¹, A. Finizio², E. Sasso¹, N. Zambrano¹

¹*University of Naples Federico II, Dipartimento Medicina Molecolare e Biotecnologie Mediche, Naples, Italy*

²*University of Naples Federico II, CEINGE Biotecnologie Avanzate Franco Salvatore, Naples, Italy*

Introduction

GD2 is a ganglioside gaining therapeutic relevance due to its high expression in tumors like glioblastoma, melanoma and neuroblastoma (NB), and minimal presence in normal tissues. It plays a role in cell signaling and tumor progression, making it an attractive target for cancer immunotherapy. Among these tumors, NB is particularly significant; it accounts for 7-8% of childhood cancers and 15% of cancer-related deaths. High-risk NB remains a major therapeutic challenge due to its heterogeneity, plasticity, and immunosuppressive micro-environment. Despite advances in multimodal treatments, survival rates for high-risk NB remain suboptimal, underscoring the need for novel strategies. A recent FDA-approved therapy targets GD2 with monoclonal antibodies (mAbs) and GM-CSF. However, GD2's low-level expression on neurons and peripheral nerve fibers leads to off-target effects, causing severe pain in treated patients. To address these limitations, we developed GD2-targeted oncolytic Herpes virus for intratumoral therapy, based on attenuated versions of HSV-1. Improved safety and specificity of the engineered vectors was obtained by replacing a key region of HSV glycoprotein D (gD) with

a single-chain variable fragment (scFv) from anti-GD2 mAbs, ensuring selective infection of GD2-positive cells.

Material and method

We modified the HSV-1 backbone using recombineering in *E. coli*. Positive clones were validated by sequencing and expanded. For optimized viral production, producing cells were transfected with constructs carrying GD3 and GD2 synthase coding sequences, and stable clones were selected via antibiotic resistance.

Result and discussion

We engineered the HSV-1 genome to obtain a viral construct characterized by high safety profile, possessing the ability to selectively target GD2-expressing tumor cells; in order to optimize viral production, we generated a stable producer cells with an improved feature of GD2 exposure on cell surface. Flow cytometry confirmed GD2 upregulation in these cells. Preliminary data show that the engineered virus preferentially infects GD2+ cells compared to GD2-negative controls, demonstrating selectivity and potential therapeutic relevance.

Conclusion

Our GD2-targeted oncolytic HSV-1 combines attenuation with de-targeting and re-targeting strategies to enhance safety and efficacy. By integrating tumor-specific targeting with immunostimulatory effects, this approach maximizes anti-tumor activity while minimizing off-target effects. Furthermore, our GD2 upregulation strategy provides a versatile platform adaptable to other cell lines, broadening its potential in targeted virotherapy. These findings lay the groundwork for further preclinical validation, offering a promising avenue for improving treatment of GD2-positive tumors, including neuroblastoma.

EACR25-1579

Therapeutic deep eutectic systems as promising selective therapeutic agents in the anticancer battle

F. Oliveira¹, A. C. Duarte¹

¹NOVA School of Science and Technology, LAQV/REQUIMTE, Department of Chemistry, Caparica, Portugal

Introduction

Considering cancer is the second leading cause of death worldwide, and colorectal cancer (CRC) ranks among the most incident and deadly ones, with conventional therapeutics lacking on selectiveness with severe consequent undesired side-effects. The main aim of this work was to design a selective anti-CRC agent aligned with pharmaceutical industry sustainable goals.

Following eutectic systems spotlight due to their remarkable physicochemical and biological properties, this work sought to push forward their reported promising cytotoxicity towards cancer cells, by unravelling eutectics specific interaction with CRC cells.

Material and method

For that, therapeutic deep eutectic systems (THEDES) based on the combination of a terpene with an anti-inflammatory drug, were prepared embodying liquid formulations that could leverage both individual components inherent therapeutic traits. Subsequently, an integrated approach was employed to evaluate

THEDES effect on several indicators of potential therapeutic value towards CRC.

Result and discussion

In a first step, combining menthol:ibuprofen (3:1), thymol:ibuprofen (3:1), perillyl alcohol:ibuprofen (3:1) and (8:1), limonene:ibuprofen (4:1) and (8:1), revealed promising anti-CRC effect by enhancing ibuprofen bioavailability, reduce reactive oxygen species, and inducing cell death via apoptosis. Secondly, THEDES specific interaction with CRC cellular metabolome showed alterations in the metabolite landscape, with deleterious effect on essential metabolic pathways, such as lipid and anaerobic glycolysis energy production. Preliminary *in vivo* systemic toxicity assessments using a Zebrafish animal model indicated non-relevant toxicity of these THEDES within their therapeutic window concentration range. Finally, a controlled drug delivery system based on liposomes (LPS) was developed foreseeing THEDES further therapeutic application. LPS with particle size within the range of 200 nm, mono-dispersed and with negative homogeneous zeta potentials were obtained, showing 27% of Me:Ibu (3:1) encapsulation efficiency.

Conclusion

In summary, this work aimed to provide a better understanding of the specific anticancer activity of THEDES, towards their establishment as an alternative or complementary therapeutic agent towards CRC.

EACR25-1583

Identification and Validation of new In-Silico Designed MYC Binders

J. Neng¹

¹University of Cambridge, Pharmacology, Cambridge, United Kingdom

Introduction

The MYC protein, as a transcription factor, is involved in the regulation of 70% human genome in response to proliferation signals. The C-terminal region plays an essential role in transcriptional activity with its obligatory binding partner-MAX by binding to E-box region of DNA. MYC deregulation has been found in various types of cancers with high prevalence, such as lung cancer, breast cancer, and ovarian cancer. In the past several decades, the MYC protein as a priority target for cancer therapies has been intensively studied due to its importance in tumorigenesis. However, due to its intrinsically disordered nature, no drug against MYC passed clinical trials in the past twenty years. Targeting MYC is challenging, however, small-molecule inhibitors have been shown promising potential recently by disrupting of MYC-MAX heterodimerization or preventing of DNA binding. However, most known MYC inhibitors have limitations, including low binding affinity, low potency, or poor tissue penetration. While many researchers still focus on small-molecule MYC inhibition, proteolysis targeting chimeras (PROTACs) are an advanced tool to reduce MYC over-expression by hijacking the ubiquitin-proteasome system (UPS) and inducing cellular protein depletion rapidly and long-lastingly. The design of PROTACs requires a ligand binding to the protein of interest, which is MYC, and a ligand recruiting UPS. Computer-aided drug discovery

has been used as a useful tool for hit compound identification, including structure-based virtual screening (SBVS) and ligand-based virtual screening (LBVS). The aim of this study is to identify and validate new MYC binders via SBVS and LBVS based on known small-molecule MYC inhibitors for the design of PROTACs against MYC.

Material and method

Ligand-based virtual screening (LBVS) and structure-based virtual screening (SBVS) were performed in parallel in three selected chemical libraries, Specs, ChemDiv, and Vitas, to identify potential MYC binders. Potential binding sites of the MYC protein in MAX-bound form were predicted by Glide in the putative active sites. Docked chemicals were ranked in GlideScore for the prediction of binding affinities and validated in auto-blind docking and GOLD docking due to the lack of concaved cavities of MYC for strong interactions. The binding abilities and the effects on MYC stability were assessed in *in vitro* and *in cellulo* assays including SPR and HiBiT system.

Result and discussion

Nine novel compounds have been identified as potential MYC binders from *in silico* screening, and three of them have been shown to bind to MYC C-terminal protein and destabilize MYC in *cellulo*. NC04 only had binding ability with no apparent effect on endogenous MYC stability whereas NC05, NC06, and NC09 showed to destabilize MYC only.

Conclusion

The work in this study offers prospective POI ligands for the construction of PROTACs against the MYC protein, although further biological evaluations are required.

Introduction

Acute myeloid leukemia (AML) is a hematologic malignancy that represents ~20% of pediatric leukemias, but accounts for most of the disease-related mortality in children. Given the genetic heterogeneity of pediatric AML that impacts patient survival rate and relapse, a single treatment strategy does not exist for all AML subtypes. This underlines the urgent need for novel targeted (genotype specific) therapies. Through a high-throughput drug screen comparing the growth inhibition of 37 AML samples and normal cord blood stem cells (CB CD34+) treated with approximately 11,000 compounds, we identified compound 280 which is structurally related to a previously reported proteasome inhibitor.

Material and method

In collaboration with the Drug Discovery Unit at the Institute for Research in Immunology and Cancer (IRIC), we synthesized and characterized over 80 analogs of compound 280. We determined the half-maximal inhibitory concentrations (IC₅₀) for these analogs in cell viability assays using three AML cell lines and conducted purified proteasome inhibition assays to further evaluate their proteasome inhibitory activities. To assess the potential mechanisms of action of these analogs, we performed a CRISPR chemogenomic screen in the B-ALL cell line NALM-6 using the top two analogs and Bortezomib (BTZ). To evaluate the behavior of these compounds *in vivo*, we have conducted pharmacokinetic (PK) studies, as well as metabolic stability in animal models.

Result and discussion

Several analogs exhibited lower proteasome inhibition compared to BTZ based on the enzymatic IC₅₀ values, but demonstrated greater efficacy in inhibiting AML cell growth, as indicated by cell-based IC₅₀ values. CRISPR chemogenomic analysis confirmed that both our analogs and BTZ target the proteasome. However, the loss of genes linked to resistance mechanisms, including those associated with drug efflux, increased cell sensitivity to the analogs, but did not alter sensitivity to BTZ. This finding suggests that while both BTZ and our novel compounds target the proteasome, they likely rely on different molecular mechanisms of resistance. PK studies indicated that the selected analogs, when administered intraperitoneally (IP), showed favorable stability, prolonged systemic exposure, and appropriate PK parameters, supporting their potential for further development.

Conclusion

Our novel proteasome inhibitor shows promising potential for clinical application in pediatric AML. By understanding how compound 280 and its analogs impact AML cell growth and resistance mechanisms, we aim to develop targeted therapies tailored to specific genetic alterations in AML patients. Furthermore, these therapies may extend their applicability to other hematologic

disorders and solid tumors, addressing a broader spectrum of cancers.

Combined siRNA targeting of oncogenic NRAS and BRAF drivers as a strategy for mole reversal and melanoma prevention

P. Jones¹, M. Rabii¹, I. Del Valle Torres¹, A. Sauvadet¹, A. Pasquier², M. Howell², D. Bryant¹, V. Kinsler¹

¹The Francis Crick Institute, London, United Kingdom

²The Francis Crick Institute, High Throughput Facility, London, United Kingdom

Introduction

An estimated 30% of melanomas arise from a pre-existing melanocytic naevus (mole), the majority expressing an activating variant in BRAF or NRAS, and naevus count is one of the major risk factors for melanoma development. Mole reversal – or induction of complete regression in naevi – is therefore highly desirable as a novel strategy in the prevention of melanoma. Recent data demonstrated siRNA targeting of NRASQ61K induces intrinsic apoptosis in primary naevus cells, that variant-allele specificity reduces off-target effects by 90%, and that it is easily deliverable into the skin *in vivo*. We sought to extend the therapeutic potential of mole reversal therapy by combining siRNAs against the three commonest melanoma drivers into a single product.

Material and method

Antisense siRNAs to siNRASQ61K (NM_002524.5 (NRAS):c.181C>A,p.(Q61K)), siNRASQ61R (NM_002524.5(NRAS:c.182A>G,p.(Q61R)) and siBRAFV600E (NM_004333.4(BRAF):c.1799T>A,p (V600E) were designed and optimised to be variant allele-specific. Melanoma cell lines, each expressing a single driver, were transfected with the relevant single and the triple combination siRNAs. Allele preferential knockdown was determined by RT-qPCR. Live cell imaging monitored cell viability proliferation and caspase 3/7 activation over 5 days post-transfection. Dose-response relationships between siRNA dose and apoptotic activity were determined.

Result and discussion

We show here that single driver variant-targeted knockdown reduces proliferation and induces intrinsic apoptosis in multiple melanoma cell lines, in a dose-dependent manner, compared to non-targeting siRNA. Combination siRNA therapy was equally effective at inducing knockdown of the relevant driver, and induction of apoptosis. Furthermore, no significant pro-apoptotic effect of individual or combination siRNAs was observed in wild type expressing cell lines, highlighting the specificity of the therapy.

Conclusion

A single combination siRNA therapy is a viable therapeutic option for mole reversal and melanoma prevention and would target 80% of naevi without the need to biopsy and genotype. The efficacy across multiple melanoma cell lines also supports exploration of this as a therapy for melanoma.

EACR25-1595

Potential of inhibition of AR to enhance the sensitivity of OVCAR-3 cells to PARP inhibitor

N. Gligorijevic¹

¹Institute for Oncology and Radiology of Serbia, Department of Experimental Oncology, Belgrade, Serbia

Introduction

Ovarian cancer (OVCA) is among the most lethal gynecological malignancies with a variety of cellular origins and has a variety of histological characteristics and therapeutic responses. The ovarian cancer treatment involves surgical de-bulking, followed by chemotherapy based on platinum drugs or taxane. The treatment challenge represents the appearance of relapse and developed drug-resistant disease. Estrogen and progesterone receptors (ER and PR) are widely expressed in normal and tumor ovarian tissues, but interestingly, the androgen receptor (AR) is more widely expressed in ovarian cancer than either ER or PR in up to 85% of cancers. The AR plays although unclear, important role in OVCA progression and lately represents an interesting potential therapeutic target for OVCA treatment. In ovarian cancer, approximately 50% of tumors display defective HR repair (homologous recombination pathway of DNA repair). This can be used to create drug-drug synthetic lethality scenario with an inhibitor of PARP. In the present study, we investigated the effect of non-steroidal, second generation, potent AR signaling inhibitor, enzalutamide (MDV-3100), in combination with the potent and selective PARP1 and PARP2 inhibitor AZD2461, an olaparib analog, in concomitant or lead-in treatment in OVCAR-3 cells. OVCAR3 cells are selected for this study, as one of the most widely studied and highly representative model of High grade serous ovarian cancer (HGSOC) cells.

Material and method

The effect of MDV-3100 in combination with the AZD2461 in concomitant or lead-in treatment in OVCAR-3 cells was determined on cell viability by MTT assay, apoptotic potential by dual Annexin/PI staining and flow cytometry and cell cycle perturbations was analyzed by flow cytometry

Result and discussion

Our results in OVCAR-3 cells showed that 3 days pre-treatment with MDV-3100 (30 μ M concentration) followed by PARP inhibitor AZD2461 treatment (30 μ M concentration) for additional 3 days, more efficiently inhibited cell viability (up to 40,73% cell survival) compared to concomitant administration (up to 54,31% cell survival) and AZD2461 alone (80,38% cell survival). This effect was result of induced cell cycle perturbations and apoptosis. Investigation of apoptotic potential confirmed higher efficiency of pre-treatment with MDV-3100 compared to the concomitant administration of MDV-3100 and AZD2461.

Conclusion

Investigation of presented treatment modality had for task to find treatment strategy with non-cytotoxic concentrations of agents in order to enhance efficacy. The pre-treatment with AR inhibitor MDV-3100 followed by PARP inhibitor AZD2461 *in vitro* is more efficient in growth inhibition and induction of apoptosis in OVCAR-

3 cells, compared to the concomitant administration. This treatment strategy may expand the benefits of using PARP inhibitors in OVCA treatment.

EACR25-1600

Oral liquid crystalline dispersion effect in chemotherapy-induced intestinal mucositis

M. Teixeira¹, M. Fialho¹, A. Almeida¹, B. Araújo¹, V. Mosqueira¹, A. Ruela¹, R. Araújo¹

¹Federal University of Ouro Preto, Ouro Preto, Brazil

Introduction

Intestinal mucositis (IM) is a common adverse effect of oncological treatments, significantly impacting the outcome of the cancer treatment. Unfortunately, treatments are often limited to palliative care. As a result, there is an urgency for effective therapies to prevent and treat chemotherapy-induced mucositis in the clinic. β -caryophyllene (BCAR) is a terpenoid with anti-inflammatory properties found in some plants such as rosemary and copaiba. One of the challenges in treating IM orally is the short residence time of the active ingredients in the intestine, which reduces their action. Sustained release systems such as liquid-crystalline (LC) dispersions can gel in contact with gastrointestinal fluids, increasing AI retention in the site and thus enhancing its therapeutic effect. Therefore, this work aims to develop *in situ* gelling LC dispersions containing BCAR and evaluate the BCAR release properties. In addition, their mucoadhesive effect was studied in a model of IM induced by chemotherapy.

Material and method

LC dispersion containing 2.5% of BCAR was prepared by a simple mixture of monolein, oleic acid, and water. BCAR release study in simulated gastric (SG) and intestinal media (SI) was performed, and its quantification was determined by high liquid chromatography. IM was induced in Balb/C male mice (20–25 g) by an intraperitoneal injection of 300 mg/kg of 5-fluorouracil. After 72 h, the IR780 free dye or the LC-BCAR-IR780 were administered orally in IM-bearing mice ($n = 3$). After four hours, animals were anesthetized using 2 % isoflurane, and whole-body images were taken using the IVIS® fluorescent optical imaging technique. Total radiant efficiency was acquired through the ROI of the whole animal and each tissue [1]. The data were analyzed by ANOVA (GraphPad Prism 5) and were expressed as mean values \pm standard deviations. P-values < 0.05 were considered significant.

Result and discussion

The LC formulation was successfully obtained for mucosal administration, resulting in an increased viscosity upon contact with gastric and intestinal fluids. The release of BCAR from LC in SI media was higher than in SG. The opposite was observed for free BCAR. Four hours after oral administration, fluorescence was seen in the gastrointestinal tracts of the animals. Ex vivo results demonstrated increased intestinal retention of IR780 associated with LC-BCAR compared to the free IR780 ($p < 0.05$) confirming the mucoadhesive properties of LC-BCAR in the intestine.

Conclusion

These results indicate that LC-BCAR can represent a potential therapeutic advantage for patients with IM once it exhibits gelling properties upon contact with gastrointestinal media and mucoadhesive characteristics, facilitating a greater presence of BCAR at the target site. [1] This work was approved by the Ethics Committee on Animal Use of the Federal University of Ouro Preto (protocol 1719080322).

Targeting Invasive Behavior in 2D, 3D, and In Vivo Models with Pentamethinium Salts as Migrastatic Agents

K. Petrlakova¹, B. Peltanova¹, M. Jakubek², M. Masarik¹

¹Masaryk University, Faculty of Medicine, Department of Pathophysiology, Brno, Czech Republic

²Charles University, 1st Faculty of Medicine, Prague, Czech Republic

Introduction

Metastasis remains a major cause of cancer-related death, underscoring the need for therapies targeting cancer cell migration and invasion. Migrastatic therapy – strategies specifically designed to disrupt cancer cell migration or invasion – represents a promising approach to preventing metastatic progression. Pentamethinium salts (PMS), compounds initially developed as mitochondrial-targeted probes, bind specifically to the inner mitochondrial membrane and inhibit oxidative phosphorylation, a critical energy source required for invasive behavior. This study evaluates the migrastatic efficacy of PMS across 2D, 3D, and *in vivo* cancer models.

Material and method

In vitro assays utilized breast cancer and melanoma cell lines. Standard wound healing and invasion assays were conducted to evaluate migratory and invasive capacities in 2D cultures. For 3D assays, spheroids were generated by culturing cancer cells under ultra-low attachment conditions. Spheroids were embedded in a collagen matrix and subsequently treated with varying concentrations of PMS. *In vivo* studies utilized syngeneic mouse models of breast cancer and melanoma. Tumor-bearing mice received intraperitoneal injections of PMS to assess their impact on metastatic dissemination. Primary tumor growth was monitored over time, and metastatic lesions in distant organs were quantified histologically.

Result and discussion

PMS significantly inhibited the invasive behavior of cancer cells across 2D, 3D, and *in vivo* models. In 2D assays, treatment with PMS markedly reduced cancer cell migration and invasion. Similarly, in 3D spheroid assays, PMS effectively prevented spheroid invasion into the collagen matrix compared to untreated controls. *In vivo*, PMS treatment resulted in a notable reduction of metastatic spread in syngeneic mouse models, without affecting primary tumor growth. These findings demonstrate the robust migrastatic activity of PMS across multiple experimental platforms and highlight their therapeutic potential in preventing metastatic dissemination.

Conclusion

PMS exhibit strong migrastatic efficacy, effectively suppressing invasive behavior in 2D, 3D, and *in vivo*

cancer models. These findings highlight their therapeutic promise as novel agents capable of targeting metastatic dissemination. Further studies aimed at elucidating their mechanisms of action and evaluating clinical translational potential are warranted.

Microneedle-mediated delivery of Iron Oxide Nanoparticles & Oxaliplatin with immune checkpoint inhibitors for its induction of ferroptosis and immunomodulation in Head and neck squamous cell carcinoma

D. Tripathy¹, J. Crane², R. Kishan¹, X. Lan³, J. Zhong¹, W. Zhou¹, J. Rivas², R. Su¹

¹The University of Hong Kong, Dentistry, Sai Ying Pun, Hong Kong, China

²Swansea University, Chemistry, Swansea, United Kingdom

³Capital Medical University, Pharmaceutical Sciences, Beijing, China

Introduction

Head and neck squamous cell carcinoma (HNSCC) has a poor prognosis with less than 50% mortality rate with the multimodal therapies. Although surgery, chemotherapy and radiation therapy are most important treatment modalities used, there are associated long term side effects with poor life expectancy which bids for new emerging treatment strategies. In this study, MN mediated delivery of iron oxide nanoparticles & oxaliplatin with immune checkpoint inhibitors (anti PD-L1, anti-CTLA-4) was evaluated for its induction of ferroptosis and immunomodulation in Head and neck squamous cell carcinoma.

Material and method

HNSCC cell line MOC-1 was treated with IONPs, Oxaliplatin, and ICI which were assessed in both In-vitro & In-vivo systems. For In-vitro studies, Cytotoxicity (CCK-8), Ferroptosis induction ROS (DCF-DA) and LPO (BODIPY C11), Apoptosis (Annexin-PI), Cell Cycle (PI) analyzed through spectrophotometry & Flow Cytometry and Ferroptosis/Apoptosis markers (GPX4, COX2, c-Caspase 3) through Western blot to compare treated/untreated groups. For In-vivo studies, MOC1-lucigtag cells injected in C57BL/6 mice subcutaneously and tumor sizes assessed in dissolvable MN NP treated groups by bioluminescence signals. IHC-P was performed with treated/untreated tissue samples.

Differential Expressed Genes (DEGs) and PCA deduced through RNA-Seq and data was analyzed through EBSeq.

Result and discussion

IONP DLIN showed the most effective cytotoxicity with least IC50 (0.20 mM) compared to unconjugated IONP (0.90 mM) and Oxaliplatin (0.45 mM) in 24h MOC-1 cells In-vitro. Significant ferroptosis induction seen in DLIN (0.30 mM) treated cells with high LPO+ (52%) and high ROS+ (64%) compared to untreated cells. Oxaliplatin (0.30 mM) showed higher ROS/LPO induction among all treatment groups In-vitro. Apoptosis induction was higher in Oxaliplatin with Annexin V + cells (30%) than DLIN (14%) or Erastin (9%) as compared to untreated (5%). Significant cell death with

high sub G1 % in DLIN (86%) than apoptotic cells and changes in protein markers such reduced GPX4 and increased COX2 expression in Erastin, DLIN and mix treated cells is implicative of ferroptosis induction. In-vivo MN-treatment showed decreased tumor with highest reduction in mixed (IONP/Oxali/ICI) as compared to untreated group. Immunomodulation was corroborated with high CD8 than CD4 and lower PD-L1, Ki67 expression in DLIN, Oxaliplatin & Mix IHC-P groups. RNA-Seq data revealed ~ 4600-7500 differential expressed genes (DEGs) (FDR < 0.05) in DLIN samples as compared to untreated both in-vitro/in-vivo groups.

Conclusion

IONP NPs has shown significant cytotoxicity with ferroptosis induction in cancer cells which was comparable to Oxaliplatin. The synergistic effect of the MN-mediated delivery of IONP/Oxali with the immune checkpoint inhibitors had enhanced cytotoxicity in tumor cells which could be targeted in cancer therapeutics strategies.

EACR25-1710

Targeting RRM2: A Dual Approach to Apoptosis and Cell Cycle Control in Atypical Teratoid Rhabdoid Tumors

L. Giang¹, T. Wong², C. Chang¹

¹Taipei Medical University, The Ph.D. Program for Translational Medicine, College of Medical Science and Technology, New Taipei City, Taiwan

²Taipei Medical University, Graduate Institute of Clinical Medicine, College of Medicine, Taipei, Taiwan

Introduction

Atypical teratoid rhabdoid tumor (ATRT) is a highly aggressive central nervous system (CNS) embryonal tumor that predominantly affects young children and remains incurable. Current treatment strategies, including upfront high-dose chemotherapy (HDC) and radiation therapy (RT), have improved survival rates; however, they often result in significant long-term neurocognitive deficits. Despite these aggressive interventions, the overall prognosis for ATRT patients remains poor. This highlights the urgent need for novel, targeted therapeutic approaches that can improve patient outcomes while minimizing detrimental side effects.

Material and method

To identify potential therapeutic targets, we analyzed multiple independent ATRT clinical cohorts and identified ribonucleotide reductase subunit M2 (RRM2) as significantly overexpressed, with elevated expression correlating with poorer patient survival. Functional studies were conducted to assess the impact of RRM2 depletion on ATRT cell proliferation, colony formation, and migration. Additionally, we evaluated the therapeutic efficacy of COH29, a pharmacological inhibitor of RRM2, in both in vitro ATRT cell models and in vivo orthotopic mouse model. Mechanistic studies were performed to elucidate the effects of RRM2 inhibition on genomic stability, homologous recombination (HR) DNA repair, and apoptotic signaling pathways. Furthermore, we investigated the involvement of the ATM/Rb/E2F1 signaling axis in mediating the cellular effects of RRM2 inhibition.

Result and discussion

Our study demonstrated that RRM2 depletion significantly reduced ATRT cell proliferation, migration, and colony formation. Treatment with COH29 effectively suppressed ATRT tumor growth both in vitro and in vivo, underscoring the potential of RRM2 as a therapeutic target. Mechanistic analyses revealed that RRM2 inhibition led to increased genomic instability, impaired HR DNA repair, and enhanced DNA damage-induced apoptosis. Further investigation into the underlying signaling pathways showed that COH29-mediated RRM2 inhibition activated the ATM/Rb/E2F1 pathway. Specifically, this resulted in reduced phosphorylation of Rb, decreased E2F1 transcriptional activity, and subsequent inhibition of cell cycle progression. These effects culminated in G1-phase cell cycle arrest, impaired S-phase entry, and compromised DNA repair capacity, ultimately driving ATRT cells toward apoptosis.

Conclusion

Our findings establish RRM2 as a critical oncogenic factor in ATRT and highlight its potential as a therapeutic target. By disrupting both DNA damage response and cell cycle regulation, RRM2 inhibition presents a promising strategy for ATRT treatment. These insights provide a strong foundation for the development of novel therapeutic approaches aimed at improving outcomes for patients with this devastating pediatric tumor.

Rhenium Complexes as Promising Selective Anticancer Agents

A. Pogorzelska¹, K. Lyczko², M. Milczarek¹, U. Czećzik^{1,3}, J. Rode², R. Kawęcki⁴, J. Dobrowolski¹

¹National Medicines Institute, Department of Biomedical Research, Warsaw, Poland

²Institute of Nuclear Chemistry and Technology, Warsaw, Poland

³Centre for Translational Medicine, University of Life Sciences, Warsaw, Poland

⁴University of Siedlce, Faculty of Science, Siedlce, Poland

Introduction

Despite the intensive development of targeted therapies, chemotherapy still plays a central role in cancer treatment. One group of classical therapies is platinum(Pt)-based drugs. However, their side effects, lack of selectivity, high systemic toxicity, and drug resistance limit their clinical use. Consequently, due to these limitations and the efficacy in cancer cells of Pt-based drugs, there is an ongoing intensive search for new, more promising metal-based anticancer drugs. Consequently, due to these limitations and the efficacy of Pt-based drugs in cancer cells, there is an ongoing intensive search for new, more promising metal-based anticancer drugs. One of the potential therapeutic anticancer metals is rhenium (Re). This study presents several new Re complexes and their cytotoxicity on cancer and non-cancerous cell lines.

Material and method

All the chemicals were purchased from Sigma-Aldrich. The neutral complexes $[Re(CO)_3((R/S)-LNO)Cl]$ and $[Re(CO)_3(LNS)X]$ ($X=Cl, Br$) were obtained in the

reaction of $Re(CO)_5X$ with the respective bidentate N, O- or N, S-donor ligands. In turn, during the reaction of $Re(I)$ precursor and (R/S)-LNO or LNS with a heterocyclic monodentate N-donor ligand (3-methylpyrazole (Hmpz), 3,5-dimethylpyrazole (Hdmpz) or imidazole (Him)), after earlier precipitation of Cl^- ions using the $AgPF_6$ salt, cationic complexes $[Re(CO)_3((R/S)-LNO)Him]PF_6$, $[Re(CO)_3(LNS)Hmpz]PF_6$ and $[Re(CO)_3(LNS)Hdmpz]PF_6$ were obtained. The dose-effect curves for the rhenium(i) complexes in the 100–3.125 μM range were plotted to determine the IC₅₀ values in the MTT assay after 24 and 48 hours of treatment. The cytotoxicity of the studied compounds was evaluated against cancer cells, including breast (MDA-MB-231), ovarian (SKOV-3), colon (Colo-205), lung (A549), and prostate (PC-3), as well as non-cancerous cells, including breast (MCF-10A), colon (CRL-1790), and prostate (PNT1A).

Result and discussion

Among the tested compounds, $ReClCl$ and $ReClBr$ exhibited the most promising activity and selectivity, demonstrating high cytotoxicity against prostate and colon cancer cells while remaining significantly less toxic to their non-cancerous counterparts. This selective cytotoxicity suggests their potential as targeted anticancer agents, effectively eliminating malignant cells while sparing healthy tissues. Notably, the $ReRLnoCl$ complex demonstrated potent cytotoxicity against triple-negative breast cancer (TNBC) cells while showing less significant toxicity toward non-cancerous breast cells, further highlighting its therapeutic selectivity.

Conclusion

Three proposed complexes showed selective cytotoxicity, highlighting their potential as selective anticancer agents.

⁵Ecole Polytechnique Fédérale de Lausanne, School of Life Sciences, Lausanne, Switzerland

Introduction

Breast cancer is the most prevalent malignancy in women and the second leading cause of cancer-related mortality worldwide. Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer and is characterized by high metastatic potential, severe side effects, and lack of targeted therapies. Therefore, novel and targeted TNBC treatment strategies are warranted. DNA polymerase 1 (POLA1) and histone deacetylase 11

(HDAC11) are critical regulators of cell proliferation, DNA replication, and epigenetic mechanisms, making them promising therapeutic targets in TNBC. We have previously shown that the adamantyl retinoid ST1926 is a POLA1 inhibitor with potent anti-tumor activities in breast cancer cells. We have synthesized two ST1926 analogues, MIR002 and GEM144, which exhibit dual inhibitory activity against POLA1 and HDAC11. We investigated the anti-tumor properties of these adamantyl compounds in human TNBC *in vitro* and *in vivo* models, focusing on GEM144 due to its superior pharmacokinetic properties.

Material and method

In silico analysis was conducted to evaluate the expression of POLA1 and HDAC11 in human TNBC versus normal breast tissues. POLA1 and HDAC11 levels were determined by immunoblotting techniques in different subtypes of human TNBC cell lines (basal-like HCC1806, luminal androgen receptor (apocrine) MDA-MD-453, and the mesenchymal stem-like MDA-MB-231) as well as the normal-like breast cell line, MCF10A. The mechanism of action of GEM144 was studied by assessing TNBC cell viability, cell death, DNA damage, and apoptosis induction. For *in vivo* studies, the mouse intraductal breast cancer model using female NSG mice was explored as a true orthotopic model for breast cancer studies. Tumor progression and treatment response were monitored using the *in vivo* imaging system (IVIS).

Result and discussion

In silico analysis did not indicate any statistically significant differences in the transcript levels of POLA1 and HDAC11 between human TNBC tumors and normal breast tissues. However, basal protein levels of POLA1 and HDAC11 were elevated in several TNBC cell lines compared to normal-like breast cells. ST1926, MIR002, and GEM144 reduced viability and increased cell death in the different tested TNBC cell lines at sub- μ M concentrations while sparing normal-like breast cells. GEM144 induced DNA damage in treated TNBC cells, as shown by increased gH2AX levels, and resulted in apoptosis, confirmed by TUNEL positivity and PARP cleavage. *In vivo* administration of GEM144 at 20 mg/kg reduced tumor burden in HCC1806 intraductal xenografts, without any major signs of toxicity.

Conclusion

Our findings highlight the therapeutic potential of DNA polymerase inhibitors in TNBC. Next, we will evaluate the effectiveness of GEM144 in combination with standard chemotherapies in TNBC cell lines and patient-derived xenografts.

EACR25-1745

Targeting RSK1 in Colon Cancer: Discovery and Evaluation of a New Small Molecule Inhibitor

U. Muhim¹, F. Comert Onder², E. Tokay¹, F. Kockar¹

¹Balikesir University Institute of Science, Molecular Biology and Genetics, Balikesir, Turkey

²Canakkale Onsekiz Mart University Faculty of Medicine, Medical Biology, Canakkale, Turkey

Introduction

Ribosomal Protein S6 Kinase 1 (RSK1) is a member of the RSK family. The expression levels and activities of

RSK family members have been reported to be dysregulated in various cancer types. RSK inhibition represents a promising therapeutic strategy, as it serves as a common target for multiple signaling pathways in cancer therapy. Currently, several small molecule inhibitors, including SL0101, BID1870, and APIO-EE-07 have been documented for use in the treatment of colon and breast cancers. However, there is a need for the discovery of more potent small molecules as RSK inhibitors. In this study, a novel inhibitor candidate targeting RSK1 was determined through *in silico* analyses and the activity and cytotoxic properties of the compound were evaluated on two different types of colon cancer cells.

Material and method

In a scope of *in silico* analyses, a pharmacophore-based virtual screening study was carried out. For this purpose, a pharmacophore model of known inhibitor was generated by using Auto Pharmacophore Generation module. Screening of various small molecule libraries through Screen library module of DS using generated model was performed. Then, molecular docking and molecular dynamics (MD) simulation analysis were performed by Glide/SP and Desmond of Maestro, respectively. Finally, binding free energy (MM/GBSA) was calculated using Prime of Maestro. Cell studies were conducted using HT-29 and SW480 cell lines. In our previous study, the cytotoxic effect of this compound (IC₅₀ value) was determined using MTT assay. The determined IC₅₀ dose of compound (IC₅₀: 78.37 μ M) was applied to the cells, and colony formation and scratch assays were performed. Additionally, the mechanism of cell death induced by the compound was identified through flow cytometry analysis.

Result and discussion

As a result, among the screened compounds, a potential inhibitor candidate of RSK1 (6190-0389) showed a strong binding ability with a docking score of -7.849 kcal/mol against RSK1 compared to known RSK1 inhibitor (-6.698 kcal/mol). Interactions were observed with key amino acid residues including Asp142, Asp148, Asp205, and Leu144 during 100 ns MD simulations. Binding free energy (MM/GBSA) was calculated to be -53.52 ± 4.82 kcal/mol. The compound inhibited colony numbers approximately 1000 fold compared with control group. In the groups treated with the compound, an increase in the percentage of wound area was observed compared to the control group. Additionally, flow cytometry analyses revealed an increase in the number of early and late apoptotic cells in the treated groups compared to the control group.

Conclusion

This compound was determined to be a potential RSK1 inhibitor candidate. The initial findings from detailed analyses of this inhibitor provide a basis for evaluating its potential applicability as a therapeutic molecule for colon cancer.

The project was supported by TÜSEB, 27777.

Mitochondrial Transplantation from Oxidatively Stressed Adipocyte-Derived Mitochondria Induces Ferroptosis in

Glioblastoma

J. Liao¹, S. Ali¹, G. Leung¹, K. Kiang¹

¹The University of Hong Kong, Department of Surgery, Hong Kong, Hong Kong, China

Introduction

Glioblastoma (GBM) is a lethal brain tumor with a median survival of 15 months, resisting standard therapies like surgery, radiation, and chemotherapy due to its ability to withstand oxidative stress and ferroptosis, an iron-dependent cell death pathway. GBM cells scavenge normal mitochondria from surrounding cells to meet energy needs and rely on low-ROS energy systems, suppressing their own oxidative phosphorylation to reduce oxidative stress. We hypothesized that transplanting dysfunctional mitochondria from oxidatively stressed adipocytes, differentiated from human preadipocyte or 3T3-L1 cell line, could disrupt these adaptations and induce ferroptosis in GBM.

Material and method

Adipocytes were differentiated from human preadipocyte or 3T3-L1 cell line (ATCC) using differentiation medium (DMEM, 10% FBS, 1 µM dexamethasone, 0.5 mM IBMX, 10 µg/mL insulin) for 48 h, then maintenance medium for 7–10 days, confirmed by Oil Red O staining. Adipocytes were stressed with 200 µM H₂O₂ for 24 h, and mitochondria were isolated, standardized to 50 µg protein equivalent as a mitochondrial quantity scale. These were transplanted into U87 and U251 GBM cells (1×10^5 cells/well) and orthotopic mouse models: U87 in BALB/c nude mice (n = 10/group) and SB28 or GL261 in C57BL/6 mice (n = 10/group/cell line), injected intratumorally (50 µg protein in 5 µL PBS) on day 7. Ferroptosis was assessed via ROS, lipid peroxidation, mitochondrial potential, GPX4, iron levels, and IHC (4-HNE, GPX4). Tumor growth was tracked by bioluminescence.

Result and discussion

In vitro, mitochondrial transplantation into U87 and U251 increased ROS 3-fold, lipid peroxidation 2.5-fold (p < 0.01), reduced mitochondrial membrane potential by 60% (p < 0.05), lowered GPX4 by 70% (p < 0.01), and raised iron 1.8-fold (p < 0.05), confirming ferroptosis. In vivo, tumor radiance dropped 50% in U87, 45% in SB28, and 48% in GL261 (p < 0.01) by day 28, with IHC showing higher 4-HNE and lower GPX4, indicating ferroptosis. This approach exploits GBM's mitochondrial scavenging and low-ROS metabolism, with consistent effects across models suggesting broad therapeutic potential.

Conclusion

Mitochondrial transplantation from stressed adipocytes induces ferroptosis in GBM, targeting its metabolic vulnerabilities and offering a novel therapeutic avenue.

⁵Institut de Chimie et Biochimie Moléculaires et Supramoléculaires, Villeurbanne, France

Introduction

Triple-negative breast cancer (TNBC) is among the most aggressive and clinically challenging breast cancer subtypes, marked by high metastatic potential, poor prognosis and limited treatment options. This underscores the urgent need to identify novel molecular targets for effective therapies. Aldehyde dehydrogenase 1 (ALDH1) enzymatic activity is a hallmark of cancer stem cells (CSCs), strongly associated with drug resistance, tumor aggressiveness, and metastasis, making it an attractive therapeutic target. However, the distinct roles of ALDH1 isoforms hindering the rational design of selective inhibitors.

Material and method

This study integrates bulk RNA-seq data from 1,103 primary breast tumors, 50 breast cancer cell lines, and single-cell RNA-seq data from 26 patients to characterize ALDH1 isoform expression across molecular subtypes and the tumor microenvironment. Functional in vitro studies, including cell signaling and evaluation of metastatic potential, along with preclinical in vivo efficacy tests were performed to demonstrate the therapeutic potential of a novel ALDH1 inhibitor, ABD0171.

Result and discussion

ALDH1A3 was predominantly expressed in basal-like TNBC tumors, primarily by epithelial tumor cells, while ALDH1A1 was enriched in stromal components, including myeloid cells and cancer-associated fibroblasts, implicating this isoform in immune suppression and metastasis. Building on this insight, we developed a novel ALDH1A3-selective inhibitor derived from DIMATE, an ALDH1A1 inhibitor currently in clinical trials for AML. Structure-activity relationship studies identified a lead compound with enhanced selectivity for ALDH1A3, sparing the critical ALDH2 and ALDH3. Functional assays revealed that this inhibitor selectively induced apoptosis in ALDH1A3-expressing basal-like TNBC cell lines. Furthermore, it suppressed metastasis by inhibiting IL-6/JAK2/STAT3 and tPA/Src/FAK signaling pathways, potentially via a regulatory mechanism involving modulation of retinoic acid production mediated by ALDH1 in both tumor cells and the microenvironment. Preclinical TNBC models demonstrated its efficacy in reducing tumor growth and preventing distant metastases.

Conclusion

This work establishes ALDH1A3 as a promising biomarker and therapeutic target in basal-like TNBC, offering a promising approach to address unmet clinical needs in aggressive TNBC.

EACR25-1772**AI and physics based methods to design biopharmaceuticals to fight triple-negative breast cancer**

³Instituto de Tecnologia Química e Biológica António Xavier, Applied Protein Biochemistry Lab, Oeiras, Portugal

Introduction

Breast cancer is among the most prevalent cancers globally, with triple-negative breast cancer (TNBC) being the most aggressive subtype. TNBC is marked by rapid metastasis, treatment resistance, and high recurrence, often linked to the Wnt/β-catenin signalling pathway, where Frizzled Class Receptor 7 (FZD7) plays a key role in carcinogenesis. The current standard of care for TNBC involves nonspecific chemotherapy, radiation, or surgery. Antibodies against FZD7 have reached clinical trials, but failed due to off-target toxicity. Small antibody-like protein scaffolds are emerging as alternatives to antibody therapeutics. These scaffolds offer higher tissue penetration, can be easily modified to have increased specificity to the target, and are more cost-effective to produce, making them attractive candidates for tackling TNBC.

Material and method

In this work, we devised a robust deep-learning based computational pipeline to design and evaluate small antibody-like protein scaffolds to target FZD7. Molecular dynamics (MD) simulations were used to better characterize the interaction of the receptor with known antibodies and with its natural effector ligand WNT3a. Binding site analyses, conducted using PyMOL, identified critical residues within FZD7 essential for disrupting Wnt/β-catenin signalling. Guided by these insights, an exhaustive protein design campaign was implemented and different protocols resorting to deep-learning methods, including RFdiffusion, ProteinMPNN, MaSIF and BindCraft were evaluated.

Result and discussion

Thousands of candidate molecules were obtained and extensive filtering was conducted using Rosetta and AlphaFold3. Rosetta scoring functions evaluated their predicted stability, binding free energy, and structural complementarity to the FZD7 binding site. Further refinement of top candidates was conducted using AlphaFold3 to predict binding interactions and structural confidence. Metrics such as predicted template modeling scores, alignment error, and folding stability were used to select the most promising designs. These were subjected to detailed analyses through MD simulations, with simulation times of at least 1 μs performed using the GROMACS package. Key properties such as root mean square deviation (RMSD), secondary structure stability, and analysis of the interaction between the designed protein and the target revealed stable interactions

between selected designs and FZD7 under physiologically relevant conditions. Experimental validation is currently being implemented to validate the computational design strategy and generate data that will be used to refine future design pipelines.

Conclusion

This work highlights how the integration of advanced computational tools can accelerate the development of innovative therapies, offering new hope for patients with aggressive cancers like TNBC.

EACR25-1779**Patient-Derived 3D metastatic melanoma models for target discovery and personalized therapy**

³Sheba Medical Center, Ella Lemelbaum institute for Melanoma, Ramat Gan, Israel

⁴Tel Aviv University, Sagol School of Neuroscience, Tel Aviv, Israel

Introduction

Advanced-stage melanoma remains a critical clinical challenge, with high mortality rates (~90%) and limited therapeutic success due to its potential for rapid progression and resistance to standard treatments. While immunotherapies have revolutionized cancer care, their success is often limited by resistance mechanisms driven by genetic mutations and the tumor microenvironment (TME). Traditional 2D cell culture models lack the complexity to accurately mimic the TME, reducing their predictive power for therapeutic outcomes. To address this, we developed 3D tumoroids and 3D-bioprinted melanoma models that integrate patient-derived tumor cells and TME cells. The patient cells are obtained from an ongoing clinical trial involving 80 patients across seven cancer types. These models provide a robust platform for studying cancer progression and evaluating personalized treatment strategies.

Material and method

Tumor tissues and blood samples collected from clinical trial patients at Sheba Medical Center were processed to generate single-cell suspensions and isolate peripheral blood mononuclear cells (PBMCs), respectively. These cells were incorporated into our 3D tumoroids and 3D-bioprinted tumor models. The 3D-bioprinted model utilized two distinct bio-inks: one containing the tumor and TME cells, and the other one for endothelial cells and pericytes to construct perfusable vascular structures. Patient-specific H&E-stained slides were analyzed using AI to generate tailored treatment recommendations. These findings were discussed in consultation with the on-call oncologist and the research team to explore potential therapeutic options. To validate the models, their structural integrity and functionality were assessed through confocal microscopy, flow cytometry, and viability assays.

Result and discussion

The 3D tumoroid models demonstrated robust capability in predicting patient-specific therapeutic responses. For instance, in a mucosal melanoma case, standard treatments failed both clinically and in the tumoroid model. Through an AI-guided approach, regorafenib (Stivarga®) was recommended, tested in the model, and administered as compassionate treatment, resulting in a durable partial response lasting almost a year. The 3D-tumoroid models from different cancer indications have consistently mirrored clinical outcomes, demonstrating their potential to accurately predict responses and reduce the translational gap between preclinical findings and real-world therapeutic applications.

Conclusion

Our 3D patient-derived models provide a transformative approach to studying tumor biology and therapy resistance. By incorporating melanoma patient-derived cells and mimicking the clinical scenario, our 3D platform offers a powerful tool for drug discovery and personalized medicine, advancing precision oncology and translational research.

GSK-3 and BCL-XL inhibition mitigates the competitive advantage of APC-mutant colorectal cancer cells

L. Atencia Taboada^{1,2}, L. Zhang^{1,2}, M. de Kroon^{1,2}, C. Elshout^{1,2}, P. Ramesh^{1,2}, R. Helderman^{1,2}, A. Torang^{1,2}, M. van Driel^{1,2}, S. van Neerven^{1,3}, J. Medema^{1,2}

²Oncode institute, Amsterdam, Netherlands

³University of Cambridge, Wellcome Trust-Cancer Research UK Gurdon Institute, Cambridge, United Kingdom

Introduction

Colorectal cancer (CRC) development is primarily driven by mutations in the gene APC, which disrupt WNT signaling and provide APC-mutant intestinal stem cells (ISCs) with a competitive advantage over their wild-type counterparts. This advantage is mediated by the secretion of WNT antagonists, allowing APC-mutant cells to out-compete the wild-types in the crypts and initiate tumor growth. In this study, we explored whether GSK-3 inhibition, which leads to upregulation of WNT signaling could enhance the effects of BCL-XL – a key regulator of cell survival – inhibition by BH3 mimetics and potentially restore the competitive fitness of normal ISCs over APC-mutants.

Material and method

CRC spheroids and intestinal organoid models were treated with the GSK-3 inhibitors, alone or in combination with the BCL-XL inhibitor A-1155463. WNT pathway activity was assessed using the TOP-GFP reporter assay, quantitative PCR for WNT target gene expression, and RNA sequencing analysis to capture transcriptional changes following treatment. Apoptotic responses were assessed via caspase-3 activation, mitochondrial BAX aggregation, and propidium iodide exclusion assays. Competitive co-culture experiments between wild-type and APC-mutant ISCs were performed to evaluate the impact of combination therapy on cell fitness.

Result and discussion

We found that GSK-3 inhibition significantly sensitized CRC cells to BCL-XL inhibition, leading to a strong synergistic induction of apoptosis. Mechanistically, GSK-3 inhibition amplified WNT signaling, potentially pushing APC-mutant cells beyond an oncogenic stress threshold. This was reflected in increased mitochondrial BAX aggregation and caspase-3 activation, indicating enhanced apoptotic priming. Gene expression analysis confirmed upregulation of WNT target genes upon GSK-3 inhibition, consistent with the observed increase in WNT pathway activity measured by the TOP-GFP reporter. Importantly, while APC-mutant cells underwent apoptosis, wild-type ISCs exhibited enhanced fitness, reversing the competitive imbalance in organoid models. This suggests that the combination therapy not only eliminates mutant cells but also restores wild-type ISC dominance, counteracting early tumor progression.

Conclusion

Our findings highlight the therapeutic potential of combining GSK-3 and BCL-XL inhibitors in CRC treatment. By simultaneously exploiting oncogenic stress in APC-mutant cells and restoring wild-type ISC fitness, this strategy may provide a targeted approach for early-stage CRC, particularly in patients with familial adenomatous polyposis (FAP).

Introduction

Colorectal cancer (CRC) remains a leading cause of cancer-related mortality, and improving outcomes upon chemotherapy is critical for patient survival. Nanoparticle (NP)-based drug delivery offers a strategy for controlled chemotherapeutic drug release. Since their cell uptake

and intracellular trafficking play key roles in therapeutic efficacy, this study investigates the uptake mechanisms, endosomal trafficking, and drug release kinetics of core@shell NPs co-loaded with 5-fluorouracil (5-FU) and irinotecan (ITC), along with their cytotoxic effects in cell models of CRC.

Material and method

Core@shell NPs were synthesized with high chemotherapy drug loads (28 wt.-% ITC, 29 wt.-% 5-FU monophosphate) and an optimized ITC:5-FU ratio of 1:1.8. Cellular uptake and trafficking were analyzed using confocal microscopy imaging and pathway inhibition assays in CRC cell lines. NP degradation and drug release were assessed in late endolysosomal compartments. Cytotoxicity was evaluated using CellTiter-Glo (CTGlo) assays and Incucyte live-cell imaging in different CRC cell lines and rectal cancer patient-derived organoids (PDOs).

Result and discussion

Core@shell NPs were internalized in CRC cells primarily via micropinocytosis and CAV1-dependent pathways. Confocal imaging confirmed core@shell NP trafficking through the endosomal pathway, accumulating in late endolysosomes where NPs are degraded to facilitate drug release. Despite slow uptake kinetics, NPs effectively released both active chemotherapeutic drugs over time. Cytotoxicity assays in CRC cells revealed that core@shell NPs exhibited a delayed onset of cell death compared to free drugs. Still, sustained drug release ultimately reduced cell viability, leading to prolonged cytotoxic effects.

Conclusion

Core@shell NPs exhibited cytotoxic effects comparable to free chemotherapeutic drugs in CRC cells. However, unlike free drugs, core@shell NPs showed distinct cytotoxicity kinetics, characterized by a delayed onset and prolonged time to induce cell death. This aligns with slow NP uptake, intracellular trafficking, and sustained drug release. These findings highlight that understanding NP uptake and trafficking pathways provides a foundation for refining NP design to enhance drug delivery efficacy in NP based CRC treatment.

²VAR2 Pharmaceuticals ApS, Frederiksberg, Denmark

³VarCT Diagnostics, Frederiksberg, Denmark

Introduction

Cancer remains the 2nd leading global cause of death despite therapeutic advancements, as novel targeted therapies face limitations due to tumor heterogeneity and low tumor specificity of antigens. The novel tumor-agnostic target, oncofetal chondroitin sulfate (ofCS), originally discovered through malaria research, was

shown to reappear in cancer. This secondary carb-hydrate modification is up to 1000x more abundant in malignant tissues (primary tumors and distant metastases) compared to healthy tissues (excluding placenta), with little intra- or inter-tumor heterogeneity, and minimal expression in benign and inflammatory tissues. Similar to its function in placenta, ofCS ensures cell growth, migration and tumor immune evasion. Its abundance and expression across various cell types, including cancer cells and stromal cells within the tumor microenvironment, makes it an ideal target for antibody-based therapies.

Material and method

Using phage display technology, we developed two high-affinity antibody fragments, Vartumabs, binding ofCS. Their specificity was validated in vitro on human cancer cells and tissues, and biodistribution and tumor uptake were assessed in mouse models upon intravenous (i.v) injection. We functionalized them into antibody drug conjugates (ADC) by conjugating cytotoxic payloads (MMAE, DXd) and evaluated their safety and efficacy across allo- and xenografted mice models of hematological and solid cancers. Non-GLP toxicity study was performed in rats in a single dose escalation and repeat dose study with ADC-MMAE, including blood profile, and kidney and liver biochemistry.

Result and discussion

Vartumabs exhibited high affinity towards ofCS, identified as a highly sulfated epitope along an extended CS. Their broad cancer specificity was confirmed, with strong reactivity to both primary and metastatic tumors across dozens of cancer types, while demonstrating minimal interaction with healthy, benign and inflammatory tissues. These results showcased their potential for tumor-agnostic cancer targeting. Biodistribution studies confirmed specific tumor accumulation upon i.v. injection, with limited uptake in normal tissues, indicating their potential for delivery of therapeutics. Vartumab ADCs eradicated tumors in multiple cancer models with no recurrence, evident adverse effect or development of treatment resistance. Lastly, pre-clinical toxicity assessment demonstrated well tolerated treatments in rats with reversible toxic effects upon recovery after the 4th dose.

Conclusion

Our strong pre-clinical package highlights these antibody fragments as promising candidates for broad cancer treatment and support further clinical development. Vartumabs are currently being tested in a Phase 0 clinical trial in PET/SCAN imaging studies across multiple cancers as the first-in-human study of ofCS target validation.

EACR25-1803

EGFR targeting restores primary cilia loss upon ETS-driven oncogenic transformation in prostate cells

S. Costa¹, B. Orr¹, M. Teixeira¹, P. Paulo¹

¹IPO Porto, Cancer Genetics, Porto, Portugal

Introduction

Primary cilia (PMC) are non-motile microtubule-based organelles presumably found on most human cells, acting as key sensory and signalling hubs. PMC loss is a common early event in carcinogenesis, including of the

prostate. Despite the well-known molecular heterogeneity that characterizes prostate cancer (PCa), genetic rearrangements leading to overexpression of ΔERG or ETV1 are the earliest known genetic drivers of oncogenic transformation, and represent ~50% and ~10%, respectively, of all PCa cases. Recently, we demonstrated that ETV1 overexpression induces EGFR activation in prostate cells. Given that EGFR inhibitors, as Erlotinib, were described to restore ciliogenesis in cancer cells, we aimed to understand whether ETS-mediated oncogenic transformation is sufficient to induce PMC loss in prostate cells and whether Erlotinib could reverse this phenotype in an ETS-specific cell context.

Material and method

We used clonal tumorigenic cell populations with de novo ΔERG or ETV1 overexpression, alongside with the respective Neo control, established from the non-tumorigenic PNT2 prostate cells. The percentage and length of PMC were evaluated in the presence or absence of FBS or EGF, followed by treatment with sub-cytotoxic Erlotinib concentrations (2- and 3-fold below IC₅₀), using immunofluorescence to Arl13B and Centrin-1.

Result and discussion

We observed that de novo ΔERG or ETV1 overexpression leads to significant PMC loss. Additionally, cells overexpressing ΔERG exhibited PMC characteristics of ciliogenesis instability, namely, shorter PMC, weakened Arl13B signal in the ciliary membrane, and frequent loss of Centrin-1 expression in the basal body. Treatment with Erlotinib partially restored primary cilia in all prostate cells, with a more pronounced effect in cells with oncogenic ΔERG or ETV1 overexpression, even in the presence of PMC disassembly-promoting growth factors (FBS or EGF). Additionally, ETV1-overexpressing cells showed enhanced sensitivity to EGF, exhibiting a faster decrease in ciliated cells upon EGF stimulation compared to control cells.

Conclusion

Ciliogenesis is strongly affected and differentially regulated across distinct ETS-driven oncogenic backgrounds, with either ΔERG or ETV1 overexpression being sufficient to drive PMC loss in prostate cells. Furthermore, we confirm a link between EGFR signalling and PMC loss and unveil a sub-cytotoxic mechanism of Erlotinib-mediated PMC restoration in ETS-positive PCa cell models of early-carcinogenesis. These findings strengthen the potential of EGFR inhibition as a therapeutic strategy for the treatment of ETS-overexpressing PCa.

⁶*Aix-Marseille University, Cancer Research Centre of Marseille (CRCM), Centre national de la recherche scientifique (CNRS), Marseille, France*

Introduction

The PI3K/Akt/mTOR pathway is highly deregulated in several cancers including lung cancer. AZD2014 (vistusertib), a dual mTOR inhibitor, targets both mTORC1 and mTORC2 complexes within this pathway. Translationally controlled tumour protein (TCTP) and heat shock protein 27 (Hsp27), commonly overexpressed in cancers, interact with the PI3K/Akt/mTOR pathway, leading to eIF4E hyperactivity, causing increased cell growth, proliferation and drug resistance. We rationalise that by targeting several proteins on a common pathway, treatment dosages can be reduced, while potentially enhancing efficacy and minimising adverse effects in prospective *in vivo* studies. Therefore, we aimed to study the therapeutic potential of combining the small-molecule AZD2014 with antisense oligonucleotides (ASO) designed to target TCTP and HSP27 expression.

Material and method

Cell viability analysis was carried out using AZD2014 in a dose-dependent manner on A549 (adenocarcinoma), H460 (large cell carcinoma) and H520 (squamous cell carcinoma) non-small cell lung cancer (NSCLC) cell lines at 24, 48 and 72 h post-treatment. Cytotoxicity of AZD2014 was studied via lactate dehydrogenase (LDH) release together with molecular and phenotypic markers of cell death mechanisms related to apoptosis and autophagy. Magnetofection-mediated cellular uptake of different concentrations of these ASOs into NSCLC cells was investigated at several time-points using flow cytometry. Changes in TCTP and HSP27 gene expression were investigated, while Western blots confirmed protein knockdown at selected ASO concentrations. 3D spheroid models of each of the three NSCLC cell lines were also developed and characterised to better study pharmacodynamics *in vitro*.

Result and discussion

AZD2014 monotherapy exhibited cytostatic activity in a time- and concentration-dependent manner. This cytostatic action of AZD2014 was also observed in NSCLC 3D models, with significant spheroid growth reduction over six days of treatment. Magnetofection induced a high cellular transfection efficiency causing TCTP and Hsp27 protein knockdown to occur between two and three days post-transfection. Combination treatment resulted in synergistic effects on NSCLC cell viability.

Conclusion

These results elucidate the validity and effectiveness of this tripartite combination which is currently being further studied in both 2D and 3D models to effectively target NSCLC and to establish safety profiles of this novel NSCLC treatment.

Introduction

Acute Myeloid Leukemia (AML) is a highly aggressive hematological malignancy with poor clinical outcome due to resistance or early relapse after treatment with current standard therapies. Despite recent therapeutic advancements, there remains an unmet need for novel, targeted strategies. Oncofetal chondroitin sulfate (ofCS) is a promising new cancer target due to its high expression on many cancer entities and low expression on healthy tissues. Our previous studies have demonstrated the potent anti-tumor efficacy of anti-ofCS antibody drug-conjugates (ADC) in solid tumor models. Here, we explore the therapeutic potential of an anti-ofCS ADC in AML.

Material and method

Cell surface expressed ofCS was analyzed in bone marrow (BM) samples from AML patients and healthy donors using flow cytometry. The cytotoxic effect of anti-ofCS ADC was assessed in vitro drug-killing assays utilizing four AML cell lines. Additionally, in vivo efficacy was evaluated in two AML patient-derived xenograft (PDX) models, established from bio-banked AML patient BM samples.

Result and discussion

Flow cytometry analyses showed significantly higher ofCS levels on BM cells from AML patients and PDX compared to BM cells from healthy donors, which exhibited low or undetectable ofCS levels. Consistently, anti-ofCS ADC demonstrated effective in vitro killing of four ofCS+ AML cell lines. Furthermore, anti-ofCS ADC treatment led to significantly prolonged survival in two AML PDX models compared to a protein drug-conjugate control, with minimal adverse effects. Notably, endpoint analysis of AML PDXs demonstrated ofCS expression on human CD45+ AML cells following the anti-ofCS ADC treatment, indicating intrinsic maintenance of ofCS expression by AML cells independently of treatment. Collectively, our findings highlight the ability of anti-ofCS ADC to selectively target and eliminate AML cells both in vitro and in vivo in preclinical trials.

Conclusion

This study provides the first evidence supporting ofCS as a specific and therapeutically relevant target for AML. Our results underscore the potential of anti-ofCS ADC as a promising new strategy for AML therapy, warranting future exploration in clinical trials.

Combination of cerium oxide nanoparticles and antimalarial drug chloroquine: characterization and anti-cancer potential for triple negative breast cancer

C. Wenzel¹, E. Kolanthai², C. Neal², C. Wyrich¹, A. Borchardt¹, C. von Montfort¹, S. Seal², P. Brenneisen¹

¹Heinrich-Heine-University Düsseldorf, Institute of Biochemistry and Molecular Biology I, Medical Faculty, Düsseldorf, Germany

²University of Central Florida, Advanced Materials Processing and Analysis Center, Nanoscience and Technology Center (NSTC), Mechanical, Materials, and Aerospace Engineering (MMAE), Orlando, United States

Introduction

The most common type of cancer in women is breast cancer including triple negative breast cancer (TNBC). Among other subtypes, TNBC shows high aggressiveness, a poor prognosis and standard therapy is often associated with harmful effects. In this regard, drug repurposing and nanomedicine have gained huge interest in cancer therapy. Therefore, we tested the anti-cancer effect of the antimalarial drug chloroquine (CQ) in combination with cerium oxide nanoparticles (CNP, nanoceria) as a novel and possibly promising tool to treat TNBC.

Material and method

Initially, material characterization was conducted via UV-Vis spectroscopy, X-Ray photoelectron spectroscopy (XPS), high-resolution transmission electron microscopy (HR-TEM), dynamic light scattering (DLS), and superoxide dismutase (SOD) activity measurements of CNP in absence and presence of CQ. Furthermore, cellular uptake of CNP, treatment efficacy and selectivity of CNP and CQ was tested in a 2D in vitro model using MDA-MB-231 and MDA-MB-468 TNBC cells as well as normal (healthy) MCF-12A breast epithelial cells. To refine the translation to a more in vivo situation, studies were also done with a 3D in vitro spheroid model.

Result and discussion

Material characterization revealed good compatibility of the novel drug combination. The presence of CQ did not affect the physical and biological nature of the nanoparticles. Thereafter, cellular uptake of CNP was verified both in the 2D and 3D in vitro spheroid model. Again, the cellular uptake of CNP was not notably affected by the presence of the antimalarial drug. Subsequently, treatment efficacy of CNP and CQ was shown in MDA-MB-231 and MDA-MB-468 TNBC cells. The novel combination did not decrease the viability of normal (healthy) MCF-12A indicating a strong selectivity. Finally, the selective anti-cancer effect of CNP and/or CQ was reproduced in a 3D in vitro spheroid model. Likewise, CNP and CQ selectively decreased the

viability of MDA-MB-231 and MDA-MB-468 spheroids without harming MCF-12A spheroids.

Conclusion

In summary, combining the antimalarial drug CQ with bioactive CNP effectively lowered the individual doses of CQ needed to kill TNBC cells and, therefore, may also lower ‘harmful’ effects of CQ-treated patients in the future. As a consequence, this study revealed that a combination of CNP and CQ may be an alternative treatment option for TNBC.

EACR25-1851

The role of drug efflux and uptake transporters in the plasma and tissue disposition of KRASG12D inhibitor MRTX1133

D. Arguedas¹, E. Ruiter¹, V. Bui¹, J. Rijmers¹, M. Lebre¹, H. Rosing¹, J. Beijnen¹, A. Schinkel¹

¹Netherlands Cancer Institute, Pharmacology, Amsterdam, Netherlands

Introduction

Due to the high frequency of oncogenic KRAS driver mutations in human tumors and the relevance of KRAS aberrant signaling pathways, intensive therapeutic development efforts have been directed towards KRAS inhibitors. To date, there are no FDA-approved KRAS inhibitors other than Sotorasib and Adagrasib, which target uniquely the KRASG12C mutation. Targeting KRASG12D is of great importance, as it is the dominant KRAS driver mutation in pancreatic cancer (37%), colorectal cancer (12.5%), bile duct carcinoma (10.9%) and the second most common KRAS alteration in NSCLC (16.4%). The first KRASG12D inhibitor to enter clinical trials was MRTX113, currently in phase 1/2, directed towards solid tumors harboring the KRASG12D mutation (NCT05737706). Pharmacokinetic (PK) studies of newly developed drugs are essential to determine their ADME properties, effective dosing regimens, toxicity and clinical drug–drug interactions. The aim of this PK study is to define which drug transporters play a role in the modulation of plasma pharmacokinetics and tissue disposition of MRTX1133.

Material and method

We tested the transport of MRTX1133 across a monolayer of MDCK-II cells overexpressing the ABC transporters human P-gp(ABCB1), human BCRP (ABCG2) and mouse Bcrp(Abcg2) in an in vitro transwell assay. In vivo, we used different knockout mouse strains lacking the drug transporters P-gp, Bcrp, and Oatp1.

Result and discussion

The transwell assay suggested that MRTX1133 is actively transported by P-gp and Bcrp. The plasma pharmacokinetics of intraperitoneally administered MRTX1133 were not substantially affected by the absence of Abcb1 and Abcg2. The brain, liver and kidney concentrations and organ-to-plasma ratios of MRTX1133 in Abcb1a/b;Abcg2^{−/−} mice were significantly increased compared to those in wild-type mice. The mouse Oatp1a/b transporters did not appear to affect the pharmacokinetics of MRTX1133. Unexpectedly, we observed

significant toxicity of MRTX1133 in some of our mice. We are currently looking further into the background and causes of this toxicity.

Conclusion

This study highlights the relevance of ABCB1/ABCG2 in the transporter-mediated restriction of brain penetration and reduction of kidney and liver accumulation of MRTX1133. We hypothesize that co-administration of the dual ABCB1/ABCG2 inhibitor elacridar could promote brain penetration and increase kidney and liver exposure for MRTX1133. The insights gained may contribute to enhancing the safety and efficacy of MRTX1133 in the clinic.

Engineering Subtype-Specific Breast Cancer Models: Decellularized ECM-Based Bioinks for Organoid Culture and Precision Oncology

J. López de Andrés¹, L. de Lara-Peña¹, M. Martín-Istillary², C. Griñán-Lisón³, A. López-Tejada³, S. Granados-Principal³, J. Marchal¹, G. Jiménez¹

¹University of Granada, Department of Human Anatomy and Embryology, Granada, Spain

²University of Granada, Granada, Spain

³University of Granada, Department of Biochemistry and Molecular Biology 2, Granada, Spain

Introduction

Breast cancer (BC) is the most frequently diagnosed cancer in women and ranks as the second most prevalent malignancy worldwide. Tumor progression is strongly influenced by the tumor microenvironment (TME), which consists of a complex network of stromal cells – such as fibroblasts, mesenchymal stem cells, immune cells, and vascular components – embedded within the extracellular matrix (ECM). This dynamic environment plays a crucial role in regulating tumor growth, invasion, and metastasis. Recent studies emphasize the importance of ECM composition and mechanical properties in shaping BC behavior. The development of decellularized ECM (dECM) technology has provided a powerful tool for reconstructing key tumor features in vitro, allowing for more physiologically relevant modeling of the TME.

Material and method

This study focuses on designing a bioink derived from dECM obtained from BC cell lines representing different molecular subtypes. The goal is to enhance the development of advanced 3D tumor models. To achieve this, we cultured MCF-7, MDA-MB-231, SKBR3, and BT474 cells and applied a carefully optimized decellularization protocol to extract ECM with maximum integrity and bioactivity. The dECMs were extensively characterized in structural components by proteomic analysis, biochemical composition, and biomechanical properties. The resulting bioinks were then evaluated for their ability to sustain the growth of key TME cell populations – including stromal, endothelial, and epithelial cells – as well as patient-derived xenograft organoids (PDXOs), which were subsequently used for drug screening applications.

Result and discussion

The dECMs obtained from different BC subtypes exhibited distinct structural and biochemical profiles, reflecting the inherent heterogeneity of BC. Stromal cells embedded within these bioengineered matrices displayed notable differences in morphology and behavior, highlighting the influence of ECM composition on cellular dynamics. Moreover, the bioinks successfully supported the culture of BC PDXOs, enabling the study of ECM-driven chemoresistance mechanisms in response to various anticancer therapies.

Conclusion

The variability observed in ECM composition across normal, tumorigenic, and metastatic states underscores the need for models that faithfully replicate the full spectrum of BC ECM characteristics rather than focusing on isolated matrix components. Our findings demonstrate that tumor-derived dECM provides a promising foundation for the development of bioinks capable of capturing BC heterogeneity. These bioinks hold significant potential for advancing preclinical research by offering a more physiologically relevant platform for studying BC progression and therapy response across different molecular subtypes.

Introduction

The Mitogen-Activated Protein Kinase (MAPK) Extracellular-signal Regulated Kinase 5 (ERK5) pathway is involved in almost all the biological features of cancer cells. Indeed, its role in the development and progression of several types of tumours has been demonstrated. Moreover, ERK5 pathway activation is among the resistance mechanisms to RAS/RAF/MEK1/2-ERK1/2 targeted therapy. Hence, several ERK5 kinase activity inhibitors have been developed. Despite their efficacy in reducing cancer cell proliferation, these compounds only work at relatively high concentrations, making them unsuitable for clinical research. In addition, some of these drugs resulted in a paradoxical activation of ERK5, by inducing its nuclear translocation. In sight of this, we aimed at developing new ERK5 kinase inhibitors.

Material and method

To test the efficacy of the compounds on the kinase activity of ERK5 we conducted *in vitro* kinase assays. To evaluate the effects of these new potential inhibitors on

cancer cell viability we performed cell counting using both wild type and ERK5-knockout (KO) cells.

Result and discussion

In silico screening of the commercial database MolPort, that contains 5M compounds, allowed to identify several candidates among which we have tested 12 compounds. With *in vitro* kinase assay we have individuated one (compound 14) that completely inhibits ERK5 kinase activity up until 1 μM and partially inhibits it until 100 nM. Interestingly, comparing the effect of compound 14 with the effects of the commercially available ERK5 kinase inhibitor JWG-071, we were able to highlight that the new inhibitor works at lower concentration with respect to JWG-071. Moreover, we studied the effect of these compounds on cell proliferation. In HeLa cells, compound 14 completely inhibits cell proliferation up until 2.5 μM, showing efficacy already at 100 nM. To deepen whether this effect relied, at least partly, on ERK5, we performed the same experiment in control and ERK5-knockout cells. We used two clones of ERK5-KO ovarian cancer cells (OV8) and one ERK5-KO hepatocellular carcinoma cell line (HUH7). Interestingly, in all three models ERK5-KO cells resulted to be less sensitive to compound 14 with respect to the control cells, starting from 100 nM up until 10 μM. Comparing these results with the ones obtained for JWG-071, we pointed out a higher specificity of compound 14 in inhibiting cell proliferation

Conclusion

In conclusion, we discovered a new potential ERK5 kinase inhibitor that has an effect at nanomolar concentrations, both in inhibiting ERK5 kinase activity and cell proliferation in an ERK5-dependent manner. Even if further evaluation regarding the capability of this inhibitor not to induce a paradoxical activation of ERK5 will be needed, these results pave the way to a new class of small molecules inhibiting ERK5 activity, that may be able to reach clinical relevance after additional preclinical evaluation.

⁵*GIMM – Gulbenkian Institute for Molecular Medicine, Faculdade de Medicina, Universidade de Lisboa, Portugal*

Introduction

Therapeutic peptides are among the most promising biopharmaceutical agents for the treatment of various malignancies, including infectious, metabolic, and cancer. Their appeal lies in their low toxicity, target specificity, high potency, and minimal drug-drug interactions. In this study, we conjugated an anticancer peptide (ACp) with a blood-brain barrier peptide shuttle (BBBpS) to develop a novel dual-active peptide conjugate. This strategy aims to facilitate BBB crossing while effectively targeting and eliminating brain metastases derived from triple-negative breast cancer (TNBC) - the leading cause of brain metastases in breast cancer patients.

Material and method

We assessed the antiproliferative effect of PepH3-vCPP2319 on a panel of cancer and healthy cell lines, the translocation across an *in vitro* BBB model, and the *in vivo* biodistribution in healthy mice.

Result and discussion

ACp exhibits strong activity against TNBC cell lines, demonstrating high selectivity, low toxicity, and a half-life of 10 hours in human serum. Meanwhile, BBBpS efficiently crosses the blood-brain barrier (BBB) via adsorptive-mediated transcytosis (AMT), a receptor-independent mechanism that allows it to return to circulation for excretion. Therefore, BBBpS preserves BBB integrity, prevents receptor saturation, and minimizes off-target interactions. The BBBpS-ACp conjugate maintains selectivity, with an IC₅₀ below 5.5 μM in various TNBC cell lines, while exhibiting minimal toxicity in non-cancer cell lines (IC₅₀ > 10.0 μM) and red blood cells (IC₅₀ > 50.0 μM). Importantly, the conjugate retains the translocation capacity of BBBpS, showing a fourfold increase in BBB penetration compared to unconjugated ACp in an *in vitro* BBB model. BBBpS-ACp is internalized via clathrin-mediated endocytosis without compromising cell membrane integrity. Furthermore, evidence suggests it induces mitochondrial disruption and reactive oxygen species (ROS) production, ultimately triggering apoptosis and cell death.

Conclusion

We have designed a dual-acting peptide capable of brain penetration and TNBC cell elimination, thus expanding the drug arsenal to fight this BC subtype and its BM.

EACR25-1899

Optimization of Bivalent Immunoliposome Preparation for Selective Cytotoxic Activity Against Triple-Negative Breast Cancer Cells

M. Milczarek¹, A. Pogorzelska¹, M. Mazur²

¹*National Medicines Institute, Department of Biomedical Research, Warsaw, Poland*

²*University of Warsaw, Faculty of Chemistry, Warsaw, Poland*

Introduction

Triple-negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer and is often associated with poor patient prognosis. The studies on

targeted therapy have highlighted the use of antibody-based drugs (ABD) as a promising strategy. In recent years, antibody-drug conjugates have been approved for the treatment of TNBC. Another group of ABD extensively researched is bivalent immunoliposomes (BIM). The surface of these liposomes is functionalized with two monoclonal antibodies against antigens that are specific to the tumor cell or characterized by over-expression on the tumor cell surface. This functionalization increases the treatment efficacy and reduces the side effects of the drug-loaded on the liposomes by increasing the treatment selectivity and internalization efficacy into the cancer cell. This study aims to prepare doxorubicin (DOX) – loaded BIM with selective cytotoxic activity against TNBC cells

Material and method

A lipid mixture of DOPC and DSPE-PEG-COOH was dissolved in chloroform and evaporated to form a thin lipid film. This lipid film was then dissolved in a mixture of DMSO and ethanol and subsequently added to a sodium sulfate solution in PBS under vigorous agitation. The solution underwent sonication, followed by freeze-thaw cycles in liquid nitrogen. The resulting liposomal solution was dialyzed. The mixture was incubated with DOX to facilitate active drug loading. After incubation, the doxorubicin-loaded liposomal solution underwent another round of dialysis. The surface of the liposomes was modified with antibodies by forming an amide bond between the amino group of the antibody and the carboxyl group of DSPE-PEG-COOH. To achieve this, EDC (1-ethyl-3-(3-dimethylaminopropyl) carbodiimide) and NHS (N-hydroxysuccinimide) were added to the liposomal solution and incubated. Unreacted EDC and NHS were then removed through dialysis. In the next step, antibodies (one or two types, in different molar ratios) were added to the activated liposomes and incubated to allow conjugation. Unbound antibodies were subsequently removed via dialysis to obtain the final antibody-modified liposomes. The efficiency of DOX encapsulation into liposomes was evaluated by absorbance measurements at 485nm. The cytotoxic activity of bivalent liposomes was determined by the MTT assay after 72 hours of treatment on cell lines. The quality of the liposomes was assessed by dynamic light scattering (DLS).

Result and discussion

The proportions of lipids used and the timeframes of the various preparation steps were optimized. The parameters determined by the DLS method (zeta potential, polydispersity index and size) and the drug encapsulation efficiency test showed the good quality of the obtained bivalent immunoliposomes. Tests on TNBC cells confirmed the anti-tumor activity of BIM.

Conclusion

The process of optimizing the BIM proved to be successful and resulted in a BIM characterized by cytotoxic activity against TNBC.

³Jagiellonian University, Department of Immunology, Faculty of Biochemistry, Biophysics and Biotechnology, Krakow, Poland

Introduction

Ubiquitin-specific protease 7 (USP7) regulates the stability and fate of many proteins, thereby influencing cellular processes such as cell cycle, chromatin remodeling, and protein synthesis. Elevated level of USP7 in cancer contributes to tumor progression by modulation of tumor microenvironment. USP7 has a variety of substrates, including MDM2 (Murine Double Minute 2) and the tumor suppressor p53 – well-established targets in cancer drug development. Here, we explored the USP7-MDM2-p53 pathway in the context of immunomodulation, rather than more studied direct cytotoxic effects on cancer cells.

Material and method

The activity and selectivity of OAT-4828, an inhibitor we designed, was assessed in enzymatic assays. After pharmacokinetic studies, the efficacy of OAT-4828 was evaluated in mouse *in vivo* models of melanoma (B16F10), colon cancer (CT-26), lymphoma (A20) and chronic lymphocytic leukemia (Eμ-TCL1). Tumor microenvironment was analyzed by flow cytometry. In *ex vivo* studies the influence of OAT-4828 was estimated in mouse and human T cells, as well as mouse bone marrow-derived macrophages by Western blotting, qPCR, ELISA tests and by a functional cell killing assay.

Result and discussion

Oral administration of USP7i resulted in a significant reduction in tumor volume in syngeneic mouse models of colon, melanoma cancer, and lymphoma and leukemia. This reduction was associated with a substantial increase in T cell activation, as evidenced by higher levels of CD69 and CD44, as well as increased production of Granzyme B and IFN-γ. Antitumor activity of USP7i was improved when combined with anti-PD-1 antibodies, while the T cell depletion completely abrogated the therapy outcome. OAT-4828 caused increased production of IL-2 and upregulation of CD25 and CD69 in human T cells, which was associated with MDM2 downregulation and p53 stabilization. Similarly, USP7 inhibition led to MDM2 downregulation in macrophages, inhibiting their M2-like functions. These results indicate that the main mechanism of action of USP7i is based on the activation and improved cytotoxic functions of T cells and promoting anti-cancer activity relevant to the tumor microenvironment.

Conclusion

We conclude that USP7-MDM2-p53 is implicated in the antitumor function of immune cells and shapes the tumor microenvironment. Altogether, we confirm USP7 as an attractive target for cancer immunotherapy and present a strong rationale for the development of USP7 inhibitors for clinical use.

⁵Theramir, Limassol, Cyprus

Introduction

Extracellular vesicles (EVs) have emerged as a promising next-generation drug delivery platform for cancer therapeutics due to their intrinsic tumor-targeting capabilities. This study presents an EV-based patented platform technology, derived from mesenchymal stem cells of the Wharton's Jelly (WJCs), designed to encapsulate and deliver microRNA_a. This miRNA directly targets LCP-1, an actin-bundling protein implicated in metastatic progression. Given the highly aggressive and metastatic nature of triple-negative breast cancer (TNBC), we explored the therapeutic potential of microRNA_a-loaded EVs in modulating tumor progression and metastasis.

Material and method

MicroRNA_a was overexpressed in WJCs using transfection, followed by EV isolation via differential centrifugation. Characterization of microRNA_a-loaded EVs was performed in accordance with ISEV guidelines, utilizing TRPS technology for concentration and size distribution analysis and western blotting for EV-specific marker validation. To evaluate efficacy, MDA-MB-231 cells were treated with microRNA_a-loaded EVs, and LCP-1 expression was assessed via RT-PCR, western blot, and fluorescence microscopy. Functional assays, including MTT cytotoxicity, transmigration, invasion, and cell cycle analysis, were conducted to examine effects on proliferation, migration, apoptosis, and ECM invasion. For *in vivo* validation, an orthotopic TNBC model in BALB/c mice was developed to assess biodistribution, tumor growth inhibition, metastasis suppression, and survival outcomes following microRNA_a-loaded EV treatment.

Result and discussion

Treatment of MDA-MB-231 cells with microRNA_a-loaded EVs significantly downregulated LCP-1 expression, confirming direct targeting. Functional assays demonstrated reduced proliferation, migration, and invasion, hallmarks of tumor progression and metastatic potential. Furthermore, treatment induced cell cycle arrest, apoptosis, and mesenchymal-to-epithelial phenotypic reversion, as evidenced by actin reorganization and fluorescence microscopy analysis. *In vivo*, microRNA_a-loaded EVs selectively homed to

tumor sites, leading to tumor growth stabilization and metastatic suppression, ultimately enhancing overall survival in treated mice.

Conclusion

This innovative EV-based platform presents a novel and efficient strategy for delivering miRNA therapeutics directly to tumor sites, targeting metastatic pathways in aggressive cancers such as TNBC. By modulating tumor progression, invasion, and survival pathways, this approach holds promise for advancing precision oncology and targeted miRNA-based therapies.

Isolation of anti-proliferative bioactive compounds from *Gypsophila erocalyx* plant extracts by activity-guided approach and its activity in prostate cancer

U. Demir¹, B. Gundogdu², D. Camli³, T. Barak⁴, H. Servi⁵

¹*Istanbul Medeniyet University, Molecular Biology and Genetics, Istanbul, Turkey*

²*Yildiz Technical University, Molecular Biology and Genetics, Istanbul, Turkey*

³*Istanbul Medeniyet University, Bioengineering, Istanbul, Turkey*

⁴*Acibadem Mehmet Ali Aydinlar University, Pharmacognosy, Istanbul, Turkey*

⁵*Yeniyüzyıl University, Pharmacognosy, Istanbul, Turkey*

Introduction

The endemic *Gypsophila erocalyx* species has been traditionally used for several purposes. However, its potential as a source of anti-cancer compound has not been studied. The aim of this study was to isolate anti-cancer compounds from *Gypsophila erocalyx* with an activity lead method.

Material and method

The aerial parts of *G. erocalyx* were dried in the laboratory and hexane, ethyl acetate, methanol, and methanol:water (70:30) extracts were obtained by maceration method. Anti-proliferative activities of the obtained extracts were examined in prostate cancer cells. As a result of the anti-proliferative activity test, it was determined that ethyl acetate extract had higher anti-proliferative activity compared to other extracts and it was decided to work with this extract. Ethyl acetate extract was separated into subfractions by chromatographic methods such as column chromatography (CC), molecular sieve chromatography (Sephadex LH-20), and preparative thin layer chromatography (PTLC). The chemical structure of the bioactive compound was elucidated by spectral methods such as nuclear magnetic resonance (NMR) and Gas Chromatography-Mass Spectroscopy (GC/MS). In vitro assays such as colony formation 3D spheroid culture were applied to assess anti-cancer potential of 3.2 subfraction and isolated bioactive compound 2,4-di-tert-butylphenol (DTBP) in prostate cancer cells.

Result and discussion

As the subfractionation continued from ethanol extract to 3 and 3.2, the IC₅₀ values were decreased. The subfraction 3.2 showed significant anti-proliferative effect in

both 2D cells and in spheroid cultures of PC3 cells. Additionally, the colony formation ability of PC3 cells were inhibited by 3.2 subfraction. As a result of spectral methods, it was determined that the active compound obtained from step-wise fractionation of *G. erocalyx* plant was 2,4-di-tert-butylphenol (DTBP). DTBP showed anti-proliferative effect in 2D and 3D culture of prostate cancer cells and it decreased colony forming potential. These results suggested that plant-based DTBP was a candidate anti-cancer agent in prostate cancer.

Conclusion

G. erocalyx is a source for anti-cancer agents. 2,4-di-tert-butylphenol was identified as an anti-cancer active compound from this plant for the first time in this study.

EACR25-1972

Defining Docetaxel's Antitumor Effects on Calu3 Lung Cancer Cells Using High-Throughput Live-Cell Imaging

L. Boekestijn¹, S. Meiler¹, I. Thijssen-van Loosdregt¹

¹*Axion BioSystems, Eindhoven, Netherlands*

Introduction

Oncology research aims to understand the cellular mechanisms underlying cancer and to develop effective treatments, with a particular focus on evaluating drug toxicity. To assess drug efficacy, a variety of assays, such as cell viability, migration, and clonogenic assays, are used to evaluate cancer cell sensitivity and resistance. These tests help determine a drug's potential by examining its effects on cell proliferation, survival, and migration. Docetaxel, a chemotherapeutic agent that inhibits microtubule depolymerization, is often studied using these assays due to its impact on cell migration and proliferation. Its effects on cancer progression are commonly analyzed in various in vitro models. The results of toxicity studies can vary significantly depending on the assay used, and combining multiple assays can offer a more complete profile of a drug. In this study, we utilized the Omni Pro 12 high-throughput live-cell imaging platform to simultaneously conduct several assays on the Calu3 lung cancer cell line.

Material and method

The Omni Pro 12 platform minimized variability by conducting all assays under consistent experimental conditions, reducing the influence of external factors on the results. The primary objective was to evaluate the impact of Docetaxel on three critical aspects of cancer progression: cell viability, migration, and colony-forming ability. To achieve this, we performed cytotoxicity, scratch, and colony assays using Docetaxel concentrations ranging from 0 to 1000 nM.

Result and discussion

The results demonstrated that higher concentrations of Docetaxel affected cell proliferation, migration, and colony formation in a dose-dependent manner. However, the assays indicated different effective concentrations for each outcome. Docetaxel inhibited Calu3 cell proliferation in a dose-dependent manner, with peripheral cells in clusters being more sensitive than central cells. Higher concentrations of Docetaxel also led to reduced proliferation recovery after 24 hours. In the cell migration assay, Docetaxel slowed Calu3 cell migration

in a dose-dependent manner, though this effect occurred more gradually compared to the inhibition of proliferation. Additionally, Docetaxel decreased the long-term colony-forming ability of single Calu3 cells in a dose-dependent manner, with 250 nM nearly eliminating colony formation after 324 hours. Long-term monitoring revealed that Calu3 cells require at least 180 hours to form detectable colonies.

Conclusion

By incorporating multiple assays and utilizing advanced technologies like the Omni Pro 12, this study provides valuable insights into the therapeutic potential of Docetaxel in lung cancer treatment. It also underscores the importance of reducing assay variability to more accurately predict drug responses and determine effective concentrations.

EACR25-1992

Combination of PARP Inhibitor Olaparib and a Vascular Disrupting Agent Reduces Tumor Growth in a Xenograft Mouse Model of Prostate Cancer

E. Sereti¹, S. Evans-Axelsson², J. Törnell³, S. Rehnmark⁴, M. Hogberg⁴, A. Bjartell¹

¹Lund University, Malmö, Sweden

²Bayer AB, Stockholm, Sweden

³Innoext AB, Göteborg, Sweden

⁴LIDDS AB, Göteborg, Sweden

Introduction

Metastatic castration-resistant prostate cancer (mCRPC) is associated with poor clinical outcomes and acquired resistance to various therapies. Targeted therapies, such as poly (ADP-ribose) polymerase inhibitors (PARPi), has expanded the treatment options by specifically targeting homologous recombination repair (HRR) deficiencies however, questions remain regarding their broader applicability beyond HRR-mutated populations and there is ongoing debate about whether an HRR mutation is a prerequisite for the response to PARPi or if HR proficient patients can also benefit from their use. Research is currently focused on exploring novel anticancer agents that could enhance the therapeutic efficacy of PARPi and improve clinical outcomes for patients. NOV202 is a novel microtubule destabilizer and a vascular disrupting agent (VDA) that has demonstrated significant anti-proliferative effects in ovarian cancer xenograft models and a large panel of cancer cells. This study investigates the combinational efficacy of the PARPi olaparib with the novel agent NOV202, evaluating whether NOV202 can enhance the *in vivo* efficacy of olaparib in prostate cancer xenografts. Additionally, we explore the anti-proliferative effects of olaparib and NOV202 *in vitro* to elucidate the underlying mechanism of action, aiming to provide deeper insights into their therapeutic potential.

Material and method

DU145 and PC-3 prostate cancer xenografts were established in NMRI nude mice and treated with vehicle, olaparib (100 mg/kg), NOV202 (30 mg/kg), or their combination. Tumor growth was monitored by non-invasive bioluminescence optical imaging (BLI) and calipers. Xenograft tissue sections were analyzed by immunohistochemistry (IHC) to detect γH2AX, RAD51,

HIF-1α, Ki67, and CD31 expression. *In vitro*, cell viability and molecular responses to treatments were studied to evaluate antiproliferative effects and investigate the mechanism of action.

Result and discussion

Both olaparib and NOV202 independently inhibited tumor growth in prostate cancer xenografts, but the combination exhibited additional efficacy only in BRCA2-mutated DU145 xenografts, suggesting that BRCA2 mutations may sensitize tumors to the combined effects of NOV202 and olaparib. Mechanistically, our study shows that DNA damage is the primary cell death mechanism followed by apoptosis in response to treatments. *In vitro*, the combination of NOV202 and olaparib exerts synergistic antiproliferative effects at low NOV202 concentrations suggesting that NOV202 in combination with olaparib could achieve enhanced therapeutic efficacy while minimizing toxicity.

Conclusion

NOV202 enhances olaparib efficacy in BRCA2-mutated prostate cancer models by inducing DNA damage and reducing vascularization. Combining NOV202 with olaparib is a promising strategy for mCRPC.

EACR25-2000

Cellular response triggered by anticancer agent, C-2028 in breast cancer cells with different expression of key receptors under normoxia and hypoxia conditions

A. Palka¹, M. Rys¹, A. Paracka¹, M. Pawłowska¹

¹Gdańsk University of Technology, Faculty of Chemistry, Department of Pharmaceutical Technology and Biochemistry, Gdańsk, Poland

Introduction

Breast cancer (BC) is one of the most common cancers in the world and the leading cause of death among women. Comparing different types of breast cancer, the treatment of triple-negative breast cancer (TNBC), which does not pose estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor-2 (HER2) remains the most difficult to cure due to its aggressiveness and limited therapies. Unsymmetrical bisacridines (UAs) are anticancer compounds synthesized at the Gdańsk University of Technology. They have shown high cytotoxicity against many human cancer cells and anticancer activity against several xenografts in nude mice. This study aimed to evaluate the impact of C-2028, one of the UA compounds, on several breast cancer cell lines with different statuses of ER, PR, and HER2 in the condition of normoxia and hypoxia.

Material and method

The studies were conducted on four BC cell lines: MDA-MB-231 (ER-, PR-, HER2-, TNBC), MDA-MB-453 (ER-, PR-, HER2+), MCF-7 (ER+, PR+, HER2-), and BT-474 (ER+, PR+, HER2+). MTT assay was used to assess the cytotoxicity of C-2028 and reference compounds: cyclophosphamide, doxorubicin, tamoxifen, paclitaxel, and cisplatin. The cellular response caused by C-2028 was evaluated via cell cycle analysis, phosphatidylserine externalization, cell membrane integrity, cell nucleus morphology, and caspase-3/7 activity. The protein level of ER, PR, HER2, and VEGF was checked

by Western blot. The hypoxic condition was achieved in a hypoxia chamber filled with proper gas containing 1% oxygen.

Result and discussion

Western blot analysis confirmed the status of ER, PR, and HER2 in each studied BC cell line. C-2028 exhibited high cytotoxicity against all four breast cancer cell lines and its IC₅₀ varied from 0.012 to 0.1 μM wherein cells lacking HER2 were more sensitive to C-2028. Reference compounds showed various activity against studied cell lines. The most active was paclitaxel with a similar to C-2028 IC₅₀ values, however, 30% of cells stayed alive even at high concentrations. Doxorubicin exhibited cytotoxicity at the level of 0.25–0.4 μM (IC₅₀).

Tamoxifen and cisplatin showed moderate activity with IC₅₀ 2.0–11.0 μM. Cyclophosphamide was the weakest drug (IC₅₀ = 400 μM). C-2028 induced apoptosis in all breast cancer cell lines. Around 40 to 55% of MDA-MB-231, MDA-MB-453, and MCF-7 cells showed features of apoptosis. In the triple-positive cell line, BT-474 cell death was observed in only 15% of cells. In MDA-MB-231 and MDA-MB-453 cells C-2028 under hypoxia condition slightly lost its activity and the IC₅₀ value was up to 2 times higher. What's more C-2028 under hypoxic conditions led to decrease in the level of VEGF in these cells.

Conclusion

C-2028 was highly active in different BC cell lines, including those lacking HER2 receptor and caused apoptotic cell death in them, which is a promising result for future therapy. C-2028 remained active under hypoxia conditions with the contribution to VEGF protein level.

EACR25-2017

Synergistic effect of 5-fluorouracil and the small molecule Wnt/beta-catenin inhibitor iCRT3 on Caco-2 colorectal cancer cells in vitro

M. Smarslik¹, J. Inal¹

¹*London Metropolitan University, School of Human Sciences, London, United Kingdom*

Introduction

Although 5-fluorouracil (5-FU) is a cornerstone of colorectal cancer (CRC) treatment, its efficacy is often limited by resistance. Wnt/β-catenin signalling plays a crucial role in CRC carcinogenesis and resistance, as Wnt expression is upregulated in 5-FU-resistant cells, protecting them from cell cycle arrest and apoptosis, thereby contributing to drug resistance. The small molecule inhibitor β-catenin responsive transcription inhibitor 3 (iCRT3) disrupts Wnt/β-catenin signalling and may enhance CRC sensitivity to 5-FU, overcoming resistance.

Material and method

In this study, the cytotoxic effects of 5-FU and iCRT3 were investigated using the Caco-2 colon adenocarcinoma cell line, marking the first investigation of their combined effects. To this end, the half-maximal inhibitory concentration (IC₅₀) values were determined using the MTT assay. Subsequently, the drugs were combined in different ways, and drug combination index

(DCI) calculations were performed to evaluate their interaction.

Result and discussion

iCRT3 was found to be 2.45-fold more potent than 5-FU ($p = 0.1982$). Drug combination significantly increased the IC₅₀ compared to 5-FU, with a 40.95-fold increase ($p = 0.0022$) when 5-FU was fixed (2.56 μM) and a 43.5-fold increase ($p = 0.0023$) when iCRT3 was fixed (2.41 μM). Two-way ANOVA showed significant impacts from both drug concentration (50.93 %) and treatment condition (25.31 %) on cell viability ($p < 0.0001$). DCI analysis confirmed strong synergism with fixed 5-FU (DCI = 0.154) and synergism with fixed iCRT3 (DCI = 0.618).

Conclusion

Our results indicate that combining 5-FU and iCRT3 could be a promising strategy for CRC treatment, warranting further investigation.

EACR25-2028

Polyoxovanadates with Anti-breast Cancer Activity and Ca²⁺-ATPase Inhibition Potential

M. Aureliano^{1,2}, H. Camilo³, B. Brito³, R. Ribeiro³, G. Fraqueza^{4,2}, G. Klassen⁵, G. Nunes³

¹*Universidade do Algarve, Faculdade de Ciências e Tecnologia, Faro, Portugal*

²*Universidade do Algarve, Centro de Ciências do Mar, Faro, Portugal*

³*Universidade Federal do Paraná, Departamento de Química, Curitiba, Brazil*

⁴*Universidade do Algarve, Instituto Superior de Engenharia, Faro, Portugal*

⁵*Universidade Federal do Paraná, Departamento de Patologia Básica, Curitiba, Brazil*

Introduction

Female breast cancer is the second most commonly occurring and the most diagnosed and deadliest worldwide. Triple-negative breast cancer is more aggressive and harder to treat than hormone-receptor-positive cancers. The intracellular calcium ions (Ca²⁺) act as a second messenger and regulate cellular migration and proliferation, two mechanisms linked to cancer [1]. Regarding breast cancers, it is known that drugs may target calcium signaling to reduce tumoral growth or cause breast cancer cell death. Decavanadate (V10), the most studied member of the class of polyoxo-vanadates (POVs), is a promising anticancer drug (Bijelic et al. Angew. Chem. 2019) and acts as an uncompetitive inhibitor of the Ca²⁺-ATPase (Aureliano et al. J. Inorg. Biochem. 2022). In this work, the mixed valence polyoxovanadates, [V15O36Cl]₆₋V15, and two [V18O42I]_{n-} polyoxidoanions with tetramethylammonium (MeV18) and tetrabutylammonium cations (ButV18) [Missina et al., Inorg. Chem. 2018; Kita et al., FEBS Lett., 2022], were evaluated in their potential anti-breast cancer activity, as well as inhibitors of the Ca²⁺-ATPase activity.

Material and method

The cytotoxicity towards MDA-MB-231 (human triple negative breast cancer cells) and HB4a (human mammary epithelial normal cells) cell lines was assessed

by the MTT assay, 24 h after treatment. Ca²⁺-ATPase activities were measured using the coupled enzyme pyruvate kinase/lactate dehydrogenase assay, using sarcoplasmic reticulum (SR) vesicles as model.

Result and discussion

MeV18 and ButV18 ($IC_{50} = 4.85$ and $9.89 \mu\text{M}$) were observed to be approximately three and two times more active against the MDA-MB-231 cells, respectively, than V15 ($IC_{50} = 17.2 \mu\text{M}$). In addition, they were also cytotoxic to the non-tumor cell line, following the order V15 > MeV18 > ButV18. The POV, V15 and MeV18 and ButV18, inhibited Ca²⁺-ATPase activity in vitro, with IC_{50} values of 14.0, 5.16 and $5.65 \mu\text{M}$, respectively. All compounds exhibited mixed-type inhibition. The most potent Ca²⁺-ATPase inhibitor, MeV18, is also the most cytotoxic POV to breast cancer cells. Moreover, stability studies performed by EPR and ⁵¹V NMR spectroscopic techniques showed that V18 presents higher stability in water than V15, which also suffers a partial breakage in the enzymatic medium.

Conclusion

POVs are promising candidates to develop effective therapeutic agents for dealing with breast cancer, using a combined strategy based on targeting calcium signaling pathways and cytotoxicity therapy.

Enhancing Therapeutic Efficacy in Patient-Derived Models of Pancreatic Ductal Adenocarcinoma Using Engineered Placental Mesenchymal Stromal Cells

V. Buocikova¹, L. Drndakova¹, M. Burikova¹, Z. Kozovska¹, U. Altanerova², J. Jakubecova², M. Andrezal², D. Vanova², B. Smolkova³, C. Altaner^{1,2}

³Biomedical Research Center of the Slovak Academy of Sciences, Cancer Research Institute, Bratislava, Slovakia

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer exhibiting a dismal five-year survival rate of less than 10%. A major obstacle in the PDAC treatment is a dense stromal environment, primarily regulated by cancer-associated fibroblasts (CAFs), the most abundant cell type in PDAC stroma. Our study aimed to develop engineered extracellular vesicles (EVs) derived from transduced placental mesenchymal stromal cells (PlacMSCs), carrying mRNA encoding the yeast cytosine deaminase::uracil phosphoribosyl transferase (yCD::UPRT) fusion gene, converting the non-toxic prodrug 5-fluorocytosine (5-FC) into the cytotoxic agent 5-fluorouracil. Furthermore, the influence of CAFs on therapeutic response was evaluated to improve the reliability of the organoid model.

Material and method

Conditioned media from PlacMSCs transduced with yCD::UPRT was concentrated (yCD::UPRT-PlacMSC-cCM) using a tangential flow filtration system (TFF-Easy, HansaBioMed Life Sciences) and EVs characterized by Nanoparticle Tracking Analysis (NTA) using NanoSight NS500 Instrument (Malvern Instruments Ltd.). The organoids (PDXOs) were generated from subcutaneous patient-derived xenografts (PDXs). Donor patient tumors and corresponding PDXOs were characterized by immunohistochemical analysis (IHC). Besides, the therapeutic effect of yCD::UPRT-PlacMSC-cCM + 5-FC was determined on patient-derived CAF primocultures (CAF31, CAF78, CAF79) and PDXOs (PDXO71 and PDXO113) by CellTiter-Glo® Luminescent/3D Cell Viability Assay (Promega Corporation). Finally, the biological activity of yCD::UPRT-PlacMSC-cCM was assessed on the cocultivation model of CAF31 and both PDXO samples.

Result and discussion

NTA detected particles in concentrations between $7.8 \times 10^9/\text{mL}$ and $9.6 \times 10^9/\text{mL}$ and the mean size ranging from 67 to 95 nm. IHC analysis revealed substantial interindividual heterogeneity in the expression of Ki-67, CEA, and CK7 markers across patient tumors and corresponding PDXOs, providing valuable insights into the proliferation, differentiation, and aggressiveness. The treatment with yCD::UPRT-PlacMSC-cCM + 5-FC induced uniform cytotoxic effect across CAF samples and PDXOs. Besides, there were no apparent differences in cell viability after the 5-day treatment with yCD::UPRT-PlacMSC-cCM + 5-FC between monocultures and coculture models.

Conclusion

Our study demonstrates the potential of engineered PlacMSC-derived EVs as a new therapeutic approach for PDAC, inducing cytotoxic effects across patient-derived models. Given the limited translation of preclinical findings into clinical practice, our findings emphasize the need for more advanced preclinical models that better recapitulate the PDAC tumor microenvironment.

EACR25-2066

Investigation of Novel Duocarmycin Payloads Antibody-Drug Conjugates (ADCs) targeting HER2 for Therapeutic Intervention

E. Arasanz Pichler¹, G. Ribeiro Morais¹, S. Smarakian¹, A. Berry¹, J. Gell¹, V. Board¹, K. Choudry¹, R. Falconer¹, K. Pors¹

¹University of Bradford, Institute of Cancer Therapeutics, Bradford, United Kingdom

Introduction

Antibody-Drug Conjugates (ADCs) have emerged as a revolutionary class of targeted therapy for cancer, with 15 ADCs clinically approved for different haematological and solid malignancies and hundreds of candidates currently undergoing clinical evaluation. By combining the selectivity of monoclonal antibodies with the potency of cytotoxic payloads, ADCs enhance the therapeutic index and efficacy while minimizing systemic toxicity. However, the poor penetration of these conjugates in solid tumours, tumour heterogeneity and acquired drug

resistance to payloads remain therapeutic limitations. Duocarmycins are ultrapotent DNA-alkylating agents with strong anticancer properties, but their clinical use as standalone therapeutics has been hindered by a narrow therapeutic window. ADCs provide an ideal platform for incorporating duocarmycin derivatives, improving their therapeutic index and broadening their clinical potential.

Material and method

In this study, we characterized a novel library of duocarmycin analogues for use as ADC payloads, conjugated to the anti-HER2 antibody Trastuzumab.

Result and discussion

Biochemical assays revealed that these analogues exhibit a slower spirocyclization (activation) rate (>2 hours) compared to the control compounds CPI-MI and CBI-MI. Transwell experiments provided insights into their ability to penetrate multilayered cancer cells. The library of analogues was tested across multiple cancer cell line types, including breast, rhabdomyosarcoma, colon or prostate lines, displaying a range of IC₅₀ values (0.1 - 100 nM). Notably, no significant differences in cytotoxicity were observed between wild-type and different drug-resistant cell lines or between p53^{+/+} and p53^{-/-} cell lines, suggesting these payloads are not greatly affected by common resistance mechanisms associated with ABC transporter expression, DNA repair or p53 status. Finally, lead duocarmycin analogues were selected for a cysteine residue bioconjugation to Trastuzumab enabling the generation of novel anti-HER2 ADCs. These conjugates are currently undergoing *in vitro* testing in HER2⁺ and HER2⁻ cancer cell lines, and new data will be disclosed at the event.

Conclusion

In conclusion, our work builds on our previous duocarmycin-based research and focuses on implementing their cancer cell-killing power in ADC designs with clinical potential.

EACR25-2084

Triptonide induces pro-apoptotic effects against medulloblastoma subtypes

M. Yaqoob¹, H. Eastham¹, J. Morovis Marchetti¹, Cassarotti¹, B. Samphire-Noden¹, D. Greensmith¹, M. Jones¹

¹*University of Salford, Biomedical Research Centre, Salford, United Kingdom*

Introduction

Medulloblastoma is a major cause of paediatric brain tumours worldwide. Whilst effective, current treatments are often associated with lifelong off-target effects resulting in lower quality of life and early mortality in paediatric patients. This necessitates the need to develop new therapies. One source of novel therapeutics are those derived from plants, as they are associated with potent effects along with lesser off-target effects (Jones et al., 2023). One species, *Tripterygium wilfordii*, has gained interest over the last decade for the treatment of cancers. Whilst many compounds from this species have shown anti-cancer efficacy, triptonide, has garnered interest due to its diverse biological activity, including the induction of apoptosis and cell cycle arrest in

multiple cancer cell types (Song et al., 2023). However, the efficacy of triptonide against medulloblastoma subtypes is limited. To address this, we sought to elucidate the anti-medulloblastoma efficacy of triptonide.

Material and method

The effect of triptonide on medulloblastoma (HD-MB-03, & DAOY) viability was determined using MTT and washout assays. Time-lapse live-cell microscopy was utilised to examine the effect of triptonide on cell morphology and cell fate profile. Flow cytometry was used to examine the cell death mechanism (Annexin V/ Propidium Iodide), and mitochondrial membrane potential (Rhodamine 123) [1].

Result and discussion

Triptonide produced time and concentration-dependent irreversible decreases in viability against both HD-MB-03 and DAOY cell lines, with IC₅₀ values of 11 nM and 0.64 μM respectively after exposure for 72 hrs. HD-MB-03 cell fate profiling found triptonide (5 nM) significantly increased total cell cycle time by 118.4 ± 22.6 % (P < 0.0001) compared to control. All concentrations examined (5-20nM) resulted in a significant concentration-dependent increase in cellular death in interphase (P < 0.0001) and produced morphological changes associated with apoptosis. Flow cytometry revealed treatment with triptolide (20 nM) significantly increased apoptosis 5.2-fold (P = 0.046) compared to control. Triptonide also significantly decreased mitochondrial membrane potential (42.8 ± 6.7 %, P = 0.006), indicative of intrinsic apoptosis.

Conclusion

These findings suggest that triptonide shows promise as a treatment for group 3 medulloblastoma subtypes through the induction of apoptosis. Further research is now required to determine the molecular mechanisms of action underpinning this observed activity.

[1] The study was ethically approved by the University of Salford Ethical Review Board (ID: 10513).

EACR25-2087

Identification of HMGA protein inhibitors as potential cancer therapy

M. Muzzo¹, L. Secco², R. Sgarra², L. Su³, F. Leng³, S. Covaceuszach⁴, G. Manfioletti², M. Fedele¹, S. Battista¹, M. Pierantoni⁵

²*University of Trieste, Trieste, Italy*

³*Florida International University, Miami (FL), United States*

⁴*Institute of Crystallography, National Research Council, Basovizza (TS), Italy*

⁵*University of Naples Federico II, Department of Molecular Medicine and Medical Biotechnology, Naples, Italy*

Introduction

The overexpression of HMGA proteins plays a pivotal role in neoplastic transformation and is responsible for aggressive tumor phenotypes, characterized by enhanced metastatic potential and resistance to chemotherapy. Notably, HMGA1 has been identified as a key regulator

of cancer stem cell self-renewal, which is crucial for tumor initiation, maintenance, therapeutic resistance, and recurrence. Several studies, including our own, have demonstrated that HMGA1 overexpression contribute to resistance against multiple chemotherapeutic agents, including cetuximab. Consequently, HMGA proteins represent promising targets for novel cancer therapies.

Material and method

To identify potential inhibitors of HMGA protein function, we conducted high-throughput screening analyses using two libraries of molecules: the Sigma LOPAC 1280 and the Prestwick Chemical Library 1280. Electrophoretic mobility shift assays (EMSA) were subsequently performed to assess the ability of the selected molecules to displace HMGA proteins from their target DNA sequences and to inhibit HMGA binding to target proteins *in vitro*. Functional assays were conducted on breast and colon cancer cell lines, with or without HMGA1 expression, to evaluate the specificity and efficacy of the identified inhibitors.

Result and discussion

Our screening identified seven molecules capable of interacting with HMGA proteins. EMSA experiments revealed that some of these compounds effectively disrupted HMGA-DNA interactions and inhibited HMGA binding to its target proteins *in vitro*. Functional assay further demonstrated that two of these molecules, tannic acid and benserazide, selectively inhibited HMGA function in breast and colon cancer cells, and reduced their aggressive phenotype, including high proliferation rate and stem cell potential.

Conclusion

These findings highlight the possibility of targeting HMGA proteins as a novel strategy to overcome chemo-resistance in aggressive cancers.

Doxorubicin and cGAMP-loaded hypoxia-sensitive polymersomes: A strategy for enhanced tumor growth inhibition and reduced systemic toxicity

J. Cieplak¹, K. Jelonek², M. Musial-Kulik², J. Jaworska², J. Czapla¹, A. Drzyzga¹, T. Cichon¹, S. Matuszcza^k¹, M. Jarosz-Bie^j¹, R. Smolarczyk¹

²Centre of Polymer and Carbon Materials, Polish Academy of Sciences, Zabrze, Poland

Introduction

Hypoxia plays a crucial role in shaping tumor progression and influencing treatment outcomes. This unique microenvironment presents both obstacles and opportunities for developing more precise therapeutic strategies. In this regard, nanomedicine has gained significant attention, utilizing hypoxia-sensitive polymersomes to enable targeted drug delivery to tumors while minimizing off-target effects. Hypoxia-sensitive polymersomes provide a versatile approach to addressing the challenges associated with the tumor microenvironment. These specialized carriers are designed to

selectively degrade in hypoxic tumor regions, ensuring more precise drug release. As a result, hypoxia-sensitive polymersomes represent a promising platform for advancing next-generation cancer therapies. In the present study, we focused on the development and characterization of hypoxia-sensitive doxorubicin or cGAMP encapsulating polymersomes for enhanced anticancer efficacy with reduced systemic toxicity.

Material and method

The experimental approach involved the synthesis of hypoxia-sensitive polymersomes comprising a poly(lactic acid)-azobenzene-poly(ethylene glycol) diblock copolymer, loaded with DOX or cGAMP. Further evaluations were conducted to assess the internalization and degradation of these synthesized vesicles in murine cancer cell lines: 4T1 (breast cancer) and B16-F10 (melanoma), at various time points and concentrations. *In vivo* studies were conducted on BALB/c mice with 4T1 tumors and C57BL/6 mice with B16-F10 [1].

Result and discussion

Hypoxia-triggered drug release from the synthesized polymersomes was confirmed, with increased cytotoxicity of DOX-loaded carriers under hypoxic conditions. IVIS imaging enabled visualization of polymersomes localization and drug release within tumors, revealing enhanced accumulation in tumor tissues while minimizing off-target distribution to healthy organs. Therapeutic efficacy was assessed by measuring tumor growth inhibition and monitoring body weight changes in treated mice. While both DOX- and cGAMP-loaded polymersomes individually suppressed tumor growth, their combination exhibited the strongest inhibitory effect. Additionally, immunohistochemical analysis of post-treatment tissues provided insights into tumor architecture and microenvironmental changes.

Conclusion

Our findings demonstrate that hypoxia-sensitive polymersomes exhibit preferential accumulation and efficient release of drugs within hypoxic tumor microenvironment, resulting in enhanced therapeutic outcomes. Additionally, the reduced systemic toxicity observed in treated mice highlight the clinical potential of these engineered nanocarriers for safer and more effective cancer treatment.

Idasanutlin in combination with PD-1 blockade - synergy or antagonism?

L. Skalniak¹, A. Nieznanska¹, M. Statkiewicz², Z. Sandowska-Markiewicz², K. Unrug-Bielawska², A. Majewska¹, M. Mikula², J. Ostrowski², T. Holak¹

¹Jagiellonian University, Department of Organic Chemistry, Faculty of Chemistry, Krakow, Poland

²Maria Skłodowska-Curie National Research Institute of Oncology, Department of Genetics, Warsaw, Poland

Introduction

The blockade of the PD-1/PD-L1 immune checkpoint has become a well-recognized strategy in the treatment of cancer. Due to the limited response in a considerable proportion of patients, diverse drug combinations have

been proposed, including small-molecule antagonists of MDM2, such as idasanutlin. In p53 wild-type cancer cells, MDM2 antagonists lead to forced activation of the p53 protein, causing potent cell cycle arrest but only limited cancer cell apoptosis. A combination of PD-1 blockade and p53 activation has been proposed to be beneficial for both treatments. This study aims at a verification of this hypothesis *in vitro* and *in vivo*.

Material and method

MDM2 antagonist idasanutlin was tested against mouse and human cancer cell lines in terms of p53-induced protein expression, cell cycle blockade, cell survival decrease, activation of apoptosis, and induction of PD-L1 expression. A syngeneic CT26/BALB/c mouse model was used to assess the therapeutic effects of the combination of PD-1 blockade and p53 activation *in vivo*.

Result and discussion

Idasanutlin effectively reactivates p53 in p53-wt human cancer cell lines, leading to potent cell cycle arrest but only limited apoptosis. Similar results are observed for mouse cell lines but at considerably higher concentrations. p53-wt/p53-mut selectivity observed for human cell lines is retained in mouse cell lines.

Idasanutlin seemingly increases the expression of PD-L1, but the introduction of a new *in vitro* model questions this notion. The combination of PD-1 blockade with low doses of idasanutlin *in vivo* leads to a positive interaction of both treatments, while high doses of MDM2 antagonist cause deleterious effects to this immunotherapy approach.

Conclusion

The results confirm the limited ability of MDM2 antagonists alone to eliminate cancer cells. The *in vivo* study underscores important aspects of combining the two therapeutic approaches, which can bring both completing and opposing effects.

This research was supported by the Preludium grant 2019/35/N/NZ5/03991 and Sonata Bis grant 2021/42/E/NZ7/00422 from the National Science Centre, Poland.

Introduction

Metastatic colorectal cancer (mCRC) treatment outcomes are significantly hindered by inter- and intra-tumor heterogeneity in patient response. Several studies have shown that three-dimensional patient-derived organoids (PDOs) can preserve specific tumor characteristics. Considering the high heterogeneity of colorectal cancer among patients and the ability of PDOs to replicate their parental tumor characteristics, they function as valuable models for drug profiling via high-throughput screening in the context of personalized therapy. The present study aimed to establish a living PDO biobank from 20 heavily pretreated mCRC patients encompassing the morphological, genomic, and transcriptomic characteristics and drug sensitivities via multi-parameter analysis.

Material and method

Hematoxylin-eosin staining was performed to evaluate phenotypic similarities between PDOs and their parental tumors. Genomic and transcriptomic profiles were analyzed using whole-exome sequencing (WES) and RNA sequencing (RNA-Seq). We then conducted drug screening using a 3D image-based approach with a library of 50 compounds to assess anti-cancer drug sensitivities by measuring organoid volume, nuclei count, and proliferation index via the EdU incorporation assay, along with three distinct fluorescent stainings. The drug responses across these three separate parameters were assessed, identifying both common and patient-specific hits.

Result and discussion

The histologic features of PDOs were validated by an independent pathologist. WES and RNA-Seq analyses of PDOs and matched tumors demonstrated a high concordance in mutations, copy number variations, and transcriptomic signatures. Multiparametric drug sensitivity analyses, including organoid volume, nuclei count, and proliferation, demonstrated greater sensitivity in identifying both common and patient-specific hits across all patients, indicating the platform's potential use and expansion into clinical decision-making.

Conclusion

In conclusion, we established a living biobank of PDOs derived from 20 patients with mCRC, incorporating genomic and drug sensitivity analyses while maintaining intratumor heterogeneity and preserving key molecular features relative to their parental tumors. Additionally, we established a protocol for image-based 3D high-content screening on PDOs and successfully applied this pipeline to evaluate 50 drugs. These results suggest that our PDO biobank, in combination with image-based screening, are effective tools for translational research and eventually for the development of personalized medicine.

EACR25-2123**Celastrol induces pro-apoptotic and anti-migratory effects against medulloblastoma subtypes**

J. Morovis Marchetti Cassarotti¹, H. Eastham¹, M. Yaqoob¹, B. Samphire-Noden¹, D. Greensmith¹, M. Jones¹

¹*University of Salford, Biomedical Research Centre, Salford, United Kingdom*

Introduction

Medulloblastoma accounts for 20–25% of all paediatric brain tumours diagnosed worldwide (de Medeiros et al., 2019). Current treatment regimens are effective.

However, most options lead to long-term off-target effects. Therefore, the continued development of new, safer treatments for children is paramount. One source of novel therapeutics are those derived from plants, due to decreased side effects compared to synthetic alternatives (Jones et al. 2023). One species which has emerged in recent years is that of *Tripterygium wilfordii* and the bioactive compounds it contains. One compound of significant interest is that of celastrol, which has been shown to possess anti-cancer properties (Shi et al., 2020). However, there is limited evidence to showcase its efficacy against medulloblastoma. Therefore, this study sought to determine the cytotoxic and anti-migratory effects of celastrol against medulloblastoma subtypes.

Material and method

The effect of celastrol on medulloblastoma (HD-MB-03, & DAOY) viability was determined using MTT assays. Time-lapse live-cell microscopy was utilised to examine the effect of celastrol on cell morphology, and cell fate profile, in addition to bulk and single-cell migration. Fluorescence microscopy was used to measure caspase 3/7 activation [1].

Result and discussion

Celastrol produced concentration and time-dependent decreases in medulloblastoma (DAOY & HD-MB-03) viability with IC₅₀ values after 72 hours found to be 151 and 232 nM respectively. Cell fate profiling showed significant increases in death in mitosis ($P < 0.0001$) but did not significantly increase cell cycle time ($P = 0.132$). Morphological analysis highlighted changes indicative of apoptosis (cell shrinkage & blebbing). Fluorescence microscopy revealed significant increases in caspase 3/7 activation ($P < 0.001$) indicative of apoptotic cell death. Exposure to celastrol significantly decreased bulk cell migration by $50.4 \pm 3.8\%$ ($P = 0.0002$). Medulloblastoma single-cell migration analysis also revealed significant decreases in cell migratory distance and speed ($30.4 \pm 4.1\%$, $P < 0.0001$).

Conclusion

These data highlight the potential of celastrol as a potential treatment for medulloblastoma through the induction of apoptosis and inhibition of cellular migration, warranting the need for further investigation into the underpinning molecular mechanisms of action.

[1] The study was ethically approved by the University of Salford Ethical Review Board (ID: 10513)

EACR25-2140**The effects of a dual GIP/GLP-1 receptor agonist, Tirzepatide, on the response of prostate cancer cells to therapy**

H. Li¹

¹*University of Bristol, Bristol Medical School, Bristol, United Kingdom*

Introduction

Worldwide, 10.3 million new cases of prostate cancer (PCa) have been diagnosed, making it the second most common cancer in 2022. Repurposing drugs can provide a new way to identify different approaches to optimising cancer treatment. We aimed to investigate the effects of combining tirzepatide (Mounjaro®), approved for the treatment of type 2 diabetes, with the antiandrogen drug enzalutamide.

Material and method

Cell culture; Prostate cancer cells- LNCaP; Western blot; Tritiated Thymidine (3H-thymidine) Incorporation Assay; Muse cell count

Result and discussion

With LNCaP prostate cancer cells, enzalutamide alone inhibited proliferation, while tirzepatide had no significant effects. However, there was an additive reduction in cell growth when tirzepatide and enzalutamide were added in combination. In contrast, no significant interactions were observed between tirzepatide and the chemotherapy drug, Docetaxel. Analysis of data from the cancer genome atlas revealed that in normal prostate tissue there was an inverse correlation between the gastric inhibitory polypeptide receptor (GIPR) and androgen receptor (AR) ($P < 0.05$), but no association was found with glucagon-like peptide-1 receptor (GLP-1R). In tumors, GLP-1R was weakly positively correlated with AR, while the GIPR remained inversely correlated.

Conclusion

The results suggest that tirzepatide appears to have no effect on the sensitivity to docetaxel but may have a role in optimizing the inhibitory effects of enzalutamide. And future work aims to understand the underlying mechanism of action and translate the mechanistic findings in prostate tissue.

EACR25-2146**Generation of Knock-In RAS Oncogenic Mutations in a KP Lung Cancer Cell Line Using CRISPR to Test the Effects of SHOC2 Inhibition**

R. Nisar¹, N. Jhala¹, P. Rodriguez Viciana¹, A. Espada Ruiz¹

¹*Cancer Institute, Medical sciences, London, United Kingdom*

Introduction

RAS is the most frequently mutated oncogene across all human cancers, yet its effective clinical targeted inhibition is limited due to resistance and toxicity. The SHOC2-MRAS-PP1 complex has been identified as a potential therapeutic target for RAS-driven cancers, as it has been reported that SHOC2 genetic knockout can reduce cell growth in KRAS mutant breast carcinoma and

increase the sensitivity to MEK inhibitors, widening their therapeutic index. Increasing evidence suggests functional differences between different codon and amino acid substitutions, and the Cancer Dependency Map project (DepMap) has indicated that the Q61x and G13D mutations may be more sensitive to inhibition of the SMP complex than other RAS oncogenic mutations.

Material and method

We used a CRISPR knock-in approach to generate an isogenic mouse model of the most prevalent RAS oncogenic mutations and explore the effects of SMP pharmacological inhibition, protein degradation or genetic ablation of SHOC2, alone or in combination with MAPK pathway inhibitors in CellTiter-Glo viability assays.

Result and discussion

Our results showed that the robust sensitization to MEK inhibitors seen upon SHOC2 absence is reproducible with genetic ablation, protein degradation and pharmacological inhibition of the SMP complex. Data also suggests that this sensitization is particularly enhanced in cells harbouring KRASQ61 and G13 mutations, correlating with the findings from the DepMap project.

Conclusion

These results provide evidence for further development of SMP inhibitors to potentially use in a clinical setting in combination with MEK inhibitors to treat RAS-driven cancers, which could be of significant benefit especially in patients positive for KRAS G13D/Q61H mutations.

⁵Faculdade de Ciências e Tecnologia (FCT), Universidade do Algarve; CCMar, Universidade do Algarve, Faro, Portugal

Introduction

Pancreatic cancer is one of the most lethal malignancies, with a 5-year survival rate of just 5%. This scenario is attributed to the aggressive nature of the disease, the late onset of symptoms and the limited diagnostic and therapeutic options, which reinforces the urgent need for innovative treatments. Polyoxometalates (POMs), compounds formed by transition metal oxyanions such as tungsten, vanadium and molybdenum, have attracted increasing interest due to their structural diversity and biomedical potential (Bijelic et al, 2019, *Angew. Chem.; Carvalho et al, 2023, IJMS*). Among the POMs, those containing tungstate (POTs) stand out for their stability and effectiveness as anti-tumor agents. They act on essential cellular processes, such as inducing apoptosis, stopping the cell cycle, interfering with ion transport and inhibiting key enzymes, affecting calcium homeostasis and intercalate DNA, compromising cellular repair mechanisms. The aim of this study was to evaluate the potential of polyoxotungstates (POTs) as antitumor therapy for pancreatic cancer.

Material and method

Three human pancreatic cancer cell lines - PANC-1, Hs766T and MIAPaCa-2 were used to evaluate the cytotoxic effects of five different POTs. Cytotoxicity was measured over a range of concentrations (0.1–100 µM) using the SRB assay, at 24h, 48h and 72h after treatment to quantify protein content.

Result and discussion

The results revealed that higher concentrations of POTs were associated with a significant decrease in protein content levels, suggesting a direct inhibition of cell proliferation. The P5W17 and P5W30, were found to be the most active, with P5W30 being the most potent one. P5W30 differs from the other compounds in its chemical formula, containing 30 tungsten and 5 phosphorus atoms, and consequently, it has a distinct three-dimensional structure, forming a Preyssler type, while the others are Keggin type (P2W12), lacunary Dawsons (P2W15; P2W17), and Dawson types (P5W18). In fact, Preyssler type have been shown to present higher levels of efficacy in several biochemical processes, in comparison with other POTs (Poejo et al, 2024, *J. Inorg Biochem.*).

Conclusion

In summary, the results obtained in this study demonstrate the promising efficacy of POTs as anti-tumor agents against pancreatic cancer, with P5W30 proving to be particularly potent. Given the therapeutic potential observed, it is essential to continue with more in-depth research, particularly into toxicity, specific molecular mechanisms and clinical application of POTs.

⁵*Imperial College London, Department of Epidemiology and Biostatistics, School of Public Health, London, United Kingdom*

Introduction

Approved cardiometabolic and hormonal medications targeting key hallmarks of cancer represent potential repurposing opportunities for cancer treatment. We aimed to investigate the repurposing potential of approved anti-hypertensive, lipid-lowering, anti-adiposity and anti-oestrogenic medications for breast and ovarian cancer treatment using the causal inference method Mendelian randomisation (MR).

Material and method

We obtained or constructed germline genetic instruments from GWAS to proxy cardiometabolic traits (body mass index (BMI), low density lipoprotein cholesterol (LDL-c), systolic blood pressure (SBP)), and the following medication targets: anti-hypertensive (angiotensin-converting enzyme (ACE), beta-1 adrenergic receptor (ADRB1), sodium-chloride symporter (NCC)), lipid-lowering (3-hydroxy-3-methylglutaryl coenzyme A reductase (HMGCR), Niemann-Pick C1-Like 1 (NPC1L1), proprotein convertase subtilisin/kexin type 9 (PCSK9)), anti-adiposity (gastric inhibitory polypeptide receptor (GIPR)) or anti-oestrogenic (cytochrome P450 Family 19 Subfamily A Member 1 (CYP19A1)). The genetically proxied effects of these traits or targets on breast and ovarian cancer mortality were investigated using summary-level MR. Current indications for these medications, for example risk of coronary artery disease, stroke, type 2 diabetes and elevated SBP, were employed as positive control outcomes to assess validity of the genetic instruments. To assess risk of collider bias, summary-level MR was performed with cancer incidence outcomes and where required, adjustments for collider bias are ongoing.

Result and discussion

Genetically proxied BMI lowering reduced breast cancer mortality (HR per SD decrease BMI: 0.89; 95% CI: 0.82–0.97), whilst genetically proxied HMGCR inhibition (HR per SD decrease LDL-c: 1.81, 95% CI: 1.15–2.83) and PCSK9 inhibition (HR per SD decrease LDL-c: 1.51, 95% CI: 1.05–2.18) increased risk of breast and ovarian cancer mortality, respectively. There was no strong evidence to support effects of any other traits or targets investigated. In general, there was evidence supporting effects of genetically proxied targets on their respective current indications, for example evidence supporting

genetically proxied HMGCR inhibition decreasing risk of coronary artery disease (OR per SD decrease LDL-c: 0.67, 95% CI: 0.56–0.80).

Conclusion

Aside from a protective effect of lower BMI on breast cancer survival, we did not observe strong evidence to support repurposing of anti-hypertensive, lipid-lowering, anti-adiposity or anti-oestrogenic medications for breast or ovarian cancer treatment. General limitations of applying MR to cancer prognosis outcomes including limited power of analyses, low heritability of cancer survival and treatment effects, in addition to collider bias may have affected analyses.

EACR25-2172

Overcoming Gemcitabine Chemoresistance in PDAC with Nanoparticle-Delivered Active Phosphorylated Gemcitabine

N. Ferreira¹, D. Rudolph², C. Feldmann², F. Alves¹

¹*Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany*

²*Karlsruhe Institute of Technology, Karlsruhe, Germany*

Introduction

Pancreatic Ductal Adenocarcinoma (PDAC) is a highly aggressive and complex disease, with nearly 80% of cases being inoperable at diagnosis and reliant on systemic chemotherapy. Gemcitabine, the standard treatment for patients with poor survival (PS), has limited efficacy due to chemoresistance, with only a 30% response rate. Enhancing drug delivery via nanoparticles (NP) loaded with active gemcitabine forms, gemcitabine monophosphate (GMP), or gemcitabine triphosphate (GTP) may overcome resistance and improve gemcitabine efficacy.

Material and method

We developed high-load (around 76% drug content) inorganic-organic hybrid nanoparticles (GMP-IOH-NPs and GTP-IOH-NPs) and tested their efficacy in advanced patient-derived PDAC organoids. Gemcitabine-resistant murine and human PDAC cells were established through gradual gemcitabine exposure. The anti-tumor efficacy of GMP-IOH-NPs and GTP-IOH-NPs on these resistant cells was assessed using live imaging (Incucyte S3) and CellTiter-Glo assays.

Result and discussion

Live imaging of PDAC organoids from three patients treated with GMP-IOH-NP demonstrated a similar reduction in organoid size and number compared to free gemcitabine, indicating comparable efficacy. However, GTP-IOH-NP exhibited superior cytotoxicity against both human and murine gemcitabine-resistant PDAC cells in comparison to free gemcitabine or GMP-IOH-NP, suggesting that the triphosphate form enhances drug potency.

Conclusion

Encapsulating the active forms of gemcitabine in nanoparticles resulted in a comparable therapeutic effect to the free drug in advanced 3D PDAC cell models. Furthermore, GMP-IOH-NPs and GTP-IOH-NPs demonstrate potent efficacy in treating gemcitabine-resistant PDAC cells, as monotherapies. This optimized

drug delivery approach holds significant promise for effectively targeting PDAC tumors that have developed resistance to gemcitabine.

EACR25-2208

Combinations of HDAC and KRAS inhibitors in lung cancer

J. Li¹, A. Hamacher¹, M. Kassack²

¹Institute of Pharmaceutical & Medicinal Chemistry, University of Duesseldorf, Duesseldorf, Germany

²Institute of Pharmaceutical & Medicinal Chemistry, University of Duesseldorf, Duesseldorf, Germany

Introduction

Lung cancer is one of the problematic cancers due to the low 5-year survival rate (< 15%). Mutations and dysregulated proteins contribute to chemoresistance in non-small (85%) and in small cell lung cancers (15%). Increased RTK signaling (e.g. EGFR family, AKT, mTOR) and overexpressed epigenetic erasers such as histone deacetylases (HDACs) lead to dysregulation of metabolism, cell cycle, cell death and signal pathways. Whereas inhibitors of RTK signaling are established therapies based on the mutation status of a patient, HDAC inhibitors are experimental in solid cancers so far. HDAC inhibitors have the potential to increase chemosensitivity of cancers against classical cytostatics and targeted therapies as e.g. kinase or KRAS inhibitors. This project investigates drug combinations of HDAC and KRAS inhibitors for synergy in drug-resistant and KRAS wildtype or mutated non-small and small cell lung cancers.

Material and method

Non-small cell lung cancers A427/97 and DV90 and small cell lung cancers DMS114 and SHP77 were investigated. Cytotoxic effect of compounds were analysed by MTT assay. Caspase activation was determined by CellEvent Caspase-3/7 Green Detection Reagent from Thermo Scientific. Drug synergy analysis was performed by Chou-Talalay using Combenefit. HDACs, kinases, KRAS and phosphorylated proteins were analyzed by western blotting.

Result and discussion

HDAC1/2/3, EGFR, pEGFR, HER2, pHER2, and KRAS are highly expressed in lung cancer cells. KRAS mutations G12D, G13D and G12V were identified in A427/97, DV90 and SHP77, respectively. Incubation with 0.5 μM of the class I HDAC inhibitor entinostat for 48h prior to addition of the pan-KRAS inhibitor BI2865 decreased the IC50 of BI2865 by a factor of 5- to 50-fold in A427/97, DV90, and SHP77. This chemosensitization of lung cancer cells against the KRAS inhibitor BI2865 by entinostat was shown to be synergistic according to Chou-Talalay. Furthermore, the combination of entinostat and BI2865 increased caspase 3/7 mediated apoptosis in a synergistic manner. Observed synergistic effects between entinostat and BI2865 are likely mediated by increased p21 expression and changes in the expression of pro- and antiapoptotic proteins.

Conclusion

Pretreatment with the HDAC inhibitor entinostat and subsequent treatment with the pan-KRAS inhibitor BI2865 is better than treatment with entinostat or BI2865

alone. The combination not only led to an increase in cytotoxicity, but also to an increased activation of caspase 3/7 with subsequent apoptosis. A proteome analysis before and after treatment provides mechanistic evidence. p21 was upregulated and various pro- and antiapoptotic proteins were differentially regulated. This combination of epigenetic and targeted therapy represents a new clinical option for the treatment of chemoresistant lung cancers.

Nanocarriers for Targeted Boron Delivery to Tumor Cells in BNCT Applications

J. Piña Marcos¹, D. Alberti¹, S. Rakhsan¹, N. Protti², S. Altieri², C. Viñas³, L. Pazderova⁴, A. deagostino⁴, S. Geninatti Crich¹

¹University of Torino, Department of Molecular Biotechnology and Health Sciences, Torino, Italy

²University of Pavia, Pavia, Italy

³Universitat Autònoma de Barcelona, Institut de Ciència de Materials de Barcelona (ICMAB-CSIC, Barcelona, Spain

⁴University of Torino, Dipartimento di Chimica, Torino, Italy

Introduction

Cancer represents a significant global health challenge due to its uncontrolled cell growth and resistance to conventional therapies. Among innovative treatments, boron neutron capture therapy (BNCT) has emerged as a promising approach. BNCT relies on the selective accumulation of boron-containing agents in tumor cells, which, after neutron irradiation, produce cytotoxic α particles via a nuclear reaction, allowing the destruction of malignant cells while minimizing damage to healthy tissues. However, the clinical success of BNCT faces challenges such as nonspecific biodistribution and rapid metabolism of boron agents and the necessity for a significant number of boron atoms to be localized on or within neoplastic cells. In this study, we explore the use of carriers, specifically apoferritin and β-cyclodextrins, to accumulate boron clusters inside tumor cells. A boron cluster, cobaltabis(dicarbollide) (Cosan) containing 18 boron atoms per molecule was used, and its nanoformulations were tested for the treatment of different types of cancer, including breast cancer, lung cancer, and mesothelioma.

Material and method

Apo ferritin nanohybrids were synthesized by encapsulating Cosan through pH-mediated disassembly at pH = 2 and reassembly at physiological pH. Encapsulation efficiency was assessed using Bradford assay and ICP-MS. Uptake studies were performed on different cell lines, with boron content analyzed by ICP-MS. Cell viability and uptake efficiency were evaluated. AB22 mesothelioma cells incubated with free Cosan or Apoferritin nanohybrids were subjected to neutron irradiation, and post-treatment effects were assessed via clonogenic assay. Cyclodextrin adducts were synthesized by incubating at pH 7.4 and 37°C β-cyclodextrin derivatives with Cosan or TLP, a curcumin derivative that includes a Cosan moiety.

Result and discussion

A high cargo loading capacity of Apoferritin was achieved, specifically 6.1 ± 1.7 Cosan molecules were effectively encapsulated within the inner cavity of apoferritin. Uptake experiments with AB22 mesothelioma cells showed a significant boron uptake, sufficient for neutron irradiation. For BNCT, AB22 cells incubated with only Cosan or apoferritin nanohybrid were neutron irradiated. Clonogenic assays showed a 50% colony reduction compared to irradiated and untreated controls, highlighting more efficacy of apoferritin for boron delivery for BNCT. Cyclodextrin adducts with Cosan and TLP showed a high affinity of both cyclodextrins, suggesting their potential use as carriers. Additionally, preliminary results indicated a TLP higher toxicity compared to Cosan in lung cancer A549 and LLC cell lines, further supporting its potential as an effective boron delivery system.

Conclusion

We successfully developed an apoferritin nanohybrid and cyclodextrin adducts, which can act as delivery systems that efficiently encapsulates boron-containing molecules for potential use in BNCT.

EACR25-2248

Subcutaneous controlled release of antibodies and antibody-drug-conjugates with zwitterionic chitosan-based hydrogels

G. Jacquot¹, C. Grange¹, S. Harlepp¹, A. Detappe¹

¹*ICANS, Strasbourg, France*

Introduction

Subcutaneous (SC) administration of monoclonal antibodies (mAbs) enhances patient compliance and therapeutic efficacy but remains challenging for antibody-drug conjugates (ADCs) due to formulation instability, delivery constraints, and immunogenicity risks. Conventional SC formulations require cold-chain storage and often display variable bioavailability. Here, we introduce a zwitterionic chitosan-based hydrogel that enables controlled release and prolonged stability of mAbs and ADCs at ambient temperature, offering a scalable alternative for clinical translation.

Material and method

Zwitterionic chitosan-based hydrogels were designed for the sustained release of trastuzumab, rituximab, trastuzumab/pertuzumab, and trastuzumab-emtansine (T-DM1). Comprehensive characterization was performed, including rheology, injectability, stability, and in vitro release kinetics. Two lead formulations were developed: chitosan@DOTAGA:chitosan for mAbs and a zwitterionic chitosan-only hydrogel optimized for ADCs to ensure cGMP compliance. Pharmacokinetic (PK) studies in murine and nonhuman primate (NHP) models compared these formulations to standard-of-care therapies (Herceptin® SC and Kadcyla® IV, respectively). Tolerability was assessed using ex vivo human skin explants, while therapeutic efficacy was evaluated in HER2+ xenograft models with multidose (trastuzumab) and monodose (T-DM1) administration.

Result and discussion

The chitosan@DOTAGA:chitosan-mAb hydrogel preserved the structural integrity of trastuzumab for up to

15 days at ambient temperature. Functional stability was confirmed via SECnMS and peptide mapping. In vivo, the hydrogel underwent complete biodegradation in both murine and NHP models, with no detectable immune activation. PK studies in NHPs revealed comparable systemic exposure profiles to SC formulations utilizing rHuPH20. For the zwitterionic chitosan-only hydrogel encapsulating T-DM1, ADC integrity was preserved for over one month at ambient temperature, with no inflammatory response detected in patient skin explants. In murine models, SC administration of the hydrogel resulted in a prolonged systemic exposure duration (9.5 vs. 5.6 mg·day/mL) compared to IV administration. In a HER2+ xenograft tumor model, therapeutic efficacy studies confirmed that tumor growth inhibition following hydrogel-mediated ADC delivery was comparable to clinically approved IV T-DM1, underscoring the potential for sustained SC drug delivery.

Conclusion

Our zwitterionic chitosan-based hydrogel formulations overcome key barriers in SC biologic delivery, providing extended stability and precise drug release while eliminating cold-chain constraints. By ensuring prolonged bioavailability and therapeutic efficacy, this platform offers a clinically viable strategy for next-generation SC biosimilars and ADC therapies.

EACR25-2253

Antitumor immune mechanisms elicited by NLRC5 expression in cancer cells

A. Shukla¹, S. Ilangumaran¹, S. Ramanathan¹

¹*U de Sherbrooke, Sherbrooke, Canada*

Introduction

Downmodulation of MHC class-I and antigen processing and presentation machinery (APM) genes is a key mechanism of cancer immune evasion. MHC-I defects in cancers occur mainly via the loss of expression of NLRC5 (NOD-Like Receptor CARD domain containing 5). NLRC5 is the key transcriptional activator of MHC-I and APM genes. We have shown that stable expression of NLRC5 in B16-F10 (B16-NLRC5) melanoma cells upregulates MHC-I, promotes tumor immunogenicity and elicits protective antitumor immunity against parental B16-F10 cells. Here, we elucidated the cellular and molecular mechanisms underlying the ability of B16-NLRC5 cells to elicit protective antitumor immunity towards exploiting NLRC5 for cancer immunotherapy.

Material and method

We carried out a proteomic analysis of B16-NLRC5 cells and B16-F10-vector controls to understand the molecular pathways modulated by NLRC5. We implanted B16-NLRC5 and B16-F10-vector cells in syngeneic C57BL/6 mice and monitored tumor growth and histological features. We examined the immune cell composition within tumors and tumor draining lymph nodes by flow cytometry. We evaluated the impact of depleting CD8+ T or NK cells on tumor growth.

Result and discussion

Proteomic analysis of B16-NLRC5 cells showed enrichment of proteasome, ubiquitin-mediated proteolysis, protein processing in the ER, spliceosome, ribosome biogenesis and peptidase pathways, which can impact the generation of canonical and non-canonical

MHC-I peptides. Notably, B16-NLRC5 cells showed downmodulation of PMEL17/gp100, DCT, TYR and TYRP1, which harbor dominant CTL epitopes. These data suggest that NLRC5 could increase tumor immunogenicity by expanding the diversity of the MHC-I peptidome. Tumors formed by B16-NLRC5 cells showed increased vascularization and abundant infiltration by CD45+ cells. Flow cytometry analysis revealed that B16-NLRC5 tumors harbored elevated numbers of CD8+ CD69+ activated/effector T cells in tumor draining lymph nodes (tdLN) and within tumor infiltrating lymphocytes (TILs). Notably, TILs from B16-NLRC5 tumors contained 10-fold more NK1.1+ cells. Depletion of either CD8+ T cells or NK1.1+ cells in B16-NLRC5 tumor bearing mice inhibited NLRC5-mediated tumor growth control.

Conclusion

Our findings indicate that (i) NLRC5 expression in tumor cells upregulates MHC-I, promotes tumor antigen presentation, broadens the MHC-I peptidome and increases tumor vascularity, and (ii) collectively, these events facilitate efficient priming of antitumor CD8+ T and NK cells, their infiltration into the tumor microenvironment and killing of tumor cells. Thus, NLRC5-based approaches can be developed for molecular immunotherapy of diverse immune escape cancers.

EACR25-2268

Effect of doxorubicin and quercetin combined treatment on osteosarcoma model systems

M. Milivojevic¹, L. Bojic¹, J. Pejic¹, J. Stojkova²

¹Institute of Molecular Genetics and Genetic

Engineering, Belgrade, Serbia

²Faculty of Technology and Metallurgy, Belgrade, Serbia

Introduction

Osteosarcoma (OS) is a highly aggressive bone tumor primarily affecting pediatric patients. Standard treatments include surgical resection, chemotherapy, and radiation for tumors that cannot be surgically removed. Although the 5-year survival rate is 65.5%, patients with metastases and recurrence have a significantly lower survival rate of ~30%. Despite this concerning statistic, the treatment for OS has remained largely unchanged over the past three decades. This stagnation in treatment innovation highlights the urgent need for further research and development in therapies tailored specifically for OS.

Material and method

We identified the DEGs between bone (7 samples) and OS (27 samples). To conduct in-depth study of the obtained upregulated DEGs, we constructed a PPI network and identified the most significant gene cluster. We investigated the effects of the combined treatment with doxorubicin and quercetin on SAOS-2 osteosarcoma cells in 2D condition and immobilized in alginate microbeads in 3D condition. We assessed the effects of treatments on cell viability using MTT and the expression of genes using qPCR.

Result and discussion

We have analysed DEGs between bone and human osteosarcoma samples and identified 630 upregulated genes. We extended the networks with information from

DrugBank to identify potential therapeutics for osteosarcoma focusing on the top 10% of interconnected genes in cluster due to their important biological functions. The identified cluster had enrichment in biological processes connected to oxidative phosphorylation and we found quercetin as a promising candidate for treating OS. We analysed quercetin's effect utilizing the Saos-2 in 2D and 3D on viability and gene expression, alone or in combination with doxorubicin. Following treatment, we assessed cell viability and the expression of genes. Our results have shown that the combined treatment statistically significantly decreased the viability of SAOS-2 cells cultured in 2D and 3D conditions compared to cells treated with doxorubicin. We analyzed the expression of genes associated with poor prognosis in patients such as pluripotency genes, an OS marker, and a resistance-related gene. Collectively our results show different responses to the combined treatment depending on the model system used.

Conclusion

The combined treatment substantially reduced cell viability in 2D and 3D models and decreased expression of genes associated with poor prognosis compared to doxorubicin alone in 3D models. We can hypothesize that microenvironment-based mechanisms modulate cell sensitivity to therapy and increase resistance to treatment of osteosarcoma cells cultured in 3D condition. Understanding the molecular mechanisms will significantly contribute to the development and enhancement of existing therapies, thereby facilitating advancements in the treatment of osteosarcoma. Acknowledgement: This study was supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia, grant no. 451-03-136/2025-03/200042 and the Science Fund of the Republic of Serbia, grant no. 7503

Unlocking the Dual Power of miR-302b in BRCA1 Wild-Type Triple-Negative Breast Cancer: PARP Inhibitor Sensitivity Enhancer and Tumor Microenvironment Shaper

V. Fogazzi¹, A. Cataldo¹, I. Plantamura¹, G. Cosentino¹, M. Kaphanke¹, S. Romero Cordoba², E. Tagliabue¹, S. Pupa¹, M. Iorio¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

²2. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Introduction

miRNAs are small non-coding RNAs, strongly regulated at epigenetic level, which play an important role in both tumor-intrinsic mechanisms and tumor microenvironment (TME) shaping. They can be released and transferred through microvesicles, contributing to the crosstalk between neoplastic and TME cells and influencing cancer progression and response to therapies. Recently, we demonstrated that miR-302b enhances chemotherapy response both in *in vitro* and *in vivo* triple negative breast cancer (TNBC) models by regulating cell cycle genes and DNA repair pathways. Additionally, we proved that the miR-302b/cisplatin combination treatment down-

modulates double-strand break repair pathways in neoplastic cells and reduces pro-tumoral M2 macrophages number, identified as CD68/Arginase-1 positive stromal elements. Starting from these findings, we aimed to further investigate miR-302b's potential as a therapeutic tool when combined with PARP inhibitors, a class of DNA repair-based drugs, and its involvement in pro-tumoral M2 macrophages phenotypic switch.

Material and method

We used MDA-MB-468 and MDA-MB-231 as BRCA1 wild-type cell models. MDA-MB-468 were treated for 5 days with 500 nM cisplatin and/or 250 nM olaparib, while MDA-MB-231 with 2 μ M cisplatin and/or 2 μ M olaparib. MiR-302b overexpression was achieved by transfection with miR-302b mimics or negative control, delivered by commercial lipid nanoparticles. Panobinostat was administered for 24 h at 1 μ M in MDA-MB-468 and 10 μ M in MDA-MB-231 cell lines, and bone marrow derived macrophages. IL-4 and/or supernatant of 4T1, treated or not with cisplatin and transfected with miR-302b or control, have been used to condition macrophages.

Result and discussion

Analyzing a proprietary TNBC cohort (GSE86948), we demonstrated that higher miR-302b expression levels correlate with BRCAneSS phenotype and PARP inhibitor sensitivity signatures. Notably, we discovered and validated BRCA1 as direct target of miR-302b, which enhances response to PARP inhibitors in combination with cisplatin in BRCA1 wild-type TNBC models, by mimicking a BRCAneSS phenotype. We also observed that miR-302b downregulation in breast cancer can occur through histone deacetylation at miRNA promoter region. Indeed, treatment with the histone deacetylase inhibitor panobinostat induces miR-302b expression, likely contributing to BRCA1 downmodulation. Lastly, we proved that miR-302b impairs M2 phenotypic switch in macrophages by directly targeting the M2 marker Irf-4, thus counteracting an immunosuppressive microenvironment.

Conclusion

These results strongly support the idea that miR-302b might be a promising adjuvant therapeutic tool in combination with PARP inhibitors/chemotherapy in BRCA1 wild-type TNBC, exerting a dual role on both neoplastic cells and the TME.

Introduction

Triple-negative breast cancer (TNBC) accounts for approximately 10–15% of all breast cancer (BC) cases. Historically, TNBC is characterized by the absence of targetable receptors, which makes chemotherapy the primary treatment option. However, recent evidence suggests that the chemoresistance and high rates of metastasis associated with TNBC may be linked to cancer cells that overexpress the frizzled-7 receptor (FZD7). While monoclonal antibodies targeting FZD7 have reached clinical trials, they have shown off-target effects. Consequently, peptide-based inhibitors are emerging as promising alternatives due to their specificity, lower toxicity, and ease of modification.

Material and method

In this study, we employed a multi-step approach to identify effective anti-FZD7 peptides. First, we used patient samples to confirm the presence of FZD7 in primary and brain metastatic TNBC biopsies. Next, we applied computational methods to identify peptide sequences found within the binding domains of published anti-FZD7 antibodies and to assess in silico binding affinity and serum stability for these peptides. Third, we synthesized ten peptides that exhibited low binding affinity ($K_D < 10^{-6}$) and high stability ($t_{1/2} > 120$ min) and evaluated their activity in vitro. Fourth, we assessed the in vivo biodistribution of the top three peptides and used this information to enhance their pharmacokinetics. Finally, the peptide with the most suitable properties was conjugated to gold nanoparticles for further in vivo studies on tumor accumulation.

Result and discussion

The data obtained demonstrated the therapeutic potential of the peptides. First, histological characterization of tumor biopsies confirmed the overexpression of FZD7 in TNBC. Notably, brain metastases exhibited significantly higher levels of the receptor, which may be linked to FZD7's role in cancer metastasis. Second, among the ten anti-FZD7 peptides identified in silico, three showed high binding affinity (nM), strong anticancer activity ($IC_{50} < \mu$ M), low toxicity ($IC_{50} > mM$), and high stability ($t_{1/2} > 120$ min). Third, the in vivo biodistribution studies indicated that all tested peptides had a short circulation time due to high renal clearance. However, one anti-FZD7 peptide exhibited better stability and tumor accumulation than the others. Based on these data, this peptide was further conjugated to gold nanoparticles to enhance circulation time and tumor accumulation. We observed significantly improved circulation time and tumor accumulation compared to the native peptide, while not increasing accumulation in other organs, thus validating the advantages of the nanoparticle-peptide conjugate.

Conclusion

In conclusion, we successfully developed a peptide-based inhibitor targeting FZD7 that is both effective and safe,

with the potential for further optimization to explore its use as a therapeutic and/or diagnostic tool.

³*physics, Rome, Italy*

Introduction

Synthetic biology, a multidisciplinary field that integrates principles from engineering, biology and mathematics to create biological systems with new “synthetic” functions, plays a key role in immunotherapies due to its capacity to engineer biological systems with precision and customization. Indeed, synthetic biology has recently emerged as a game changer in engineered cell-based immunotherapies based on T cell (CAR-T), or bacteria engineering. The latter leverage on bacterial ability to infiltrate tumors, due to unique features of the TME including necrosis, hypoxia, and reduced immuno-surveillance. The ease genetic modification of bacteria contributes to their appeal as therapeutics. Particularly, probiotic *E. coli* Nissle 1997 gained attention as smart-microbe platform to deliver therapeutic cargos in the tumor, particularly due to its safety in humans. Synthetic bacterial therapy is based on the design of intracellular sensor-actuators that specifically recognize the conditions of tumor microenvironment (e.g. hypoxia, acidosis or stiffness) and trigger a specific output in response (e.g. cytokines, cAMP, ICIs nanobodies). On the other hand, optogenetics is a powerful tool for studying new genetic circuits in bacteria, particularly for precise spatio-temporal control and multiplexing applications. It allows researchers to control gene expression and cellular behavior using light, enabling dynamic and reversible modulation.

Material and method

The project aims to engineer *E. coli* to undergo lysis upon light exposure using optogenetic tools. To achieve this, we engineered *E. coli* with synthetic DNA circuits carrying the CcaS-CcaR system, which regulates the expression of phage-based lytic proteins in response to light: they are activated under green light and repressed under red light. We also tested the potential of this platform for cargo delivery, specifically for the controlled release of immune-stimulating nanobodies and cytokines.

Result and discussion

We successfully engineered an optogenetically controlled lytic system, characterizing its behavior and identifying its limitations. To counteract the emergence of resistant strains, we took a rational design approach to improve the system, incorporating a third light-inducible module for effective biocontainment. Furthermore, we developed a comprehensive mathematical framework to describe the critical genetic elements, complementing theoretical insights with experimental validation. Our engineered

bacterial platform also demonstrated precise, light-controlled delivery of immune-stimulating nanobodies and cytokines.

Conclusion

Our platform enables precise biocontainment and targeted therapeutic delivery, with applications in cancer immunotherapy. It also holds potential for control by synthetic promoters responsive to the tumor microenvironment, expanding its therapeutic possibilities.

EACR25-2325

Triptolide induces pro-apoptotic effects against medulloblastoma subtypes

H. Eastham¹, J. Morovis Marchetti Cassarotti¹, M. Yaqoob¹, B. Samphire-Noden¹, D. Greensmith¹, M. Jones¹

¹*University of Salford, Biomedical Research Centre, Salford, United Kingdom*

Introduction

Medulloblastoma is a common cause of cancer in children, accounting for 20–25% of all paediatric brain tumours worldwide (de Medeiros et al., 2019). Whilst current treatments are effective, they are associated with substantial off-target effects, which impact patients’ quality of life for decades after remission is achieved (Jones et al., 2023). This necessitates the need for the development of new treatments, with phytochemicals offering a novel source of new compounds. Extracts of *Tripterygium wilfordii* have been used in Traditional Chinese Medicine for centuries (Shan et al., 2023), with recent evidence suggesting that compounds derived from this species, such as Triptolide, exert anti-cancer effects (Noel et al., 2019). However, there is no evidence of if this effect translates to medulloblastoma. To address this, we sought to elucidate the fundamental anti-medulloblastoma effect of triptolide.

Material and method

The effect of triptolide on medulloblastoma (HD-MB-03, & DAOY) viability was determined using MTT, long-term proliferation and washout assays. Time-lapse live-cell microscopy was utilised to examine the effect of triptolide on cell morphology, cell fate profile and cellular migration. Flow cytometry was used to examine the cell death mechanism (Annexin V/Propidium Iodide) [1].

Result and discussion

Triptolide produced irreversible concentration and time-dependent decreases in medulloblastoma viability in both HD-MB-03 and DAOY cells, with IC₅₀ values after exposure for 72 hours found to be 18 nM and 169 nM respectively. HD-MB-03 cell fate profiling revealed that exposure to triptolide (10 nM) produced significant concentration-dependent increases in cellular death within interphase ($P < 0.0001$) and a significant $38.5 \pm 6.9\%$ increase in the time take to progress through the cell cycle compared to control ($P < 0.0001$). Morphological analysis showed triptolide to induce blebbing and cellular shrinkage, indicative of apoptosis. Flow cytometric analysis confirmed this, with a significant 5.2-fold increase in apoptotic cells ($P = 0.0002$) following treatment with triptolide (20 nM) for 72 hours. Triptolide

produced no significant impact on cellular migration at all concentrations (5–20 nM) examined.

Conclusion

These data highlight the potential of triptolide as a novel potent treatment for medulloblastoma. Further work is now required to elucidate the molecular mechanism of action associated with the observed pro-apoptotic effect.

Introduction

Oncology clinical trials fail frequently due to not fully characterizing the clinical candidates to identify the true target, off-target effects, or mechanism of action. Clinical candidates generally are characterized with limited tools based on the target and the known target indications. These biases have contributed to failed clinical trials. Using cutting-edge novel technologies, like large-scale PRISM profiling of 900 cell lines that have been genetically profiled in the Dependency Map, with machine learning analysis will provide a more thorough and agnostic understanding of oncology drugs. We show that systematic characterization of our Oncology Reference (OncRef) library of over 200 well-known oncology drugs, of which 64% have never been tested before with large-scale cell line profiling, enables better understanding of on-target and off-target effects.

Material and method

Over 200 drugs, including encorafenib, dabrafenib, pevonedistat, palbociclib, ribociclib, abemaciclib, docetaxel and paclitaxel were screened across ~900 PRISM cell lines at 8 point dose in triplicate. Mixtures of 20–25 cell lines were plated in 384 well plates in RPMI 1640 with 10%–20% FBS. After 5 days, cells were lysed and mRNA was amplified by RT-PCR prior to detection with Luminex FlexMap scanners.

Result and discussion

Of the over 200 drugs that were screened, 41% of 192 inhibitory molecules had their target as the top CRISPR or shRNA correlation. This confirmed that PRISM can be used to generate high-quality data in a short amount of time across a large panel of cell lines. Two interesting findings include the reported target of pevonedistat, of NEDD8 activating enzyme (NAE) inhibitor, and the specificity of the CDK4/6 inhibitors palbociclib, ribociclib and abemaciclib. Pevonedistat, a drug that failed in phase III clinical trials in AML was found to be broadly toxic and had no gene expression or functional genomic correlations with the target. If pevonedistat had been tested with a large-scale cell line panel, they would have further optimized the compound prior to clinical trials. For the CDK4/6 inhibitors that are approved in

HR+/HER2- breast cancer, palbociclib only had CRISPR and shRNA correlations with CDK6 and ribociclib and abemaciclib only had CRISPR and shRNA correlations with CDK4.

Conclusion

Our findings establish the OncRef dataset and PRISM as a benchmark for evaluating current and emerging cancer therapies. Using large-scale systematic PRISM cell line profiling, genomic characterization and machine learning analysis enables better characterization of oncology drugs and will potentially reduce clinical trials failures.

⁵Humanitas Research Hospital, Precision Medicine research laboratory, Pieve Emanuele, Italy

Introduction

Colorectal Cancer (CRC) comprises a complex family of tumors different for morphology, immune infiltration, drug response and genetic alterations, including APC/KRAS/TP53/SMAD4. Mutations in KRAS oncogene, mostly at codons 12 and 13, are associated with CRC initiation and progression, but they are missing in clinics of target inhibitors. Patient-Derived Organoids (PDOs) have been demonstrated a cutting-edge 3D in vitro model suitable for drug testing since they resemble the patient specifics.

Material and method

We performed a selective KRAS/MAPK pathway targeted drug screening of seven compounds on NCM460D normal colon mucosa cells and Difi (KRASWT), HCT116 (KRASG13D), LS-174T (KRASG12D) CRC cells and on 14 PDOs, including two normal colon PDOs and 12 CRC PDOs presenting KRASG12*/G13*, KRASA**, KRASWT and BRAFV600E. We tested ten concentrations of each drug (0.1 nM–30 uM) and after 72hrs of treatment we evaluated the cell viability to calculate each drug-response curve. Next, we performed western blot and immunofluorescence (IF) on treated CRC PDOs followed by selective phosphoproteomic analysis in Trametinib (MEKi) and MRTX1133 (KRASG12Di) treated CRC PDOs.

Result and discussion

We identified Trametinib as the most effective inhibitor of the MAPK pathway (low pM EC50), while MRTX1133 had an on-target effect at 20pM–1uM range exclusively in KRASG12D CRC PDOs. Western blot and IF pointed out that Trametinib and MRTX1133 were able to downregulate pErk expression in all PDOS and in

KRASG12D, respectively. Phosphoproteomic data showed downregulation of MAPK linked pathways, like mTOR and PI3K/Akt, in both Trametinib and MRTX1133 treated PDOs, while highlighted a possible selective effect of MRTX1133 in KRASG12D CRC PDOs on Casein kinase (CSNK) and Ribosomal Proteins (RPs) activity. These results might possibly show a preferential pattern of differentially expressed proteins linked to KRASG12D.

Conclusion

Our CRC PDOs model greatly strengthens the use of patient-derived 3D *in vitro* cultures as a more reliable platform to explore new therapeutic strategies in CRC precision medicine, and pointed out mutation-driven perturbed systems, as for KRASG12D. We aimed to understand the biological landscape of KRASG12D in CRC, and we are currently investigating in depth the effect of MRTX1133 in KRASG12D CRC PDOs to highlight the drug specific mechanism and the KRASG12D linked landscape of altered pathways.

³*University General Hospital of Elche, Elche, Spain*

Introduction

Colorectal cancer (CRC) is one of the most prevalent malignancies worldwide, and its increasing incidence in individuals under 50 years old is a growing concern. Early-onset CRC (EOCRC) often presents at more advanced stages and with aggressive clinical features, making early detection and targeted therapies a major unmet need. Emerging evidence suggests that EOCRC exhibits unique metabolic alterations compared to late-onset CRC, which could serve as potential biomarkers or therapeutic targets. The METABOAGE study applies targeted metabolomics to uncover metabolic vulnerabilities in EOCRC, aiming to develop biomarker-driven therapeutic strategies that could improve patient outcomes.

Material and method

Peripheral blood samples were collected from CRC patients and healthy individuals in two age groups (<50 and >70 years old; n = 10). A targeted metabolomic analysis was conducted using the Shimadzu LCMS-8050 triple quadrupole system with the LCMS/MS Method Package for Primary Metabolites. Statistically significant metabolic alterations were identified and evaluated in colorectal cancer cell lines (HCT-116, HGUE-C1, HT-

29, Caco-2, SW480). Functional assays assessed cell viability, cell cycle progression, migration, and transcriptomic changes, providing insights into their therapeutic potential.

Result and discussion

Targeted metabolomic profiling revealed distinct metabolic signatures in EOCRC compared to late-onset CRC and healthy controls, with key metabolic pathways showing significant alterations. Several metabolites were identified as potential biomarkers or therapeutic targets, as they appeared to correlate with disease progression and cellular phenotypes associated with tumor aggressiveness. Functional assays suggested that some of these metabolic changes may play a role in tumor cell proliferation, survival, and adaptation to stress, highlighting their potential as novel therapeutic targets. Pathway analysis indicated an association between these metabolic alterations and oncogenic signaling networks relevant to CRC progression, supporting further investigation into their therapeutic modulation.

Conclusion

The METABOAGE study provides evidence that EOCRC is characterized by metabolic alterations distinct from late-onset CRC, identifying potential biomarkers and novel metabolic dependencies that could serve as therapeutic targets. These findings highlight the potential of targeted metabolomics in precision oncology, guiding the development of biomarker-driven therapies tailored to younger CRC patients. Future research will focus on validating selected metabolic targets and exploring their modulation through small molecules, metabolic inhibitors, or alternative therapeutic strategies. Integrating metabolomics into personalized CRC treatment could contribute to innovative therapeutic approaches addressing the specific challenges of EOCRC.

Introduction

Maslinic acid (MA) is a natural pentacyclic triterpenoid that has gained increasing attention due to its broad therapeutic potential and lack of harmful effects. In particular, MA exhibits significant antitumor activity both in vitro and in vivo, making it a promising candidate for cancer therapy. However, its clinical application is limited by its poor solubility in aqueous solutions. To overcome this challenge, we developed Maslinic Acid Solid Lipid Nanoparticles (MASLiN), which significantly enhance MA solubility, enabling its biomedical application. In this study, we evaluated the potential of MASLiN as a nanoplatform for cancer therapy, assessing their ability to encapsulate hydrophobic drugs, their stability under physiological conditions, cytotoxicity, cellular uptake in pancreatic and breast cancer cells, and their in vivo toxicity and biodistribution.

Material and method

MASLiN were synthesized using the solvent displacement method with Poloxamer 407 and Dicarboxylic acid-Poloxamer 407 as surfactants. The formulation was optimized, and the colloidal stability of MASLiN was assessed under varying pH and ionic strength conditions. Curcumin encapsulation efficiency was also evaluated. The cytotoxic effects of free MA and MASLiN were assessed in BxPC3 pancreatic cancer cells and MCF7 human breast cancer cells, with comparisons to primary human fibroblasts. Cellular uptake studies were conducted to determine nanoparticle internalization. Additionally, the toxicity and biodistribution of orally and intravenously administered MASLiN were investigated in mice.

Result and discussion

MASLiN significantly improved the solubility of both MA and curcumin, addressing a key limitation of these compounds. Cytotoxicity assays demonstrated that MASLiN exhibited higher cytotoxic effects against BxPC3 and MCF7 cancer cells compared to human primary fibroblasts, highlighting their selective antitumor activity. Nile Red-loaded MASLiN were rapidly internalized by BxPC3 and MCF7 cells, with distinct cytoplasmic distribution patterns depending on the cell line. In vivo studies revealed no signs of toxicity following oral or intravenous administration of MASLiN in mice. Furthermore, fluorescence imaging of intravenously administered MASLiN demonstrated homogeneous biodistribution, supporting their potential as nanocarriers.

Conclusion

Our findings highlight MASLiN as a promising nanoplatform for cancer therapy, demonstrating their potential as efficient nanocarriers for hydrophobic anticancer drugs. Additionally, their stability and inherent cytotoxicity support their use as targeted nanodevices for improved cancer treatment strategies.

Introduction

Prostate cancer (PC) is a pressing public health issue, ranking first in incidence and second in mortality in Colombia. Approximately 15–20% of patients with advanced PC develop castration resistance (CRPC), a phenotype highly refractory to Docetaxel (DCT), the most cost-effective approved treatment according to clinical practice guidelines. Consequently, the search for therapeutic alternatives, such as drug repurposing for CRPC treatment, is imperative. Considering this, we propose using two compounds, citrate (CIT) and acetyl-L-carnitine (ALCAR), as a promising combination therapy with DCT for treating advanced PC and CRPC.

Material and method

Two cell lines were used: PC3, a cellular model of the CRPC phenotype, and LNCaP, a model of advanced metastatic PC. The lethal concentration 50 (LC50) of DCT, CIT, and ALCAR was determined using crystal violet and MTT assays. Additionally, pharmacological combinations of DCT:CIT and DCT:CIT:ALCAR were tested at different treatment ratios (5:1, 3:1, and 1:1 of the LC50). Combination indices (CI) were evaluated using isobolograms with the Chou-Talalay method. For the most promising combinations, apoptosis and glucose/lactate metabolic profile.

Result and discussion

The LC50 values of DCT and CIT were lower than the reported maximum plasma concentrations. No cytotoxic effect was observed with ALCAR in either cell line; therefore, its incorporation was adjusted to form a new active compound with CIT at a concentration of 6 μM ALCAR, following pharmacokinetic parameters. Isobologram analysis highlighted a strong synergistic effect in most interactions, which was more pronounced at 3:1 and 5:1 ratios for both DCT:CIT and DCT:CIT:ALCAR. Differences were observed in apoptosis induction and glucose/lactate metabolism among the most promising combinations.

Conclusion

We found strong synergistic effects in the combinations of DCT and CIT, as well as CIT and ALCAR, in the LNCaP and PC3 cell models. By using pharmacological concentrations lower than the maximum reported plasma levels for each drug in treatment, we demonstrated that these combinations exhibit a promising effect as a potential therapy for CRPC.

Introduction

Retinoblastoma (Rb) is the most common intraocular malignancy in children, with high metastatic potential. Local therapies like cryotherapy and thermotherapy target small tumors, while advanced cases require systemic chemotherapy, radiation, or enucleation. PDT offers tumor-selective cytotoxicity without inducing DNA mutations, reducing secondary malignancy risks. Among 4,5,6,7-tetrahydropyrazolo[1,5-a]pyridine-fused tetraphenylchlorins, the dihydroxymethyl derivative (PX1) shows promise. PX1 was selected for its superior *in vitro* performance, including a significantly lower IC50. This study evaluates PX1-based PDT efficacy and safety in Rb treatment.

Material and method

In vivo studies were conducted on RNU rats injected intravitreally with Y79-GFP-luc cells in the left eye.

After PX1-based PDT, treated and control animals were examined using optical coherence tomography (OCT), electroretinography (ERG), bioluminescence imaging (BI) and immunohistochemistry (IMH) to assess PDT outcomes.

Result and discussion

Initially, OCT identified tumors in the vitreous cavity alongside retinal structures. In untreated eyes, tumors expanded, obstructing OCT imaging. PDT-treated eyes were categorized as large (LT) or small tumors (ST). Post-PDT, LT remained opaque to OCT, whereas ST allowed light passage, showing no major retinal alterations. PDT had no significant impact on retinal layer thickness. Scotopic threshold response, scotopic and photopic ERG, and the Flicker test indicated stable retinal function post-PDT in the ST group. BI confirmed PDT's efficacy in reducing ST, though LT showed a modest response. Regrowth was observed one week post-treatment, suggesting that multiple PDT sessions may be necessary. IHC revealed decreased Ki67 expression in tumor cells in PDT-treated eyes. Rb induced microglial and astrocyte activation, while PDT per se induced minor effects and preserved retinal ganglion cells.

Conclusion

PX1 is a promising photosensitizer for Rb treatment. IMH, OCT and ERG confirmed retinal structure and function preservation, supporting its safety profile. PDT effectively targets ST, warranting further investigation into optimized protocols to prevent recurrence and disease progression.

Introduction

Endometrial cancer (EC), which primarily affects post-menopausal women, also impacts young women (5% under 40), posing challenges regarding treatment options. Photodynamic therapy (PDT), which induces cytotoxicity in tumour cells using a photosensitiser (PS), light and molecular oxygen, has become a promising conservative treatment for EC, especially in women with a reproductive desire or high surgical risk. PDT is minimally invasive, maintains anatomy and organ function, and has few adverse reactions. Even so, PDT can present some challenges, such as insufficient light penetration into deeper tissues, insufficient accumulation of PS and hypoxia in certain tumour areas. Therefore, this study aimed to evaluate how the remaining EC cells after PDT behave, focusing on their division, migration and invasion ability.

Material and method

HEC-1-A and ECC-1 cell lines were treated with two PS, the dihydroxymethyl derivative of tetraphenylchlorin (PX1) and temoporfin, at an inhibitory concentration of 25% of cell proliferation and submitted to an irradiation for activation after 24 hours. Doubling time (DT), migration and invasion studies were performed after 72 hours of this conditioning protocol.

Result and discussion

The cell line DT was not significantly affected by the PDT conditioning with PX1 and temoporfin. While untreated and PX1-conditioned HEC-1-A cell migration significantly reduced the gap from 72 hours ($p < 0.04$), temoporfin-conditioned cells showed a significant gap decrease immediately after 48 hours ($p = 0.005$). ECC-1 cells showed limited migration without significant differences between controls and conditioned cells until 72 hours. Concerning the invasion capacity, conditioning with PX1 and temoporfin also did not induce changes both in HEC-1-A (1.09 and 0.91) and ECC-1 (0.99 and 1.02) cells, respectively.

Conclusion

The results indicate that the remaining EC cells exhibited similar DT and invasion profiles after PDT. Nevertheless, temoporfin appears to potentiate the migration ability of HEC-1-A cells.

Evaluation in vitro and in vivo of the therapeutic effect of the melatonin-furanochalcone hybrid in colorectal cancer

V. Bedoya-Betancur¹, V. Estrada-Vélez¹, D. López-Buitrago¹, A. Yépez-Pérez², W. Cardona-Galeano², T. Naranjo³

¹*CIB-UPB-UdeA-UDES, Medellín, Colombia*

²*Universidad de Antioquia, Medellín, Colombia*

³*Universidad Pontificia Bolivariana, Medellín, Colombia*

Introduction

Colorectal cancer (CRC) is one of the most prevalent types of cancer worldwide, ranking among the main causes of morbidity and mortality. Current therapeutic strategies for CRC are often associated with significant adverse effects, driving the search of alternative treatments based on natural, synthetic, or biological compounds that offer greater efficacy and specificity. In recent years, melatonin (N-acetyl-5-methoxytryptamine) and chalcone have garnered considerable attention due to their anti-inflammatory and antioxidant properties, making them as promising candidates for the treatment of various diseases, including cancer. Therefore, this study aimed to evaluate the therapeutic potential of a novel hybrid compound combining melatonin and furanochalcone (MFC) in colorectal cancer.

Material and method

First, in vitro assays were performed to evaluate the cytotoxicity, selectivity and antiproliferative activity of the MFC hybrid using SW480 (human colon adenocarcinoma), CT26 (murine colon adenocarcinoma) and NCM460 (non-tumorigenic human colon) cell lines. Then, lethal dose 50 (LD50) of hybrid compound was determined in BALB/c mice via oral administration, following the procedure described in the OCDE guideline 425 for testing of chemicals. Subsequently, 50% of the LD50 dose was orally administered to mice to evaluate genotoxic effect in liver and colon tissues using the comet assay, and mutagenicity in bone marrow through the micronucleus assay. Finally, a first pilot study was conducted to assess the antitumor effect of the MFC hybrid by administering 25% of the LD50 to mice with colitis-associated colorectal cancer, induced via azoxymethane and dextran sodium sulfate.

Result and discussion

In vitro assays showed selectivity, cytotoxic effect and antiproliferative activity of the MFC hybrid on the malignant cells, mainly in the SW480 cell line. In vivo, the hybrid compound exhibited an LD50 greater than 2000 mg/kg, suggesting low acute toxicity. Furthermore, no DNA damage or chromosomal alterations were observed under the evaluated conditions. In the pilot study, administration of the MFC hybrid between four and eight weeks after CRC induction, resulted in delayed tumor progression. This effect was evidenced by a reduced tumor burden and slower progression of preneoplastic lesions in treated mice compared to untreated controls.

Conclusion

These findings suggest that the melatonin-furanochalcone hybrid could be a promising therapeutic candidate for CRC, as demonstrated by its antiproliferative activity and capacity to delay tumor progression while exhibiting low acute toxicity and genotoxicity. However, further studies are required to validate its efficacy and clarify its mechanisms of action including its potential roles in immunomodulation, apoptosis induction, cell cycle arrest, inflammatory regulation, among others.

EACR25-2381

Anagrelide induced remodeling of the PDE3-SLFN12 interactome provides insights into translation initiation dynamics and molecular glue mechanisms

S. Salmikangas¹, N. Sultana¹, X. Liu², I. Lindholm¹, N. Merikoski¹, K. Toivanen¹, M. Varjosalo², T. Böhling¹, T. Vesterinen³, H. Sihto¹

¹*University of Helsinki, Department of Pathology, Helsinki, Finland*

²*University of Helsinki, Institute of Biotechnology, HiLIFE Helsinki Institute of Life Science, Helsinki, Finland*

³*University of Helsinki and Helsinki University Hospital, Department of Pathology / HUSLAB, HUS Diagnostic Center, Helsinki, Finland*

Introduction

The molecular glue anagrelide induces proximity between phosphodiesterase 3 A (PDE3A) and Schlafend-12 (SLFN12) in cancers with high PDE3A expression, triggering SLFN12 tRNase activity, tRNA-Leu-TAA degradation, and ultimately, translation inhibition and cell death. However, other mechanisms, such as the GCN2-eIF2α-mediated stress response, also contribute to the anticancer effects of molecular glues, suggesting multiple parallel mechanisms. Here, we aimed to elucidate these mechanisms by using an interactomics approach to identify the altered protein-protein interactions (PPIs) in the PDE3-SLFN12 complex.

Material and method

We used proximity dependent biotin labeling (Bio-ID) to discover the PDE3A-SLFN12 complex PPIs. SLFN12, PDE3A, and GFP-containing MAC-Tag-N expression plasmids were generated and transfected into SA-4 and HeLa cells. After biotin and either DMSO or anagrelide treatment, cells were lysed and analyzed via LC-MS. High-confidence interactors were filtered with Significance Analysis of INTERactome (SAINT) and Contaminant Repository for Affinity Purification (CRAPome). The results were validated with immunofluorescence, and new complexes were modeled with AlphaFold.

Result and discussion

Peripheral eIF3 subunit PPIs were induced, while core eIF3 subunit PPIs were suppressed. As the peripheral eIF3 complex localizes to the opposite ribosomal face relative to the core eIF3 complex, these results suggest a shift in PDE3-SLFN12 localization to the ribosomal mRNA entry channel upon complex formation. Immunofluorescence confirmed increased colocalization of PDE3 and SLFN12 with ribosomes and each other following anagrelide treatment. AlphaFold modeling of the PDE3-SLFN12-eIF3 PPIs further supported these findings. Functional enrichment analysis via the STRING database revealed significant enrichments in ribonucleoprotein biogenesis, translation initiation and aminoacyl tRNA biosynthesis, reinforcing the complex's role in translation control. Conversely, suppressed PPIs linked to protein folding, antiviral defence, and proteasome function indicated impaired nascent polypeptide folding, loss of

SLFN12's innate immune role, and disrupted PDE3A/SLFN12 degradation, respectively.

Conclusion

Anagrelide-induced remodeling of the PDE3-SLFN12 interactome localizes the complex to the ribosomal mRNA entry channel, inducing ribosomal and peripheral eIF3 PPIs while suppressing proteasomal, chaperonal, and core eIF3 PPIs. This provides insights into complex stabilization, altered translation dynamics and affected signaling pathways. Suppressed PPIs suggest impaired protein folding and disrupted PDE3A/SLFN12 turnover, contributing to translational stress and cell death. Together, these findings enhance our understanding of molecular glue mechanisms and support the design of improved therapeutics.

The m6A RNA modification sustains neuroblastoma tumor aggressiveness

D. Sighe¹, E. Destefanis¹, G. Montuori¹, F. Broso¹, L. Pasini¹, R. Gilmozzi¹, G. Pouletzas¹, J. Vigna², I. Mancini², A. Quattrone¹

¹*University of Trento, Department of Cellular, Computational and Integrative Biology (CIBIO), Trento, Italy*

²*University of Trento, Department of Physics, Trento, Italy*

Introduction

Neuroblastoma (NB) is the most frequent extracranial solid tumor in children, accounting for 15% of all childhood cancer deaths. Although the 5-year survival rate of patients with high-risk disease has increased in recent decades, NB remains a challenge in pediatric oncology, and identifying novel therapeutic targets and agents is an urgent clinical need. N6-methyladenosine (m6A), the most abundant post-transcriptional mRNA modification in mammals, is tightly regulated by 'writers' and 'erasers', which deposit and remove the modification, respectively, and by 'readers', which can detect changes in mRNA modification status and influence downstream cellular processes. m6A and related key proteins have been found frequently altered in many different tumors and may represent a good therapeutic target also in NB.

Material and method

By modulating the expression of the writer complex component METTL14 or the demethylase ALKBH5, we evaluated the impact of m6A mRNA modification on NB tumor aggressiveness both *in vitro* and *in vivo*. We also investigated the effect of inhibiting m6A recognition by knocking out YTHDF reader proteins. Next, to identify a molecule capable of interfering with YTHDF m6A mRNA recognition, we screened *in silico* a library of 1.5 million non-redundant compounds against the YTHDF1 protein (PDB entry: 4RCJ) and subsequently evaluated the 113 best-scoring compounds by homogeneous time-resolved fluorescence. We selected compound A as a low micromolar pan-YTHDF inhibitor and synthesized and tested more than 30 analogs in a qualitative structure-activity relationship (SAR) study.

Result and discussion

METTL14 overexpression promotes cell proliferation and invasion *in vitro* and tumor progression *in vivo*,

leading to faster tumor growth and larger tumor masses. Conversely, ALKBH5 overexpression or METTL14 knockout leads to opposite results, with a significant decrease in cell proliferation, an increase in apoptosis, and reduced invasion ability *in vitro*, while dramatically slowing tumor growth *in vivo*. Consistent with these observations, knockout of YTHDF paralogs or YTHDF inhibition with compound A also results in decreased NB cell proliferation and reduced clonogenic potential. We are now finalizing our SAR study.

Conclusion

Our results show that high levels of m6A correlate with higher NB aggressiveness and that targeting m6A deposition or m6A recognition on mRNAs could be an effective therapeutic strategy for NB treatment.

Introduction

Breast cancer (BC) is the most prevalent cancer among women of all ages, with high incidence and mortality worldwide. It is a heterogeneous disease, and current therapies have limitations, including recurrence and adverse effects. In this regard, new therapies are

emerging, and cold atmospheric plasma (CAP) has been investigated as a potential anti-tumor approach, however, the mechanisms of action remain unclear. As we have been investigating how CAP influences the hallmarks of cancer, the main goal of this work was to evaluate its effect on BC cell invasion and metastasis potential regarding cell migration and E-cadherin expression. Cell membrane permeability was also evaluated.

Material and method

The migration assay was performed in five distinct cell lines: two triple-negative (HCC1395 and HCC1806), two luminal A subtype (HCC1428 and MCF7), and one representative of the normal breast tissue phenotype (MCF12A). These cells were submitted to CAP treatment for 60 and 120 seconds after a scratch. To assess E-cadherin expression and cell membrane permeability, flow cytometry was used.

Result and discussion

CAP treatment inhibited cellular migration in BC cell lines over time. In HCC1395, HCC1806 and MCF7 cells, migration was significantly reduced at 48 and 72 hours. The effect was stronger with longer exposure: (83.72 ± 5.17)% to (30.53 ± 7.29)%, p < 0.0001; (96.96 ± 1.96)% to (60.68 ± 3.86)%, p = 0.0023; and (83.85 ± 3.05)% to (33.59 ± 3.23)%, p < 0.0001, for each cell line respectively. However, MCF12A showed no significant migratory changes. Previously, we observed that CAP significantly reduced cell invasion in a time-dependent manner on triple-negative BC, supporting its potential to modulate this hallmark. Moreover, E-cadherin expression and cell permeability seemed to be dependent on BC cell type. HCC1395 showed a significant decrease after 120 s (73.96 ± 3.96)%, p = 0.0012. Our preliminary results for MCF7 and HCC1428 suggest a tendency to increase the membrane permeability after 120 s, (125.88 ± 1.00)% and (115.74 ± 3.37)%, respectively. Additional studies will be performed to confirm these findings.

Conclusion

These findings suggest that CAP impairs breast cancer cell migration and invasion while modulating E-cadherin expression and membrane permeability in a cell-type-dependent manner. These results encourage further studies on CAP to pave the way for novel therapeutic approaches in BC treatment.

Introduction

Circadian rhythms are natural, internal biological cycles that regulate various physiological and behavioral processes over a roughly 24-hour period, including metabolism and DNA repair. Disruption of these rhythms can profoundly affect tumor development and therapeutic response. Leukemic cells often exhibit altered expression patterns of circadian rhythm genes, underscoring the need to better understand their role in disease progression and treatment efficacy. In this context, this study aimed to evaluate, *in vitro*, the influence of circadian rhythms on DNA damage repair capacity and the impact of chrono-therapy on the treatment of myeloid leukemia.

Material and method

For this purpose, two myeloid leukemia cell lines, HL-60 and K562 cells, and a normal lymphocyte cell line, IMC, were used. The expression levels of circadian rhythm genes (CLOCK, BMAL1, BMAL2, PER1, PER2, PER3, CRY1, CRY2, and ROR α) and BCR::ABL1 were quantified by qPCR. DNA repair activity was evaluated by measuring chromosomal damage levels (micronucleus assay; microscopy) and double-strand breaks (γ H2AX; flow cytometry) in synchronized cells every 4h for 24h after circadian synchronization. The trypan blue exclusion test assessed the sensitivity to imatinib (IMA) and cytarabine (ARA-C) at the time points of highest and lowest DNA repair. Statistical analyses were performed with statistical significance defined as $p < 0.05$.

Result and discussion

Our results showed that HL-60 and K562 cells exhibit circadian rhythm gene alterations compared to normal cells, such as ultradian expression of CLOCK gene and arrhythmic expression of PER2. DNA repair capacity oscillated throughout the day in both leukemia cell lines. At the highest DNA repair activity (4h after circadian synchronization), HL-60 cells repaired 35% of induced DNA damage, while at the lowest (12h after circadian synchronization), only 21% was repaired. In the K562 cells, repair was more effective at 4h (29%) and less effective at 16h (12%). Additionally, treatment with IMA in K562 cells and ARA-C in HL-60 cells was more effective when administered at the time of lowest DNA repair activity (IMA = 30 ± 1%; ARA-C = 35 ± 2%; $p < 0.05$) and less effective when administered at the time of highest DNA repair capacity (IMA = 49 ± 2%; ARA-C = 76 ± 3%; $p < 0.05$), compared to conventional administration without circadian synchronization (IMA = 40 ± 3%; ARA-C = 62 ± 2%). No rhythmicity was observed in the expression of the BCR::ABL1 gene, the molecular target of IMA.

Conclusion

In conclusion, *in vitro* myeloid leukemia cells exhibit circadian dysregulation and rhythmicity in DNA repair activity. Chronotherapy demonstrated promising results, improving therapeutic response when drugs were administered during the phase of the day with lower DNA repair activity.

Introduction

Hepatocellular carcinoma (HCC) is the primary tumor of the liver and the 5th most prevalent cancer in the world. The incidence of HCC has been rising worldwide over the last 20 years, despite the progress in vaccination strategies and management of hepatitis virus infections. Currently, first-line therapies remain poorly effective, highlighting the urgent need for novel treatment options. Nutraceuticals provide a vast array of bioactive molecules with potential pharmacological exploitation. The Mediterranean diet (MD), known for its health benefits, is a rich source of natural compounds, including secoiridoids found in extra-virgin olive oil (EVOO). Among them, Oleacein has demonstrated antioxidants, anti-inflammatory and anti-proliferative properties contributing to its potential anti-cancer effects. In this study, we explore the anti-tumoral potential of Oleacein and investigate the molecular mechanisms underlying its anti-proliferative capacity in HCC cell lines.

Material and method

Human HCC cell lines, HepG2 and Huh7, were treated with Oleacein and cell viability was determined by MTS assay. Cell cycle profiles of Oleacein-treated cells were analyzed by flow cytometry following propidium iodide staining. Senescent cells induced by Oleacein were identified by an SA- β -gal assay, while senescence-associated gene expression related to the SASP was examined via quantitative real-time PCR. Additionally, Western blot analysis was conducted to investigate the molecular mechanism underlying the anti-proliferative effects of Oleacein in HCC cells.

Result and discussion

Oleacein inhibits the viability of HCC cells with an IC₅₀ >100 μ M in Huh7 cells and approximately 30 μ M in HepG2 after 72 hours. Our findings demonstrate that Oleacein reduces cell viability of HCC cells by inducing cell cycle arrest and promoting senescence. After 24 hours of incubation with 50 μ M Oleacein, HepG2 cells exhibited a slight increase in the G0/G1 phase cell populations with a dose-dependent increase of p21 and p16 mRNA. In contrast, Huh7 cells showed an accumulation of cells in G2/M phase of the cell cycle along with increased p21 mRNA levels, when compared with untreated control cells. In both cell lines, Oleacein treatment drove cells into a senescent state, as evidenced by senescence-associated β -galactosidase (SA- β -GAL) activity. This was further supported by increased expression levels of interleukin 8, interleukin 1, interleukin 6 and matrix metalloproteinase 3 (MMP3) genes,

factors secreted by senescent cells. Additionally, a reduction in Lamin B levels, a senescence-associated biomarker, further confirmed the induction of senescence.

Conclusion

Overall, our findings suggest that oleacein exhibits anti-cancer effects inducing senescence in HCC cells, highlighting its potential as a promising therapeutic candidate for HCC.

Expression profiles of target genes for approved antibody-drug conjugates in the context of high-grade serous carcinoma

E. Pöllänen¹, T. Muranen¹, A. Lahtinen¹, D. Afenteva¹, A. Pirttikoski¹, S. Holmström¹, A. Vähärautio¹, A. Virtanen², J. Hynninen³, S. Hautaniemi¹

¹*University of Helsinki, Research Program in Systems Oncology, Faculty of Medicine, Helsinki, Finland*

²*Helsinki University Hospital, Department of Pathology, University of Helsinki and HUS Diagnostic Centre, Helsinki, Finland*

³*University of Turku and Turku University Hospital, Finland, Department of Obstetrics and Gynaecology, Turku, Finland*

Introduction

High-grade serous carcinoma (HGSC), the most common subtype of ovarian cancer, is characterised by a five-year survival of only <40%. While patients initially respond well to the standard platinum-based chemotherapy, most will experience disease recurrence and eventually treatment resistance. Platinum-resistant HGSC lacks alternative treatment options, and the molecular heterogeneity makes it challenging to find precision approaches via clinical trials. Last year the first antibody-drug conjugate (ADC), Mirvetuximab soravtansine-gynx (Elahere), targeting FOLR1, was approved for platinum resistant ovarian cancer. This brought HGSC to the frontline of ADC-based cancer therapy. Here, we have analysed the expression profiles of the approved ADCs' target genes to map the potential for drug repurposing.

Material and method

For discovery analysis, we used bulk RNA (910 samples, 313 patients) and single-cell RNA (95 samples, 57 patients) sequencing data from the DECIDER clinical trial (NCT04846933). The bulk RNA data was decomposed with PRISM to correct for varying cancer fractions, and TPM normalised. To identify patterns of inter- and intra-patient variation in the expression of the ADC target genes, we fitted linear mixed effects model on the bulk RNA data, with tumor site as a fixed co-factor, the patient and patient-tumor site interaction as random effects.

Result and discussion

Seven ADC target genes (FOLR1, ERBB2, TACSTD2, EGFR, NECTIN4, F3, and CD22) had detectable baseline expression in the cohort. FOLR1 and TACSTD2 demonstrated several patients with high expression, while in contrast, high expression of the other genes was limited to a few patients. On the cohort level, we observed wide variance in the expression for all genes, suggesting high inter-patient heterogeneity. Based on our linear model, only a small part of the observed variance

was explained by tumor site, while the patient-effect explained most of the variation. We used single-cell data to show that the high FOLR1 or TACSTD2 expression was cancer cell-specific. Furthermore, in cancers with high overall expression level of these genes, the expression was highly stable across all cancer cells. For the other ADC target genes, we detected notable heterogeneity with an overall high expression in a cancer sample accompanied by heterogeneity in expression across individual cancer cells.

Conclusion

Our analysis suggests that TACSTD2-targeting ADC could potentially be repurposed to HGSC. TACSTD2 demonstrated patterns of expression comparable to FOLR1 with potentially even wider patient group suitable for the treatment. The other genes studied here might be targetable in a few patients, but the decreased stability of their expression might pose a challenge for the clinical practice. Since our analysis enables the investigation of both intra- and inter-sample heterogeneity, we could use this setup as a discovery platform in the future to identify novel ADC targets.

³*Thermo Fisher Scientific, Seville, Spain*

⁴*Thermo Fisher Scientific, Toronto, Canada*

Introduction

Traditional 2D cancer cell lines often fail to accurately model primary cancer cells, hindering the translation of in vitro research to the clinic. An emerging solution is the use of patient tissue-derived cells expanded in 3D, known as cancer organoids or tumoroids. In this study, we performed a comprehensive proteomic analysis of patient-derived tumoroids using the Thermo Scientific™ Orbitrap™ Astral™ Mass Spectrometer.

Material and method

Tumoroids were first established from dissociated cells from patient tumor resections using Gibco™ OncoPro™ Tumoroid Culture Medium, and have previously been shown to maintain strong concordance in gene expression with primary tumor material. However, little has been done to investigate protein-level expression patterns in these patient-derived models. The proteomic profiles, generated from over 10,000 unique proteins identified in each sample, revealed significant insights into the signaling pathways associated with breast cancer, specifically MAPK, ALK, and ERBB2 pathways, as well as protein and RNA metabolism.

Result and discussion

In comparing transcriptomic and proteomic datasets, particularly where expression varied across tumoroid

models, there was significant overlap in terms of ECM and adhesion-related proteins, as well as lipid metabolism. This overlap underscores the importance of these proteins in the biological processes of cancer and emphasizes the value of integrating proteomic and transcriptomic data to achieve a more comprehensive understanding of tumoroid biology. While transcriptomics provides a snapshot of gene expression, proteomics offers a deeper understanding of the functional state of the cell by identifying post-translational modifications and protein interactions. This multi-omics approach enhances our ability to model the complex heterogeneity of cancer and supports the development of personalized treatment strategies.

Conclusion

Future work will focus on validating these proteomic findings, including making protein-level comparisons between established tumoroids and primary tissue, and exploring post-translational modifications. Taken together, these new insights are expected to further improve the efficacy of tumoroid models in precision oncology and drug discovery.

EACR25-2477

Coffee Exosomes Have Distinct Effects on Melanoma and Glioblastoma Cancer Cells via PTEN Tumor Suppressor Protein

E. Korkmaz¹, S. Kucukvardar², B. Temizci²

¹Hisar High School, Istanbul, Turkey

²Istanbul Technical University, Molecular Biology and Genetics, Istanbul, Turkey

Introduction

Exosomes composed of bilayer lipids release nucleic acids, proteins, lipids, and other biomolecules, playing a function in delivering biological signals to surrounding cells. Plant-derived exosomes have the capacity to penetrate mammalian cells and regulate biological activities. Plant exosomes are being investigated for cancer treatment as a possible approach for conveying therapeutic cargo to mammalian cells due to their low immunogenicity and high intracellular intake rate. While cohort studies related to coffee consumption indicate an adverse association between coffee drinking and risk of many cancers there is no study investigating mechanistic effects of coffee exosomes in cancer cells. We previously examined the effects of coffee exosomes on melanoma skin cancer and glioblastoma multiforme (GBM) brain tumor cells. While coffee exosomes had apoptotic and anti-proliferative effects on SK-MEL-28 melanoma cells, they did not induce apoptosis and caused an increase in proliferation of T98G GBM cells.

Material and method

In order to investigate these distinct effects of coffee exosomes on SK-MEL-28 and T98G cells, we conducted transcriptome analysis, and the alterations in the expression levels of target signaling pathway-related proteins were then evaluated in both SK-MEL-28 and T98G cells by western blot analysis. Moreover, we also investigated the effects of coffee exosomes on migration ability and tumor growth in these cells by using wound-healing and spheroid formation assays, respectively.

Result and discussion

Our results showed that coffee exosome treatment significantly decreased the SERPINA1 mRNA levels in SK-MEL-28 cells. Since SERPINA1 could decrease the expression level of PTEN, which is mutant in T98G cells, we investigated the expression levels of proteins involved in PI3K/Akt and MAPK signaling pathways that are regulated by PTEN activity. We revealed that the coffee exosome reduced the expression of MAPK and PI3K/Akt signaling pathway-related proteins in SK-MEL-28 cells, whereas the levels of these proteins were increased in T98G cells. These findings suggest that coffee exosomes decrease proliferation of SK-MEL-28 cells by increasing the activity of PTEN and thereby suppressing PI3K/Akt and MAPK signaling pathways. However, since PTEN is inactive in T98G cells due to mutations, the decrease in SERPINA1 expression could not affect PI3K/Akt or MAPK signaling pathways. Supporting these findings, we observed that exosome administration reduced the size of spheroids formed by SK-MEL-28 cells while increasing the size of those formed by T98G cells. Finally, wound-healing analysis showed that coffee exosomes decreased migration of SK-MEL-28 cells, whereas they prevented migration of T98G cells.

Conclusion

These results suggest that coffee exosomes could potentially be used in treatment of both melanoma and glioblastoma cancer cells by targeting proliferation and migration properties, respectively.

EACR25-2497

Highly-targeted personalised siRNAs for BRAF-fusions inhibit melanocytic proliferation

S. Barberan-Martin¹, C. Muehlschlegel¹, M. Rabii¹, A. Sauvadet¹, D. Bryant¹, V. Kinsler¹

¹Francis Crick Institute, London, United Kingdom

Introduction

Congenital melanocytic naevus (CMN) syndrome is a mosaic disorder caused by classical melanoma oncogenic variants arising during in utero development, and is the highest risk factor for melanoma development in children worldwide. BRAF-fusions are a recently described cause of this disease, with a particularly proliferative and symptomatic phenotype. Oral trametinib reduces cutaneous proliferation, however the naevi themselves persist and the melanoma risk therefore remains. We have recently reported induction of apoptosis of NRAS-variant naevus cells using allele-specific siRNA in vitro, and successful delivery into mouse skin. Given the specificity of the sequence of gene fusions and the highly targeted nature of siRNA designed against the fusion breakpoint, as well as the accessibility of skin for delivery of siRNA, we sought to explore the potential of BRAF-fusion siRNA therapy in primary cultures.

Material and method

Primary melanocytic cells were derived from affected skin biopsies from two patients with BRAF-fusion driven CMN syndrome, one from benign naevus tissue and one from a primary melanoma. Patients each had a different 5' partner gene fused to the BRAF kinase domain: PHIP:BRAF and GOLGA4:BRAF, respectively. siRNAs were designed across the fusion breakpoint to target

specifically the fusion transcript, transfected alone and in combination with MEKi trametinib, and compared to non-targeting siRNA and vehicle controls. Proliferation and apoptosis were assessed over five days using IncuCyte® high-throughput phase contrast imaging alongside a DNA-binding fluorescent caspase 3/7 dye. Gene expression was evaluated through qRT-PCR and MAPK activation by Western Blot, both three days post-treatment.

Result and discussion

Fusion-specific siRNAs in all cases specifically and effectively reduced the expression of the fusion transcript compared to non-targeting controls, leaving wild-type transcripts unaffected. Treatment with a single dose of siRNA alone markedly decreased proliferation compared to controls, and significantly more effectively than current standard of care trametinib. Combination of siRNA with trametinib was not more effective than siRNA alone. Induction of apoptosis was seen in both patient cell lines. Mechanistically, siRNA therapy significantly reduced MAPK activation in all lines and decreased the expression of survival genes BIRC5 and ARL6IP1.

Conclusion

Taken together, these findings suggest that siRNA therapy might serve as a more effective treatment for CMN patients with BRAF fusions than trametinib, and induction of apoptosis supports potential resolution of lesions rather than only stabilisation. The accessibility of skin for delivery of siRNA and the specificity of fusion-targeted siRNA would be expected to keep off-target effects to a minimum.

³*Candiolo cancer institute-FPO, IRCCS, Candiolo Turin, Italy*

⁴*Pathology Division, S.Antonio and Baigio Hospital, Alessandria, Italy*

Introduction

Malignant pleural mesothelioma (MPM) remains a lethal cancer due to difficulties in early diagnosis, a scarcity of targets for innovative treatments, inherent resistance to chemotherapy, and an immune-suppressive tumor microenvironment. Previous research has demonstrated that asbestos fibers induce DNA damage in cells, thereby contributing to the molecular diversity seen in MPM. It has been reported that 10–15% of MPM samples contain alterations in genes associated with homologous recombination (HR) or other DNA repair mechanisms. We proposed that these genetic alterations might create a susceptibility in certain MPMs to treatments that target the DNA damage response (DDR) pathways.

Material and method

We assembled a panel consisting of 22 MPM human cell lines and 3 murine cell lines sourced from commercial suppliers or developed from patients at Azienda Ospedaliera SS. Antonio e Biagio in Alessandria and San Luigi Hospital in Orbassano, Italy. Molecular characterization involved whole-genome sequencing and comprehensive methylome profiling of the cell lines. Long-term cell proliferation assays lasting 7 to 15 days were conducted using various concentrations of the following DDR inhibitors: berzosertib and ceralasertib (ATR inhibitors), AZD0156 (an ATM inhibitor), olaparib (a PARP inhibitor), adavosertib (a WEE1 inhibitor), and rabusertib (a CHEK1 inhibitor). We quantified RAD51 nuclear foci after treatment with DDR inhibitors or exposure to ionizing radiation to evaluate DNA damage and HR activation.

Result and discussion

The paucity of preclinical MPM models has hindered advancements in identifying targets and effective therapies for this uncommon tumor type. By gathering a substantial collection of MPM models, we discovered that 10 out of 22 human and 2 out of 3 studied murine MPM lines exhibited remarkable sensitivity to all DDR inhibitors. We identified genomic alterations of unclear significance impacting 112 HR and 132 DDR genes; however, these did not correlate with sensitivity to the drugs. Additionally, the deficiency of BAP1 protein did not serve as a predictor for drug response. MPMs that failed to form RAD51 foci after exposure to ionizing radiation, which are known to induce double strand breaks, were among the most DDR-sensitive cell lines. Intriguingly, drug refractory cell lines showed either sarcomatoid or biphasic histology, whereas drug sensitive lines showed epithelioid features, suggesting a previously unrecognized role of tumor histology in modulating DDR in MPM.

Conclusion

These results represent a preclinical rationale for designing clinical trials with DDR for MPM patients.

Preclinical Evaluation of Novel Phosphoinositide 3-Kinase Inhibitors: Antitumor Activity and Toxicity Assessment

M. Fonseca Peixoto¹, G. Stringhetta¹, I. Faria Gomes¹, P. Silva Resende¹, R. Ferraz do Amaral¹, T. Gabriel Castro², V. Lobo², R. Manuel Reis¹, M. Gonçalves Carvalho², R. José Silva Oliveira¹

¹*Barretos Cancer Hospital, Molecular Oncology Research Center, Barretos, Brazil*

²*University of Minho, Department of Chemistry, Braga, Portugal*

Introduction

Dysregulation of the phosphatidylinositol-3-kinase (PI3K) pathway, via mutations and amplifications, is common in cancers, including colorectal cancer (CRC). This study evaluated 10 novel class I-selective PI3K inhibitors for targeted therapy in CRC models.

Material and method

The efficacy of the PI3K inhibitors was assessed in a two-step process using HCT-116, HCT-15, and DIFI

CRC cell lines, with HaCat cells as a normal control. In the first step, cells were exposed to the inhibitors and Alpelisib (a PI3K inhibitor) at a single dose, followed by a five-dose step to determine IC₅₀ values using the MTS assay. Selectivity indices were calculated by comparing IC₅₀ values between tumor and healthy cell lines. Proliferation pathways were analyzed via Western blot, and apoptosis was assessed by flow cytometry. A 3D cell culture model of HCT-116 was used to evaluate cell viability using CellTiter-Glo, Calcein AM, and Propidium Iodide staining. Six patient-derived CRC organoids were also treated with the most effective PI3K inhibitors. To correlate treatment response with molecular characteristics, the mutational status of 48 genes was assessed by next-generation sequencing (NGS), and the PI3K expression profile was evaluated by immunohistochemistry [1]. In silico analyses using ADMETlab software was conducted. Molecular docking studies were performed to assess binding interactions between the inhibitors and class I PI3K isoforms.

Result and discussion

The compounds VL336 and VL311 interacted with the PI3K α isoform, particularly binding to valine and lysine residues within the active site. Both molecules significantly inhibited tumor cell growth (<50%), outperforming Alpelisib. These compounds also demonstrated high selectivity for tumor cell lines, with low IC₅₀ values of 1.51 ± 0.35 μM and 1.59 ± 0.44 μM , respectively, in HCT-116 cells. Among the CRC cell lines, HCT-116 was the most sensitive to VL336 and VL311, showing greater responsiveness than to Alpelisib. Further analysis revealed that VL311 significantly reduced the phosphorylation of AKT and ribosomal protein S6 expression, which demonstrates disruption of PI3K-mediated signaling and induced late apoptosis. In 3D spheroid models, VL311 reduced cell viability more effectively than Alpelisib. Finally, 3 out of 6 patient-derived samples were sensitive to VL311 and VL336. PIK3CA mutations were absent, but high PI3K expression correlated with greater inhibitor sensitivity.

Conclusion

VL336 and VL311 showed significant in vitro efficacy in 2D, 3D, and patient-derived CRC models, highlighting their therapeutic potential, warranting further investigation of their therapeutic potential, clinical applicability and toxicity.

Alpha-aminobutyric acid attenuates DEN and diet-induced MASLD/MASH mice model by suppression of oncogenic signalling pathways KRAS, STAT3 via gut microbiome modulation

F. Felicianna¹, E. Lo¹, C. Chen¹, M. Jasiel¹, F. Zhang¹, M. Leung¹, H. El-nezami^{1,2}

¹The University of Hong Kong, School of Biological Sciences, Hong Kong, Hong Kong, China

²niversity of Eastern Finland, Institute of Public Health and Clinical Nutrition, Kuopio, Finland

Introduction

As obesity continues to rise and metabolic dysfunction-associated steatotic liver disease (MASLD) becomes more prevalent, the occurrence of hepatocellular carcinoma (HCC) linked to MASLD and/or metabolic dysfunction-associated steatohepatitis (MASH) is expected to grow, emphasizing the critical need for effective treatment options. Alpha-aminobutyric acid (ABA) is a non-proteinogenic amino acid, a metabolite which could be generated from the metabolism of methionine, threonine, serine and glycine or as a gut-microbiome-derived metabolite. It had previously been shown to ameliorate the progression of MASLD, showing anti-inflammatory and antioxidative properties.

Material and method

This present study aimed to investigate the effect of oral ABA supplementation on the progression of diethylnitrosamine (DEN)-high-fat/high-cholesterol diet (HFD)-induced MASLD/MASH-associated hepatocellular carcinoma (HCC) mice model.

Result and discussion

The administration of ABA was found to mitigate several parameters associated with MASLD/MASH-related HCC, including liver weight, tumor count, and size, along with decreased levels of serum ALT, AST, triglycerides, and both free and total cholesterol. Additionally, ABA markedly diminished hepatic steatosis and the expression of inflammatory markers while enhancing antioxidative and anti-inflammatory capacities. Mechanistically, ABA was shown to suppress the oncogenic KRAS/RAF/ERK and STAT3/SOCS3 signaling pathways, as well as inhibit the activity of the mTOR/PI3K/AKT pathway. Notwithstanding, ABA was shown to remodelled the gut microbiome composition, decreasing the abundance of 12 bacterial species, and enriching 7 bacterial species. Additionally, the glucuronate pathway was seen to be both enriched in liver RNAseq and the KEGG microbial function analysis, which was previously shown to be linked to promoting the synthesis of the antioxidant glutathione and could contribute to the overall improved outlook of HCC progression.

Conclusion

Overall, our findings demonstrated the anti-tumor effects of ABA and its possible mechanism and suggest that ABA could be used as a promising therapeutic approach for the intervention of MASLD/MASH-associated HCC.

EACR25-2601

Isothiocyanate-derived mercapturic acids potentiate tubulin polymerization inhibitors anticancer activity in urinary bladder cancer models (in vitro and in vivo studies)

M. Cuprych¹, M. Psurski¹

¹Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland

Introduction

Urinary bladder cancer is currently the fourth most common cancer in men in Poland, with a continuously increasing incidence and mortality rate. Over the last 30 years, numerous studies have demonstrated that naturally occurring isothiocyanates possess significant chemo-

preventive and antitumor potential, combined with low toxicity. Their multi-targeted mode of action, including effects on mitotic division, along with their natural origin, makes them promising adjuvants for currently used oncological therapies. The metabolism of isothiocyanates via the mercapturic acid pathway leads to the formation of biologically active isothiocyanate-derived mercapturic acids, which accumulate at high concentrations in urine and urinary bladder tissue, making them particularly relevant for bladder cancer treatment.

Material and method

A set of tubulin polymerization modulators (e.g., vinorelbine, colchicine, paclitaxel, combretastatin A4) was tested in vitro with structurally different mercapturic acids. Experiments included assessments of anti-proliferative activity, apoptosis rate, cell cycle analysis, and glutathione levels. Antiproliferative effects were analyzed using synergy models to determine interactions. The most promising combinations were further evaluated in vivo using orthotopic cancer models established by ultrasound-guided cancer cell inoculation.

Result and discussion

Our in vitro studies demonstrated for the first time that mercapturic acids synergistically enhance the anti-proliferative activity of microtubule polymerization inhibitors (such as colchicine, vinflunine, and combretastatin A4), but not microtubule stabilizers (such as paclitaxel). This leads to reduced proliferation and increased apoptosis. We also discovered that the chemical structure of mercapturic acids influences their potency; for instance, the benzyl isothiocyanate derivative was significantly more potent than the sulforaphane derivative. Follow-up studies revealed that the observed synergistic effect resulted from an increased apoptosis rate during the G2/M phase (without substantial changes in the overall cell cycle profile), decreased glutathione and βIII-tubulin levels in combination-treated cells, and reduced tubulin polymerization in cell-free experiments. In vivo studies using orthotopic models indicated a moderate enhancement of the anticancer activity of combretastatin A4 and vinflunine by benzyl isothiocyanate-derived mercapturic acid. This effect was associated with reduced angiogenesis and tumor perfusion, without signs of increased toxicity.

Conclusion

These findings suggest that mercapturic acids enhance the anticancer efficacy of tubulin polymerization inhibitors (but not stabilizers), synergistically increasing mitotic catastrophe rates.

Novel Antibody Therapeutics: Anti-BCMA.ECD for Personalised Cell Therapy in Multiple Myeloma

G. Dagar¹, A. Gupta¹, R. Chauchan¹, K. Luthra²,

M. Singh¹

¹All India Institute of Medical Science, Medical Oncology, New Delhi, India

²All India Institute of Medical Science, Department of Biochemistry, New Delhi, India

Introduction

Multiple myeloma is characterized by the expansion of malignant plasma cells in the bone marrow (BM), which is associated with excessive production of monoclonal immunoglobulins in blood and urine in patients. The addition of monoclonal antibodies as immunotherapies in MM has further improved patient outcome. However, MM remains incurable for most patients, since drug-resistant clones constantly emerge and evolve. BCMA has been found to be overexpressed in MM and is being explored as a target for both antibody based and live cell therapy.

Material and method

BCMA expression in MM patients was quantified using RQ PCR, and soluble BCMA was quantified using ELISA. The consensus BCMA.ECD sequence was cloned into a vector, sequenced, and protein expression was carried out using the Expi293 system, characterized by SDS-PAGE. Mice were immunized, and hybridoma cells were generated for the production of Anti-BCMA.ECD antibodies, which were further purified and characterized using western-blotting and other assays. The best binders were identified, and the ScFv sequence was incorporated into a novel second-generation CAR (Chimeric Antigen Receptor) T-cell, which was screened using flow-cytometry.

Result and discussion

We characterized BCMA expression in a cohort of MM patients and found it to be elevated at the mRNA level. Serum or soluble BCMA levels were also elevated, predicting inferior therapeutic outcomes in MM patients. BCMA was validated as a candidate for Anti-BCMA therapy. BCMA.ECD protein was expressed in a eukaryotic system and used to generate hybridomas, resulting in twenty different clones. These clones were screened for the best binders, characterized by their binding affinity to BCMA.ECD protein using ELISA. The best binder (9C4) was used for deciphering the ScFv sequence for the development of a novel second-generation CAR.

Conclusion

This study led to the characterization of BCMA expression and variation in Indian MM patients and the development of an Anti-BCMA.ECD antibody for a second-generation CAR.

EACR25-0102

DLL3-targeting CAR-T cells enhanced by co-deletion of PD1 exhibit better efficacy and persistence in a pre-clinical animal model for small cell lung cancer

B. Zhou¹, F. Xu², Y. Wan³, Y. Cui¹, J. Yu¹, L. Deng¹, J. Lin¹, Y. Choi¹, J. Hua³, H. Zhang¹

¹SPH Biotherapeutics (HK) Limited, R&D, Hong Kong, Hong Kong, China

²SPH Biotherapeutics (HK) Limited, R&D, Hong Kong, Hong Kong, China

³SPH Biotherapeutics (Shanghai) Limited, R&D, Hong Kong, Hong Kong, China

Introduction

Small cell lung cancer (SCLC) is an aggressive and high-grade neuroendocrine disease with few treatment options. Delta-like ligand 3 (DLL3) is highly expressed on SCLC and several other types of neuroendocrine cancers with minimal or absent expression in normal adult tissues, making it a promising CAR-T target for SCLC and other solid tumor indications.

Material and method

A VHH antibody (D4) for human DLL3 was selected and generated from a humanized Camelid synthetic library. Subsequently, it was made into a second-generation CAR format and the one with additional PD1 intracellular retention (a non-gene editing technique to remove membrane proteins), both of which were compared for in vitro activities and an in vivo subcutaneous SHP77 tumor animal model for target-dependent T cell cytotoxicity and persistence.

Result and discussion

The DLL3 CAR with PD1 intracellular retention demonstrated a much better long-term cytotoxicity against SHP77 tumor cells than the unmodified CAR in vitro by repeatedly adding two more rounds of the tumor cells in an Incucyte's real-time killing assay at an E:T ratio of 1:2. To further evaluate the activities of both DLL3 CAR T cells in vivo, 5×10^6 /mouse of SHP77 cells were implanted subcutaneously in nonobese diabetic SCIDgamma (NSG) mice and allowed to engraft for 7 days, reaching a mean size of approximately $40\text{--}60\text{mm}^3$ before treatment with a single tail vein injection of 2×10^6 CAR+ T cells/mouse. For this well-established in vivo solid tumor model, we found that the PD1-deleted CAR-T group started to show the tumor growth slowing down D13, soon reaching the peak volume D20 at a mean size of 1500 mm^3 , and then steadily declining close to the baseline D30. But the unmodified CAR-T group was observed to have a much delayed and gradual decline of the tumor volume starting D20 instead at a mean size of 2500 mm^3 , with shrinkage down to a mean tumor volume of 600 mm^3 D30 and further down to the 300 mm^3 D34. In addition, both groups showed the CAR-T cell expansion during the tumor shrinkage and no signs of GVHD in the study.

Conclusion

Although both CAR-T groups exhibited good tumor suppression capabilities, the PD1-deleted DLL3 CAR-T showed a quicker and stronger response in this adoptive T cell therapy against solid tumors in a pre-clinical animal model. The findings of Improved preclinical efficacy and persistence warrant further evaluation of PD1-deleted DLL3 CAR-T cells as a potential clinical candidate for the treatment of SCLC.

EACR25-0109

Nanobodies against PSMA as the foundation for new tracers for prostate cancer imaging and treatment

T. Yang¹, S. Kavousipour², J. Veldhoven-Zweistra¹, W. van Weerden¹, N. Lumen³, R. Tooyserkani¹, G. Jenster¹

¹Erasmus MC, Urology, Rotterdam, Netherlands

²Hormozgan University, Incubator center and technology transfer department, Bandar Abbas, Iran

³UZ Gent, Urology, Ghent, Belgium

Introduction

Nanobodies (VHHs) are the variable domains derived from heavy-chain-only antibodies (HcAbs) found in camelids or sharks. Their small size, stability, and ease of engineering make them valuable for research and clinical applications. Prostate-specific membrane antigen (PSMA) is a transmembrane glycoprotein highly expressed in prostate cancer, serving as a key biomarker for imaging and therapy. To enhance the specificity and affinity of new tracers, we identified and validated PSMA-binding nanobodies.

Material and method

Three llamas were immunized with PSMA-expressing prostate cancer cell lines or patient-derived materials to generate nanobody libraries. Phage display technology was used to screen for PSMA-specific nanobodies, followed by Next Generation Sequencing (NGS) of ~ 1 million bound phages per panning. PSMA knockdown in LNCaP cells was achieved using FOLH1 shRNA lentiviral infection, and knockdown efficiency was assessed via Western blot. Nanobody candidates with high PSMA-binding ratios were validated through a four-step workflow, including Cell ELISA, immunocytochemistry, tissue microarray staining, and flow cytometry using LNCaP WT/shPSMA cells. Selected nanobodies were mapped for epitope binding, produced as His-tagged proteins, and tested in competitive binding assays using Alexa-labeled phage nanobodies. In silico docking analyses with AlphaFold3, Robetta, and HADDOCK2.4 identified binding epitopes.

Result and discussion

Fourteen PSMA nanobodies (PSMANbs) were selected for in vitro analysis. ELISA confirmed their high affinity for PSMA-positive cell lines (LNCaP, B16-PSMA) with minimal binding to PSMA-negative lines (DU145, B16-WT). Six PSMANbs demonstrated strong specificity, with A7 and PSMANb9 exhibiting the highest selectivity in immunocytochemistry and tissue histology across 20 cell lines and 20 normal human tissues. Flow cytometry confirmed reduced binding of AF488-labeled A7 and PSMANb9 in PSMA-knockdown cells. Competitive binding assays showed that A7 and PSMANb9 target distinct, non-overlapping PSMA epitopes, which was further supported by in silico structural modeling. Importantly, their binding does not interfere with the clinically used PSMA-617 tracer.

Conclusion

Six PSMA-specific nanobodies were identified, with A7 and PSMANb9 showing the highest affinity and specificity. Both bind distinct PSMA epitopes without interfering with PSMA-617, making them promising candidates for diagnostic and therapeutic applications in prostate cancer.

EACR25-0177

Efficacy and toxicity of half dose BCG vaccine in bladder cancer

S. Acharya¹

¹Assam Cancer Care Foundation, Oncology, Lakhimpur, India

Introduction

Bacillus Calmette–Guérin (BCG) has been successfully used as immunotherapy to treat non-muscle invasive bladder cancer (NMIBC) for more than four decades. BCG is the only intravesical agent shown to reduce the risk of progression of NMIBC to muscle-invasive disease. Unfortunately, BCG therapy is not a universal panacea and it still fails in up to 40% of patients. This prospective cohort study was designed to document efficacy and toxicity of half dose (40 mg) BCG.

Material and method

Eligibility criteria include intermediate and high-grade NMIBC and carcinoma in situ after 3 weeks of TURBT. Weekly BCG therapy (40 mg, half dose) was given for 6 weeks as induction and a weekly dose for 3 weeks at 3, 6, 9 and 12 months was given as maintenance therapy. The entire procedure was done as an outdoor procedure.

Result and discussion

21 patients were included in the study from 2019 to February 2023. All patients had T1 disease, 7 had low grade (Intermediate risk) and 14 had high grade (High risk without very high-risk features) cancer. Cystitis is the most common symptom experienced by all patients to varied extent but fortunately all are self-limiting. 3 patients had fever which subsided with paracetamol. No serious adverse effect observed in any of the 18 patients, and all were discharged on the same day of admission. After 36 months of mean follow up period, 8 patients had recurrence.

Conclusion

BCG therapy is an effective treatment in intermediate and high-grade NMIBC and carcinoma in situ after TURBT. With half dose of BCG the toxicity is low and the cost of treatment is just over 20\$ for each session.

EACR25-0203

Scoparone attenuates PD-L1 expression in human breast cancer cells by MKP-3 upregulation

H. Kim¹

¹Inha University College of Medicine, Department of Molecular Medicine, Incheon, Korea (Republic of)

Introduction

Breast cancer is a frequently occurring malignant tumor that is one of the leading causes of cancer-related deaths in women worldwide. Monoclonal antibodies that block programmed cell death 1 (PD-1)/programmed cell death ligand 1 (PD-L1) – a typical immune checkpoint – are currently the recommended standard therapies for many advanced and metastatic tumors such as triple-negative breast cancer. However, some patients develop drug resistance, leading to unfavorable treatment outcomes. Therefore, other approaches are required for anticancer treatments, such as downregulation of PD-L1 expression and promotion of degradation of PD-L1. Scoparone (SCO) is a bioactive compound isolated from *Artemisia capillaris* that exhibits antitumor activity. However, the effect of SCO on PD-L1 expression in cancer has not been confirmed yet. This study aimed to evaluate the role of SCO in PD-L1 expression in breast cancer cells *in vitro*.

Material and method

SCO was obtained from MedChem Express, and various antibodies, including anti-PD-L1 and phospho-protein antibodies, were sourced from Cell Signaling Technology, Abcam, and Santa Cruz Biotechnology. MCF7 and MDA-MB-231 cells were cultured in RPMI 1640 medium with 10% FBS and 1% antibiotics at 37°C in a 5% CO₂ incubator. Cell viability was assessed using a CCK-8 assay after 24-hour SCO treatment (0–500 μM), with absorbance measured at 450 nm. Western blot analysis was performed using SDS-PAGE and chemiluminescence detection. Total RNA was extracted using the AccuPrep kit, and RT-qPCR was conducted with 18S rRNA as the reference gene. MKP-3-targeting and control siRNAs were transfected into MDA-MB-231 cells using Lipofectamine RNAiMAX, and knockdown efficiency was verified by western blotting. Statistical analyses were performed using ANOVA, with data expressed as mean ± SD, and significance set at *p* < 0.05.

Result and discussion

Our results show that SCO downregulated PD-L1 expression in a dose-dependent manner, via AKT inhibition. Interestingly, SCO treatment did not alter PTEN expression, but increased the expression of mitogen-activated protein kinase phosphatase-3 (MKP-3). In addition, the SCO-induced decrease in PD-L1 expression was reversed by siRNA-mediated MKP-3 knockdown.

Conclusion

Collectively, these findings suggest that SCO inhibited the expression of PD-L1 in breast cancer cells by upregulating MKP-3 expression. Therefore, SCO may serve as an innovative combinatorial agent for cancer immunotherapy.

EACR25-0279

Exercise to boost the immune system and optimise immunotherapy responsiveness in pancreatic cancer

B. Hapuarachi¹, S. Danson¹, J. Wadlsey², M. Muthana¹

¹University of Sheffield, Division of Clinical Medicine, Sheffield, United Kingdom

²Sheffield Teaching Hospitals NHS Foundation Trust, Oncology, Sheffield, United Kingdom

Introduction

Evidence suggests exercise boosts the immune system supporting anti-cancer activity, potentially enhancing cancer immunotherapy. The pancreatic tumour micro-environment (TME) lacks immune cells inhibiting immunotherapy responsiveness. Treatments are limited contributing to its poor prognosis. We hypothesise that exercise will improve immunity in pancreatic cancer and enhance the response to immunotherapy.

Material and method

20 C57BL/6 mice underwent orthotopic implantation of Panc02 (murine pancreatic adenocarcinoma) cells and were divided into 4 groups (*n* = 5); exercise with anti-Programmed Cell Death Protein 1 (PD1), exercise with isotype, no exercise with anti-PD1 and no exercise with isotype. Treadmill running was performed 20 minutes/day, 4 days/week at 12 metres/minute. Resistance training consisted of hanging upside down on a wire mesh screen for 1 minute 2 days/week. Flow cytometry

determined TME immune populations. Tumour and liver samples were harvested, paraffin wax embedded/sectioned and analysed using SlideViewer®. Alongside this, immune profiling of bloods from healthy volunteers was carried out pre and post high intensity interval exercise and the effects of exercise conditioned serum on pancreatic cells (PANC1) in vitro were explored.

Result and discussion

Exercise/anti-PD1 was feasible from Day 2 following surgery throughout the study. A 73.5% reduction in Myeloid Derived Suppressor Cells (MDSCs) occurred in the TME of exercising mice ($p = 0.0426$). Liver metastatic burden was significantly reduced with treadmill running (92.9%, $p = 0.0087$) with a 66.8% reduction seen in the exercise/anti-PD1 group ($p = 0.0286$). Tumour necrosis was significantly higher in the exercise/anti-PD1 group ($p = 0.0182$). Similarly, in healthy volunteers an increase in NK cells (32.6%, $p < 0.0001$) and a reduction in regulatory T cells by 31.0% ($p < 0.0001$) was seen post exercise. Exercise conditioned serum significantly reduced PANC1 cell migration ($p = 0.03$) and increased caspase 3/7 (apoptotic) activity ($p < 0.0001$).

Conclusion

Exercise/anti-PD1 improves tumour response and limits metastatic potential in this aggressive pancreatic cancer model. MDSCs in the TME promote immune tolerance allowing tumour propagation. Exercise significantly reduces MDSCs and trends towards regulatory T cell reduction. These TME modulations promote anti-cancer immune responses demonstrating exercise as an effective immunotherapy enhancer. High intensity interval aerobic exercise in healthy volunteers significantly increases NK cells and reduces Regulatory T cells, promoting cytotoxicity and reducing immune tolerance. Exercise conditioned serum increases apoptosis and reduces migration of pancreatic cancer cells in vitro. Exercise could be a promising immunotherapy adjunct in pancreatic cancer. Clinical studies are warranted to explore these benefits in pancreatic cancer patients.

EACR25-0289

Epigenetic Modulation of CAR-T cells against Group 3 Medulloblastoma

S. Chan¹, J. Anderson¹, L. Donovan¹

¹*UCL GOS Institute of Child Health, Developmental Biology and Cancer, London, United Kingdom*

Introduction

Medulloblastoma (MB) is the most common malignant brain tumour in children. Group 3 MB represents the most aggressive subgroup, with high recurrence rates and poor survival outcomes. Current treatments, including surgery and chemotherapy, are associated with significant morbidity, underscoring the need for innovative therapies. Chimeric antigen receptor T-cell (CAR-T) therapy has shown promise in hematologic malignancies and preclinical solid tumour models, but its efficacy against solid tumours is often hindered by T-cell exhaustion and limited persistence. Epigenetic regulation, particularly DNA methylation, plays a crucial role in T-cell exhaustion. Azacytidine (AZA), a DNA methyltransferase inhibitor approved for clinical use, has been

proposed to enhance CAR-T function by preventing exhaustion-associated epigenetic modifications.

Material and method

We investigated the effects of AZA priming on CAR-T cells targeting B7-H3 and EphA2, antigens highly expressed in Group 3 MB but absent from normal paediatric brain tissue. CAR-T cells were expanded in the presence of AZA, and their cytotoxicity, cytokine secretion, proliferation, and memory/exhaustion phenotypes were assessed via flow cytometry, ELISA and luciferase assays.

Result and discussion

While previous studies have suggested that hypomethylating agents, including decitabine and AZA, may enhance CAR-T function in certain contexts, our findings indicate that AZA priming of B7-H3 and EphA2 CAR-T cells did not significantly alter cytotoxicity, cytokine production, or exhaustion/memory marker expression in vitro. However, AZA treatment led to a notable decrease in CAR-T proliferation, as demonstrated by Cell Trace Violet dilution assays, suggesting that DNA methylation inhibition may influence CAR-T expansion kinetics. Given the promising role of epigenetic modulation in T-cell function reported in other CAR-T models, further investigations are warranted to clarify context-dependent effects of AZA on different CAR constructs and tumour types. To explore an alternative strategy, we are now evaluating whether treating Group 3 MB cells with AZA can enhance tumour immunogenicity and synergize with CAR-T therapy.

Conclusion

This study highlights the complex effects of epigenetic modulation in CAR-T therapy and suggests that AZA may differentially affect CAR-T cell function depending on target antigen, tumour type, and in vitro expansion conditions. By shifting our focus to tumour-directed AZA priming, we aim to assess whether epigenetic modification of Group 3 MB cells can enhance CAR-T efficacy. These findings contribute to the growing understanding of how hypomethylating agents interact with immunotherapy and may help refine epigenetic combination strategies for rare paediatric CNS tumours.

EACR25-0347

Unveiling interactions between senescent tumor cells and the host immune system - Implications for Senolytic Immunotherapy

B. Bosco¹, P. Richter-Pechanska², Y. Horokhovskiy³, O. Popp⁴, P. Mertins⁴, T. Krieger⁵, J. Liepe³, S. Keppler⁶, C. Schmitt⁷, J. Dörr¹

⁶Medical University of Graz, Department of Internal Medicine, Graz, Austria

⁷Johannes Kepler University, Medical Department of Hematology and Oncology, Linz, Austria

Introduction

Therapy-induced senescence (TIS) halts tumor growth and enhances treatment outcomes in numerous preclinical cancer models. However, it also alters tumor biology and reshapes the tumor environment, thereby contributing to treatment resistance and tumor relapse. Several studies have described the complex and dynamic relationship between senescent tumors and the host immune system, yet the molecular mechanisms underlying this interaction remain unclear, and its impact on treatment efficacy contingent upon cancer type. Consequently, elucidating the interplay between senescent tumor cells and the host immune system is a critical priority for improving cancer therapy, including the development of novel senolytic immunotherapies.

Material and method

We employed RNA and proteome analyses, along with immunophenotyping by flow cytometry, in various pediatric tumor mouse models and human tumor cell lines before and after DNA-damaging therapy to characterize TIS-associated changes in tumor biology. To further investigate the interaction between TIS tumor cells and different cells of the host immune system (e.g., macrophages, T cells, and NK cells) *in vivo*, we utilized immune mass cytometry (IMC) and spatial multiplex immunofluorescence imaging (MACSima). Additionally, we applied genetic and pharmacological approaches to modulate T-cell interactions with TIS tumor cells and alter T-cell cytotoxicity in senolytic therapies.

Result and discussion

Upon TIS, various mouse and human cancer cell lines exhibited increased expression of immunologic gene sets and surface markers associated with immune system activation. Investigation of *in vivo* tumor-host interactions by spatial imaging revealed that TIS promotes the infiltration of both CD4⁺ and CD8⁺ T cells into senescent tumor sites, facilitating their direct interaction with TIS cells. Immunophenotyping of these T cells identified Fas ligand (FasL) overexpression as a key actionable moiety that induces apoptosis in Fas receptor (FasR)-positive TIS cells. To further elucidate the significance of this interaction in senolytic therapies and treatment outcomes, we employed *in vivo* and *in vitro* genetic and pharmacological approaches to manipulate FasL–FasR binding, demonstrating its crucial role in TIS-targeted therapeutic strategies and treatment outcome.

Conclusion

This study elucidates the impact of TIS on tumor cell immunogenicity, demonstrating enhanced immune system activation and increased susceptibility to T cell-mediated apoptosis through direct interaction of both CD4⁺ and CD8⁺ T cells via the FasL–FasR pathway. These findings highlight novel actionable moieties to enhance the efficacy of senescence-based immunotherapies across different cancer types.

Introduction

Inhibiting programmed-cell-death protein 1 (PD-1) and programmed-death ligand 1 (PD-L1) by immune checkpoint inhibitors (ICIs) has proven efficacy in the treatment of multiple cancers through targeting evasion of host immune responses, a key hallmark of cancer. We aimed to assess the repurposing potential of these ICIs to additional cancer indications using the causal inference method Mendelian randomisation (MR).

Material and method

Germline genetic instruments were constructed to proxy serum PD-1 and PD-L1 protein levels in normalised protein expression (NPX) units with summary statistics from a GWAS of general population participants.

Summary-level MR was performed to investigate the genetically proxied effects of PD-1 and PD-L1 lowering on breast, colorectal, lung, melanoma, ovarian or prostate cancer mortality. Where data were available, HRs were estimated for participants stratified by cancer stage or subtype. Cancer survival at sites with current PD-1 or PD-L1 inhibitor indications (breast, colorectal, lung, melanoma) were positive control outcomes. Instrument validity was evaluated in cancer patient cohorts. Risk of collider bias was assessed through investigating the effects of PD-1 and PD-L1 on cancer incidence using summary-level MR.

Result and discussion

We observed evidence to support effects of genetically proxied PD-1 lowering on risk of death in colorectal (HR

per NPX unit decrease PD-1: 0.84, 95% CI: 0.71-1.00), lung (HR per NPX unit decrease PD-1: 0.88, 95% CI: 0.78-1.00) and ovarian cancer (HR per NPX unit decrease PD-1: 0.88, 95% CI: 0.78-0.99). Little evidence was observed for effects of genetically proxied PD-L1 lowering, aside from on risk of colorectal cancer mortality (HR per NPX unit decrease PD-L1: 0.90, 95% CI: 0.81-0.99). There was no strong evidence to suggest that effects of PD-1 and PD-L1 on colorectal cancer mortality were restricted to any specific stage or site. Generally, the lead PD-1 and PD-L1 instruments demonstrated consistent direction of effect with their respective protein levels in the cancer patient compared to general population cohorts. There was no strong evidence to support effects of PD-1 or PD-L1 lowering on cancer incidence at any included site.

Conclusion

We found evidence to support PD-1 inhibitor repurposing for ovarian cancer treatment, a possible new indication. We additionally found evidence to support potential PD-1 and PD-L1 inhibitor repurposing to broader colorectal cancer patient populations than current indications. Although there was evidence to support the validity of the instruments in cancer patient populations and we observed a low risk of collider bias, MR evidence was not consistent across cancers with currently approved indications. These findings should thus be interpreted with caution and highlight the remaining challenges of applying MR in cancer survival settings, for example low heritability of cancer prognosis or treatment effects.

⁵Lisbon, Lisbon, Portugal,

Introduction

Despite significant advances in cancer immunotherapy, tackling immunosuppression remains critical for more effective responses. While developing a zebrafish xenograft model, we found that some tumors engraft very efficiently (“progressors”), while others are cleared by the host (“regressors”). We showed this to be dependent on innate immunity, which recognizes and eliminates certain cancer cells, while others are able to evade/suppress it. This opened an opportunity to perform an *in vivo* phenotypic drug screen to find compounds that induce clearance by boosting innate-tumor rejection.

Material and method

Zebrafish xenografts of human colorectal (CRC) and breast cancer (BC) cell lines that show a high engraftment/low clearance phenotype (progressors) were used to screen an FDA-approved small compound library. Tumor cells were injected into 2 days post-fertilization embryos and subjected to compound testing. At 3-5 days post-treatment, clearance rates were quantified, and hits defined as compounds that increase tumor clearance.

Result and discussion

We screened 500+ drugs and obtained a total of 23 confirmed hits, with multiple of them showing effect in both CRC and BC xenografts. We characterized how the hits modulate the innate tumor microenvironment (TME) using transgenic zebrafish (myeloid reporters and mutants) and have observed phenotypes such as increasing macrophage/neutrophil recruitment and/or infiltration, as well as a macrophage reversion from a pro to an anti-tumoral polarization. We are currently characterizing the molecular mechanism behind the top hit, a muscarinic receptor inhibitor (MRI). The MRI was also tested in a CRC xenograft mouse model, to assess its efficacy in a fully immune-competent host, as well as their synergy with the αPD-1 immune checkpoint blocker. Treatment led to a significant decrease in tumor volume as monotherapy and showed a synergistic effect with αPD-1, with an additional increase in survival. We are currently performing immune profiling of the tumors, to better understand how the compound modulates immunity.

Conclusion

We are confident that we have found an FDA-approved compound that can be repurposed to be used in combination with immune checkpoint blockers, engaging both the innate and adaptive arms of the immune system to overcome the suppressive TME, and consequentially increase treatment efficacy rates.

Introduction

Immunotherapy based on immune-checkpoint inhibitors (ICIs) is the first-line treatment for advanced cancers like non-small cell lung cancer (NSCLC) and clear cell renal cell cancer (ccRCC). However, only a small percentage of patients benefit from it, becoming crucial to find therapies that enhance ICIs effectiveness. Epigenetic therapies, involving DNA methyltransferase (DNMT) and histone deacetylase (HDAC) inhibitors, could modify tumor cells and the tumor microenvironment, potentially improving ICIs responses. Recent studies have shown

that epigenetic drugs can activate transposable elements (TEs) like LINE-1 and human endogenous retroviruses (HERVs), suggesting a link between epigenetic drug-induced antiviral responses and increased immunogenicity. An abnormal expression of these elements can induce a state of viral mimicry, in which the cell triggers an immune response upon detecting foreign nucleic acids in the form of double-stranded RNA (dsRNA). This study aimed to evaluate the effect of two epigenetic drugs on NSCLC and ccRCC cell lines to improve ICIs responses.

Material and method

We used two NSCLC cell lines (H-2009 and H-2087) and two ccRCC lines (786-O and Caki-2). Epigenetic treatments included azacitidine (DNMT inhibitor) and vorinostat (HDAC inhibitor). Cell viability was assessed using the XTT assay, and gene expression was analyzed via qPCR. The cell cycle was examined by flow cytometry, and dsRNA production was assessed using immunofluorescence.

Result and discussion

The IC₅₀ values were calculated for each cell line and drug after 48 hours of treatment. IC₅₀ is the concentration of a drug required to cause 50% cell viability. All cell lines were sensitive, with IC₅₀ values ranging from 12.83–29.19 μM for azacitidine and 4.62–8.00 μM for vorinostat. Azacitidine induced morphological changes, especially in H-2009, and increased mesenchymal markers (ZEB1, ZEB2 and SNAIL) in all cell lines. CDH1 expression slightly decreased in lung cell lines. S-phase arrest was observed in H-2087 and Caki-2. No significant changes in LINE-1 expression, except for a slight increase in 786-O. Both renal lines showed an increase in HERVs, while lung cell lines remained unchanged. dsRNA production increased in 786-O and H-2087. Regarding vorinostat, no notable morphological changes were observed, but mesenchymal markers (VIM, ZEB1, ZEB2 and SNAIL) increased. G1 and G2 arrest were seen in H2009 and 786-O, respectively. Both LINE-1 and HERVs expression rose, and dsRNA production was enhanced in all lines.

Conclusion

Both treatments induced mesenchymal traits in all cell lines, with vorinostat causing more prominent TEs activation and dsRNA production. Therefore, vorinostat may induce a state of viral mimicry, triggering an immune response. These findings suggest HDAC inhibition could be a promising therapy to enhance ICIs efficacy in lung and renal cancers.

Preclinical double humanized CD47/SIRPα mouse model and MC38 cell line expressing human CD47 for efficacy and safety assessment of anti-CD47/SIRPα-targeting therapies

P. De La Rochère¹, A. Pappalardo¹, S. Mattar², S. Skah², L. Diomande², N. Richartz², Y. Cherifi¹, G. Martin¹, F. Sônego¹, K. Thiam¹

¹genOway, Lyon, France

²Caedo Oncology, Oslo, Norway

Introduction

CD47 is overexpressed on many human tumor cells and interacts with its ligand, the signal-regulating protein alpha (SIRPα), a protein expressed on macrophages and dendritic cells, to induce a “don’t eat me” signal. CD47 and its interaction with phagocytes is therefore a promising therapeutic target to treat cancer (S.B. Willingham et al., Proc Natl Acad Sci U S A. 2012). Here, we describe a double humanized knock-in model, the genO-hCD47/hSIRPα model, designed for the efficacy and safety assessment of human CD47/SIRPα-targeting therapies in immunocompetent mice.

Material and method

This model was generated by intercrossing genO-hCD47 and genO-hSIRPα mice, with both models designed to enable the expression of all human isoforms of hCD47 and hSIRPα.

Result and discussion

hCD47 and hSIRPα are expressed at physiological levels, which enabled the assessment of biodistribution of anti-SIRPα nanobodies, used as tracers in non-invasive in vivo tumor imaging (T.R. Wagner et al., Front Immunol. 2023). Activity of anti-CD47-targeting compounds were investigated in the model and a murine MC38 colon adenocarcinoma cell line expressing hCD47 was developed to reproduce as much as possible the interactions between hCD47 and hSIRPα upon tumor engraftment in this syngeneic mouse model. Magrolimab analog (Hu5F9-G4) induced tumor growth inhibition studies in the genO-hCD47/hSIRPα model inoculated with MC38 expressing hCD47. Furthermore, safety assessment of Magrolimab analog in naïve genO-hCD47/hSIRPα mice showed a drop on the number of red blood cells (RBCs) and hemoglobin 1 day post-treatment, with a recovery by 8 days post-treatment. Additionally, MC38-hCD47-bearing genO-hCD47/hSIRPα mice treated with Magrolimab also recapitulates the clinical findings, with a decline in RBCs and hemoglobin post treatment (C.K. Brierley et al., Transfusion. 2019).

Conclusion

Altogether, these data suggest that the genO-hCD47/hSIRPα model enables assessment of efficacy and safety of CD47 and/or SIRPα-targeting agents. The model is currently being upgraded to express humanized Fcγ receptors (FcγR), which will facilitate the assessment of Fc-mediated functions of antibodies targeting human CD47 and/or SIRPα.

EACR25-0586

Development of the in vitro 3D Spheroid High-Throughput Screening Platform for the Development of Immune Checkpoint Inhibitors

M. Rudnik¹, C. Vesser¹, T. Gamma¹, M. Zbinden¹, I. Agarkova¹, L. Ligeon¹

¹InSphero AG, Schlieren, Switzerland

Introduction

Immune checkpoint inhibitors (ICI) have revolutionized cancer immunotherapy, leading to significant clinical success in multiple malignancies. Despite their effectiveness, the high costs associated with ICI development and treatment pose a substantial economic burden. Additionally, the reliance on animal models in preclinical

research raises ethical concerns and often presents translational limitations due to the difficulties to accurately predict human immune responses. There is a pressing need for more physiologically relevant and cost-effective *in vitro* pre-clinical models to evaluate novel ICI candidates.

Material and method

To address this challenge, we developed a high-throughput 3D spheroid culture platform in our proprietary AkuraTM384-well format for the evaluation of immuno-modulatory and anti-tumor efficacy of ICIs. Our system utilizes spheroids composed of tumor cell lines and primary cancer-associated fibroblasts, to effectively recapitulating the tumor microenvironment. HLA-matched aCD3/CD28 pre-activated peripheral blood mononuclear cells (PBMCs) were added to 3D human tumor spheroids to assess immune-mediated tumor killing. Treatment conditions included ICIs and isotype control antibodies. Tumor viability and growth were monitored via bright field images and fluorescence measurements, while cleaved caspase-3/7 activity served as a marker of T-cell-induced apoptosis. Additionally, cytokine levels were quantified in the supernatant. Flow cytometry analysis of single spheroid was performed to assess immune cell phenotype and expression of tumor markers such as PD-L1 and EpCAM.

Result and discussion

Our results demonstrate that CD3/CD28/ICI treatment significantly enhances T-cell-mediated tumor cell apoptosis, as evidenced by increased cleaved caspase-3/7 activity compared to controls. Fluorescence-based viability assays confirmed a reduction in tumor spheroid growth upon ICI treatment. Moreover, cytokine profiling revealed an upregulation of immune-activating cytokines, supporting the immunostimulatory effect of ICI within the spheroid model. Flow cytometry analysis indicated an induction of an activated phenotype in T cells, further validating the model's relevance for immune response evaluation. The platform successfully captures key aspects of the tumor-immune microenvironment, providing a robust and scalable assay for drug screening.

Conclusion

We have developed a physiologically relevant, high-throughput 3D spheroid model for the evaluation of novel ICI candidates. This platform closely reflects clinical scenarios, allowing for efficient screening of immunotherapies while reducing reliance on animal models. The system's scalability and reproducibility make it a powerful tool for accelerating the development of next-generation immune checkpoint inhibitors.

Integrating the Fasting-Mimicking Diet to Augment Anti-tumor Immunity following Adoptive Cell Transfer in Breast Cancer

E. Pavlou¹, O. Blazevits², G. Salvadori³, F. Pisati⁴, V. Longo⁵

¹*IFOM, Molecular Oncology, Milano, Italy*

²*IFOM, Longevity and Cancer, Milano, Italy*

³*IFOM, Metabolic Reprogramming in Solid Tumors, Milano, Italy*

⁴*IFOM, Histopathology, Milano, Italy*

⁵*University of Southern California, Longevity and Cancer, Los Angeles, United States*

Introduction

Cancer arises within a complex cellular milieu, where the extent and composition of tumor-infiltrating immune cells strongly influence tumor defense and patient prognosis. Additionally, tumors do not exist in isolation, but rather, engage in constant crosstalk with the immune system including the bone marrow and the spleen. Emerging research highlights the therapeutic promise of fasting-mimicking diets (FMDs) in delaying cancer onset, providing cellular protection, and regulating immunity. Adoptive cell transfer (ACT) is a treatment approach that isolates and amplifies potent anti-tumor immune cells before re-infusing them into cancer patients for therapeutic purposes. My project investigates immune profiles resulting from FMD exposure, either independently or with therapeutic drugs, before and after ACT. It aims to elucidate the distinct roles of immune cell subsets and their impact on tumor advancement through promoting anti-tumor immunity.

Material and method

Using the 4T1 TNBC syngeneic model in BALB/c mice, the impact of FMD and drug treatments on tumor growth and immune competence is assessed. The project includes two rounds of 4T1 cell transplantation in hosts exposed to either a normal diet or FMD, with some groups receiving chemotherapeutic drugs. The first round focuses on the characterisation of favourable immune cell subsets recruited at tumor sites, spleens, and bone marrows using FACs and IHC. In the second round, infiltrated tumor masses and splenocytes are transplanted into recipient hosts with naïve 4T1 cells to assess tumor progression, immunity acquisition, and cytotoxicity.

Result and discussion

Preliminary data show reduced tumor volumes and delayed progression following exposure to FMD and doxorubicin, confirming synergistic effects. The combinatorial treatment also led to a reduction in splenomegaly while preserving the morphology and structure of a healthy spleen. Additionally, it induced phenotypic and functional changes regarding total and specific subpopulations of leukocytes in both, spleens and bone marrows, underlying the enrichment of immune signatures previously, associated with improved clinical prognosis. Thorough characterisation remains ongoing as we continue to define the most relevant immune cells in modulating anti-tumor responses in this setting, prior to the initiation of the transplantations.

Conclusion

Combining FMD with ACT may enhance anti-tumor immunity, improve treatment outcomes, and expand efficacy across cancer types. Exploring FMD mechanisms could uncover ways to stimulate beneficial immune cell patterns, opening new avenues in cancer treatment.

ROR1-Specific CART-Cells: Advancing Targeted Immunotherapy for Cancer

A. Tigu¹, D. Kegyes¹, R. Tomai¹, M. Nistor¹, D. Cenariu¹, R. Munteanu¹, R. Feder¹, M. Pavel-Tanasa², D. Gulei¹,

C. Tomuleasa¹

¹"Iuliu Hatieganu" University of Medicine and Pharmacy, 400349 Cluj-Napoca, Romania, Department of Personalized Medicine and Rare Diseases, MEDFUTURE—Institute for Biomedical Research, Cluj-Napoca, Romania

²Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania, Department of Immunology, Iasi, Romania

Introduction

The receptor tyrosine kinase-like orphan receptor 1 (ROR1) is critical during embryogenesis regulating cell migration, differentiation and growth. It is demonstrated that ROR1 expression is low in adult tissues, and unfortunately the expression increases in various malignancies such as Mantle Cell Lymphoma (MCL), Multiple Myeloma (MM), Triple Negative Breast Cancer (TNBC), Non-Small Cell Lung Carcinoma (NSCLC), colorectal cancer (CRC) or Melanoma (MEL), all being highly aggressive and their management is challenging. ROR1 targeted therapies are continuously developing, with remarkable achievements in terms of novel mAbs, ADCs or small molecules. Our study aims to highlight that the use of CAR T-cells could improve the outcomes and offer new perspectives by targeting ROR1.

Material and method

The full length of CAR was synthesized and subcloned into lentivirus vector by Creative Biolabs. The insert was confirmed by Sanger seq. The iCasp9-pMD2.G-psPAX2 virus was generated by transfecting HEK293FT packaging cells. The target pH-R-iCasp9 plasmid, the packaging vector, psPAX2 and the envelope, pMD2.G were acquired from AddGene. FuGENE® was used as transfection reagent. Lentiviral supernatants were harvested at 24h and 48h. CAR ROR1 Jurkat cells were spinoculated in 8 µg/mL polybrene and viral supernatant. On day 3 after transduction, fluorescence microscopy confirmed the presence of mCherry+ cells. CAR ROR1 Jurkat cells were expanded for 14 days, followed by mCherry/GFP-highly positive cells sorting, on a FACS ARIA III platform. The co-culture efficacy of different effector-target (E:T) ratios was evaluated by flow cytometry. Target cells were identified by staining with an APC anti-human ROR1 antibody. The supernatant was stored and further used for LDH titration by an ELISA assay.

Result and discussion

The presence of eGFP and mCherry red signal confirmed the successful generation of anti-ROR1 CAR T-cells. The analysis at different E:T ratios showed that the CAR T cells successfully inhibited the targets, with a significant cytokine release measured by ELISA assays, all tests being done in comparison with Mock - Jurkat cells. The highest inhibitory rate was observed in the MCL cell line, accompanied by a significantly higher cytokine release compared to the controls. As the CAR T-cells are immortalized due to the use of Jurkat cells, we evaluated the suicidal capacity using various concentrations of AP1903. AP1903 induced iCasp9 dimerization, and the flow cytometry analysis revealed that apoptosis was initiated in most of the CAR T-cells. Apoptotic rate was determined by a 7-AAD/PO-PRO1 flow cytometry assay on an LSRII cytometer. This remained evident at a very

low concentration (6.25 nM), which is still well below the clinical concentration for AP1903.

Conclusion

Anti-ROR1 CAR T-cells showed a significant inhibitory rate against multiple targets, indicating that the new approach could be considered for further in vivo evaluations.

Improved Adoptive T Cell Therapies for Colorectal Liver Metastases by Stabilization of IFNAR1 on Tumor-Specific T-Cells

A. Castiglioni¹, C. Giordano¹, G. Delfanti¹, I. Stefanetta¹, L. Ferreira¹, A. Monestiroli¹, L. Guidotti^{1,2}, G. Casorati¹, P. Dellabona¹, G. Siti¹

¹IRCCS San Raffaele Scientific Institute, Division of Immunology, Transplantation and Infectious Diseases, Milan, Italy

²Vita-Salute San Raffaele University,

Introduction

Diagnosis for Colorectal cancer (CRC) are surging, and distant metastases, particularly to the liver, plays a crucial role in determining poor prognosis, despite improvements in surgical, chemotherapeutic and targeted therapies. Adoptive T-cell therapies (ACT) show promise for cancer treatment but often struggle in solid tumors due to the immunosuppressive tumor microenvironment (TME) and one factor to this failure is the down-regulation of the type I Interferon receptor (IFNAR) on T cells, which abolished their ability to respond to anti-tumor immune signals. To overcome these limitations, we improved tumor-specific CD8+ T cells or CAR T cells by the stabilization of IFNAR1 on cell surface, through genetic and pharmacologic approaches, blocking its endocytosis, induced by tumor-released type I IFNs, thus avoiding cells exhaustion and death, and promoting regression of CRC liver metastasis.

Material and method

We dissected the TME of human CRC synchronous liver metastases ($n = 3$) with AKOYA spatial multiplex-immunofluorescence staining for IFNAR1 and immune cells markers. Then, with mouse established CRC cell lines we investigated the molecular mechanisms. MC38 cells have been chosen, also by RNASeq data, as model of high releasing type I IFNs, opposed to mouse established CRC-derived organoids MTO-140, which are low releasing. We utilized both in vitro differentiated OT-I and OT-I-SA CD8+ T cells for ACT targeting MC38OVA liver metastases, and Chimeric Antigen Receptor T cells (CAR-T) genetically engineered to express IFNAR1-SA and that recognize hCEA, and MC38hCEA as target.

Result and discussion

Here, we observed that IFNAR1 is downregulated in liver metastasis in a cohort of human CRC synchronous liver metastasis ($n = 250$) and this correlates with a high production of type I IFNs by the same tumors. Type I IFNs chronically released by tumor contribute to reducing the anti-tumor immune response exhibited by the sustained internalization of IFNAR1 on CD8+ T cell that cause their death, and a decreased frequency of intra-

tumor effector CD8+ T cells (Teff). Thus, exploiting advantage for genetics and pharmacological compounds to block receptor phosphorylation or internalization by endocytosis, we highlighted that the stabilization of IFNAR1 on CD8+ T cells, is necessary and sufficient to leverage tumor-released type I IFNs to control the growth of liver metastasis by preventing T cell death. Indeed, MC38-OVA-derived liver metastasis escape OT-IWT CD8+ T immune response and continued to grow, but not with the OT-ISA T cells that are highly infiltrated in TME and control tumor growth, and this occurs even with engineering CAR-T with both IFNAR1-SA and hCEA receptor.

Conclusion

Overall, these results indicate that genetic stabilization of IFNAR1 on ACT cellular products enhances their viability and persistence within CRC metastatic lesions, significantly improving the efficacy of ACT and hold promise for future development.

EACR25-0738

A Pro-Tumorigenic Cytokine with an Unexpected Anti-Cancer Role: TGF β Enhances NK cell Immunotherapy for pancreatic cancer

G. Valenzano¹, C. Ball², S. Russell¹, K. Jones³, E. O'Neill¹

¹University of Oxford, Oncology, Oxford, United Kingdom

²University of Oxford, Centre for Advanced Preclinical Imaging, Oxford, United Kingdom

³University of Oxford, Surgical Sciences, Oxford, United Kingdom

Introduction

TGF β has been recognised for decades as a driver of tumour progression and resistance to therapy. It induces exhaustion or inhibition in immune cells within the tumour microenvironment (TME), such as cytotoxic CD8+ T cells and NK cells, thus representing a major barrier to cancer immunotherapy. Recent studies have found tissue-resident NK cells (trNK) to be enriched in solid tumours, highlighting their anti-cancer potential. Specifically, TGF β in the TME promotes their anchoring by inducing CD103 expression. While these cells are positioned to attack tumours, their cytotoxicity is suppressed by the immunosuppressive TME. We hypothesised that combining TGF β exposure with cytokine stimulation could generate tissue-resident NK cells with preserved cytotoxic ability for solid cancer immunotherapy.

Material and method

PBMCs from healthy donors were expanded in vitro using IL-2, IL-15, and IL-21, with or without TGF β , to generate cytotoxic NK cells (cNK) or cytotoxic tissue-resident NK cells (c-trNK). Their phenotype was characterized using spectral flow cytometry, and their cytotoxicity was assessed against K562 leukemia and MiaPaCa2 pancreatic cancer cells. To evaluate their in vivo localization and tumor control, mCherry-expressing MiaPaCa2 cells were orthotopically injected into Rag2^{-/-} Il2rg^{-/-} mice, followed by intravenous NK cell

administration. NK cell distribution was tracked using IVIS fluorescence imaging.

Result and discussion

The optimised expansion protocol generated viable cells with minimal T cell contamination (CD56+CD3-fraction: 98.1 ± 1.1), critical for reducing the risk of GvHD in translational applications. The addition of TGF β was essential for the optimal expansion of NK cells expressing tissue residency markers, with over 90% of c-trNK cells expressing both CD49a and CD103. TGF β did not significantly alter the expression of most activating or inhibitory receptors but led to decreased CD16 expression, impairing c-trNK cells' ability to perform antibody-dependent cell cytotoxicity. Chemokine receptor expression varied, with TGF β promoting higher CXCR6 expression, a key factor for tumour site migration. At high effector-to-target ratios, TGF β did not significantly impair cytotoxicity, and c-trNK cells successfully eliminated K562 cells and nearly all MiaPaCa2 cells in vitro. In vivo, c-trNK cells mediated partial tumour control and were detected in high numbers in the livers, lungs and guts of tumour-bearing mice, suggesting successful migration to tumour and non-tumour epithelial sites. Interestingly, c-trNK were also detected in the blood and spleen.

Conclusion

These findings demonstrate that TGF β -exposed NK cells, when combined with cytokine stimulation, can generate tissue-resident NK cells with preserved cytotoxic function. This approach holds promise for enhancing the effectiveness of cancer immunotherapy, with potential for improved tumour control and tissue-specific dissemination.

⁹The University of Hong Kong-Shenzhen Hospital, Shenzhen, China

Introduction

Hepatocellular carcinoma (HCC) is the predominant form of primary liver cancer. It ranks the third leading cause of cancer-related death globally, with high incidence and mortality in Southeast Asia. Unfortunately, majority of HCC patients are diagnosed at intermediate to advanced stages when treatment options are limited and the chance of tumor recurrence is high. Our previous studies demonstrate that endogenous and circulating annexin A3 (ANXA3) promotes self-renewal, tumor growth, and resistance to standard chemotherapy and targeted therapy in HCC, thus potentially offering a new target for HCC treatment. The use of humanized antibodies is more clinically relevant than non-humanized counterparts because of their reduced risk of triggering immune responses in human patients. In the era of precision medicine, there is a growing emphasis on tailor-made treatment considers personal genetic differences or environmental conditions. With advances in technology enabling the rapid detection of ANXA3 expression in an individual, the potential use of a humanized anti-ANXA3 antibody alone or in combination with other approved therapeutics represents a meaningful step forward to improving therapeutic outcomes of HCC patients with ANXA3 upregulation.

Material and method

Herein, a humanized anti-ANXA3 monoclonal antibody was developed and extensively characterized for its therapeutic efficacy utilizing both *in vitro* and *in vivo* HCC models.

Result and discussion

In vitro, our humanized anti-ANXA3 mAb in combination use with standard chemotherapy cisplatin or targeted therapy sorafenib or lenvatinib demonstrated synergistic effects in suppressing cell proliferation, inducing apoptosis, reducing tumor-initiating cell frequency, and re-sensitizing therapy-resistant cells to their respective treatments. *In vivo*, the combinational treatments similarly showed maximal tumor shrinkage, tumor-initiating frequency reduction, and therapy-resistant tumor re-sensitizing effects. Importantly, the humanized anti-ANXA3 mAb administration did not elicit any toxicity on a humanized peripheral blood lymphocyte (Hu-PBL) mouse model with respect to animal body weight and tissue weight changes and plasma biochemistry panel readouts. Animal behavioural tests also showed no significant difference in animal muscle strength, locomotor ability, and anxiety level.

Conclusion

Findings of this study also explored the potential of expanding the use of the humanized anti-ANXA3 mAb to multiple malignancies with ANXA3 overexpression.

Next Generation Protein Characterization of CD19-CAR Signaling Cascades

F. Ramirez¹, W. Higgs², D. Smedley³, C. Haitjema¹, A. Singh⁴, D. Hermanson³, C. Heger¹

¹Bio-Techne, San Jose, United States

²Bio-Techne, Abingdon, United Kingdom

³Bio-Techne, Minneapolis, United States

⁴Cell Signalling Technology, Denver, United States

Introduction

Chimeric antigen receptor (CAR)-T cell therapy is a revolutionary new pillar in cancer treatment with success in treating specific subsets of B cell leukemia, lymphoma, and multiple myeloma.¹ Much attention is focused on expanding CAR-T cell therapy to other hematologic malignancies and solid tumors. Central to engineering effective CAR-T cell therapies is a detailed understanding of the signaling cascades that regulate CAR-T cells, including trafficking and tumor infiltration, preventing antigen escape, resisting immunosuppressive responses, and ameliorating potentially fatal toxicity.¹ Detailed characterization of extracellular and intracellular signaling molecules is required, often with limited and complex sample types.

Material and method

To study CAR-T signaling, we leveraged a non-viral gene editing platform (TcBuster) to introduce a CD19-CAR into T-cells. Chemically selected cells were isolated and CAR surface expression was verified by flow cytometry analysis using an antibody raised against the peptide linker within the CAR scFv. We then stimulated the CAR-T cells with immobilized CD19 and implemented automated solutions to characterize IFN- γ secretion using automated ELISA (Simple Plex) and intracellular signaling events using a capillary immunoassay platform (Simple Western). The capillary immunoassay provided multiplex protein expression measurements of multiple signaling molecules, including phosphorylated and total protein isoforms, with specific molecular weight characterization, and required only 3 μ L of lysate for analysis.

Result and discussion

Here, we leveraged non-viral genome editing and advanced protein analytical solutions to shine new light on CAR-T cell activation, CAR trafficking, and signal transduction. We validated an antibody targeting the Whitlow/218 linker (CST) using Simple Western technology, enabling the measurement of CAR expression in whole-CAR-T cell lysates in addition to flow cytometry. The flow cytometry and Simple Western results showed that CAR-T cells downregulate CAR expression in less than 10 minutes following antigen engagement. However, CAR presence at the cell surface may linger for 15 minutes or longer. Furthermore, the Simple Western results indicate CAR expression increases again at 4 hours, suggesting a ‘recycling’ of the CAR in T cells. Simple Western analysis revealed detailed kinetics of intracellular CAR-T cell signaling events with reproducible quantification for both CAR expression and intracellular signaling molecules. Finally, the Simple Plex assay provided quantitative results of 4 secreted cytokine concentrations ranging in ng/mL levels at 4 hours post-activation in a single hands-free run in less than 90 minutes.

Conclusion

Together, these data show the importance of Fit-For-Purpose Analytical Tools to enable the measurement and understanding of the delicate interplay between signaling molecules that regulate CAR-T function.

EACR25-0955

The effect of STING agonist on lung metastases and immune landscape in murine model of spontaneous breast cancer metastasis

A. Drzyzga¹, J. Czapla¹, T. Cichon¹, E. Pilny¹, M. Jarosz-Biejska¹, J. Cieplak¹, S. Matuszczak¹, R. Smolarczyk¹

¹Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice Branch, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland

Introduction

Immunotherapy emerged as the most promising tool in cancer treatment. Among its modalities the activation of the cGAS-STING pathway, which boosts anti-tumor immune response, is considered as encouraging therapeutic approach. STING activation enables production of type I interferons and pro-inflammatory cytokines leading to the activation of multiple immune cells. The process of metastasis represents one of the hallmarks of cancer. The appearance of metastases constitutes the major poor prognosis factor which limits the possibilities and opportunities of cancer therapies and is responsible for the greatest number of cancer-related deaths. Thus, the aim of current research was to assess the impact of STING agonist administration on the number and size of lung metastases and immune landscape in murine model of spontaneous breast cancer metastasis.

Material and method

The experiments were conducted on murine model of 4T1 breast cancer. cGAMP was injected intratumorally in a dose of 5 µg/mice. To estimate cGAMP-induced oxidative burst, the assessment of luminol chemiluminescence have been conducted. In the metastasis assessment experiments four days post cGAMP administration mice were deeply anaesthetized and the primary tumors were surgically excised. After next 16 days lung metastases were visualized by intratracheal injection of 15% India Ink solution. To assess STING agonist-induced reprogramming of lung immune cells, twelve hours post cGAMP administration lungs were collected and digested. The isolated cells were stained with antibodies against: neutrophils, monocytes macrophages, NK cells, T lymphocytes. The analyzes were performed with flow cytometry, gates dividing negative from positive cells were based on fluorescence minus one (FMO) control.

Result and discussion

Intratumoral administration of STING agonist resulted in the appearance of luminescence signal around the tumors twelve hours post treatment. Both cGAMP-treated and control mice exhibited luminescence signal in the area of lungs. Local - intratumor administration of STING agonist decreased the number and size of spontaneous 4T1 lung metastases. STING agonist induced decreased in the number of lung neutrophils with simultaneous switch of their phenotype toward anti-tumor one.

Increase of pro-inflammatory monocytes (CD11b+ Ly6Chi) and polarization of pro-tumor (MHC-II- CD206+; CD86+CD206-) macrophages toward anti-

tumor one (MHC-II+CD206-; CD86+CD206-) was noted. STING agonist increased infiltration and activation of NK cells (CD49b+NKP46+; CD49b+ CD69+) and decreased anergic (CD8+PD-1+; CD8+ CD69-) T lymphocytes number.

Conclusion

Local treatment with STING agonist induces systemic immune response, enabling reprogramming of lung immune cells phenotype that leads to decrease of metastasis spread in murine breast carcinoma model.

The work is a result of the research project no. UMO-2019/35/N/NZ5/02506, financed by National Science Centre

Tumor-infiltrating immune cell types predicting recurrence-free survival in melanoma patients receiving adjuvant PD-1 inhibitor therapy

A. Ladányi^{1,2}, B. Hegyi^{3,2}, T. Balatoni^{4,2}

¹National Institute of Oncology, Department of Surgical and Molecular Pathology, Budapest, Hungary

²National Institute of Oncology, National Tumor Biology Laboratory, Budapest, Hungary

³National Institute of Oncology, Department of Chest and Abdominal Tumors and Clinical Pharmacology, Budapest, Hungary

⁴National Institute of Oncology, Department of Oncodermatology, Budapest, Hungary

Introduction

Adjuvant treatment of melanoma patients with PD-1-based immunotherapy has improved recurrence rate, and became a standard treatment. However, a considerable proportion of patients still recur within 1-2 years, necessitating the identification of predictive markers. Our study aimed to examine the association of intratumoral infiltration by specific immune cell subsets with the recurrence-free survival of melanoma patients receiving adjuvant PD-1 inhibitor therapy.

Material and method

Archived paraffin blocks of pretreatment surgical samples (71 lymph node and 12 skin/subcutaneous metastases) from melanoma patients receiving adjuvant PD-1 inhibitor therapy at the National Institute of Oncology between 2019 and 2024 (nivolumab n = 20, pembrolizumab n = 28) were selected. The intratumoral density of immune cells expressing the following markers: CD8, FOXP3, CD20, CD103, OX40, PD-1, and PD-L1 were determined by immunohistochemistry, and the associations with recurrence-free survival were analyzed. The follow-up time was median 46 months (14–72). The Fisher's exact test was used for statistical analysis comparing the proportions of cases in different groups, and Kaplan-Meier analysis with log-rank test for calculating survival differences.

Result and discussion

Eighteen of the 48 patients developed recurrence during the follow-up period. In this group the ratio of patients showing strong immune cell infiltration was significantly lower compared to recurrence-free patients in the case of CD8+ T cells (2/18 vs. 16/30, p = 0.0050), CD103+ tissue resident T cells (2/18 vs. 13/30, p = 0.0259), and the activation/checkpoint markers OX40 (4/17

vs. 19/30, p = 0.0145) and PD-1 (2/18 vs. 14/30, p = 0.0134). High intratumoral density of the above cell types was accompanied with significantly longer recurrence-free survival.

Conclusion

Our findings indicate the importance of immune cell infiltration in the efficacy of adjuvant PD-1 inhibitor treatment in a “real world” patient cohort.

The work was supported by the National Research, Development and Innovation Office, National Laboratories Program (project: National Tumor Biology Laboratory, 2022-2.1.1-NL-2022-00010).

Pioneer Platform: A Novel Biotherapeutic Antibody Discovery Platform

P. Genevini¹, J. Cardone²

¹*Bio-Rad, Custom Antibodies, Neuried, Germany*

²*Bio-Rad, Custom Antibodies, Kidlington, United Kingdom*

Introduction

The Pioneer™ Antibody Discovery Platform by Bio-Rad is designed for biotherapeutic lead generation. Central to this platform is the Pioneer Antibody Library, which has 2.25×10^{11} unique antibodies and is optimized for therapeutic candidate selection. The platform uses SpyDisplay, a novel selection system based on SpyTag technology, enabling rapid selection of high-affinity antibodies. These candidates can be integrated with Bio-Rad’s TrailBlazer™ modular antibody assembly platform for versatile screening. This poster presents data on antibody selection against several antigens, showing the platform’s capability to deliver diverse, high-affinity leads. Using anti-TIGIT antibodies as an example, the performance is comparable to clinical trial antibodies.

Material and method

Library Design: The Pioneer Antibody Library comprises 2.25×10^{11} unique antibodies, with 96% functionality confirmed by next-generation sequencing (NGS).

Selection Technology: The SpyDisplay system uses a SpyTag/SpyCatcher technology to display Fab fragments on *E. coli*, enabling a rapid one-day panning protocol without subcloning. **Screening and Characterization:** After phage selections, unique antibodies were expressed and purified in Fab format. Monovalent binding affinities were determined using bio-layer interferometry (BLI). Functional assays, including the TIGIT/CD155 blockade bioassay, evaluated antibody efficacy

Result and discussion

Library Quality: The Pioneer Library showed high sequence diversity and quality, with reduced post-translational modification sites in CDRs. The design focused on germlines with favorable properties, increasing the probability of selecting useful hits.

Selection Efficiency: The SpyDisplay system was efficient, yielding high-affinity antibodies. The absence of a Fab-pIII fusion resulted in correctly folded and displayed Fabs. **Anti-TIGIT Antibody Selection:** The platform selected high-affinity, potent antibodies against TIGIT. Of the identified antibodies, 25% had affinities below 1 nM. The selected antibodies exhibited high diversity and covered nine distinct epitope bins.

Functional Assays: The anti-TIGIT antibodies showed comparable or superior performance to benchmark

antibodies in a TIGIT/CD155 blockade bioassay. They demonstrated good developability parameters, including stability and low polyreactivity.

Conclusion

In summary, the Pioneer Antibody Discovery Platform, with its large and diverse library, efficient selection technology, and robust screening capabilities, is a powerful tool for generating high-affinity therapeutic antibodies. The platform’s ability to deliver lead candidates comparable to clinical-stage antibodies highlights its potential in biotherapeutic development.

EACR25-1026

Novel Harnessing of Innate and Adaptive Anti-Cancer Immunity: NLRP3-Inflammasome Activation Facilitates Immune Checkpoint Blockade in the Treatment of Mesenchymal Stage IV Colorectal Cancer

L. Klimpe¹, E. Neuwirt², R. Kesselring¹, O. Groß², C. Berlin¹

¹*University Freiburg, General and Visceral Surgery, Freiburg, Germany*

²*University Freiburg, Neuropathology, Freiburg, Germany*

Introduction

The role of the NLRP3 inflammasome in colorectal cancer (CRC) progression remains unclear (1). While some studies link high NLRP3 activity to cancer progression, others suggest protective roles, depending on the clinical context (2–4). Clinical trials mainly focus on inhibition of NLRP3 activity (5). This highlights the urgent medical need for the evaluation and development of targeted NLRP3-activating therapies in tumors where activation could provide therapeutic benefit. Hence, we evaluated the effect of NLRP3 activation in the treatment of mesenchymal stage IV CRC in an organoid-based metastatic CRC mouse model *in vivo* and in organoid-immune-cell-cocultures *in vitro*.

Material and method

In vitro experiments involved coculturing of peritoneal mouse immune cells with murine CRC organoids.

Within, NLRP3 inflammasome activation was induced using EMT-244, a novel and potent NLRP3 activator. Results were validated utilizing immune cells from mice harboring a CRE-inducible active NLRP3 mutant.

Therapeutic effects on the coculture were quantified using viability assays. **In vivo**, we employed an orthotopic, organoid-driven mesenchymal stage IV CRC mouse model, which mimics an aggressive and treatment-resistant human CRC subtype (6). To evaluate the impact of EMT-244 in combination with immune checkpoint blockade (ICB: anti-PD-1 antibody) on the metastatic process, tumor samples were analyzed using macroscopic and microscopic approaches, including Ki67 staining to assess proliferation and TUNEL staining to detect apoptosis.

Result and discussion

In vitro, we demonstrated an EMT-244-dependent reduction of CRC organoid viability during coculture with peritoneal murine immune cells ($p = 0.0498$). Importantly, this effect was not abundant when treating

CRC organoids alone, highlighting the necessity of an immunological tumor microenvironment. We identified a concomitant upregulation of pro-apoptosis-related proteins, e.g. ‘cleaved Caspase-8 and -3’ in respective coculture. In vivo experiments using our organoid-driven stage IV CRC mouse model revealed that EMT-244, in combination with ICB, significantly reduced liver and even more drastically peritoneal metastatic burden compared to ICB monotherapy ($p = 0.0114$ and $p = 0.0026$), which was also confirmed on histological level ($p = 0.0006$). Furthermore, liver metastases exhibited a significant decrease in Ki67 positivity ($p = 0.0157$) and an increase in TUNEL positivity ($p = 0.0388$) in the EMT-244 + ICB group, indicating reduced proliferation and increased apoptosis.

Conclusion

NLRP3 inflammasome activation by EMT-244 facilitates ICB in mesenchymal stage IV CRC, presenting a promising new treatment approach, particularly as a first-line immunotherapy for metastases. This study highlights the critical need for a paradigm shift towards investigating NLRP3 inflammasome-activating therapies in the context of CRC disease progression.

⁵Technical University of Munich, School of Medicine and Health, Institute for Medical Microbiology, Immunology and Hygiene, Munich, Germany

⁶Malteser Krankenhaus St. Franziskus-Hospital, 1st Medical Department, Flensburg, Germany

Introduction

Multiple myeloma (MM) is a clonal plasma cell malignancy characterised by abnormal production of monoclonal proteins (M proteins). It accounts for approximately 10% of all haematological malignancies and remains incurable despite therapeutic advances. Immunotherapeutic strategies, including chimeric antigen receptor (CAR) T-cell therapy, monoclonal antibodies, antibody-drug conjugates and bispecific antibodies, have demonstrated the potential to harness the immune system to target MM cells. Adoptive T-cell receptor (TCR)-T cell therapy, which targets tumour-specific neoantigens presented via the human leukocyte antigen (HLA) complex, is not limited to extracellular proteins, thereby broadening the spectrum of targetable antigens. Early

studies show promising results and a favourable safety profile.

Material and method

We used an immunopeptidomics approach to identify neoantigens in MM. Whole exome sequencing (WES) and RNA sequencing (RNAseq) of MM cell lines, primary MM tissue from osteolytic lesions and autologous PBMCs (as healthy controls) were combined with immunoprecipitation of HLA peptide complexes (pHLA) and liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis of myeloma samples. Candidate neoantigens (NeoAgs) were rigorously validated based on MS spectra and a database search was performed to exclude single nucleotide polymorphisms (SNPs) and canonical RNA editing events. To assess immuno-genicity, HLA-matched allogeneic and autologous PBMCs were stimulated in an accelerated co-cultured dendritic cell (acDC) assay followed by IFN γ ELISpot readout. Neoantigen-specific TCRs were analyzed by comparing the clonal frequencies of unstimulated and stimulated cells using single-cell RNA sequencing (scRNAseq).

Result and discussion

A total of twelve neoantigens were identified in three MM cell lines and seven in eight primary tumour samples. In MM cell lines, neoantigens were derived equally from DNA and RNA variants, whereas in primary tumour tissue, most were derived from RNA variants. Four neoantigens from MM cell lines showed immunogenicity. Three were derived from somatic mutations in PRPF8, FBXL6 and IQGAP2, while the fourth immunogenic candidate arose from an RNA variant in an IgV pseudogene. One neoantigen from MM cell lines and three from primary tumour tissue were used in an scRNAseq approach to identify neoantigen-specific TCRs. The 20 clones with the highest fold change in clonal frequency are currently being tested for reactivity.

Conclusion

Mass spectrometry-based immunopeptidomics allows the identification of neoantigens in multiple myeloma with potential for personalised TCR-based therapies. However, given the low mutational burden of MM, direct neoantigen identification remains challenging, highlighting the need to enhance MS sensitivity for improved detection.

Bridging the Gap Between In Vitro and In Vivo: STC-1010 Cancer Vaccine Efficacy in 3D Tumor Spheroids

M. Zbinden¹, I. Richert², T. Gamma¹, M. Rudnik¹, L. Chalus², B. Pinteur², I. Agarkova¹, P. Bravetti², L. Ligeon¹, G. Alzeeb²

¹Insphero, Schlieren, Switzerland

²Brenus Pharma, Lyon, France

Introduction

Immunotherapy has revolutionized cancer treatment, but low-immunogenicity tumors often escape immune detection. To address this challenge, Brenus Pharma developed the Stimulated Ghost Cells (SGC) platform, an allogeneic cancer vaccine technology that enhances immunogenicity by expanding antigen coverage. It

overcomes also previous cancer vaccines challenges thanks to a standardized manufacturing process increasing access for patient. Here, we present STC-1010, a therapeutic colorectal cancer (CRC) vaccine, developed by exposing HCT116, HT-29, and LoVo cell lines to stress conditions – serum deprivation, irradiation, heat shock, and chemotherapy – mimicking standard CRC treatments and relapse conditions. The cells were then haptenated to boost immune response induction.

Material and method

Initial validation in a 2D ex vivo model demonstrated STC-1010's anti-tumor efficacy: Functional validation via ex vivo immune activation assays using monocyte-derived dendritic cells (mDCs) from several donors demonstrated STC-1010's immunostimulatory capacity.

Result and discussion

Vaccine-exposed mDCs showed increased IL-8 secretion, enhanced antigen processing and presentation, and activation of IL-6/JAK/STAT3 and phagosome pathways, confirmed by GSVA using KEGG/Hallmark databases. STC-1010 successfully primed mDCs, with haptenated epitopes detected. Primed CD8+ T cells induced higher apoptosis in HCT116, HT-29, and SW620 cells compared to controls. However, conventional 2D models inadequately replicate tumor complexity, contributing to high failure rates in clinical translation. To better mimic the in vivo tumor microenvironment, we developed 3D CRC spheroids by co-aggregating HCT116, HT29, SW620, and LoVo cells with colorectal fibroblasts (CCD-18Co). Tumor cells were fluorescently labeled to monitor viability in co-culture with stromal and immune cells. Spheroids were characterized by bright-field microscopy, fluorescence analysis, and histology. Quality control (QC) and release criteria were established, including tumor size evaluation and chemotherapy response. Additionally, the 3D CRC spheroid models were co-cultured with T-cells, and their activation was assessed by monitoring tumor killing and cytokine secretion. Furthermore, we developed a process to enable preservation of the 3D spheroids – an essential step toward generating off-the-shelf preserved spheroid panels for STC-1010 potency testing.

Conclusion

This innovation overcomes ethical, financial, and time limitations of in vivo models while preserving key tumor resistance mechanisms. Our results support STC-1010 as a promising immunotherapy and demonstrate the value of 3D spheroids as reliable preclinical tools for evaluating new treatments. Overall, this work enhances strategies to overcome immunotherapy resistance and accelerates translational research with scalable, physiologically relevant models.

³Allogenica, Lyon, France

Introduction

Recently, immunotherapy has rapidly become the "fifth pillar" of cancer treatment, along with surgery, radiotherapy, chemotherapy, and other targeted treatments. Various categories of immuno-oncology (IO) treatments have been developed, including monoclonal antibodies, Antibody Drug Conjugates (ADCs), Immune Checkpoint Inhibitors (ICIs), vaccines, adoptive cell therapies, immune system modulators. During pre-clinical phase, rodents still represent the most commonly used in vivo model. However, these models have several drawbacks, such as the immunodeficiency of humanized models, ethical constraints, time requirements and a high cost. Therefore, an alternative, pertinent, 3Rs-compliant in vivo model is strongly needed for accelerating cancer immunotherapy research. In this work, the chicken ChorioAllantoic Membrane (CAM) assay is used to investigate different types of IO treatments.

Material and method

On embryonic development day (EDD) 9, different human tumor cell lines are grafted on the upper CAM. A treatment with different immunotherapy reagents is performed between EDD10 and EDD18: monoclonal Abs (bevacizumab, trastuzumab, rituximab) in 4 doses; ADC (trastuzumab emtansine) in 1 dose; ICIs (pembrolizumab, nivolumab, atezolizumab, avelumab) in 5 doses; tumor cell based vaccine (STC1010) in 3 doses; CAR-T cells & CAR-NK cells in 1 dose. IO reagents are evaluated in monotherapy or in combination with other drugs. The in ovo part ends at EDD18. Anti-cancer efficacy is evaluated on tumor growth through tumor mass weight, on metastatic invasion through Alu sequence detection in the lower CAM based on the qPCR, on angiogenesis development by counting the vessels surrounding the tumor, on immune response activation through tumor infiltrating immune biomarker quantification based on the RT-qPCR.

Result and discussion

The efficacy of different IO reagents is revealed in ovo: all treatments lead to a significant tumor growth regression (24.79%-49.53%), on different tumor models. Additional analyses show more conclusive evidence, including metastasis regression, the inhibition of angiogenesis development, as well as immune activation and immune cell infiltration in the tumor. Furthermore, the combination regimens show increased anti-tumoral potential when compared to the monotherapy.

Conclusion

Our work demonstrates that the CAM assay is suitable for testing different IO anticancer treatments. The presence of an active immune system allows a suitable characterization of the effects of immunotherapy reagents on tumor cells, the microenvironment, and the entire organism. As one part of New Approach Methodologies (NAMs), the CAM assay provides a relevant alternative, 3Rs-compliant, in vivo model for testing novel immunotherapies on a large spectrum of cancer types, as a monotherapy or as an in combination approach.

⁴*Annunziata Hospital, Pathology Unit, Cosenza, Italy*

⁵*IRIB-CNR, DMSC, Catanzaro, Italy*

⁶*University Magna Graecia- UNICZ, DSS, Catanzaro, Italy*

Introduction

Malignant Melanoma (MM) is an aggressive disease of melanocytes, characterized by high metastatic potential and mortality rate. Although recent immunotherapies and targeted agents have improved outcome, there remains a pressing need for additional therapeutic strategies. Bispecific T-cell Engagers (BTCEs) have recently emerged as a promising approach to harness the immune system by directing T cells specifically against tumor cells, gaining increasing relevance in the evolving therapeutic landscape. UMG1 is a unique epitope of CD43 that differs from the molecule's canonical expression profile. While CD43 is broadly expressed across many cell types, thus limiting its suitability for targeted interventions, the UMG1 epitope is notably restricted to cortical thymocytes and a small subset of peripheral T lymphocytes, becoming prominent only when CD43 is aberrantly expressed in malignancies. This distinctive pattern makes UMG1 an appealing immuno-therapeutic target. Previous studies have demonstrated potent antitumor activity of UMG1/CD3ε-BTCE in hematologic malignancies, prompting further investigation of UMG1 as a tumor-specific target in MM.

Material and method

UMG1 reactivity was assessed by immunohistochemistry on Tissue Microarrays (TMAs) and pathology slides from MM specimens. Immunofluorescence was performed on primary and metastatic MM cell lines to confirm UMG1 expression. UMG1-positive MM cells were co-cultured with healthy donor-derived Peripheral Blood Mononuclear Cells (PBMCs) in the presence of escalating concentrations of UMG1/CD3ε-BTCE for 72 hours. Cytotoxicity was measured via tumor cell viability, and T-cell activation was evaluated using markers CD69, CD25, and CD107a.

Result and discussion

Approximately 50% of MM samples showed variable membrane staining for UMG1, while normal skin tissues were negative. Immunofluorescence confirmed these findings in both primary and metastatic MM cell lines, underscoring UMG1's role as a MM-specific marker. UMG1/CD3ε-BTCE induced a robust, dose-dependent T cell-mediated cytotoxic response against UMG1-positive MM cells. This response occurred together with significant upregulation of CD69 and CD25, and enhanced CD107a expression on CD8+ T cells, reflecting effective T-cell activation and degranulation. These results indicate that targeting the UMG1 epitope effectively engages T cells to eliminate MM cells.

Conclusion

UMG1 is a novel promising therapeutic target in MM due to its distinct, tumor-specific expression. UMG1/CD3ε-BTCE elicits potent T cell responses and significant cytotoxicity, offering a novel immunotherapy approach. These findings support *in vivo* investigations to validate the translational potential of UMG1-targeted therapy against MM.

²*University of Turin, Department of Oncology, Orbassano, Italy*

³*CNR Institute for Biomedical Technologies, Bari, Italy*

⁴*Boston Children's Hospital, Harvard Medical School, Department of Pathology, Boston, United States*

⁵*European Institute of Oncology IRCCS, Division of Haematopathology, Milan, Italy*

Introduction

Small cell lung cancer (SCLC), representing 15% of all lung cancers, is an aggressive and highly metastatic neuroendocrine carcinoma of the lung with an extremely poor prognosis. SCLC is classified into four molecular subtypes based on the expression of key transcriptional factors, with ASCL1 or NEUROD1 subgroups accounting for the vast majority of cases. Nevertheless, SCLC biology remains largely unexplored, highlighting the urgent need for preclinical studies to investigate more effective therapeutic strategies. Anaplastic lymphoma kinase (ALK) is a receptor tyrosine kinase expressed in specific regions of the nervous systems. Given the neuroendocrine nature of SCLC, we evaluated ALK expression in a subset of SCLC cell lines.

Material and method

Correlation studies between ALK and NEUROD1 expression were conducted *in silico* using the SCLC CellMiner Cross Database. ALK, NEUROD1 and ASCL1 expression were evaluated by Western blot, while ALK extracellular expression was confirmed by flow cytometry. NEUROD1 knock-out was performed by CRISPR-Cas9 genome editing. Human ALK.CAR-T cells were generated using CD3+ cells from healthy donors. Luciferase-GFP-expressing (Luc-GFP) COR-L279 and H82 ALK+ SCLC cell lines were exposed to hALK.CAR-T and killing activity was measured by luciferin addition 72h post-coculture. INFγ, TNFα, Perforin and Granzyme B levels were assessed by intracellular flow cytometry.

Result and discussion

Bioinformatic analysis revealed an overall positive correlation between NEUROD1 and ALK expression in SCLC cell lines, which we verified *in vitro* in NEUROD1+ SCLC cells by Western Blot. Upon NEUROD1 knock out, ALK expression was lost both at the transcriptional and protein level. Remarkably,

NEUROD1 knock out in SCLC cells was also associated with the downregulation of neuroendocrine differentiation markers such as Synaptophysin and Chromogranin A, along with the upregulation of the epithelial marker E-cadherin, indicating a transcriptional rewiring towards a more epithelial phenotype.

Susceptibility of COR-L279 and H82 ALK⁺ SCLC cells to hALK.CAR-T cells was then evaluated. Both cell lines were significantly and specifically killed in vitro by hALK.CAR-T cells in a dose-response manner. Large amounts of Perforin, Granzyme B, and pro-inflammatory cytokines (i.e., IFNg and TNFa) were released when hALK.CAR-T cells were challenged with ALK⁺ tumor cells. In vivo studies to confirm these findings are currently ongoing and will be presented at the meeting.

Conclusion

Although further investigation and clinical validation of ALK-targeted immunotherapy are required, targeting ALK with CAR-T cells could represent a promising strategy to overcome current treatment limitations and improve patient outcome in a subset of ALK⁺ SCLC.

EACR25-1143

Understanding bystander killing by bispecific monoclonal antibodies

M. Ke¹, C. Belinchón Moreno¹, N. Alrishedan¹, W. Bodmer¹

¹*University of Oxford, Department of Oncology, Oxford, United Kingdom*

Introduction

Bispecific T cell engaging monoclonal antibodies (BiMAbs) provide an exciting immunotherapy option as they simultaneously bind an antigen on tumour cells and a surface molecule on T cells drawing the T cells to the tumour to induce antibody mediated tumour lysis (Labrijn et al. 2019). This is, so far, the only antibody based immunotherapy that can kill bystander target negative cells (Bodmer and Golubovskaya 2023). This is highly advantageous for successful treatment since cancer is generally heterogeneous with respect to expression of potential targets for immune attack.

BiMAbs can trigger bystander killing by T cells that have been activated by killing target-positive cancer cells and then killing target-negative cancer cells in their vicinity (Ross et al. 2017). However, much is still unknown about the mechanism of action as to how the activated T-cells kill surrounding target negative cancer cells (Meier et al. 2022). This project aims to study the basic biology of bystander effects by different populations of T-cells.

Material and method

By treating cells from a panel of colorectal cancer derived cell lines with BiMAbs and peripheral blood mononuclear cells (PBMCs), we investigated targeted immune responses against target-positive cells. Target-positive cell lines were treated with BiMAbs and PBMCs. Following treatment, activated CD4⁺ and CD8⁺ T cells were sorted to evaluate their cytotoxic roles. A variety of viability assays, including the M30 CytoDeath™ ELISA kit, were used to quantify apoptosis while the xCELLigence Real-Time Cell Analysis provided a direct quantitative readout of cell killing.

Result and discussion

Our data suggests that PBMCs activated by BiMAbs though attaching them to appropriately targeted cancer cells, mediate bystander killing by killing non-target cancer cells through binding to ICAM-1 and other possible non-specific receptors. The expression of these non-specific receptors is induced in the cancer cells by cytokines released by the T cell activation. Preliminary data has shown that, for example, ICAM-1 blockade partially inhibited activated T cell killing of cells negative for the BiMAb target, suggesting that the activated T cell attack of ICAM-1 is contributing to bystander killing.

Conclusion

These findings highlight the potential of bystander killing by BiMAbs of target negative cancer cells and provide insights for optimizing BiMAb-based anti-cancer immunotherapies.

EACR25-1156

Redirecting cytomegalovirus immunity against pancreas cancer for immunotherapy

R. Marrocco¹, J. Patel², R. Medari², P. Salu², S. Brunel¹, A. Martsinkovskiy², K. Gulay², A. Lowy², C. Benedict¹, T. Hurtado de Mendoza²

¹*La Jolla Institute for Immunology, Center for Vaccine Innovation and Center for Autoimmunity and Inflammation, San Diego, United States*

²*University of California San Diego, Surgery, San Diego, United States*

Introduction

Immunotherapy has had limited success in pancreatic cancer, largely due to a low mutational burden and immunosuppressive microenvironment. Here we hypothesized that pre-existing antiviral immunity could be redirected to control pancreatic cancer growth. Cytomegalovirus (CMV, a β-herpesvirus) was chosen, as the majority of the population has been previously infected and it induces an extremely large/broad memory T cell response.

Material and method

Mice latently infected with murine CMV (MCMV) were orthotopically implanted with pancreatic cancer cells and treated with systemic injections of MCMV T-cell epitopes.

Result and discussion

The therapy promoted preferential accumulation of MCMV-specific T cells within pancreatic cancer, delaying tumor growth and increasing survival. Immuno-phenotyping and scRNAseq analyses showed these T cells were highly activated and cytotoxic, leading to increased tumor necrosis and caspase-3 activation.

Finally, therapy was enhanced when combined with low dose gemcitabine chemotherapy. Together, these results show that CMV-specific T cells can be repurposed to combat pancreatic cancer.

Conclusion

Our studies reveal that CMV immunity can be re-directed to control a solid tumor normally refractory to immunotherapy via intravenous injection of viral epitopes. This mutation agnostic approach has significant potential for development of “off-the-shelf” therapeutics by

stimulating pre-existing antiviral T cells and is widely applicable due to high prevalence of CMV immunity.

EACR25-1196

Comparative analysis of neoadjuvant PD1+Lenvatinib versus PD1 alone in the tumour immune microenvironment of melanoma: Correlation of immune profiling with pathological response.

J. Conway¹, J. Braden¹, J. Beckwith¹, L. Smith¹, A. Ramanathan¹, M. Carlino², R. Scolyer¹, A. Menzies¹, G. Long¹, I. Pires Da Silva¹

¹*Melanoma Institute Australia, Sydney, Australia*

²*Crown Princess Mary Cancer Centre, Westmead and Blacktown Hospitals, Sydney, Australia*

Introduction

Neoadjuvant immunotherapy (NeoIT) has emerged as a transformative approach for resectable stage III melanoma, with a major pathological response (MPR) being a strong predictor of recurrence-free survival. However, the impact of different PD-1 based regimens on the tumour microenvironment (TME), and their association with response, remains unclear. This study examines the immune profiles in the TME from patients (pts) receiving neoadjuvant anti-PD1 alone (PD1 alone) versus PD1+Lenvatinib (NeoIT-L), to identify treatment specific features associated with pathological response.

Material and method

Stage III melanoma pts treated with 6 weeks of NeoIT-L (NCT04207086) or PD1 alone (NCT02858921) were included. Multiplex immunohistochemistry (mIHC) and RNA sequencing (RNAseq) analysis were performed on tumour samples collected at baseline (BL) and at week 6 (wk6) post treatment.

Result and discussion

Of 40 pts included, 19 had PD1 alone (7 [37%] had MPR ($\leq 10\%$ viable tumour cells at wk6) and 21 had NeoIT-L (12 [57%] had MPR). As previously reported by our group, mIHC analysis confirmed that in NeoIT-L MPR pts, mature follicular B cells (CD21+CXCR5+ B cells) ($p = 0.03$) and lymphoid aggregates ($p = 0.02$) significantly increase from BL to wk6. These changes were not observed in non-MPR pts. In contrast, no significant changes, in these cell types, were detected in mIHC, from BL to wk6, in pts treated with PD1 alone irrespective of response. When analysing gene signatures, NeoIT-L induced a significant upregulation of B-cell receptor (BCR) and T-cell receptor (TCR) signalling along with downregulation of cell cycle pathways, including the G2M checkpoint ($p < 0.05$), in MPR pts, but not in non-MPR. PD1 alone led to an upregulation of antigen processing, chemokine and cytokine signalling, including IFN- γ and TNF- α pathways ($p < 0.05$), in MPR pts, but not in non-MPR. When analysing 897 genes that were commonly upregulated from BL to wk6 in MPR pts from both treatment groups, we found these were specifically enriched for chemokine signalling pathways ($p < 0.001$). When the unique differentially expressed genes were directly compared between treatments, NeoIT-L specifically promoted BCR signalling and down-regulation of cell cycle pathways ($p < 0.05$). In contrast,

no distinct pathways were exclusive to PD-1 alone, as some genes related to IFN- γ response for example in fact overlapped between cohorts.

Conclusion

NeoIT-L and PD-1 alone induce distinct immune changes linked to pathological response. NeoIT-L responders exhibited changes in BCR/TCR signalling and suppressed cell cycle pathways suggesting enhanced immune activation and reduced tumour proliferation with the addition of a short duration (6 weeks) of lenvatinib. In contrast, PD-1 alone responders showed changes in antigen processing and cytokine signalling without significant cell cycle changes. Ongoing CyTOF analysis will further characterise the peripheral immune changes.

EACR25-1203

A novel synthetic peptide HS1002 Enhances T Cell-Mediated Antitumor Immunity

J. Park¹, H. Lee¹, Y. Kang¹, S. Lee¹, D. Lim¹, H. Kim¹

¹*Sungkyunkwan University, School of Pharmacy, Suwon, Korea (Republic of)*

Introduction

T cells play a crucial role in antitumor immunity. However, their function is frequently suppressed within the tumor microenvironment, limiting the efficacy of immunotherapy. Treatment with hTERT-derived peptides has been shown to enhance the production of effector T cells. HS1002, a novel synthetic peptide, was designed using sequences from gonadotropin-releasing hormone (GnRH) and human telomerase reverse transcriptase (hTERT). The present study aimed to evaluate the ability of HS1002 to enhance T cell-mediated immunity and improve the effectiveness of anti-PD-1 therapy.

Material and method

To assess the immunostimulatory effects of HS1002, ELISpot assays were performed to measure IFN- γ secretion in PBMCs. The Incucyte ZOOM system was used to evaluate PBMC-mediated cytotoxicity against LNCaP cells. Cytokine array analysis was conducted to characterize HS1002-induced changes in cytokine secretion. Flow cytometry was performed to analyze immune cell populations in syngeneic tumor models.

Result and discussion

HS1002 treatment increased IFN- γ secretion and enhanced PBMC cytotoxicity against LNCaP cells. Cytokine profiling revealed elevated levels of CXCL1, CXCL10, CCL2, TNF- α , and IL-2, indicating a heightened immune response. To evaluate the antitumor effects of HS1002, tumor growth inhibition was assessed in syngeneic tumor models. HS1002 significantly reduced tumor volume in the MC38 model, whereas no significant effect was observed in the 4T1 model, suggesting that tumor immune environment influences HS1002 responsiveness. Flow cytometry analysis showed increased CD45 $^+$ immune cell infiltration and CD8 $^+$ T cell activation, as evidenced by elevated granzyme B and IFN- γ expression in MC38 tumors. Gene analysis further confirmed enrichment of immune-related pathways in HS1002-treated MC38 tumors. In the poorly immunogenic 4T1 model, co-administration of HS1002 with anti-PD-1 antibody significantly reduced tumor volume and

increased immune cell infiltration and T cell populations, which were diminished by anti-PD-1 monotherapy. While PD-1 expression on T cells remained unchanged, CD8⁺ T cells in the combination group exhibited increased granzyme B and IFN- γ expression, suggesting an enhancement in cytotoxic activity.

Conclusion

HS1002 enhances T cell-mediated antitumor immunity by promoting immune cell infiltration and T cell function. Moreover, its synergy with anti-PD-1 therapy highlights its potential as a promising immunotherapeutic strategy.

EACR25-1288

CD25-Biased IL-2/Anti-IL-2 Complexes Enhance Antigen-Primed CD8⁺ T Cell Expansion, Overcome Treg-Mediated Suppression, and Exhibit Significant Antitumor Activity

P. Weberová¹, I. Kilic¹, K. Behalova¹, B. Ptacek¹, M. Sirova¹, V. Mazhara¹, K. Kubesova¹, B. Rihova¹, M. Kovář¹

¹Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic

Introduction

Interleukin-2 (IL-2) is essential for T cell proliferation, survival, and effector function. However, its clinical use in cancer immunotherapy is hampered by severe toxicity and the unintended expansion of regulatory T (Treg) cells. Complexes of IL-2 and anti-IL-2 monoclonal antibodies have previously demonstrated high biological activity in vivo. In particular, IL-2/anti-IL-2 mAb JES6-1A12 complexes (IL-2/JES6) are highly selective and potently stimulate the expansion of CD25⁺ cell populations. Our study examines whether these CD25-biased IL-2/JES6 complexes can selectively expand antigen-primed CD8⁺ T cells while mitigating Treg-mediated suppression. The primary objective is to assess and optimize these complexes for further application in cancer immunotherapy.

Material and method

We employed an adoptive transfer model using OT-I CD8⁺ T cells in congenic B6 mice primed with ovalbumin. The expansion of transferred CD8⁺ T cells and the expression of activation markers (CD25, granzyme B, and perforin) were analyzed by flow cytometry. In vitro Treg suppression assays were performed to assess the ability of IL-2/JES6 complexes to counteract Treg-mediated inhibition, and in vivo antitumor efficacy was evaluated in murine models of glioma (GL261) and colon carcinoma (CT26).

Result and discussion

CD25-biased IL-2/JES6 complexes induced robust expansion of antigen-primed OT-I CD8⁺ T cells and enhanced their expression of CD25, granzyme B, and perforin. Although Treg cells were also expanded, in vitro assays confirmed that saturating doses of IL-2/JES6 effectively overcame Treg-mediated suppression. Notably, treatment with IL-2/JES6 led to significant antitumor activity in both GL261 and CT26 models, supporting the potential of this strategy for tumor immunotherapy.

Conclusion

Despite the concurrent expansion of Treg cells, CD25-biased IL-2/JES6 complexes enhance CD8⁺ T cell effector functions and overcome Treg-mediated suppression to achieve marked antitumor responses. Future work will focus on optimizing dosing regimens and advancing clinical translation to maximize therapeutic benefit.

Induction of TWIST1-specific antitumor immunity by DNA vaccine encoding a truncated TWIST1 antigen

Z. Tan¹, M. Chiu², W. Wang², H. Yu², Z. Chen²

¹The Hong Kong Polytechnic University, Department of Applied Biology and Chemical Technology, Hong Kong, Hong Kong, China

²The University of Hong Kong, Microbiology, Hong Kong, Hong Kong, China

Introduction

TWIST1, a basic helix-loop-helix transcription factor, is overexpressed in a variety of tumors such as melanoma, breast, colon cancer and mesothelioma, and associated with tumorigenesis and metastasis. We have previously shown that full-length TWIST1 vaccine elicited cytotoxic T lymphocytes (CTLs) that recognized TWIST1-expressing tumors and conferred protection against tumor challenge in the form of DNA vaccine and adenovirus-associated viral vector system, highlighting TWIST1 as a promising target for cancer immunotherapy. In this study, we sought to apply optimization approach on the TWIST1-based vaccine platform in order to enhance T cell immunity and reduce potential toxicity.

Material and method

We developed a novel soluble PD-1 (sPD1)-based DNA vaccine encoding a truncated version of TWIST1 (sPD1-TruncT1) that includes a conserved region found in both human and mouse proteins. The immunogenicity and antitumor efficacy of the TruncT1 vaccine were evaluated and compared in parallel to full-length TWIST1 vaccine in two murine models of TWIST1-expressing tumors.

Result and discussion

By doing epitope mapping, we identified immunodominant T cell epitopes within the TWIST1 antigen, showing that majority of T cells recognized a C-terminal conserved region. sPD1-based DNA vaccine encoding epitopes of this conserved region, via in vivo electroporation (EP), elicited more robust TWIST1-specific T cell responses compared to full-length TWIST1 vaccine. Furthermore, these TWIST1-specific T cells were polyfunctional because they produced multiple effector cytokines when encountering TWIST1-expressing tumors. In addition, immunotherapy with the sPD1-TruncT1 vaccine showed a notable enhancement in antitumor efficacy in both preventive and therapeutic scenarios.

Conclusion

With the widespread expression of TWIST1 in different cancer types, truncated TWIST1 vaccination has high potential for cancer immunotherapy and warrants investigation in human clinical trials to evaluate its

applications as a vaccine for patients with WT1-expressing cancers.

²Queens University Belfast, School of Pharmacy, Belfast, United Kingdom

³Tezpur University, Department of Food Engineering and Technology, Tezpur, Assam, India

⁴Dublin City University, School of Mechanical & Manufacturing Engineering, Dublin, Ireland

Introduction

High grade serous ovarian carcinoma (HGSC), accounting for >75% of ovarian cancer, is a highly aggressive gynaecological cancer with ≤30% 5-year and <15% 10-year overall survival rate. This study addresses the unmet clinical need for effective immunotherapeutic strategies by leveraging the antigens overexpressed in the tumour microenvironment to develop a pDNA vaccine for the treatment of HGSC. DNA vaccines produce higher CD8+ CTL response along with a CD4+ T-cell response in comparison to other vaccination strategies. The vaccine was delivered using nanoparticles (NPs) formulated with a cationic cell penetrating peptide RALA designed to encapsulate anionic nucleic acid cargo and overcome the barriers of naked DNA delivery, facilitating cellular entry.

Material and method

Antigen expression was confirmed using multi-dataset analyses. A plasmid was designed encoding the selected antigen (PRAME), which is overexpressed in all stages of HGSC. pPRAME was complexed with RALA to make NPs. The size, charge and PDI was measured using a DLS zetasizer and encapsulation efficiency was measured by Ion exchange Chromatography. In vitro transfection efficiency of the NPs was measured in NCTC-929 and D.C 2.4 cells using ELISA. The optimal NPs were lyophilised with trehalose and assessed in a murine (C57BL/6) model to analyse the immune response and therapeutic effect of the NPs.

Result and discussion

Elevated PRAME expression was observed throughout the different stages of HGSC in analysed datasets. Physicochemical characterisation revealed optimal RALA/pPRAME NPs with size (< 150 nm), high encapsulation efficiency (>95%) and stability upon lyophilisation with Trehalose. In vitro transfection demonstrated significant overexpression of PRAME in D.C 2.4 and NCTC-929 cells with cell viability >80%. In vivo C57BL/6 mice immunised with RALA/pPRAME NPs elicited robust immune response, evidenced by ELISpot analysis showing higher INF-γ+ splenocytes with both RALA/pPRAME and RALA/pPRAME+GM-CSF vaccine groups ($p < 0.05$) compared to GM-CSF only. Therapeutic efficacy was evaluated in a E0771 PRAME overexpression tumour model, demonstrating

reduced tumour burden in RALA/pPRAME NP treated groups compared to controls.

Conclusion

The findings in this study demonstrate RALA/pPRAME NPs as a promising vaccine platform for therapeutic vaccination against PRAME overexpressing HGSC with strong potential for clinical translation.

⁴Sheba Medical Center, Pathology, Ramt-Gen, Israel

⁵Tel Aviv University, The Faculty of Medical and Health Sciences, Tel Aviv, Israel

Introduction

A significant challenge in studying cancer immunotherapy is the lack of robust, accessible experimental models that can closely represent human tumors and immune responses. We developed an ex-vivo organ culture (EVOC) model using malignant pleural effusions (PEs) to investigate immunotherapy responses in advanced non-small cell lung cancer (NSCLC) patients. PEs, accumulation of abnormal fluid in the pleural space surrounding each lung, occur in approximately 20% of NSCLC patients and are associated with worse prognosis. Our project's main goal was to develop a tool to study response to immune checkpoint inhibitors (ICIs). To achieve this, we established EVOCs from PEs of metastatic NSCLC patients, serving as a valuable model to investigate the mechanisms of ICI response and resistance.

Material and method

PEs were collected from metastatic NSCLC patients at Sheba Medical Center. Cell populations were characterized by flow cytometry and immunohistochemistry. Freshly isolated cells were cultured for 4 days and treated with ICIs: Durvalumab (anti-PD-L1) alone or combined with Tremelimumab (anti-CTLA4) and IL2 as an immune activator. Response was assessed by IFNγ protein secretion (ELISA) and gene induction (RT-PCR). Bulk RNA seq analysis was conducted to find differentially expressed genes between responders and non-responders.

Result and discussion

We analyzed 49 PE samples, primarily containing T cells lymphocytes (mainly CD4+), B cells, macrophages and varying percentages of cancer epithelial cells. Of 15 PE-EVOCs treated with ICIs, 47% responded to ICIs and exhibited significant IFNγ induction and secretion. RNA-seq analysis of sorted CD3+ T cells and B cells (CD19+/CD20+) from 12 PE samples revealed 27 differentially expressed genes in B cells between responders and non-

responders, while no differences were observed in the CD3+ population, suggesting a specific role for B cells in ICI response. Initial analysis of DE genes revealed some interesting candidate that has a role in B cell activation and response to ICIs.

Conclusion

EVOCs from malignant pleural effusions of lung cancer patients provide insights into immune responses to ICIs, potentially improving patient selection and treatment outcomes. Our findings highlight a role for B cells in ICI response. We are currently investigating the identified genes of interest in our laboratory to elucidate their specific functions in B cells and their impact on ICI response, aiming to enhance our understanding and develop more effective immunotherapy strategies.

²University of Coimbra, Centre for Mechanical Engineering, Materials and Processes, Department of Chemical Engineering, Coimbra, Portugal

³University of Coimbra, Faculty of Pharmacy,

⁴University of Coimbra, Faculty of Pharmacy, Coimbra, Portugal

Introduction

Cancer immunotherapies have emerged as a leading treatment strategy, particularly those that leverage antigen-presenting cells (APCs) to elicit Th1 immune responses and prime cytotoxic T lymphocytes. Cancer vaccination involves delivering tumor antigens directly to APCs to activate antigen-specific immunity against cancer cells. In this study, we explore sugar-functionalized Lipid Nanoparticles (SF-LNPs) as a cancer vaccine platform for the efficient delivery of mRNA-encoded antigens to APCs and subsequent immune activation/maturation.

Material and method

A sugar-modified lipid was synthesized via a coupling reaction, and the chemical structure of the compound was confirmed by ¹H-NMR spectroscopy. SF-LNPs were generated using the Nanoassemblr™ microfluidic platform. Particle size, polydispersity index, and zeta potential (ZP) were measured using dynamic light scattering and electrophoretic light scattering, respectively, with a Zetasizer Ultra. Encapsulation efficiency was quantified using the Quant-iT RiboGreen™ fluorescence assay. Cellular uptake and eGFP-mRNA expression of DiD-labeled SF-LNPs and non-functionalized LNPs (NF-LNPs) were assessed at multiple time points through flow cytometry and confocal microscopy. Experiments were conducted with RAW264.7 and JAWSII cell lines, as well as with human monocytes, monocyte-derived dendritic cells and monocyte-derived macrophages. Cell surface receptor

expression and cytokine production were evaluated using flow cytometry and ELISA, respectively.

Result and discussion

SF-LNPs exhibited a uniform size distribution with an average particle size below 100 nm, and a neutral ZP. Encapsulation efficiency of eGFP-mRNA within SF-LNPs reached values above 85 %. Flow cytometry and confocal microscopy analysis demonstrated higher and faster cellular uptake of DiD-labeled SF-LNPs than NF-LNPs. Additionally, SF-LNPs showed increased eGFP-mRNA expression compared to NF-LNPs. Flow cytometry results revealed upregulation of activation and maturation cell surface markers, while ELISA assays indicated increased secretion of pro-inflammatory cytokines, suggesting effective immune activation by SF-LNPs.

Conclusion

These findings highlight the potential of SF-LNPs as a versatile and effective cancer vaccine platform, offering a promising strategy for mRNA-based immunotherapies.

Accelerating the Manufacture of γδ T Cells for Allogeneic Cancer Therapies: Integrated Cell Differentiation and Expansion in Bioreactors

M. de Almeida Fuzeta^{1,2}, B. Painho^{1,2}, C. Costa^{1,2}, B. Fazendeiro^{1,2}, L. Pérez³, S. Casadó³, V. Díaz³, S. Theoharis³, M. Costa^{1,2}, M. Serra^{1,2}

¹iBET, Instituto de Biologia Experimental e Tecnológica, Oeiras, Portugal

²Instituto de Tecnología Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal

³OneChain Immunotherapeutics, Parc Científic de Barcelona, Barcelona, Spain

Introduction

Chimeric antigen receptor T cell (CAR T) therapies are emerging as a promising therapeutic option for cancer treatment. However, their wide application remains challenging due to barriers imposed by HLA-disparities, limiting most therapies to autologous settings. To overcome this, γδ T cells arise as a powerful alternative. γδ T cells have potent immunosurveillance activity and are HLA-independent so they do not cause graft versus host disease (GvHD), enabling their application in allogeneic settings. Due to the low abundance of γδ T cells in the human body, strategies to generate high numbers of γδ T cells while retaining their quality attributes are needed for their application in the clinical setting. To date, protocols available to generate γδ T cells from hematopoietic stem/progenitor cells (HSPC) rely on OP9 mouse stromal cell lines overexpressing Notch ligands, a strategy not easily scalable and compatible with Good Manufacturing Practices (GMP). Herein, we propose to develop a scalable and animal origin-free bioprocess to differentiate HSPC into γδ T cells.

Material and method

To achieve this goal, we cultured CD34+ HSPC, obtained from human umbilical cord blood, in the presence of

recombinant Notch ligands. This process, optimized to be entirely free of animal-derived products, was initially implemented in static conditions (96 well-plates) and scaled-up to a fully controlled, miniaturized bioreactor system (Ambr®15, Sartorius).

Result and discussion

Differentiation was similar between static and bioreactor systems, with 80–90% of the cells reaching the Pro T cell stage by day 21 of differentiation. Although selection of an optimal timeframe for TCR stimulation is expected to further maximize the yields of $\gamma\delta$ T cells, currently $1-2 \times 10^3$ CD3+TCR $\gamma\delta$ + cells were obtained per initial CD34+ HSPC, after 42 days of culture. $\gamma\delta$ T cells obtained through this strategy expressed key cytotoxicity markers (e.g. CD8, NKG2D, NKp30) and displayed cytotoxic activity in vitro against a leukaemia cell line (MOLM-13), when originated both in static and bioreactor conditions.

Conclusion

Overall, we have developed a scalable and GMP-compatible bioprocess to generate $\gamma\delta$ T cells, suitable for off-the-shelf therapies, namely in the context of allogeneic CAR T cell products.

EACR25-1544

Blockade of PD-L1 endocytosis by uPAR antagonist peptides to improve cancer immunotherapy

E. Frediani¹, C. Anceschi¹, S. Martinelli¹, A. Chillà¹, J. Ruzzolini¹, A. Laurenzana¹, F. Margheri¹

¹Università degli studi di Firenze, Florence, Italy

Introduction

Immunotherapy has revolutionized the field of tumor immunology. Recent evidences have revealed the clinical efficacy of programmed cell death-1/programmed death ligand-1 (PD-1/PD-L1) antibodies in patients with metastatic breast cancer, melanoma and non-small-cell lung cancer. The therapeutic efficacy of PD-1/PD-L1 inhibitors is high in patients with high PD-L1 expression. Recently, Tseng et collaborators showed that targeting Plasminogen Activator Inhibitor (PAI-1) by its inhibitor tiplaxtinin (TPX) synergizes with anti-PD-L1 checkpoint blockade in a model of murine melanoma. PAI-1 induced the internalization of surface PD-L1, resulting in the reduction of PD-L1 at membrane level. Binding of PAI-1 to uPA/uPAR complex results in the recruitment of low-density lipoprotein receptor protein 1 (LRP1) and triggers the endocytosis process leading to the internalization of PAI-1-uPA-uPAR-LRP1 quaternary complex. The endocytosed PAI-1 and uPA then undergoes lysosomal degradation, whereas uPAR and LRP1 are transported back to the plasma membrane by recycling endosomes. Another limiting factor of ICIs is the PD-L1 packaging within specific membrane-enclosed extracellular vesicles (EVs), the so-called exosomal PD-L1. We propose to inhibit PDL-1 endocytosis by uPAR inhibitors to maintain high-cell-surface levels of PD-L1 and, at the same time, to reduce the expression of exosomal PD-L1. Moreover, we propose to set up 3D co-culture system between non-small cell lung cancer cells and T cells to assess efficacy of uPAR inhibitors on immunotherapy responses.

Material and method

2D and 3D cultures from A549 (non-small cell lung cancer cells) were treated with TPX and uPAR antagonist (IPR803) to evaluate the effect of TPX and IPR803 treatment on PD-L1 modulation. Conditioned media from untreated and treated TPX tumor cells were used for exosomes isolation to evaluate the effect of TPX treatment on exosomal PD-L1. 3D co-cultures were seeded between A549 previously treated with anti-human PD-L1 and IPR803 and T cells CD8+ CD4+ to assess cytotoxic effect of T cells on tumor cells.

Result and discussion

Our result evidenced that in 2D and 3D cultures of A549 TPX and uPAR antagonist peptides are able to block the PD-L1 internalization and, consequently, to increase PD-L1 membrane levels. Moreover, we demonstrated that exosomes from TPX-treated A549 show a decrease of exosomal PD-L1 levels, compared to untreated cancer cells. In parallel, our data highlighted in 3D co-cultures an improvement of cytotoxic effect of T cells on A549 treated with uPAR antagonists and anti-PD-L1 antibodies

Conclusion

Our results evidenced that blockade of PD-L1 endocytosis induced a decrease of exosomal PD-L1 levels. Furthermore, our data demonstrated that uPAR inhibition by uPAR antagonist peptides result in a significant increase in surface PD-L1 levels, opening the way for new combined therapeutic strategies with uPAR inhibitors and anti-PD-1/PD-L1.

Characterization of radiolabelled single-domain anti-HER2 antibodies as potential radioimmunotherapeutics for breast cancer

Z. Napora¹, K. Juszczak¹, N. Razzaq¹, K. Kilian², M. D'Huyvetter³, M. Pruszyński¹

¹Institute of Nuclear Chemistry and Technology, Warsaw, Poland

²University of Warsaw, Faculty of Chemistry, Warsaw, Poland

³Vrije Universiteit Brussel, Brussels, Belgium

Introduction

Human Epidermal Growth Factor Receptor 2 (HER2) is a membrane-bound kinase regulating cell's proliferation and viability. Overexpression of HER2 occurs in 25–30% of breast, 10–15% of ovarian, 5–15% of stomach cancers and is associated with metastases, therapy resistance and poor prognosis. However, HER2 is a promising therapeutic target, due to its extracellular accessibility and differential expression in normal and tumour cells. Radioimmunotherapy delivers radiation selectively to the neoplasm, induces DNA damage and thus enhances therapeutic effect. Here, we use a single-domain antibodies derived from Camelidae heavy-chain antibodies, called nanobodies, offering an improved pharmacokinetics and minimizing off-target radiation. In our study, we radiolabelled two anti-HER2 nanobodies - internalising 2Rb17c and non-internalising 2Rs15d [1] - with various radioisotopes to evaluate and compare therapeutic potential of the final radiobioconjugates.

Material and method

Nanobodies were coupled with DOTA chelators. Bioconjugation kinetics was examined by HPLC, products were characterized by ESI mass spectrometry and radiolabelled with ^{177}Lu / ^{161}Tb / ^{225}Ac . Radiolabelling kinetics and chemical purity were measured by iTLC. Stability was determined in PBS, cell culture medium and human serum. Specificity, binding affinity and internalization assays were done on SKOV-3 cells (HER2+) followed by cell toxicity examined by MTS assay.

Result and discussion

Nanobody-chelator coupling reaction was optimized and products were obtained with high efficiency. Bioconjugates were successfully radiolabelled. Cell studies showed that chelator coupling and radiolabelling are not impairing nanobody specificity to HER2. The resulting radiobiocoujugates were applied to cells and MTS results revealed cytotoxic effect on HER2 positive cells.

Conclusion

Performed studies provided promising results and indicate that both radiobiocoujugates may be considered as potential therapeutics for HER2 positive tumour. Moreover, their application may be shifted to diagnostic agents by means of radioisotope with proper emission spectrum. Collectively, these outcomes encourage to investigate these compounds in further aspects.

Project was financed by Narodowe Centrum Nauki (NCN), award ID: 2019/34/E/ST4/00080, principal award recipient: M. Pruszynski.

Glycopolymer-Mediated Gene Delivery for Efficient CAR-T Cell Production

D. Correia¹, D. Santo², H. Faneca¹, R. Cordeiro¹

¹CNC - Center for Neuroscience and Cell Biology, University of Coimbra; CIBB - Centre for Innovative Biomedicine and Biotechnology, University of Coimbra, Coimbra, Portugal

²CEMMPRE, ARISE, Department of Mechanical Engineering, University of Coimbra, Coimbra, Portugal

Introduction

Gene-engineered T cell immunotherapies have shown great promise as a treatment for various non-solid cancers, offering significant therapeutic benefits. However, the significant production costs and limited availability associated with virus-based genetic manipulation present notable challenges for cellular immunotherapies. As a result, non-viral gene delivery platforms, particularly those based on cationic polymers, emerged as a possible alternative. This work aims to develop a new generation of non-viral gene delivery nanosystems based on cationic glycopolymers for T cell engineering.

Material and method

A library of well-defined copolymers based on 2-aminoethyl methacrylate (AMA) and 2-lactobio-namidoethyl methacrylate (LAMA) was synthesized using ARGET ATRP. These glycopolymers were complexed with plasmid DNA encoding green fluorescent protein (GFP) at polymer/DNA N/P ratios of 8/1 and 10/1. After 15 min of magnetic stirring at RT, polyplexes were incubated with Jurkat cells, and GFP expression was assessed after 48 h via flow cytometry. Additionally, the size and

surface charge of the polyplexes were characterized using dynamic light scattering and electrophoretic measurements, respectively.

Result and discussion

Glycopolymers with different carbohydrate/cationic ratios and monomers distribution (random/block) were tested: PAMA90-b-PLAMA113, PAMA92-co-PLAMA95 and PAMA114-co-PLAMA20. All glycopolymers demonstrated the ability to complex with nucleic acid, forming polyplexes with suitable physicochemical properties for cellular uptake. Nano-carriers revealed enhanced gene reporter expression at a N/P ratio of 10/1, indicating that the higher tested N/P ratio improved transfection efficiency. Notably, all the developed formulations exhibited higher transfection activity than that obtained with the gold-standard polymer for gene delivery application – the polyethyleneimine (PEI). Among them, polyplexes prepared with PAMA114-co-PLAMA20 demonstrated the best performance, achieving a threefold increase in the percentage of transfected cells while maintaining low cytotoxicity compared to PEI. This superior performance is likely due to the higher cationic content, which plays a key role in both polyplex formation and endosomal escape.

Conclusion

Results demonstrated the transfection ability of the developed glycopolymer-based polyplexes, with PAMA114-co-PLAMA20-based polyplexes standing out as a promising nanosystem for gene delivery.

Introduction

Despite the notable success of immune checkpoint inhibitors (ICI) in increasing survival rates across several cancer types, the complexity of the tumor microenvironment still poses significant challenges cancer therapy. The therapy-induced changes in tumor microenvironment (TME) cell composition and their regulation as predictive biomarkers remain incompletely understood.

Material and method

To comprehensively investigate TME dynamics under ICI therapy, we curated a large-scale single-cell RNA sequencing (scRNA-seq) dataset comprising 417 samples from 242 patients across 11 cancer types, including 187 longitudinally site-matched samples. Additionally, we included 18 scRNA-seq samples from 12 patients

collected before and approximately one week after ICI treatment as a validation cohort.

Result and discussion

We retrieved and processed pan-cancer datasets as reference, enabling the comprehensive annotation of non-malignant TME cells into 68 immune subtypes and 15 non-immune subtypes. Using generalized linear mixed models, we identified a consistent increase in Tpex, Tf_h, TREM2⁺ macrophages, and SPP1⁺ macrophages following immune checkpoint inhibitor (ICI) therapy across multiple cancer types. Nonnegative matrix factorization (NMF) revealed a distinct cellular program dominated by angiogenic and immune suppressive macrophages, which exhibited significant correlations with both treatment status and response. Additionally, we identified a co-regulatory community centered around M2-like C1QC⁺ macrophages, which showed a negative correlation with the naive CD4⁺ T cell community. This polarized trend was further confirmed through unsupervised clustering, which highlighted a clear distinction between non-responder-enriched groups and other patient groups.

Conclusion

The consistency of these dynamics across diverse cancer types, coupled with response-dependent variations, underscores the necessity of systematic approaches to unravel the intricate interactions within the TiME, paving the way for advancements in immunotherapeutic strategies.

Redox-Responsive Self-Immulative Nanogels for Cellular Immunotherapies

E. Figueiredo¹, D. Correia¹, D. Santo², H. Faneca¹, R. Cordeiro¹

¹CNC - Center for Neuroscience and Cell Biology, University of Coimbra; CIBB - Centre for Innovative Biomedicine and Biotechnology, University of Coimbra, Coimbra, Portugal

²CEMMPRE, ARISE, Department of Mechanical Engineering, University of Coimbra, Coimbra, Portugal

Introduction

Cancer has become a major public health challenge and a significant societal and economic issue in the 21st century. These highly complex diseases are characterized not only by the overgrowth of malignant cells but also by an altered immune response. Current treatment options primarily include chemotherapy, radiation, and surgery; however, these often result in adverse side effects and therapeutic resistance. Immunotherapy presents a groundbreaking alternative, utilizing the body's immune system to selectively target and eliminate tumor cells. Chimeric Antigen Receptor T cell (CAR T cell) therapy is a personalized treatment that harnesses T cells to combat cancer. However, the success of this technique depends on efficient gene delivery systems. In this regard, this study explores the potential of redox-responsive nanogel formulations, based on a cationic glycopolymer, as non-viral platforms for gene delivery.

Material and method

The nanogels were prepared at RT for 18 h using a cationic glycopolymer, previously developed by our

group via ARGET ATRP, a plasmid DNA encoding the green fluorescent protein (GFP), and a crosslinker. Various nanogels were prepared at different polymer/DNA (N/P) ratios in PBS or purified water at pH 8.5. After incubation with Jurkat cells, GFP expression was assessed via flow cytometry after 48 h. Particle size and surface charge were characterized using dynamic light scattering and electrophoresis.

Result and discussion

Nanogels prepared in purified water at pH 8.5 exhibited a smaller hydrodynamic diameter and higher surface charge than those in PBS, indicating enhanced colloidal stability due to electrostatic repulsion. These results highlight the critical influence of solvent choice on the formulations' physicochemical properties. Transfection assays confirmed that all nanogels successfully transfected T cells with minimal cytotoxicity.

Conclusion

We successfully developed nanogels with distinct physicochemical properties able to carry DNA, highlighting the versatility of the formulation approach. Additionally, these nanogels effectively transfected T lymphocytes.

³Research Institute for Medicines (imed), Faculty of Pharmacy, University of Lisbon, Lisboa, Portugal

⁴Research Institute for Medicines (imed), University of Lisbon, Lisboa, Portugal

Introduction

CAR (chimeric antigen receptor)-T cell therapy, which involves genetically modifying T cells with synthetic receptors that target specific tumor antigens, has shown remarkable success in hematologic malignancies. However, its application in solid tumors remains challenging due to limited tumor infiltration and strong immunosuppression. Nucleolin, a membrane-nucleus shuttling protein, has been demonstrated to be over-expressed on the surface of cancer and endothelial cells from tumor blood vessels, across different solid tumors. Accordingly, anti-nucleolin nanobodies, previously developed by our group, showed strong binding to nucleolin-positive cell lines, suggesting nucleolin as a potential CAR-T cell target. Here, we describe the initial steps in generating anti-nucleolin CAR-T cells and evaluate their in vitro activity against solid tumor-derived cell lines of diverse histological origin.

Material and method

Peripheral blood mononuclear cells were isolated from healthy donors, activated with CD3/CD28 agonists, and transduced with CAR-encoding lentivirus. Transduction efficiency and stability were evaluated by both reporter

gene and CAR surface expression, at multiple timepoints. To assess CAR-T cells anti-tumor activity, specific lysis of different nucleolin expressing cancer cell lines was analyzed by real-time impedance-based co-culture assays, at different E(effector):T(target) ratios.

Untransduced and mock-transduced T cells were used as controls. Proliferation in the presence or absence of target cells and immunophenotyping studies by spectral flow cytometry were also performed.

Result and discussion

CAR expression ranged between 40% and 60% and remained stable for at least six days in culture. Anti-nucleolin CAR-T cells displayed significantly higher cytotoxicity than respective controls, and higher effector cell ratios led to increased target cell death. This effect was more pronounced in tumor cells with superior surface nucleolin expression. Phenotypic analysis revealed a predominance of central memory (CCR7⁺ CD45RO⁺) CAR-T cells, and differences on exhaustion markers expression, namely PD-1 and LAG-3, were observed over 10 days in culture, suggesting dynamic changes in activation and exhaustion profiles.

Conclusion

In summary, this work demonstrates the successful generation and in vitro validation of anti-nucleolin CAR-T cells, against different cancer cell lines, supporting nucleolin as a potential new target in CAR-based immunotherapy for solid tumors.

Development of PD-L1 based cancer vaccine conjugating a novel T cell epitope

T. Nishikawa¹, Y. Kuan¹, J. Tai¹, K. Yamashita¹, H. Nakagami²

¹Osaka University, Department of Device Application for Molecular Therapeutics, Osaka, Japan

²Osaka University, Department of Health Development and Medicine, Osaka, Japan

Introduction

Programmed cell death 1 (PD-1)/PD-L1 binding negatively regulates adaptive immune response mainly by inhibiting the activity of tumor-infiltrating cytotoxic T lymphocytes and promotes tumor growth and metastasis. An effective PD-L1 antibody producing vaccine is needed to restore antitumor T cell responses and cause long-term remission in a subset of cancer patients. In this study, we have designed a conjugate vaccine containing T cell epitope and PD-L1 epitope. This PDL1 conjugated vaccine was administered to tumor model mice in a form of peptide or plasmid DNA to evaluate tumor control efficacy and antitumor immune reactions.

Material and method

The PDL1 conjugated recombinant protein vaccine was intradermally administered to mice three times at 2-week intervals by using pyro-drive jet injector (PJI), which shoots out a solution by pressure of gunpowder explosion. On day 7 after the third immunization, the mouse was injected with MC38 (murine colon adenocarcinoma) on back. On day 14 after tumor challenge, the

mice sacrificed and tumor tissues and sera were collected. The tumor tissue sections were histologically stained with anti-CD4, -CD8 and F4/80 antibodies to detect tumor infiltrating T cells and macrophages. Anti-PDL1 antibody titers were measured by ELISA. The PDL1 conjugated plasmid DNA vaccine was intradermally administered to mice three times at 2-week intervals by using PJI. On day 7 after the third immunization, the mouse was injected with CT26 (murine colorectal carcinoma). On day 21 after tumor challenge, the mice sacrificed and splenocytes and sera were collected. IFN- γ and TNF- α secretion from splenocytes were measured by ELISpot assay. Tumor diameters were measured every other day and the tumor volumes were calculated.

Result and discussion

Tumor section staining showed that strong CD4+, CD8+ T cell and macrophage infiltration in PDL1 conjugated vaccine injected group. Anti-PDL1 antibody titer in PDL1 conjugated vaccine injected group was up-regulated. Compared with negative control, PDL1 conjugated pDNA inhibited tumor growth. Both IFN- γ and TNF- α secretion was significantly upregulated only in PDL1 conjugated pDNA group with tumor cell stimulation. These data suggest that PDL1 conjugated pDNA vaccine might have induced a PD-L1-specific immune response and delayed tumor growth.

Conclusion

Our data is suggesting that the pDNA vaccine containing PD-L1 epitope reverses the PD1/PD-L1 axis causing suppressive tumor phenotype. Therefore, this novel conjugate vaccine is a promising strategy for cancer immunotherapy.

EACR25-1700

Immunization against a mutant p53-derived neoantigen by a personalized oncolytic adenovirus

A. Munoz¹, A. Pandya¹, C. Kut¹, H. Quon¹, E. Bunz¹

¹Johns Hopkins University, Radiation Oncology, Baltimore, United States

Introduction

Replication-competent oncolytic adenoviruses (OAd) are promising anticancer therapeutics. Adenoviruses have a lytic life cycle and can be engineered to selectively replicate in tumor cells. An important attribute of OAds is their immunogenicity. When they infect and subsequently kill tumor cells, OAds elicit robust local and systemic immune responses that can counteract an immunosuppressive tumor microenvironment. Neoantigens released during a lytic infection can stimulate T cell activation by professional antigen presenting cells, thereby increasing the immune response to the tumor. Unfortunately, immune responses are primarily directed against the virus itself; cross reactivity against the targeted tumor is frequently limited. To enhance anti-tumor immunity in the context of an active infection, we have developed OAds that can reconstitute pHLA-immunopeptide complexes on the surface of infected cells.

Material and method

We employed a platform technology called AdenoBuilder to create OAds that stimulate robust

immune responses to antigenic peptides incorporated into the viral capsid. With the AdenoBuilder platform, synthetic adenovirus genomes are enzymatically assembled from plasmid components and directly packaged. This modular approach permits the rapid production of recombinant viral vectors with modifications across the viral genome. Our personalized OAds enhance neoantigen presentation by the transgenic expression of tumor-specific neoantigens and compatible HLA alleles that can be matched to the allelotype of individual patients. To further enhance antigen presentation, our current replication-competent OAds also express β2-microglobin and the IL-12 complex.

Result and discussion

We tested a prototype OAd designed to elicit specific T cell responses against the public neoantigen HMTEVVRHC (derived from the p53R175H mutant protein) which was systematically modified to enhance its binding affinity for HLA-A*0201. The optimized peptide sequence was incorporated into the capsid of an OAd that also expressed HLA-A*0201, β2-microglobin and the IL-12 complex. We demonstrated that this neoantigen-expressing OAd could stimulate robust, neoantigen-specific anti-tumor responses in an HLA-A2-transgenic mouse model.

Conclusion

OAds that express specified pHla-immunopeptide complexes are an emerging form of precision immunotherapy. This study demonstrates the feasibility of using the AdenoBuilder system to rapidly generate OAds that are personalized to individual patients and their tumors.

EACR25-1757

Selection and identification of nanobodies against a cancer-testis antigen, placenta-specific protein 1

P. Tiraratchailert¹, M. Paenthong¹, T. Phanaksri¹

¹*Thammasat University, Chulabhorn International College of Medicine, Pathum Thani, Thailand*

Introduction

Placenta-specific protein 1 (PLAC1) is a surface cancer-testis antigen protein mainly expressed in the placenta, ovary and testes. In addition, it is also highly expressed in multiple types of cancer such as breast, ovarian, head and neck, liver, and colorectal cancer. High levels of PLAC1 expression promote cancer proliferation, angiogenesis, invasion and metastasis. Therefore, PLAC1 has been considered as an attractive target for the development of cancer therapeutics. In this work, we aimed to select specific nanobodies targeting the PLAC1 protein.

Material and method

We used a synthetic nanobody library for biopanning with the E. coli-expressed extracellular domain of PLAC1 (PLAC1e). We also performed phage enzyme-linked immunosorbent assays (phage-ELISA) for affinity screening of the candidate clones of nanobody-displayed phages. Nanobody nucleotide sequences were verified by DNA sequencing and translated to protein sequences using the Expasy Translate Tool.

Result and discussion

As a result of phage-ELISA screening, the candidate nanobody selected from the biopanning process

demonstrated binding with high affinity to the target protein. Deduced amino acids of ten candidate clones revealed CDR3 length with 14 and 19 amino acids. Nanobodies with a CDR3 length of 19 amino acids were shown by phage-ELISA to have higher absorbance than those with a CDR3 length of 14 amino acids.

Conclusion

This study provides potential specific nanobodies to PLAC1 isolated from a synthetic nanobody library. From these findings, the synthetic nanobody library offers a useful tool for application in the selection of specific antibody domains. Furthermore, the anti-PLAC1 nanobodies discovered can be used in further studies for the development of nanobody-based T cell engagers or other nanobody-based tumor therapeutic agents.

EACR25-1815

Patient-derived tumor tissue cultures (PDTTCs) as a new platform for assessing T cell engager efficacy in glioblastoma

R. Iurlaro¹, A. Neva Alejo¹, L. Carrillo-Bosch¹,

L. Cuesta-Casanovas¹, I. Cuartas¹, J. Seoane¹

¹*VHIO, Barcelona, Spain*

Introduction

Glioblastoma (GBM) is the most common brain cancer of the adult and a clear medical unmet need. Although immunotherapy is showing great results in several cancer types, in GBM there are still several barriers for its successful implementation. The tumor microenvironment (TME) has been shown to play a fundamental role in the response to immunotherapies and to T cell engagers therapies. However, the study of human TME has been limited by the lack of good experimental models.

Material and method

For this purpose, we have developed patient-derived tumor tissue cultures (PDTTCs), a powerful preclinical model that preserves tumor tissue architecture and TME and accurately represents the complexity of GBM patient tumors and their immune system.

Result and discussion

We recently characterized a novel EGFRvIII-TCB that showed specificity for EGFRvIII mutation and promoted tumor cell killing as well as T cell activation and cytokine secretion in patient-derived models expressing EGFRvIII. We have shown that the PDTTC model is a powerful platform to study the impact of the TME on T cell engagers therapies in GBM that can be deeply explored through single cell and spatial transcriptomics technologies. We showed that incubating the PDTTCs with leukocytes from the same patient that donated the tumor and EGFRvIII TCBs or EGFRvIII CARTs we can assess the interaction, infiltration and response of the immune cells to the tissue, as well as the efficacy of the therapeutic candidates.

Conclusion

Through our studies, we expect to identify novel therapeutic targets and biomarkers that could facilitate the response to T cell engagers and select the patients that may benefit from them.

EACR25-1817**ENO3PEP vaccine enhances chemotherapy efficacy in pancreatic cancer by boosting anti-tumor immunity**

S. Brugia paglia¹, S. Intonti¹, M. Perin¹, A. Zarechian Soudani¹, F. Spagnolo², A. Scagliotti¹, R. Spadi³, P. Cappello¹, C. Curcio¹, F. Novelli¹

¹University of Turin, Dept. Molecular Biotechnologies and Health Sciences, Torino, Italy

²Ufficio Medical Situation Awareness IGESAN, Roma, Italy

³A.O.U. Città della Salute e della Scienza di Torino, Centro Oncologico Ematologico Subalpino, Torino, Italy

Introduction

Pancreatic ductal adenocarcinoma (PDA) is a highly aggressive malignancy with poor prognosis and limited treatment options. Standard chemotherapy, such as gemcitabine plus nab-paclitaxel (GemNab), offers only modest survival benefits. Immunotherapy has emerged as a promising strategy to enhance treatment efficacy. One potential immunogenic target is Alpha-Enolase (ENO1), a glycolytic enzyme overexpressed in PDA. The ability of an ENO1-based vaccination (ENO3PEP) to boost GemNab chemotherapy by inducing a more robust anti-tumor immune response was assessed in this study.

Material and method

The most immunogenic ENO1 sequences were identified based on proliferative response and cytokine release in donors and PDA patients, then cloned into the pVax plasmid to generate the ENO3PEP vaccine. KPC mice, which spontaneously develop PDA, were vaccinated at 8 weeks of age and received booster doses every two weeks for four rounds before being sacrificed at 18 weeks. Mice were treated with GemNab (gemcitabine 1 mg/mouse; Abraxane 0.6 mg/mouse) at 9 and 11 weeks alone or in combination with ENO3PEP. Anti-ENO1 antibody levels were assessed by ELISA, and IFN γ -secreting T cells were measured using ELISpot. Tumor burden and metastases were evaluated through hematoxylin and eosin (H&E) staining, immune infiltration via immunohistochemistry (IHC), and collagen deposition using Masson's trichrome stain. Flow cytometry was used to characterize tumor-infiltrating and lymph node-resident immune cells.

Result and discussion

In KPC mice, ENO3PEP significantly reduced pancreatic tumor burden and metastases. It enhanced the humoral response by increasing anti-ENO1 IgG and IgG2c antibodies, the latter associated with Th1-driven immunity, suggesting a shift toward a stronger anti-tumor response. At the cellular level, ENO3PEP increased IFN γ secretion by ENO1-stimulated T cells and remodeled the tumor microenvironment by reducing collagen deposition and recruiting more activated cytotoxic immune cells through enhanced antigen presentation. ENO3PEP combined with GemNab shown enhanced therapeutic efficacy relative to each treatment individually, markedly decreasing tumor burden and enhancing both humoral and cellular anti-tumor immune responses.

Conclusion

Overall, the findings of this study suggest that ENO3PEP has the potential to serve as a promising boost to standard

chemotherapy, improving immune activation and enhancing treatment outcomes for PDA patients.

EACR25-1822**IL17A depletion remodels pancreatic tumor matrix and boosts ENO1 vaccine efficacy**

G. Tiberti¹, P. Diez¹, A. Scagliotti¹, I. Depetro¹, M. Erreni², L. Mortati³, A. Andolfo², P. Cappello¹

¹University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy

²San Raffaele Scientific Institute, Milan, Italy

³INRIM, Turin, Italy

Introduction

Pancreatic ductal adenocarcinoma (PDA) accounts for ~90% of all pancreatic cancers and has a poor prognosis, with a 5-year survival rate below 10%. This is largely due to the huge desmoplastic reaction and its immuno-suppressive tumor microenvironment (TME), dominated by a fibrotic extracellular matrix (ECM) rich in collagen, fibronectin, and structural proteins. The ECM acts both as a physical barrier to therapies and as a biochemical shield, releasing suppressive signals that prevent immune infiltration. Recent studies identified Interleukin 17A (IL17A) as a key driver of PDA progression, fostering immune evasion by promoting myeloid recruitment at the expense of T cells. This evidence highlights IL17A as a promising therapeutic target.

Material and method

To assess IL17A's role in ECM remodeling and immune responses, we bred KPC mice, a spontaneous PDA model, with IL17A knockout mice (KPC/IL17A^{+/+} and KPC/IL17A^{-/-}). Decellularized tumor matrices from both IL17A proficient and deficient KPC were analyzed by mass spectrometry to map ECM composition. Cancer-associated fibroblasts (CAFs) from both genotypes were isolated and used to generate 3D-spheroids (homotypic and heterotypic), to evaluate invasive properties and ECM deposition. Atomic Force Microscopy (AFM) was performed on OCT-embedded tumors to assess stiffness. Lastly, IL17A depletion was combined with ENO1-DNA vaccine, and immune responses were analyzed by flow cytometry and ex vivo functional assays.

Result and discussion

IL17A depletion led to significant ECM remodeling, with increased levels of tumor-restraining Collagen I and decreased pro-metastatic Collagen VI, Fibronectin, and VEGFR. IL17A-depleted cancer cells and spheroids showed reduced invasion and downregulation of EMT transcription factors. AFM revealed that IL17A-deficient tumors exhibited softer matrices, which favored immune cell infiltration. IL17A depletion combined with ENO1-DNA vaccination prolonged survival of KPC mice, by increasing CD8⁺ T cells and NK cells within tumors and enhancing their cytotoxicity. Depleting CD8⁺ or NK cells abolished the vaccine's efficacy, confirming their critical role.

Conclusion

Our data show that IL17A promotes a pro-invasive, immune-excluding ECM in PDA, supporting immune evasion and therapy resistance. IL17A depletion reprograms the TME, reducing stiffness, boosting immune

infiltration, and enhancing anti-cancer vaccine efficacy. Targeting IL17A may thus ameliorate immune-based therapies in PDA.

EACR25-1823

Enhanced natural killer cell anti-tumor activity with Erastin mediated ferroptosis and potential therapeutic application in neuroblastoma

V. Anthonydhason¹, E. Islamagic², T. Martinsson², S. Fransson², F. Thoren², G. Umapathy²

¹The University of Newcastle, Newcastle, Australia

²University of Gothenburg, Gothenburg, Sweden

Introduction

High-risk neuroblastoma (NB) is rare, it often relapses and becomes refractory to treatment, making it a significant contributor to childhood cancer mortality. Addressing the challenges posed by NB's resistance to conventional apoptosis-inducing therapies has become a pressing concern in pediatric oncology research. In recent years, the growing comprehension of alternative cell death modalities distinct from apoptosis has revealed a promising avenue in the endeavor to combat treatment-resistant cancers. One such mechanism, ferroptosis, has attracted increasing attention for its potential role in combating therapy-resistant cancer cells. High-risk NB typically aligns with the immune exclusion phenotype, where substantial immune cell infiltration is notably absent. While the role of immune cell infiltration in NB is of significant interest, the underlying mechanisms remain elusive.

Material and method

Cell viability and proliferation were assessed using MTT and colony formation assays. Lipid peroxidation levels were measured to confirm ferroptosis induction.

Transcriptomic analysis was performed using RNA sequencing to identify differentially expressed genes upon Erastin treatment. ULBP1 expression was validated using qRT-PCR and flow cytometry. Co-culture experiments with NK-92 cells were conducted to assess NK cell-mediated cytotoxicity using a standard cytotoxicity assay. ATF4 involvement in ULBP1 regulation was investigated using siRNA-mediated knockdown and western blot analysis. Statistical analyses were performed using GraphPad Prism.

Result and discussion

Here, we show that induction of ferroptosis using Erastin, a cysteine-glutamate antiporter inhibitor reduced NB cell proliferation and foci formation. Furthermore, our transcriptomics analysis showed upon treatment with Erastin of NB cells increased expression of ULBP1 (NKG2D ligand). Co-culture of NK cells and NB cells upon treatment with Erastin showed a significant increase NK cell cytotoxicity. Additionally, we found transcription factor ATF4 driver ULBP1 expression in NB cells upon ferroptosis induction.

Conclusion

Our results suggest that the NK cell's cytotoxic function can be enhanced with Erastin mediated ferroptosis which might be beneficial for NB patients.

EACR25-1904

Generation of versatile tumor target cell lines using the SpyCatcher/SpyTag system

F. Trigo de Moraes^{1,2}, I. Cardoso^{1,2}, J. Duarte¹, M. Thomaz^{1,2}, R. Castro^{1,2}, X. Garate^{1,2}, H. Hauser^{1,3}, N. Duarte^{1,2}

¹Instituto de Biologia Experimental e Tecnológica, Oeiras, Portugal

²Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal

³Helmholtz Centre for Infection Research, Braunschweig, Germany

Introduction

Immunotherapies, such as therapeutic monoclonal antibodies and engineered chimeric antigen receptor (CAR) T cells, are powerful tools in cancer treatment, particularly effective against hematological malignancies. However, tumor escape mechanisms, such as down-regulation of tumor antigens or tumor heterogeneity, often contribute to the clinical failure of these therapies. To address these challenges, it is essential to develop robust in vitro platforms for assessing effector cell potency during the development of novel immuno-therapies.

Material and method

We have established a versatile tumor target cell line, Spy target, which can be post-translationally decorated with tumor antigens. This platform allows precise control over antigen selection, antigen density and the combination of multiple antigens within the same cell line. The Spy target system is based on the SpyTag/SpyCatcher technology, derived from the fibronectin-binding protein (FbaB) of Streptococcus pyogenes. SpyTag and SpyCatcher spontaneously form a covalent isopeptide bond upon interaction. We engineered two cell lines (HEK293T and MDA-MB-231) expressing SpyCatcher on the cell membrane and performed a clonal selection of the transfected cell lines to further obtain a homogenous population expressing high levels of SpyCatcher. As a proof of concept, we tested HER2, a clinically relevant tumor antigen overexpressed in various solid tumors (breast, ovarian, gastric) and associated with poor prognosis. SpyTag-HER2 fusion protein was produced in HEK293-E6 cells as a soluble recombinant protein and subsequently displayed on the Spy target cells. We then performed a functional characterization of Spy target cells displaying different levels of HER2 antigen.

Result and discussion

Antibody-dependent cell cytotoxicity assay (ADCC) was conducted using a reporter cell line that stably expresses the FcγRIIIa receptor and an NFAT response element driving firefly luciferase expression. Titration of the therapeutic anti-HER2 antibody (trastuzumab) demonstrated specific effector cell dose-dependent activation only in the presence of Spy target cells decorated with SpyTag-HER2.

Conclusion

We are currently expanding this platform by incorporating additional tumor antigens and implementing further functional assays. These include

testing the potency of CAR T cells, CAR macrophages, and different monoclonal antibodies in ADCC assays, further advancing the development of novel immunotherapies.

EACR25-1935

The immune and metabolic profile in metastatic and early-stage triple negative breast cancer patients treated with immune checkpoint inhibitors

L. Serrano García¹, G. Quintas², D. Collado-Martínez³, M. Torregosa³, S. Marín⁴, V. Puglia⁵, J. O'Connor Blasco⁶, A. Llobart Cussac⁴, M. Fernández-Murga¹

¹Hospital Arnau de Vilanova, Molecular Oncology, Valencia, Spain

⁴Hospital Arnau de Vilanova, Medical Oncology, Valencia, Spain

⁵Hospital Arnau de Vilanova, Pathological Anatomy, Valencia, Spain

⁶Universitat de Valencia, Bioquímica, Valencia, Spain

Introduction

Immune checkpoint inhibitors (ICIs) are a promising option for triple negative breast cancer (TNBC) treatment. However not all the patients respond equally and causes are unknown. The objective of the present study is to research immune and metabolic profiles through non-invasive methods that allows to differentiate the stage of the disease and the response to ICIs.

Material and method

51 TNBC patients were enrolled: 13 under first line of treatment with ICIs (MET) and 38 under neoadjuvant chemotherapy with ICIs (NEO). Blood samples were collected before the start of treatment (baseline) in all patients. In NEO patients we collected samples after 3 weeks of treatment (3W) and at the end of treatment (endpoint). NEO patients were classified as responders (R) and non-responders (NR) based on whether they achieved histologically complete pathological response respectively after treatment. Immune profile were characterized by flow cytometry and metabolomics profile was determined by mass spectrometry.

Result and discussion

MET group showed significant higher levels of total Myeloid Derived Suppressor Cells (MDSCs) ($p = 0.0057$) and granulocytic MDSCs (G-MDSCs) ($p = 0.0025$) at baseline point compared to NEO patients.

Metabolomic analysis revealed significant differences in metabolites of the Tyrosine and Purine pathways between both groups ($p < 0.005$). In NEO patients we observe a significant increase during the treatment in the percentage of total T lymphocytes ($p < 0.0001$), Natural Killer Cells (NKTs) ($p = 0.001$) and cytotoxic T lymphocytes (TCD8+) ($p < 0.0001$). When classified into responses, only the R group obtained a significant increase in NKT ($p < 0.001$) and TCD8+ ($p < 0.001$) after therapy. NR group showed higher percentages of MDSCs at all sample points. This increment was statistically significant for total MDSCs at baseline ($p = 0.01$) and G-MDSCs at baseline ($p = 0.0087$), 3W ($p = 0.02$) and

endpoint ($p = 0.027$). In addition, results obtained revealed changes in metabolic pathways in all time points including the Phenylalanine, Tyrosine and Tryptophan metabolism. The analysis of 3W samples showed additionally differences in Purine and Steroid hormones pathways.

Conclusion

Advanced disease (MET) presents higher immuno-suppressive cells (MDSCs) than early stage (NEO) and metabolomic differences at baseline point. In NEO patients immunotherapy is capable to promote an activation of the immune system through the increase of antitumor cells TCD8+ and NKTs especially in responder subjects. Non responders present activated immuno-suppression mechanisms such as MDSCs. The cellular changes, along with the differences in the metabolomic profile of each group, allow us to establish personalized patterns that inform the stage of disease and response to ICIs therapy in TNBC and could help in clinical decision-making. This study is still in the recruitment phase with the expectation that this trend will continue.

EACR25-1965

Exploring CAR-T Cell Killing Dynamics Through Live-Cell Fluorescence Microscopy

N. Opdam-van de Laar¹, S. Meiler¹, I. Thijssen-van Loosdregt¹, D. Sullivan²

¹Axon BioSystems, Eindhoven, Netherlands

²Axon BioSystems, Atlanta, United States

Introduction

Harnessing the potent cytotoxicity of chimeric antigen receptor T (CAR-T) cells has revolutionized cancer immunotherapy. Human epidermal growth factor receptor 2 (HER2) has emerged as a critical target in CAR T-cell therapy. HER2 is notably overexpressed in a significant portion of A549 lung cancer cells and SKOV3 ovarian cancer cells, making these cell lines valuable models for studying HER2-targeted therapies. Traditional cytotoxicity assays provide only static endpoint measurements and often rely on 2D cell culture models, which fail to capture the structural complexity of tumors *in vivo*. Therefore, fluorescence live-cell imaging can play a pivotal role in advancing CAR T-cell research by enabling real-time monitoring of CAR T-cell interactions with fluorescent HER2-positive cancer cells in 3D. This study aims to explore the dynamics of CAR-T cell-mediated cytotoxicity using the Omni platform.

Material and method

A549-GFP cells and SKOV3-GFP cells were detached from flasks and dissociated via trypsinization and counted using the Exact FL (Axion BioSystems). Next, cells were centrifuged and resuspended to a final concentration of 20,000 cells/mL, and 100 μ L cell suspension was added to a 96-well U-bottom plate and centrifuged at 1000 rpm for 4 minutes. After 48 hours of incubation, CAR T-cells were added to the SKOV3-GFP and A549-GFP spheroids with the following effector: target (E:T) ratios: 0:1 (Ctrl), 1:10, 1:5, 1:2, 1:1, 2:1, 5:1 and 10:1. The plate was imaged hourly for 72 hours on the Omni.

Result and discussion

Results showed that the potency of CAR T-cell-mediated cytolysis was dose-dependent, with higher E:T ratios leading to greater target cell killing. SKOV3 spheroids, which overexpress HER2, were more susceptible to HER2 CAR T-cell-mediated killing, while A549 spheroids with low HER2 expression required higher E:T ratios for effective cytolysis. For example, SKOV3 spheroids treated with CAR T-cells showed a dose-dependent decrease in fluorescence intensity, with higher E:T ratios (2:1, 5:1, and 10:1) resulting in approximately 75% reduction in fluorescence intensity by 72 hours. In contrast, A549 spheroids only exhibited significant killing at 5:1 and 10:1 E:T ratios. Non-treated spheroids showed continuous growth over time, indicated by a steady increase in fluorescence intensity.

Conclusion

The Omni platform enables real-time monitoring of CAR T-cell interactions with target cells, providing key insights into the cytotoxic potential of these immune cells. Fluorescent metrics were used to track immune cell-mediated killing, with changes in fluorescence confluence and intensity reflecting the extent of target cell death. Real-time monitoring with live-cell imaging tools like Omni provides valuable insights into the dynamics of immune cell interactions, helping to refine and improve CAR T-cell therapies.

EACR25-2022

Detecting changes in the tumour microenvironment and in CART infiltration following chemotherapeutic priming using intravital imaging

M. Dinevska¹, B. Pereira¹, V. Lee¹, A. Fontaine-Titley¹, C. Scheffler², S. Harrison³, P. Darcy², R. Taylor³, G. Risbridger³, P. Timpson¹

¹*Garvan Institute of Medical Research, Sydney, Australia*

²*Peter MacCallum Cancer Centre, Melbourne, Australia*

³*Monash University, Melbourne, Australia*

Introduction

Chimeric antigen receptor (CAR) T cell therapies have shown remarkable efficacy in haematological malignancies but demonstrate limited efficacy against solid tumours including prostate cancer. This is in part due to an immunosuppressive and fibrotic tumour micro-environment (TME) which leads to restricted CAR T cell tumour infiltration, reduced CAR T cell persistence and CAR T cell exhaustion. Accumulating evidence suggests that chemotherapies can modulate the TME to dampen immunosuppression and potentially improve CAR T cell efficacy.

Material and method

Our work aims to optimise and develop an intravital imaging pipeline to both longitudinally image and trace changes in the TME following chemotherapeutic priming, and track CAR T cell infiltration in patient-derived xenograft (PDX) models of prostate cancer. To achieve this, we are using optical imaging windows in prostate cancer PDXs and repeated longitudinal imaging to assess tumour dynamics.

Result and discussion

Using this imaging-based approach, we can

longitudinally detect any changes in fibrosis through second-harmonic generation (SHG) imaging, changes in blood vasculature using quantum dots, and assess CAR T cell dynamics in PDX models of prostate cancer following chemotherapy. This approach can enable us to optimise chemotherapeutic priming to modulate the TME and observe improvements in CAR T efficacy including cell tumour infiltration, persistence, movement and dwell time.

Conclusion

Our work highlights the advantages of optical imaging windows in guiding CAR T cell delivery and potentially improving response rates in solid tumors.

EACR25-2039

POSTER IN THE SPOTLIGHT

Cytotoxic ILC-1 cells determine outcome of PD-(L)1 blockade in microsatellite instable cancers

P. van Royen¹, E. Voest¹, J. van de Haar¹

¹*The Netherlands Cancer Institute, Amsterdam, Netherlands*

Introduction

PD-(L)1 blockade has revolutionized the treatment of mismatch repair deficient (dMMR)/microsatellite instable (MSI) cancers. However, dMMR/MSI tumors frequently lose HLA class I-mediated antigen presentation, rendering them resistant to the dominant effectors of PD-(L)1 blockade: adaptive CD8+ T-cells. Previously it has been shown that innate antitumor immunity is an important determinant of response. However, the role and clinical relevance of innate lymphoid cells (ILCs) in this context remains largely undefined.

Material and method

To study the role of ILCs in dMMR/MSI cancers, we analyzed the transcriptomes and clinical outcomes of 74 metastatic dMMR/MSI tumors treated with anti-PD-(L)1 in the DRUP study. We performed an in-depth phenotypic characterization of ILC1-like cells in dMMR/MSI tumors, using flow cytometry, imaging mass cytometry (IMC) and scRNA-sequencing. Furthermore, we optimized an in vitro expansion protocol and performed functional characterization of ILC1-like cells in co-cultures with dMMR/MSI cancer cells with/without antigen presentation defects.

Result and discussion

Among dMMR/MSI cancers in the DRUP study, expression of the key lymphocyte marker CD7 was strongly associated with clinical benefit of PD-(L)1 blockade, broadly implicating lymphocytes at the core of these responses. Surprisingly, however, infiltration by classical lymphocytic effector populations did not seem to underly this effect, as markers of CD8+ T cells, CD4+ T cells, and NK cells were not associated with response. In contrast, marker gene analysis identified ILC1-like cells as the main lymphocytic subset associated with clinical outcome in our cohort. In-depth phenotypic studies showed that ILC1-like cells infiltrating dMMR/MSI tumors highly expressed markers of activation, proliferation, and cytotoxicity, as well as immune check-

points including PD-1 and a selection of activating innate immune receptors and “missing self” KIR-receptors. In vitro expanded tumor-infiltrating ILC1-like cells showed cytotoxic antitumor responses in co-culture with dMMR/MSI tumor organoids and cell lines. Importantly, the powerful tumor killing capacity of ILC1-like cells was independent of HLA class I expression.

Conclusion

Cytotoxic ILC1-like cells are a clinically relevant tumor-reactive pool of ILCs in dMMR/MSI cancers, predicting outcome of PD-(L)1 blockade in this disease. These data contribute to our understanding of the mechanism of action of immune checkpoint blockade in this largely HLA class I-negative disease and demonstrate the potential of ILC1-like cells in cancer immunotherapy.

⁵SYNENTEC GmbH, Elmshorn, Germany

⁶Christian-Albrechts-University, University Medical Center Schleswig-Holstein, Department of Gynecology and Obstetrics, Kiel, Germany

⁷SYNENTEC GmbH, Application Development, Kiel, Germany

Introduction

Antibody-based treatment strategies have revolutionized the therapy of some cancer entities. Yet, assessing antibody-based immunotherapy approaches in vitro is challenging and heterogeneous. One aspect involves studying Fc-mediated effects like antibody-dependent cellular phagocytosis (ADCP). ADCP targets cancer cells with monoclonal antibodies for clearance by phagocytic immune cells. Standard phagocytosis assays rely on endpoint measurements, providing limited kinetic information and often requiring destructive protocols. In contrast, many live-cell imagers have limited capacity, hindering high-throughput screening. This study uses SYNENTEC’s live-cell imaging automation system (CELLAVISTA 4K®, SYBOT-1000®, CYTOMAT®) to analyze ADCP in a high-throughput format.

Material and method

Donor-derived macrophages, differentiated from peripheral blood mononuclear cells (PBMCs), were co-cultured with pHrodo®-labeled REH cell lines or primary patient-derived cells from acute lymphoblastic leukemia (ALL) patients in 96-well flat-bottom plates.

The plates were automatically imaged over time using the automation system, and ADCP was automatically quantified by determining fluorescent spots using YT-SOFTWARE®.

Result and discussion

At first, glycine-treated REH cells were used as a positive control to determine the optimal exposure time and thresholds for the image analysis. Using these parameters, the treated cells showed a significantly higher number of fluorescent spots than untreated cells. Secondly, we compared whether our assay demonstrated differential responses to various treatments. While DMSO or an isotype control antibody did not increase the fluorescent signals, antibody and chemotherapy treatments showed a moderate effect. The highest effect was observed with a combination treatment. Thirdly, we tested whether the assay also worked with primary ALL cells. Again, we observed treatment-dependent differences in ADCP induction, depicting that the device can also be used to analyze primary samples.

Conclusion

Using the automation system improved the reliability and throughput of our imaging processes, enabling us to measure more than two plates for parallel screening. This increased throughput has the potential to greatly advance the study of phagocytosis assays, by reducing the time, resources, and cost required to identify promising drug candidates or combination treatments. Therefore, high-throughput screening can ultimately contribute to the development of more effective antibody-based therapies.

⁴Pediatric Hospital Bambino Gesù, Innate lymphoid cells Unit, Roma, Italy

Introduction

The effectiveness of immunotherapeutic mAbs or CAR-T therapies can be hindered by tumor cells losing antigen expression and upregulating neoantigens and immune checkpoint (IC) ligands. In contrast, NK cells are not dependent on specific antigens for cytotoxicity, offering promise in cellular immunotherapy. Allogeneic NK cells have a lower risk of graft-versus-host disease (GvHD) and cytokine release syndrome (CRS), making them a safer, “off-the-shelf” option. However, a hostile tumor microenvironment can lead to resistance and reduce NK cell efficacy. To enhance their therapeutic potential, NK cells can be genetically engineered to target tumor markers common to a broad range of tumors (as IC ligands) and to overcome the hostile TME.

Material and method

NK cells, isolated from peripheral blood of healthy donors, were genetically modified using retroviral vectors. The retroviral tri-cistronic vectors encode chimeric proteins composed of IC extracellular domains (specifically extracellular PD1-exPD1) fused to the cytoplasmic NKG2D domain linked to 4.1BB co-stimulatory in frame with NKG2A single chain variable fragment (scfv) and IL15.

Result and discussion

exPD1-NK cells, obtained upon transfection, increased the cytotoxicity against PD-L1+ tumor cells. Moreover, exPD1-NK cells constitutively release NKG2A-scfv fragment and IL15. The NKG2A-scfv fragments disrupted the NKG2A/HLA-E interaction and blocked the NK inhibitory receptor NKG2A signal in the TME. In addition, the release of IL15 supported the NK cell survival and proliferation in vivo. The ability to release NKG2A scfv and IL15 makes exPD1-NK cells better able to kill even PD-L1 negative cells.

Conclusion

Our findings provide a comprehensive strategy to overcome significant obstacles in NK cell therapy, demonstrating the potential of these innovations to improve the effectiveness of NK cell-based immunotherapies and offer new therapeutic options for patients with solid tumors. This research could contribute to a paradigm shift in cancer treatment.

Neutrophil serine proteases alter IL-18 to a superkine

A. Wöhr^{1,2}, M. Gabl^{1,2}, R. Riise^{1,2}, J. Josef Husein^{1,2}, K. Christenson^{1,3}, F. Bergh Thorén^{1,2}

²*University of Gothenburg, Department of Medical Biochemistry and Cell Biology, Institute of Biomedicine, Gothenburg, Sweden*

³*University of Gothenburg, Institute of Odontology, Gothenburg, Sweden*

Introduction

IL-18 is a key cytokine stimulating IFNγ production in NK cells. Clinical trials using IL-18 monotherapy have yielded limited success, as IL-18, despite being safe, failed to generate sufficient therapeutic effects. A possible explanation could be its inability to elicit strong immune responses. Therefore, developing IL-18 variants that are more potent is essential for improving its therapeutic potential. Here, we characterize a neutrophil-altered IL-18 variant with increased capacity to induce IFNγ production in NK cells.

Material and method

IFNγ produced by primary NK cells or KG-1 cells upon stimulation with PMN or neutrophil serine protease (NSP) pre-exposed IL-18 was determined using ELISA or flow-cytometric analysis of intracellular IFNγ. NSP enzyme activity was measured with a FRET substrate.

Result and discussion

Our study demonstrates that neutrophils regulate the bioactivity of IL-18 in a fine-tuned manner. Exposure of IL-18 to low numbers of neutrophils significantly

enhanced its bioactivity and induced augmented IFNγ responses in NK cells and KG-1 cells. With increasing numbers of neutrophils this phenomenon shifted to degradation of the IL-18 molecule and abolished IFNγ release. We found that PMN-processed IL-18 increased the percentage of IFNγ+ CD56bright NK cells and IFNγ production per CD56bright NK cells as determined by the mean fluorescence intensity (MFI) of IFNγ+ NK cells. Using purified NSP, we found that in particular Proteinase 3 was capable of triggering increased IFNγ production in KG-1 cells.

Conclusion

Our results suggest the existence of a fine-tuned system to modulate the bioactivity of IL-18 during an acute inflammatory response, affecting cytokine production in immune cells, such as NK cells. NSP-altered IL-18 variants could be harnessed to boost NK cell-based cancer therapies.

Introduction

The standard treatment for triple-negative breast cancer (TNBC) relies on chemotherapy, increasingly combined with immune checkpoint inhibitors (ICIs). Different chemotherapeutic agents may uniquely influence both the tumor and its microenvironment (TME), particularly in terms of immune modulation. While some evidences exist in preclinical models, data from clinical tumours remain limited. This study aimed to compare the early impact of various neoadjuvant chemotherapy regimens on cancer pathways, immune-related features, and single gene expression in TNBC patients.

Material and method

We analysed RNA-seq data from paired core biopsies collected before and after the first cycle of neoadjuvant chemotherapy in four TNBC patient cohorts. Patients were treated with nab-paclitaxel/carboplatin (PNabT, n = 93), doxorubicin/cyclophosphamide (AC, n = 19), nabpaclitaxel (NabT, n = 15), or paclitaxel (T, n = 17). Using the singscore R package, we quantified 80 gene sets related to the TME, immune function and signalling in cancer. Treatment-induced dynamics for single genes and signature scores were identified by ANOVA analysis. P-values were adjusted for multiple testing using the Benjamini-Hochberg method. Gene with cell-

type specific expression were annotated using external single cell data to aid data interpretation.

Result and discussion

On-treatment expression profiles showed an overall up-regulation of immune cell- and immune function-related signatures, alongside a down-regulation of proliferation-related pathways. However, treatment-dependent differences emerged. Tumours treated with AC or NabT exhibited the greatest up-regulation of T cells, macrophages and dendritic cell signatures, whereas over 20% of tumours in the PNabT and T groups showed a decrease, particularly when baseline expression was high. NabT-treated patients displayed the strongest up-regulation of B, plasma, and mast cell signatures, while proliferation-related signatures were most significantly down-regulated in PNabT and NabT groups. Expression patterns of well established cell markers confirmed these patterns. Notably, in tumours with high immune infiltration, PD-L1 expression further increased in over 90% of TNBCs receiving AC, while a decrease was observed in 40-60% of tumours receiving alternative chemotherapies.

Conclusion

These findings highlight the early immuno-modulatory effects of neoadjuvant chemotherapy in TNBC, with anthracyclines and nab-paclitaxel alone eliciting a particularly strong immune response. These insights may have clinical implications for optimising chemotherapy combinations with immune checkpoint inhibitors in TNBC treatment.

EACR25-2299

Inhibition of Furin in CAR macrophages directs them toward a proinflammatory phenotype and enhances their antitumor activities

L. Ziane Chaouche¹

¹PRISM, U1192, Lille, France

Introduction

CAR T-cell therapy has shown efficacy in hematological malignancies, but its application to solid tumors is hindered by poor infiltration and tumor-induced immunosuppression. Macrophages, key players in the tumor microenvironment, can infiltrate solid tumors, interact with stromal components, and phagocytose tumor cells. We hypothesize that genetically engineering macrophages to express a CAR targeting tumor antigens, combined with an activation strategy, could enhance their anti-tumor activity and trigger a robust T cell response

Material and method

In this project, we first developed complex preclinical tumoroid models incorporating macrophages to better mimic the tumor microenvironment and assess the engineered macrophages expressing a CAR receptor targeting the HER2 antigen. This CAR, which includes an intracellular CD3ζ domain similar to the FcεRI-γ protein, enhances macrophage phagocytic activity upon activation by antibody-antigen complexes.

Approximately 30% of the transduced macrophages expressed the CAR.

Result and discussion

CAR-modified macrophages (CAR-M) exhibited

significantly enhanced phagocytosis of HER2-coated beads and HER2+ cancer cell lines compared to wild-type macrophages. Co-culture experiments with patient-derived breast cancer tumoroids confirmed the efficacy of CAR-M in a complex tumor environment. However, within the tumor microenvironment, macrophages often adopt an anti-inflammatory phenotype, reducing their anti-tumor potential. To address this issue, we employed a dual strategy involving the inhibition of proprotein convertases, particularly Furin, in CAR-M. Furin inhibition led to increased expression of pro-inflammatory markers and enhanced macrophage activation in the presence of cancer cells. Additionally, Furin-inhibited CAR-M displayed enhanced phagocytic activity against HER2+ targets. Our findings highlight the critical role of proprotein convertases in regulating macrophage phenotype. Furthermore, CAR-M demonstrated the ability to activate T cell proliferation, an effect further enhanced by Furin inhibition.

Conclusion

Our therapeutic strategy is based on the dual activation of tumor-infiltrating macrophages: first, by enhancing their phagocytic activity through CAR receptor expression targeting tumor antigens, and second, by reprogramming them towards a pro-inflammatory phenotype through Furin inhibition. Additionally, while CAR cell immunotherapy is increasingly attractive, identifying sufficiently specific tumor targets remains a challenge. Recent advances in antigen identification have introduced a new class of proteins: alternative proteins (AltProts) derived from previously non-coding regions of the transcriptome. Incorporating these proteins has allowed us to identify new antigenic targets for CAR-M therapies.

EACR25-2311

A positive crosstalk between chemokine receptor CXCR4 and intrinsic programmed cell death-1 receptor (iPD-1): anti PD-1, nivolumab, impairs CXCL12-induced signaling, proliferation and migration in human colon cancer cells

C. Ieranò¹, C. Vetrei¹, G. Rea¹, F. Auletta¹, D. Di Febraro¹, A. Trotta¹, G. Di Maiolo¹, S. Santagata¹, M. Napolitano¹, S. Scala¹

¹Istituto Nazionale Tumori - IRCCS - Fondazione G. Pascale, Napoli, Italy

Introduction

Colorectal cancer is a significant contributor to cancer-related mortality, with metastasis being a primary cause of death. CXCR4 was previously reported to have a prognostic value in colorectal cancer. PD-1 signaling typically mediates immune exhaustion in immune cells. Recently, PD-1 expression was also described on tumor cells. Interestingly, PD-1 expression promotes tumor survival and chemoresistance in melanoma, while in colon and non-small cell lung cancer may contribute to growth suppression. The heterogeneity in PD-1's role within different cancers makes it an intriguing target for therapeutic interventions. Aim of the work is to investigate and delineate the cross talk between the two receptors to identify targetable interactions potentiating

the efficacy of immunecheckpoint inhibitors in human colon cancer cells

Material and method

PD-1 and CXCR4 expression in human colon cancer cell lines HCT116, HT29, and LoVo was determined through flow cytometry with APC anti-human CD279 (clone MIH4) and PE anti-CXCR4 (FAB170P); immunofluorescence using primary anti-hCXCR4 and mouse monoclonal anti-hPD-1. Co-immunoprecipitation assay was performed in HCT116, HT29, LoVo to assess direct interaction between PD-1 and CXCR4. The protein extracts were immunoprecipitated using A/G-Agarose and incubated with mouse monoclonal anti-hPD1. IPs were run on an SDS-PAGE gel followed by immunoblotting to evaluate CXCR4. CXCL12-induced cell viability and transwell migration assay were conducted in the presence nivolumab, NIVO 1-10 μ M, and CXCR4 inhibitor, R54 0.1,1 μ M). Additionally, intracellular signaling CXCR4-PD-1 was assessed through ERK1/2 and Akt and SHP2

Result and discussion

CXCR4 and PD-1 were co-expressed in HT29 (47% CXCR4; 22% PD1), HCT116 (CXCR4 30% and PD-1 30%), LOVO (45% CXCR4 and 25% PD-1) cells. Through immunofluorescence, CXCR4 and PD-1 co-localized in HT29, HCT116 and LoVo cells. Co-immunoprecipitation confirmed a direct interaction between PD-1 and CXCR4 in HT29, HCT116, LoVo cells. NIVO (1 μ M) inhibits CXCL12 migration in LoVo and HT29 (by 2-fold). Similarly, PD-1 ligand, PD-L1 induced colon cancer migration impaired by the newly developed CXCR4 inhibitor- R54 in a dose dependent manner. Additionally, NIVO (1 μ M) impaired CXCL12-induced cell proliferation and CXCL12 induction of ERK/Akt suggesting, as PD-1 is not a known receptor of CXCL12, that CXCL12/CXCR4 signaling impairment depends on PD-1 blocking. Conversely, CXCL12 activates SHP2, a key downstream effector of PD-1 transduction while NIVO (1 μ M) inhibited it.

Conclusion

These results demonstrate the crosstalk between PD-1/PD-L1 and CXCR4/CXCL12 in human colon cancer cells. This positive crosstalk highlights a potential therapeutic target in cancer immunotherapy. Nivolumab not only counteracts immune suppression but also reduces migration induced by CXCL12, offering a potential therapeutic target for inhibiting metastatic progression in colon cancer

Würzburg, Germany

⁴University of Rome Tor Vergata, Department of Biology, Rome, Italy

Introduction

Autophagy is intimately involved in the immunological control of malignant transformation, tumor progression and therapy response. Medulloblastoma (MB) is the most common pediatric brain tumor with aggressive Group3 (G3) subtype characterized by poor prognosis, therapy relapse, and high dependence on autophagy. Natural Killer cells (NKs)-based immunotherapy represents a promising therapeutic value in the treatment of G3 MB. Here, we explore the targeting of autophagy as an immunomodulatory approach to promote the homing of effector NK cells into MB tumor sites and sensitize it to engineered-NKs based immunotherapy.

Material and method

Flow cytometry and western blotting were used to investigate the G3 MB NK-related activating ligands and the cytotoxic potential of NK cells.

Result and discussion

We demonstrate that G3 MB cell lines and in G3 MB patients-derived cells show low levels of NKs-related activating ligands (ULBPs, CD155, CD112, MICA/B) in compared to others MB subgroups. Interestingly, genetic and pharmacologic inhibition of autophagy increases NKs-related ligands expression on cell surface of MB G3 cells, and boosts G3 MB sensitiveness to NKs-mediated cytotoxicity. In addition, genetic inhibition of autophagy in G3 MB cell line modulates cytokines and chemokines secretion and improves in vitro NKs migration. Chloroquine treatment improves also the efficacy of NKs to reduce tumor growth in G3 MB xenograft model. In order to optimize our model, we hypothesize that using engineered NK cells could improve their therapeutic efficacy. We found that engineered NK cells are more capable of eliminating G3 MB cells in vitro.

Interestingly, autophagy inhibition is able to enhance the therapeutic efficacy of engineered NK cells against G3 MB cells in vitro, as well in an orthotopic G3 MB in vivo model.

Conclusion

The completion of our project would be helpful to design a novel therapeutic approach for children with high-risk MB, aiming to a higher clinical response rate coupled with less toxicity than conventional therapies.

EACR25-2349

Anti-IL-7R α antibodies: a targeted therapy for T-cell Acute Lymphoblastic Leukemia

M. Duque¹, J. Santos², M. Pajuelo², A. Parada², R. Fragoso¹, J. T. Barata¹

¹Gulbenkian Institute for Molecular Medicine, Signaling in Cancer Lab, Lisbon, Portugal

²FairJourney Biologics, Porto, Portugal

Introduction

T-cell Acute Lymphoblastic Leukemia (T-ALL) is an aggressive sub-type of ALL. Despite high therapeutic efficacy in children, adult cases and refractory/relapse disease remain a significant hurdle. Interleukin-7 receptor (IL-7R) is expressed in around 70% of T-ALL cases and IL-7 promotes T-ALL cell proliferation and viability in

vitro and leukemogenesis in vivo. Moreover, 10% of T-ALL cases display IL-7R α gain-of-function mutations. T-ALL cell dependence on IL-7R α provides a robust rationale to target this pathway using anti-IL-7R α monoclonal Antibodies (mAbs).

Material and method

To identify anti-human IL-7R α mAbs with clinical potential, we evaluated the ability and specificity of a panel of 48 mAbs (generated by FairJourney Biologics) to bind to human IL-7R α , using flow cytometry (FC). mAbs with high binding capacity were further characterized for their:

- 1) ability to block IL-7-mediated signaling in T-ALL cells (western blot);
- 2) impact on the viability and proliferation of T-ALL samples (FC analysis);
- 3) internalization kinetics (FC analysis);
- 4) capacity to induce Antibody-dependent cellular cytotoxicity (ADCC) and/or
- 5) Antibody-dependent cellular phagocytosis (ADCP). The FJB45 mAb was tested in vivo, using a T-ALL patient-derived xenograft (PDX) mouse model in a phase II-like clinical trial setting. NSG mice were transplanted with 10 different T-ALL PDX samples and treated with placebo or the FJB45 mAb.

Result and discussion

Four mAbs with high affinity binding to hIL-7R were selected: FJB26, FJB29, FJB45 and FJB48. None of these mAbs blocked IL-7R α -mediated signaling in T-ALL cell lines and PDX cells, as evidenced by the lack of impact on the phosphorylation levels of downstream effectors of IL-7R and on IL-7-mediated viability and proliferation of T-ALL cells. However, they all showed ADCC potential, with FJB45 displaying the strongest effect in T-ALL PDX cells. Moreover, FJB29, FJB45 and FJB48 exhibited ADCP potential, with the latter inducing the strongest effect. Thus, FJB45 was selected to be tested in vivo. In a phase II-like clinical trial setting, FJB45 clearly extended overall mouse survival in 4 out of 10 PDX samples. On average, FJB45 mAb extended mouse survival for 14 days. Remarkably, there was one PDX that responded exceptionally well to FJB45 mAb, with an increase in overall survival of 150 days.

Conclusion

We determined that FJB45 has ADCC- and ADCP-promoting capacity and is effective in vivo. Our studies contribute to the growing evidence that anti-IL-7R mAbs may be valid therapeutic tools for the treatment of IL-7R-positive T-ALL.

Introduction

Immune checkpoint blockade (ICB) targeting programmed cell death protein 1 (PD-1)/PD-ligand (PD-L1) has revolutionized cancer therapy, yet resistance remains a challenge, often due to poor T-cell infiltration, an immunosuppressive tumor microenvironment (TME), and T-cell exhaustion. Overcoming these barriers requires innovative strategies to boost tumor immunogenicity and reshape the TME. Here, we developed a nanovaccine (NV) designed to enhance melanoma-dendritic cells (DC) interactions, promoting antigen-specific T cell activation.

Material and method

A poly(lactic acid) (PLA) and mannose-conjugated poly(lactic-co-glycol) (PLGA) NV was engineered to co-deliver a melanoma neoantigen and toll-like receptor (TLR) ligands. NV physicochemical properties, entrapment efficiency (EE), internalization by DCs, and impact on DC viability were assessed. DC activation in lymph nodes (LN) of NV-immunized mice was evaluated. The therapeutic efficacy of NV in combination with three PD-1/PD-L1 modulators – a monoclonal antibody (α PD-L1), small interference RNA (siPD-L1) incorporated within NV, and an in-house discovered small-molecule inhibitor (SM56) – was evaluated in melanoma mouse models via tumor growth analysis and immune profiling [1].

Result and discussion

NV exhibited a mean size of around 200 nm, low polydispersity index, neutral charge, and spherical morphology. EE was 60–65% for the neoantigen and above 80% for TLR ligands. NV were efficiently internalized by DCs, particularly those with mannose conjugation, without compromising viability. NV treatment promoted DC activation in LNs, increasing CD80/CD86 expression and enhancing cytokine-secreting T-cell responses. In vivo, NV combination therapies showed distinct efficacy profiles: siPD-L1 failed to enhance tumor suppression significantly, while α PD-L1 and SM56 demonstrated potent anti-tumor effects. The strongest tumor regression and CD8+ T-cell infiltration were observed in the NV + α PD-L1 and NV + SM56 groups. Notably, only NV + SM56 reduced immunosuppressive cells in the TME, suggesting superior ability to reshape the immune landscape.

Conclusion

These findings underscore the potential of polymer-based NV to overcome ICB resistance by promoting T-cell responses and modifying the TME. Additionally, SM56 emerged as a promising alternative to monoclonal antibodies, demonstrating a strong synergistic effect with NV. This work supports the rationale for nanotechnology-driven combination strategies to improve melanoma immunotherapy outcomes.

Improving Triple-Negative Breast Cancer immunogenicity via viral-mediated epigenetic remodeling

S. Russo¹, Y. Giannoula¹, J. Chiaro¹, M. Gronholm¹

F. Hamdan¹, V. Cerullo¹

¹University of Helsinki, Helsinki, Finland

Introduction

Immunotherapy has emerged as a promising treatment for various cancers; however, the efficacy of such therapies is often hindered by the suppression of immune responses via the tumor microenvironment (TME). The TME is characterized by a complex relationship between cancer and its proximal non-cancerous cells and is heavily based on cell-cell communication via direct interaction, secretion of biomolecules, and cancer-derived extracellular vesicles. A clear example of this cancer-induced alteration is represented by myeloid-derived suppressor cells (MDSCs). Several studies have convergently shown that the expression of DNA-methyltransferase-1 (DNMT1) results in MDSCs protection from necroptosis and enhanced accumulation in vivo. Conversely, targeting DNMT1 through hypo-methylating agents (HMAs) has shown promising therapeutic potential by not only reducing the accumulation and suppressive activities of MDSCs but also synergistically with immune checkpoint inhibitors (ICI) to enhance cancer immunogenicity.

Material and method

Murine 4T1 (triple-negative breast cancer) and CT26 (colon carcinoma) cell lines were used as syngeneic tumor models in BALB/c mice. An oncolytic adenovirus expressing a DNMT1-targeting shRNA (OAd-shDNMT1) was engineered and validated for DNMT1 knockdown and genome-wide methylation reduction. Small extracellular vesicles (sEVs) were isolated from virus-infected cancer cells and characterized for RNA content and uptake by myeloid-derived suppressor cells (MDSCs). MDSC differentiation and suppressive function were assessed in vitro using flow cytometry and co-culture assays with murine splenocytes. In vivo, tumor-bearing mice received intratumoral OAd-shDNMT1, Decitabine (DAC), or immune checkpoint inhibitors (anti-PD-1), and tumor growth, immune infiltration, and systemic MDSC levels were evaluated.

Result and discussion

Collectively, in this study, we report that, by using virally infected TNBC murine cells as a source for shDNMT1-loaded sEV production, OAd-shDNMT1 successfully reduced MDSC levels in vitro and in vivo. Furthermore, the co-administration with ICI resulted in a significant tumor growth reduction in mice bearing poorly immunogenic TNBC 4T1 cells, and, in addition, promoting anti-tumor immunity and prolonged survival in modestly immunogenic colon CT26 cancer cells.

Conclusion

This multifaceted strategy based on OV-mediated immune stimulation and reduction of MDSC levels via sEVs, may improve clinical outcomes and the success of immuno-based regimens for patients facing MDSC-rich and highly aggressive cancer subtypes.

⁵Children's Hospital of Brasília, Laboratory of Translational Research and Department of Oncohematology, Brasília, Brazil

⁶Sabin Diagnosis and Health, Department of Hematology, Brasília, Brazil

Introduction

The most common pediatric hematologic cancer is B-lineage Acute Lymphoblastic Leukemia (B-ALL). Blinatumomab® destroys CD19+ leukemic cells, this study assessed its use in Brazilian children with Relapsed/Refractory (R/R) Ph-negative B-ALL

Material and method

This is a retrospective, prospective, and longitudinal cohort study that analyzed Blinatumomab® as a bridging therapy for Hematopoietic Stem Cell Transplantation (HSCT) in 16 pediatric patients with Ph-negative R/R B-ALL, during the years 2017 to 2024 (Follow-Up: 7 years), treated at the Children's Hospital of Brasília, Brazil. The study included real-world children and adolescents, aged between 0 and 21 years, with B-ALL in first hematological remission, maintaining a positive Minimal Residual Disease (MRD), with $\geq 0.01\%$ blasts in the Bone Marrow (BM) after first-line treatment. The data were collected from electronic medical records and all BM samples were studied following EuroFlow SOPs, with the acquisition of at least 5×10^6 events per sample. The FACSCanto cytometer and Infinicyt software were used to acquire and analyze MRD monitoring. The local ethics committee approved the study

Result and discussion

The recent emergence of targeted therapies has revolutionized the treatment of B-ALL. In this study, a total of 16 bone marrow samples were obtained from children with Ph-negative R/R B-ALL, with 62.5% being male and 37.5% female, with an average age of 6.81 years (0-21). The samples were studied at different times points during treatment with Blina®, including pre-transplant ($n = 16$) and pre- and post-transplant ($n = 3$), defining negative Minimal Residual Disease (MRD) as $< 0.01\%$ blasts in the BM. Blinatumomab® was administered as a continuous intravenous infusion for four weeks, at a dose of $5 \text{ mcg/m}^2/24\text{H}$ during the first 7 days of treatment (1st cycle), increasing to $15 \text{ mcg/m}^2/24\text{ H}$ on the subsequent days (2nd cycle). We observed a response to Blina® in 7 out of 16 patients (43.75%), with 93.75% ($n = 15$) using only the 1st infusion cycle, while 6.25% ($n = 1$) received both cycles. The predominant

side effect was febrile reactions, and 1 out of 16 patients developed an event associated with neurotoxicity and cytokine release syndrome. So far, 43.75% (n = 7) of the patients responded to treatment with Blina® and achieved remission. Among the non-responders, 37.5% (n = 6) were relapsing, and 18.75% (n = 3) died from causes unrelated to the use of immuno-therapy. This study demonstrates that pediatric patients can benefit from the use of Blinatumomab® from the first infusion cycle, paving the way for the HSCT procedure and resulting in complete remission in Ph-negative R/R B-ALL, marking a significant advancement in pediatric treatment.

Conclusion

Although our study had some limitations regarding its retrospective design and the limited patient population, the response rate in our cohort demonstrated that Blinatumomab® has a tolerable toxicity profile, providing hope for improvements in cure rates.

Advancing CAR-T clinical development with high-parameter CyTOF technology

M. Klug¹, L. Wang¹, S. Hasan², S. Li², M. Cohen², C. Loh²

¹Standard BioTools, Berlin, Germany

²Standard BioTools, Markham, Canada

Introduction

Adoptive immunotherapy using chimeric antigen receptor (CAR)-T cells is considered a recent revolutionary treatment in cancer therapy. CAR-T therapy has achieved great success in hematological B cell malignancies, however it has faced significant challenges in solid tumors due to various factors, such as complex tumor microenvironments, restricted trafficking, impersistent anti-tumor activity, and toxicities. A better understanding of CAR-T biology will accelerate development of CAR-T therapies with improved anti-tumor efficacy, durability, and decreased toxicities.

Material and method

High-parameter flow cytometry has been a powerful tool to functionally characterize CAR-T cells at multiple stages of clinical development, from product characterization during manufacturing to longitudinal evaluation of the infused product in patients. However, fluorescence-based cytometry faces significant challenges with signal overlap and autofluorescence, limiting sensitivity and the number of targets that can be detected in CAR-T cells. Consequently, rare cell populations are poorly resolved and functional read-outs of CAR-T cells are unreliable. CyTOF technology overcomes these limitations with low signal overlap and no autofluorescence. Further, CyTOF enables a streamlined and flexible workflow in clinical research using freezing antibody cocktails and stained cell samples. Here, we present a 40+ parameter CyTOF panel to simultaneously analyze phenotypic and functional protein expression in CAR-T cells from in vitro co-culture with tumor cells.

Result and discussion

CD19 CAR-T cells were expanded in vitro and co-cultured with Nalm6 cells at different E:T ratios for 2-5 days. A high-parameter CyTOF panel including over 40 surface, cytoplasmic and nuclear markers was used to

stain CAR-T cells. Samples co-cultured at different time points were stained, barcoded, frozen and simultaneously acquired on CyTOF XT at a later date. The cytotoxicity, activation, proliferation, differentiation and exhaustion of CAR-T cells were evaluated. Comprehensive profiling revealed that CAR-T cells became activated, proliferated and produced cytokines in in vitro co-culture with tumor cells and showed reduced cytotoxicity and exhaustive phenotype after an extended period of expansion.

Conclusion

Overall, we demonstrate that the high-parameter CyTOF panel enables deep functional characterization of CAR-T cells by simultaneous detection of surface, cytoplasmic and nuclear markers, supporting the continuous clinical development of CAR-T products.

Introduction

The tumour microenvironment (TME) in multiple myeloma (MM) is characterized by immune suppression, impairing anti-tumour responses. MM progression is driven by complex interactions between malignant plasma cells and the TME, fostering immune evasion and resistance to therapy. Natural Killer (NK) cells, vital for tumour surveillance, often display dysfunction and exhaustion within the MM TME. Characterizing NK cell states in the TME is critical for identifying therapeutic targets to restore their activity.

Material and method

We constructed an MM single-cell atlas using publicly available single-cell RNA sequencing (scRNA-seq) data from GEO and the clinical trial E-PRISM, comprising 108 samples deriving from BM aspirates across all stages of MM and healthy controls. NK cells were classified into active, tissue-resident (rNK), or exhausted (eNK) states using a gene expression signature-based scoring algorithm. Differential gene expression, Cell-cell interaction analysis, and transcription factor (TF) enrichment analysis were conducted to characterize NK cell regulation and prioritize potential therapeutic targets for NK reactivation.

Result and discussion

The MM atlas included 373,981 cells, and the healthy dataset contained 148,692 cells. We found significant shifts in the cell type compositions along the disease progression with the reduction of progenitors cell types (HSC&MPPs, and B cell progenitors the most afflicted), CD56brightCD16- NK cells and non-classical monocytes showed an increasing trend during the disease

progression, and, as expected higher numbers of plasma cells in all the disease stages. eNK proportions were significantly higher in disease states compared to healthy samples (mean: 19.3%), increasing with progression: MGUS (32.6%, $p = 0.04$), SMM (40.9%, $p < 0.001$), PMM (40.8%, $p < 0.001$), and RRMM (59.2%, $p < 0.001$). eNK showed increased expression and activation of immune checkpoint receptors with the most active being KLRC1 (NKG2A), LAG3, and LAIR1. Ranking the active TF by immune suppression-related genes we identified STATs, ETS1, EOMES, and other key TF involved in NK development and regulation. The highest-ranked TF in the dataset after the exclusion of samples receiving any kind of therapy was a nuclear receptor.

Conclusion

This study showed deep changes in the cell type compositions of BM during the progression to MM. Also, eNK cells during MM progression reveal a continuous accumulation with the activation of known immune checkpoint receptors. Finally, we identified a glucocorticoid receptor, that taking the heavy use of dexamethasone to treatment of MM, unveils valuable information about NK biology, and paves the road to the development of novel engineered NK cell-based therapies. We are proceeding with the development of an exhaustion model to further investigate the role of this nuclear receptor in the NK activity.

EACR25-2558

Accelerating immuno-oncology research with flexible workflows using modular Flex-Fit CyTOF panels

M. Klug¹, S. Hasan², L. Wang², S. Li², C. Loh³

¹*Standard BioTools, Berlin, Germany*

²*Standard BioTools, Markham, Canada*

³*Markham, Canada*

Introduction

Deep functional profiling of immuno-oncology markers and cytokines in whole blood (WB) reveals immune signatures that inform disease prognoses, immunotherapy selection, and outcomes in cancer patients. WB is best analyzed within 24 hours of collection to capture clinically relevant immune signatures; however, WB collection and cytometric analysis are often performed at different sites, which can lead to significant delays. WB stabilizers can overcome this challenge, yet not all antibody panels are compatible with these reagents. To enable flexible experimental workflows for deep profiling of immuno-oncology markers and cytokines in WB we developed modular Flex-Fit CyTOF® panels compatible with stabilizers.

Material and method

CyTOF-mediated high-parameter flow cytometry enables single-tube staining to identify 50+ markers at the single cell level. CyTOF provides exceptional resolution without spectral unmixing or compensation, while Flex-Fit CyTOF panels allow simple and quick panel design by combining a customizable selection of pre-validated sub-panels. We built two high-parameter antibody panels for analysis of fresh and stabilized WB. The first panel has 21 markers and identifies 12 immuno-oncology markers in 10 major cell subsets. The second panel has

31 markers and identifies 10 cytokines in 32 cell subsets. Stimulated WB samples from two healthy donors were either freshly stained, or they were stabilized with PROT1, RBC lysed, and stained. Liquid antibodies in the panel were pooled together and frozen (-80°C) as single-use aliquots for surface and intracellular staining to reduce technical variability from staining.

Result and discussion

Optimal panel design during penel design ensured that all markers in both panels could be used to accurately identify target cell populations in PROT1 stabilized WB. Following stabilization, non-specific staining was not observed when compared with freshly stained samples. Cell populations maintained the anticipated co-expression of markers in PROT1 stabilized WB. Prominent cytokines such as IL-17A, TNF- α , IL-10, etc. could be detected in stabilized WB.

Conclusion

Overall, we show that PROT1 compatible high-parameter antibody panels enable functional immune profiling immune cells by identifying immuno-oncology markers and cytokines. Compatibility with WB stabilization reagents provides workflow flexibility for carrying out functional profiling in longitudinal and multi-center studies in clinical research and healthcare settings. Furthermore, freezing antibody cocktails is a unique feature of CyTOF flow cytometry, ensuring staining consistency. Together, flexible CyTOF workflows enable fast and convenient panel design for high-parameter cytometric analysis of WB and can facilitate biomarker discovery, immunotherapy selection, and tracking disease prognoses in cancer. For Research Use Only. Not for use in diagnostic procedures.

RAS(ON) G12C-selective and multi-selective doublet combination overcomes clinical resistance mechanisms to KRAS G12C(OFF) inhibitors and sensitizes to immune checkpoint blockade in preclinical models

C. Blaj¹, X. Wei², M. Ali³, M. Moreno Ayala¹, Y. Yang²,

A. Salmon¹, J. Smith⁴, M. Singh², J. Jiang², E. Quintana¹

¹*Revolution Medicines, Cancer Immunology, Redwood City, United States*

²*Revolution Medicines, Translational research, Redwood City, United States*

³*Revolution Medicines, DMPK, Redwood City, United States*

⁴*Revolution Medicines, Biology, Redwood City, United States*

Introduction

Oncogenic RAS promotes carcinogenesis by sustaining cell proliferation and driving immune evasion. KRAS G12C(OFF) mutant selective inhibitors provide clinical benefit to patients with NSCLC however most patients will eventually develop resistance through reactivation of the RAS pathway, underlining the need for therapeutic approaches that maximize RAS inhibition. Elironrasib (RMC-6291), a RAS(ON) G12C mutant-selective, covalent inhibitor and daraxorrasib (RMC-6236), a

RAS(ON) multi-selective, noncovalent inhibitor have shown profound antitumor activity as monotherapies in preclinical models and, more recently, showed promising clinical activity in patients with RAS-driven tumors at doses that were well tolerated.

Material and method

Here we tested the RAS(ON) doublet combination of elironrasib with daraxonrasib in a panel of KRAS G12C NSCLC xenograft models, including those harboring alterations associated with clinical resistance to KRAS G12C(OFF) inhibitors such as increased RTK signaling, KEAP1 co-mutations and KRAS amplification. In addition, we evaluated the potential for the RAS(ON) doublet to sensitize an immune-refractory syngeneic NSCLC model to anti-PD-1.

Result and discussion

The combination of elironrasib with daraxonrasib significantly improved the depth and durability of response compared to the respective monotherapies. PK/PD/efficacy modeling suggested that the combination of elironrasib and daraxonrasib, even at sub-optimal mono-therapy doses, could drive deep and durable MAPK pathway suppression. In an anti-PD-1 refractory NSCLC syngeneic model elironrasib, daraxonrasib, and the RAS(ON) doublet combination induced rapid, transient tumor regressions, but in all treatment arms some tumors relapsed on treatment. Elironrasib, daraxonrasib and the RAS(ON) doublet favorably modulated the tumor micro-environment, increasing tumor infiltrating lymphocytes, decreasing myeloid cells and inducing immunological memory. Only the RAS(ON) doublet combination upregulated MHC I expression, increasing the possibility of recognition of the tumor by T cells. While the combination of either elironrasib or daraxonrasib alone with anti-PD-1 did not achieve significant combination benefit in this model, the triple combination of the RAS(ON) doublet and anti-PD-1 achieved 100% complete regressions.

Conclusion

These preclinical findings suggest that the RAS(ON) doublet combination can improve the depth and durability of response compared to the respective monotherapies and overcome mechanisms of clinical resistance to KRAS G12C(OFF) inhibitors. Furthermore, in an immuno-refractory model the RAS(ON) doublet combination reversed the immune-evasion mechanisms governed by oncogenic RAS. Collectively, these preclinical data support the clinical evaluation of the elironrasib with daraxonrasib RAS(ON) doublet in combination with anti-PD-1 in patients with KRAS G12C mutant NSCLC cancers.

EACR25-0040

Clinical Analysis of CNS WHO Grade 4 Gliomas with IDH-mutant versus IDH-wildtype Focused on CDKN2A

Homozygous Deletion

D. Park¹, K. Kim², Y. Kim¹

¹Sungkyunkwan University School of Medicine, Neurosurgery, Changwon, Korea (Republic of)

²Sungkyunkwan University School of Medicine, Pathology, Changwon, Korea (Republic of)

Introduction

Despite there no definite consideration of CDKN2A homozygous deletion as poor prognosis factor in gliomas, its prognostic role has been widely investigated in CNS tumors, such as malignant meningiomas. CDKN2A is a gene acting as tumor suppressors by suppressing the cell cycle, especially blocking traversal from G1 to S-phase. Herein, we are primarily investigating the prognostic role of CDKN2A in CNS WHO grade 4 gliomas.

Additionally, traditional prognostic factors for grade 4 gliomas will be examined, and our results will be validated.

Material and method

We conducted retrospective analysis of glioma cohorts in our institute. Medical records were reviewed for 142 glioblastoma patients for 15 years, and pathological slides were examined again for the updated diagnosis according to 2021 WHO classification of CNS tumors. The IDH mutation and CDKN2A deletion were examined by NGS analysis using ONCOaccuPanel®. Traditional prognostic factors including age, WHO performance status, extent of resection, and MGMT promoter methylation were examined.

Result and discussion

Mean follow-up duration was 27.5 months (ranged from 4.1 to 43.5 months) and mean overall survival (OS) was 19.4 months (95% CI 16.3-20.9 months). After the exclusion of 4 patients with poor status of pathologic samples, total 109 glioblastoma which were diagnosed by previous WHO criteria were changed into 26 (23.9%) astrocytoma, IDH-mutant, CNS WHO grade 4 and 83 (76.1%) glioblastoma, IDH-wildtype, CNS WHO grade 4. Among them, 61 patients (56.0%) had CDKN2A deletion. Group A was classified for 59 patients with IDH-wildtype and present CDKN2A deletion, group B was classified for 16 patients with IDH-mutant and present CDKN2A deletion, group C was classified for 48 patients with IDH-wildtype and absent CDKN2A deletion, and group D was classified for 13 patients with IDH-mutant and absent CDKN2A deletion. Group A had a mean OS of 15.70 months (95% CI 13.86-17.54 months), group B had a mean OS of 19.37 months (95% CI 13.43-25.30 months), group C had a mean OS of 22.63 months (95% CI 20.10-25.17 months), and group D had a mean OS of 33.38 months (95% CI 29.35-37.40 months). Multifactor analysis showed following factors were independently associated with OS; age (\geq 50 years vs. <50years; HR 4.642), extent of resection (gross total resection vs. others; HR 5.523), WHO performance (0, 1 vs. 2; HR 5.007), MGMT promoter methylation, (methylated vs. unmethylated; HR 5.075), IDH mutation (mutant vs. wildtype; HR 6.358), and CDKN2A deletion (absence vs. presence; HR 13.452).

Conclusion

The presenting study suggest that CDKN2A deletion should play a powerful prognostic role in CNS WHO grade 4 gliomas as well as low grade glioma. Even if CNS WHO grade 4 gliomas had mutant IDH, they can have poor clinical outcome due to CDKN2A deletion.

EACR25-0060

Enhanced antitumor immunity following neoadjuvant chemotherapy in triple-negative breast cancer

X. Zhongxun¹

¹Chongqing University Cancer Hospital, Breast Cancer Center, Chongqing, China

Introduction

Peripheral immune responses are increasingly recognized as occupying an important role in anticancer immunity.

Material and method

We evaluated serial blood samples from patients with triple-negative breast cancer (TNBC) undergoing neoadjuvant docetaxel, doxorubicin and cyclophosphamide chemotherapy (TAC) to characterize the evolution of the peripheral immune cell function and composition across the course of therapy. Serial blood samples from 10 patients with advanced TNBC treated with neoadjuvant chemotherapy (TAC) were collected before the initiation of chemotherapy, after the third and sixth cycles, and approximately 2 months after completion of chemotherapy. T-cell function was evaluated using ex vivo IFN γ ELISpot assays, and the dynamics of T-cell repertoire and immune cell composition were assessed using bulk and single-cell RNA sequencing (RNAseq). T cells exhibited an improved response to viral antigens after TAC, which paralleled the decrease in CEA and CA125 levels. Single-cell analysis revealed increased numbers of memory T-cell receptor (TCR) clonotypes and increased central memory CD8+ and regulatory T cells throughout chemotherapy.

Result and discussion

Finally, administration of TAC was associated with increased monocyte frequency and expression of HLA class II and antigen presentation genes; single-cell RNAseq analyses showed that although driven largely by classical monocytes, increased class II gene expression was a feature observed across monocyte subpopulations after chemotherapy.

Conclusion

TAC may alleviate tumor-associated immunosuppression by reducing tumor burden and may enhance antigen processing and presentation. These findings have implications for the successful combinatorial applications of immune checkpoint blockade and therapeutic vaccine approaches in TNBC.

EACR25-0062

Facilitators and barriers of gastroscopy screening in high-risk populations for gastric cancer: a qualitative study

Y. Tan¹

¹Southwest Hospital, Department of Gastroenterology, Chongqing, China

Introduction

To investigate the facilitators and barriers of gastroscopy screening in high-risk populations for gastric cancer, so as to provide reference for medical staff to develop intervention measures to enhance the compliance of

gastric cancer high-risk individuals with gastroscopy screening.

Material and method

From January to August 2023, the maximum difference purposive sampling was used to select patients in high-risk of gastric cancer who were recruited at the Southwest Hospital of the Army Medical University. A one-to-one, semi-structured in-depth interview method was used to collect data, and the data collection was terminated when saturation was reached.

Result and discussion

A total of 21 patients participated in the semi-structured interview. Facilitators of gastroscopy screening included three themes and eight subthemes: ability factors (rich disease knowledge, rich screening knowledge), motivation factors (awareness of susceptibility, awareness of warning symptoms, enhancement of screening awareness, perceived benefits), and opportunity factors (family support, social support); Barriers of gastroscopy screening included three themes and nine subthemes: ability factors (lack of disease knowledge, lack of screening knowledge, poor literacy), motivation factors (fear of gastric endoscopy, perception barriers), and opportunity factors (economic barriers, environmental and resource constraints, unpleasant screening experiences, low trust in medical care).

Conclusion

Multiple factors affect the compliance in gastric cancer high-risk patients for gastroscopy screening. Medical staff should develop the intervention measures to promote gastroscopy screening based on facilitators and barriers, so as to enhance the early detection rate and survival rate of gastric cancer.

EACR25-0064

Bioinformatics analysis for the identification of key genes and microRNAs related to bone metastasis in prostate cancer

F. Yao¹

¹People's Hospital of Chongqing Banan District, Urinary Surgery, Chongqing, China

Introduction

Prostate adenocarcinoma (PCa) is the leading cause of cancer-related mortality in men, with bone metastasis being the primary contributor to mortality in PCa patients. Therefore, elucidating the etiology and molecular mechanisms underlying bone metastasis is crucial for early detection, accurate diagnosis, and personalized treatment.

Material and method

In this study, differentially expressed mRNA(DEGs) and miRNAs (DE-miRNAs) selected from datasets (GSE32269, GSE77930 and GSE21036) available in the Gene Expression Omnibus (GEO). Enrichment analysis for pathway and process among the DEGs was performed and detect the interactions of the DEGs and construct the PPI network and miRNA-mRNA regulatory network. Diagnostic and survival analyses were performed with logistic regression and Cox regression to evaluate the clinicopathological characteristics associated with overall

survival.

Result and discussion

Five eligible miRNAs(miR-636, miR-491-5p, miR-199b-5p, miR-149-5p, and miR-143-3p) had prognostic significance in biochemical recurrence-free survival. Logistic regression analysis revealed that the ectopic expression of these DE-miRNAs was associated with the histological type, anatomical region, and pathological grade of bone metastasis in PCa. The differentially expressed genes were significantly enriched in Erbb signaling pathway, mTOR signaling pathway, FoxO signaling pathway, Ras signaling pathway. Three hub genes (MMP12, NR4A2 and THY1) with worse biochemical recurrence-free survival and one hub gene (MMP9) with worse overall survival were detected.

Conclusion

These DEGs and DE-miRNAs may serve as potential biomarkers for the early diagnosis of bone metastasis in PCa and we have successfully defined molecular signatures of bone metastasis in PCa.

EACR25-0198

Trends of prostate cancer stage and grade over a 12-year period in Northern Ireland; a population-based analysis

J. Murphy¹, R. Murphy², A. Cole¹, S. Jain¹, E. Allott¹

¹*Queen's University Belfast, Patrick G. Johnston Centre for Cancer Research, Belfast, United Kingdom*

²*Ulster University, Centre for Genomic Medicine, Coleraine, United Kingdom*

Introduction

In 2022, prostate cancer (PCa) became the most diagnosed cancer among males in the UK. Its incidence has significantly increased over time in comparison to other cancer types. This rise may be attributed to increased use of PSA blood testing, improvements in diagnostic procedures (MRI, PSMA-PET), and an aging population. Whilst it is important to diagnose high risk PCa in a timely manner, contemporary guidelines are in place to minimize the over-diagnosis of low-risk disease. These guidelines, together with advancements in diagnostic methods, may lead to a shift in the classification of lower-grade PCa. Using data from the Northern Ireland Cancer Registry (NICR), this study examines population-based trends in incident PCa according to tumour characteristics at diagnosis, and with respect to age and deprivation status.

Material and method

The NICR provides comprehensive, population-based data on cancer diagnosis in Northern Ireland (NI). This study analysed 14,273 incident PCa cases diagnosed from 2010–2021 in NI to assess trends in stage and grade at diagnosis. PCa cases were categorized using Grade Group (GG) and registry-derived TNM stage. Yearly trends were analysed to assess shifts toward more/less favourable disease characteristics.

Result and discussion

PCa diagnoses in NI increased 45% (973 in 2010 to 1,413 in 2021), with 65–69 years as the most affected age group (20% of cases). Over this 12-year period, there was a fourfold increase in stage 1 diagnoses (139 in 2010 to 663 in 2021) and a fourfold decrease in stage 2 cases (368 to 86). Stage 3 and unknown cases remained stable,

while stage 4 diagnoses doubled (126 to 258). Gleason grade distribution showed a 2.5-fold increase in GG3 cases. Low-risk (\leq GG1) cancers declined, dropping from 313 in 2012 to 153 in 2020. Deprivation analysis is the examination of how the lack of resources and opportunities can impact cancer incidence, outcomes and survival. This analysis showed a correlation between higher deprivation and more advanced disease. More deprived populations had fewer stage 1 diagnoses and more stage 4, suggesting delayed diagnosis or limited access to early detection. Similarly, high-risk Gleason scores (\geq GG4) were more frequent in more deprived areas, whereas low-risk scores (\leq GG1) were more common in less deprived groups.

Conclusion

PCa diagnoses in NI have risen, in conjunction with global trends, with earlier detection due to diagnostic advances. However, the increase in stage 4 cases highlights persistent late-stage diagnoses. Socioeconomic disparities remain evident, with higher deprivation linked to advanced disease, further emphasising the need for early detection and targeted interventions. Future directions include assessing trend correlations with clinical guideline changes (with clinician oversight) and identifying target populations that could benefit from: improved education, earlier screening, or adjustments in clinical settings.

EACR25-0385

Application of Mendelian randomization to appraise causality of the relationship between the gut microbiome and cancer

A. Dawes¹, C. Hatcher¹, A. McKinlay¹, K. Wade¹

¹*University of Bristol, 1. Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, UK. 2. Medical Research Council (MRC) Integrative Epidemiology Unit (IEU) at the University of Bristol, Bristol, UK., Bristol, United Kingdom*

Introduction

The gut microbiome has been implicated in cancer aetiology; however, its causal relevance is not clear. Mendelian randomization (MR) is increasingly being applied to assess the causal role of the gut microbiome on several health outcomes; however, the complexities and limitations of the method are not fully addressed in much of the current literature. Here, we aimed to appropriately apply MR to understand the role of the gut microbiome in cancer aetiology, whilst demonstrating the range of sensitivity analyses required to provide clarity in causal estimates.

Material and method

Two-sample MR was used to examine the causal relationship between microbial traits from two large microbiome genome-wide association studies (GWAS) (Hughes et al.(1) and MiBioGen(2)) and risk for cancers of the lung, breast, colorectum, pancreas, prostate, ovary, endometrium and oesophagus from the largest cancer GWASs, with replication sought in UK Biobank and FinnGen. Genetic instruments were selected using SNPs associated with microbial traits at genome wide significance ($P < 5 \times 10^{-8}$). A range of sensitivity analyses were performed to appraise the robustness of findings to violations of MR assumptions. These include ancestry-

specific analysis to account for differences in population structure, use of lenient p-value thresholds to select directionally consistent genetic instruments which are directionally consistent across the contributing GWAS cohorts, genetic colocalisation analysis to identify shared causal variants, a genome-wide approach to identify potential pleiotropic pathways, and Steiger filtering and reverse MR to identify potential reverse causality.

Result and discussion

Whilst our MR analyses suggested a putative causal role of 16 microbial traits across the eight cancers, few results were replicated in both UK Biobank and FinnGen and sensitivity analyses implied violations of MR assumptions, suggesting that these findings were unlikely to reflect causality. We did find that the relative abundance of bacteria in the class of Actinobacteria was associated with an increased risk of colorectal cancer, which was replicated in FinnGen. Colocalisation analysis suggests there could be a shared causal variant between the relative abundance of bacteria in the class of Actinobacteria and colorectal cancer, and MR results using a lenient P-value threshold were directionally consistent across pleiotropic methods and the main MR analysis. However, there were many additional traits associated with the SNP rs182549 in the genome-wide analysis which suggests that the SNP could influence colorectal cancer through a pleiotropic pathway.

Conclusion

Through testing for violations of core MR assumptions, our work demonstrates the importance of performing sensitivity analyses when assessing the robustness of MR findings, especially in the context of understanding the causal relevance of the gut microbiome on health outcomes.

EACR25-0531

Malignancies of the small intestine: incidence and trends in a nationwide registry.

P. Schafraat¹, F. van Erning², E. Dekker³, A. Farina Sarasaqueta⁴, J. de Vos-Geelen⁵, S. Bouwense⁶, R. Goedegebuure⁷, L. Vermeulen¹, I. de Hingh⁸, D. Sommeijer⁹

²Netherlands Comprehensive Cancer Organization, Department of Research and Development, Utrecht, Netherlands

³Amsterdam UMC, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands

⁴Amsterdam UMC, Department of Pathology, Amsterdam, Netherlands

⁵Maastricht UMC, Department of Medical Oncology, Maastricht, Netherlands

⁶Maastricht UMC, Department of Surgery, Maastricht, Netherlands

⁷Meander MC, Department of Internal Medicine, Amersfoort, Netherlands

⁸Catharina Hospital, Department of Surgery, Eindhoven, Netherlands

⁹Flevo hospital, Department of Internal Medicine, Almere, Netherlands

Introduction

Regardless the rising global incidence, malignancies of the small intestine remain rare. As it is a clinically heterogeneous group, knowledge about the different malignant entities is of importance to optimize diagnostic approaches and treatment strategies, and to ultimately improve prognosis.

Material and method

This nationwide retrospective cohort study, with data from the Netherlands Cancer Registry, included all patients diagnosed with a malignancy of the small intestine in the Netherlands between 2000 and 2022. Malignancies were divided into seven subgroups; adenocarcinomas, neuroendocrine neoplasms (NENs), gastrointestinal stromal tumors (GISTs), lymphomas, other sarcomas, metastases, and “other”. Age-standardized incidence rates, overall- and relative survival were reported.

Result and discussion

A total of 11,194 patients with a malignancy of the small intestine were included. Age-standardized incidence rates (reported per 100,000 person-years) more than doubled between 2000 and 2020 (1.88 to 3.94, $p < 0.001$), with the largest increase in NENs (0.53 to 1.57, $p < 0.001$), followed by adenocarcinomas (0.78 to 1.22, $p = 0.004$) and GISTs (0.14 to 0.53, $p < 0.001$). The age-standardized incidence of lymphomas remained relatively stable (0.32 to 0.46, $p = 0.088$) and sarcomas showed a decrease in age-standardized incidence (0.10 to 0.02, $p = 0.005$). Survival varied significantly between subgroups, with unchanged survival of patients with adenocarcinomas and NENs, in contrast to improved survival of patients with lymphomas and GISTs.

Conclusion

The incidence of malignancies of the small intestine in the Netherlands has more than doubled over the past two decades, mostly due to an increase in NENs and adenocarcinomas. Survival outcomes for these patient groups have not improved, highlighting the urgent need for further research on these rare cancers.

EACR25-1041

Exploring circulating proteins as intermediates between physical activity and cancer risk

L. Goudswaard¹, L. Hobson¹, R. Richmond¹, M. Gunter², B. Lynch³, K. Tsilidis⁴, S. Lewis¹

¹University of Bristol, Population Health Sciences, Bristol, United Kingdom

²Imperial College London, Department of Epidemiology and Biostatistics, London, United Kingdom

³Cancer Council Victoria, Melbourne, Australia

⁴Imperial College London, United Kingdom

Introduction

Higher levels of physical activity (PA) are associated with a decrease in risk of several cancers, including breast, colorectal and endometrial cancers. In this study we investigated circulating proteins as potential intermediates between PA levels and risk of breast, prostate, endometrial and colorectal cancers.

Material and method

Data were used from UK Biobank (UKB), a cohort of 500,000 participants aged between 40-69 who were recruited between 2006-2010. Circulating proteins were measured by the Olink Explore 3072 panel at baseline. PA was measured between 2013-2015 using an Axivity AX3 wrist-worn triaxial accelerometer. Three PA measures were included: overall acceleration average, proportion of time doing moderate-vigorous activity and proportion of time sedentary. Cancer registry data were leveraged, and the international classification of disease codes (ICD9 and ICD10) were used to determine cancer case status, deriving a prevalent cancer variable, or incident cancer variable if diagnosed more than two years after enrolment into UK biobank. Linear or logistic regression were used to determine the association between variables, adjusting for potential confounders (including body mass index), accounting for multiple testing. Where there was evidence for an association between PA and protein levels, two sample Mendelian randomization (MR) was additionally applied to explore causal evidence for the relationship between PA ($N = 100,000$ in UKB) and Olink circulating proteins ($N = 34,000$ in UKB), using genetic variants strongly ($p < 5 \times 10^{-8}$) and independently ($R^2 < 0.0001$) associated with overall physical activity.

Result and discussion

Higher levels of PA were associated with a lower risk of breast, colorectal and endometrial cancers. All three PA measures were associated with levels of 114 proteins ($p < 2.7 \times 10^{-5}$), for example, more physical activity was associated with lower levels of osteoglycin. Of the 114 proteins associated with physical activity, 16 were associated with cancer outcomes ($p < 4 \times 10^{-4}$), 9 with incident cancer and 14 with prevalent cancer status. Higher levels of osteoglycin were associated with higher risk of breast cancer. For 16 proteins associated with both PA and cancer risk, MR evidence suggested a potential causal relationship between higher overall PA and lower levels of two proteins, osteoglycin and E3 ubiquitin-protein ligase RNF149, and estimates were concordant in direction with the observational result.

Conclusion

These analyses point towards proteins which associate with both physical activity levels and cancer risk. One of the proteins highlighted, osteoglycin, has previously been shown to have altered expression in breast tumour tissue and warrants further exploration. Sensitivity analyses including multivariable MR and reverse MR are ongoing to further understand the likely direction of effects.

EACR25-1151

Time to diagnosis for ovarian cancer in England: Associations with 'alternative explanation' comorbidities and recent menopause

I. Rogers¹, E. Ford¹, M. Cooper¹, A. Memon²

¹Brighton and Sussex Medical School, Primary Care and Public Health, Brighton, United Kingdom

²Brighton and Sussex Medical School, Primary Care and Public Health, United Kingdom

Introduction

Ovarian cancer is diagnosed at a late-stage 3/4 in the majority (62%) of patients resulting in poor survival and high morbidity and mortality. Several factors, i.e., biological, patient/healthcare system-related, and socio-economic factors contribute to delayed diagnosis of ovarian cancer. This also include lack of specific "alarm symptoms", and cancer symptoms are often attributed to chronic conditions especially irritable bowel syndrome, recurrent urinary tract infections or menopause-related changes.

Material and method

Patients in England born before 1955 and diagnosed with incident ovarian cancer between 1990 and 2019 were identified in the Clinical Practice Research Datalink (CPRD) Gold and CPRD Aurum databases and linked hospital admission and cancer registry data. 'Diagnostic interval' (or time to diagnosis) was defined as time from first presentation in primary care with a relevant sign/symptom to diagnosis. Associations between presenting sign/symptom, comorbidities offering "alternative explanations" for symptoms, and recent menopause and diagnostic interval were investigated using multivariable linear regression models adjusting for patient characteristics including age, presence of other comorbidities and consultation frequency. Models were run for Gold and Aurum databases separately, and results combined using meta-analysis.

Result and discussion

Complete data were available for 2010 patients in CPRD Gold and 1885 patients in CPRD Aurum. Presenting sign/symptom was associated with substantial variation in diagnostic interval. Compared to patients presenting with abdominal or pelvic pain, diagnostic interval was 125% higher in patients with back pain, and 63% higher for patients with urinary symptoms, but was substantially reduced (i.e., halved) in patients presenting with abdominal mass, distension or ascites. The diagnostic interval was also increased by 27% in women with two or more "alternative explanation" comorbidities versus those with none, and by 32% among women with recent menopause.

Conclusion

Our study provides evidence that ovarian cancer diagnosis may be delayed in women with chronic conditions such as irritable bowel syndrome and/or menopause-related symptoms/changes. Raising awareness of this possibility (i.e., symptom ambiguity) among primary care physicians may reduce the number of late-stage diagnosis, improve survival and reduce morbidity and mortality from ovarian cancer.

⁵University Of Balamand, Faculty of health sciences, Tripoli, Lebanon

Introduction

Cancer remains a major global public health concern with low and middle-income countries (LMICs) disproportionately affected. Lebanon, a low-income country (LIC), faces a significant cancer burden, particularly in vulnerable communities. This study aims to characterize the cancer profile of vulnerable communities in North Lebanon by analyzing data from patients receiving support from Sanabel Nour, a local NGO providing medical assistance to underserved communities in Tripoli.

Material and method

This retrospective chart review analyzed data from 440 cancer patients. Socioeconomic status was assessed using the Lebanese Multidimensional Poverty index. Data on demographics, tumor characteristics, and comorbidities were extracted from patient records. Descriptive statistics were employed for data analysis.

Result and discussion

The majority of participants were females (65.5%). Among females ($n = 288$), breast cancer is the most prevalent (48.6%), followed by colorectal cancer (7.6%). For males ($n = 152$), bladder cancer is the most common (18.1%), followed by colorectal cancer (14.6%). A concerning trend is the late-stage diagnosis of many cancer cases. Notably, the median age at diagnosis for female breast cancer patients is lower than the national average, and the mean age at diagnosis for colorectal cancer patients is also lower than the national mean.

Conclusion

Comprehensive cancer profiling across the country is essential for tracking disease trends and developing targeted interventions. Early screening programs are crucial to improve survival rates and patient outcomes

Introduction

Brain tumors represent a complex and heterogeneous group of neoplasms arising from abnormal cell growth within the brain. Previous observational studies have demonstrated a correlation between brain tumors and the risk of neurodegenerative diseases (NDs), but the causality and direction of their associations remain unclear. This relationship is complex and an area of ongoing research. Alzheimer's disease (AD) is the most common neurodegenerative disorder that shows epidemic associations with many types of tumors including brain tumors, sharing genetic characteristics. On the other hand, the antioxidant activity of natural compounds derived from olive oil appears to affect cancer behavior and, at the same time, mitigate neuroinflammation related to NDs. We explored *in vitro* the correlation between AD and neuroblastoma to evaluate the effects of the polyphenol Oleacein in modulating the principal genes associated with AD.

Material and method

Oleacein was prepared as reported by Procopio et al. Cell-Titer Glo assay was used to analyze cell viability of SHSY-5Y, a human neuroblastoma cell line, and 3Tg-I-Astro, an established immortalized astroglial cell line from 3xTg-AD mouse. SHSY-5Y cells treated with Oleacein (5 μ M) were tested using TaqMan Array 96-Well Plate AD by qRT-PCR reaction. Datasets from TCGA database at UALCAN were interrogated to obtain the differential expression of specific human genes. Reactome Pathway Browser was used to visualize common correlated canonical pathways.

Result and discussion

First, we evaluated the effect of Oleacein on cell viability (48 hours), resulting in a significant reduction in SHSY-5Y cell proliferation, with no effect in 3Tg-I-Astro cells. In addition, four AD-related genes were modulated by Oleacein in SHSY-5Y cells. In detail, we found an upregulation of Gap Junction Beta1 (GJB1), Beta-Secretase2 (BACE2) and Acetylcholinesterase (ACHE) genes, while Solute Carrier Family 30 member 3 (SLC30A3) gene was downregulated. In TCGA-UALCAN database, the upregulated ACHE and GJB1 genes were reported to be downregulated in human brain tumor samples compared to normal ones. Network analysis provides interactions of modulated genes in common canonical pathways suggesting novel predictive and therapeutic targets.

Conclusion

AD and neuroblastoma seem to have common genetic implications. Oleacein antioxidant and anti-inflammatory activities in SHSY-5Y cells could modulate the expression levels of AD-related genes, offering new diagnostic and therapeutic opportunities.

⁸*FMUP - Faculty of Medicine of the University of Porto, Porto, Portugal*

Introduction

CTNNA1 germline variants were associated with hereditary diffuse gastric cancer (HDGC), and in 2020, CTNNA1 was recognized as a HDGC-associated gene, despite the scarce supporting research. Despite joint efforts to improve knowledge on CTNNA1-associated disease and cancer lifetime risks, CTNNA1-related disease spectrum, variant-type causality and clinical criteria driving genetic testing remain vastly understudied. This lack of knowledge limits clinical management of CTNNA1 variant carrier families and definition of criteria for variant classification. We aim to explore CTNNA1 genotype-phenotype associations to improve clinical criteria driving genetic testing, surveillance and risk-reduction recommendations for carriers.

Material and method

Using molecular, clinical and population data from 351 CTNNA1 variant carrier families from Europe and America, we analysed genotype–phenotype associations with multivariable logistic regression, and further compared results to a CDH1 variant carrier cohort. We knockout (KO) CTNNA1 using CRISPR/Cas9 in gastric cancer (GC) cells, developed CTNNA1 humanized Drosophila models and analysed diffuse GC (DGC) tumour samples from CTNNA1 carriers, to assess CTNNA1 associated loss-of-function mechanisms. We redefined current HDGC clinical criteria to improve CTNNA1 genetic testing yield.

Result and discussion

We found that Nonsense Mediated mRNA Decay (NMD) degrades CTNNA1 transcripts bearing premature stop codons, and that DGC tumours from CTNNA1 truncating carriers lose α E-catenin. Using our humanized Drosophila model, we demonstrated that truncating transcripts are non-functional, unlike non-truncating ones. Analysis of clinical data showed that the likelihood of DGC development is 8-fold higher in truncating than in non-truncating carriers. Also, risk of GC development is 7-fold higher in CTNNA1 truncating carriers compared to wild-type individuals, but is significantly lower than the 38-fold higher risk of GC development in CDH1 carriers. Lobular breast cancer is recurrent among CTNNA1 truncating carrier families, some lacking HDGC criteria. Refining HDGC criteria increased CTNNA1 carrier families' pick-up rate by 9%.

Conclusion

We provide compelling evidence supporting that CTNNA1 truncating variants are positively associated

with DGC development and that NMD is the pathophysiological mechanism leading to CTNNA1 downregulation in HDGC. We demonstrate that, compared to CDH1, CTNNA1 is a moderate penetrance HDGC gene. This knowledge is new and essential to define surveillance and/or prophylactic surgery measures for CTNNA1 carrier individuals/families.

Introduction

Thyroid cancer is the most common endocrine neoplasia and about 10% of all cases are of familial origin. Non-syndromic familial non-medullary thyroid carcinoma (FNMTC) is a form of hereditary thyroid cancer characterized by its polygenic nature, autosomal dominant inheritance pattern and incomplete penetrance. Despite its clinical significance, few FNMTC susceptibility genes have been identified, making early diagnosis challenging and hindering the development of targeted therapies. Building on our team's previous contributions to the genetic characterization of FNMTC, this study aims to identify novel candidate genes that may confer susceptibility to the disease in a representative family from our cohort.

Material and method

Five members from a large FNMTC family were selected for analysis, including two with papillary thyroid carcinoma (PTC), two with multinodular goiter (MNG), and one with Hashimoto's thyroiditis. Whole exome sequencing was performed in leucocyte DNAs and significant variants were selected through bioinformatic analyses.

Result and discussion

A pathogenic TGFBI p.R666S missense mutation was found to affect three members of the family, one with PTC and two others with MNG and Hashimoto's thyroiditis. A previously known pathogenic FOXE1 variant (p.A248G) affecting other FNMTCs, as well as a pathogenic TPO p.Q660E missense mutation were found in the same two members with PTC and with MNG. Besides the TGFBI p.R666S missense mutation, the third

member with Hashimoto's thyroiditis also harbored pathogenic missense mutations affecting AR (p.P392S), MEFV (p.A744S) and SLC34A3 (p.G196R). In addition, the fourth member with MNG was found to harbor a pathogenic LRP2 p.D2054N missense mutation. The final member with PTC did not exhibit any identifiable pathogenic variants, suggesting that the PTC in this case is likely sporadic rather than genetically inherited.

Conclusion

A range of pathogenic missense variants was identified in the majority of the FNMTC-affected family members, suggesting a polygenic inheritance pattern. Subjecting additional members of the same family to whole exome sequencing is hence required to ascertain which pathogenic variant is susceptible to promote a FNMTC phenotype.

Introduction

Colorectal Cancer (CRC) is the second leading cause of cancer-related deaths worldwide, with most of the cases being sporadic and resulting from the combination of external factors and genetic variations, specifically single nucleotide polymorphisms (SNPs). Over the years, genome-wide association studies (GWAS) have identified numerous risk SNPs associated with sporadic CRC. However, most of these studies have been conducted in European populations, which lack representativeness of admixed populations, such as the Brazilian one. Therefore, this study aims to perform the first GWAS on sporadic CRC in Brazil, using 850k Axiom™ PMDA to discover and validate new risk biomarkers.

Material and method

A total of 1,371 CRC patients and 1,922 cancer-free Brazilians were included, with mean ages of 60 and 54 years, respectively. All Brazilian regions were represented, with the predominance of the Southeast region (53%) for both cases and controls. DNA genotyping was performed using the 850K Axiom™ Precision

Medicine Diversity Array (PMMA), constituted by 788,623 variant regions. Data analysis was conducted using the Applied Biosystems™ Axiom™ Analysis Suite, and SNP quality control (QC) was performed via PLINK. Population stratification was assessed by constructing a Multidimensional Scaling (MDS) plot based on the 1000 Genomes dataset. A genome-wide significant threshold of $-\log_{10}(1.58e-07)$ was applied for association testing.

Result and discussion

MDS analysis confirmed our cohort population is genetically admixed. The Manhattan plot identified 50 significant CRC-associated variants, with the most significant being rs10255340 ($p = 1.64e-10$; RELN \leftrightarrow ORC5; OR = 0.6528). Variants rs62251956 (TRIM71; OR = 1.804; $p = 8.11e-8$) and rs11790363 (NTRK2 \leftrightarrow AGTPBP1; OR = 1.866; $p = 1.50e-7$) exhibited higher odds ratio, indicating a significant association with increased CRC risk. These findings provide novel insights into CRC susceptibility in admixed populations and highlight the importance of genetic studies in diverse groups.

Conclusion

This is the largest GWAS assessing the risk of sporadic CRC in Brazil. It suggests 50 potential risk loci for this admixture population. Further studies will be conducted to calculate a significant polygenic risk score (PRS), and additional validation will be performed in a larger population.

⁹*Kaiser Permanente Southern California and 10. Kaiser Permanente Bernard J. Tyson School of Medicine, Research and Evaluation, Pasadena, United States*

Introduction

Survivors of adolescent and young adult (AYA) hematologic malignancies have a high risk of chronic medical conditions. We evaluated the cumulative incidence and

incidence rate ratio (IRR) for several conditions in cancer survivors compared to a matched cohort without cancer.

Material and method

We used data from Kaiser Permanente (KP) Northern and Southern California to identify AYAs diagnosed at age 15–39 years with Hodgkin lymphoma (HL), non-Hodgkin lymphoma (NHL), acute myeloid leukemia (AML), or acute lymphoblastic leukemia (ALL), from 2006–2020, who survived ≥ 2 years after diagnosis. KP members without a history of cancer were matched (10:1) to survivors by age, sex, diagnosis year, and KP site. We calculated the cumulative incidence of each condition, accounting for death as a competing risk. Multivariable-adjusted Poisson regression estimated rate ratios in survivors versus the matched cohort, adjusting for age at diagnosis, sex, and race/ethnicity.

Result and discussion

Among 2,624 AYAs with hematologic malignancies (42% HL, 40% NHL, 9% AML, 9% ALL), with a median follow-up of 5.9 years (interquartile range: 3.7–9.3), the 10-year cumulative incidence was 43.9% for any chronic medical condition (vs. 22.4% in the matched cohort) and 16.1% for ≥ 2 conditions (versus 4.4%).

Overall, after adjusting for demographic factors, cancer survivors had 2.7- and 4.8-times higher rates of developing 1 and ≥ 2 conditions, respectively (IRR = 2.7, 95% CI 2.5–2.9 and 4.8, 95% CI 4.2–5.4), with IRRs ranging from 1.8 (95% CI 1.6, 2.1) for respiratory disease to 56.2 for avascular necrosis (95% CI 29.4, 107.5). In patients with ALL and AML, the highest IRRs were, respectively, for VTE (36.8, 16.4), renal disease (15.4, 14.1), diabetes (8.3, 6.1), and cardiovascular disease (6.3, 6.5). In patients with NHL and HL, the highest IRRs were, respectively, for avascular necrosis (34.2, 7.4), VTE (8.1, 7.0), renal (4.8, 5.8), and cardiovascular disease (2.9, 3.1). In AYAs with lymphomas, risk of most conditions was higher for those diagnosed with regional or distant disease (vs. localized). Elevated IRRs were observed across all demographic groups, insurance types, and neighborhood deprivation levels.

Conclusion

AYA survivors of hematologic malignancies had a higher risk of all chronic conditions than the non-cancer comparison cohort. Long-term surveillance, risk mitigation through lifestyle changes, and effective disease management should be evaluated to improve quality of life and reduce premature mortality.

EACR25-1706

Chamosite in Late Permian C1 coal and the high incidence of lung cancer in Xuan Wei

R. Ji¹, J. Luo², N. Yu², Z. Han¹, H. Lin¹, H. Dou³, J. Bai³, J. Li⁴, X. Guan², L. Tian¹

¹*The University of Hong Kong, School of Public Health, Hong Kong, Hong Kong, China*

²*The University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong, China*

³*Institute of Coal Chemistry, Chinese Academy of Sciences, State Key Laboratory of Coal Conversion, Taiyuan, China*

⁴*Stanford University Medical Center, Urology, Stanford, United States*

Introduction

The Xuan Wei area of Yunnan Province, in the southwest of China, bears the abnormally high incidence and mortality rate of lung cancer in the world.

Epidemiological studies have suggested that this has been associated with the domestic combustion of C1 coal from the high incidence of lung cancer area in Xuan Wei, which contains iron-rich chamosite. However, the underlying molecular mechanism of lung cancer induced by chamosite-containing C1 coal is not clear. Thus, our study provides experimental insights into how particles in C1 coal contribute to the development and progression of lung cancer, which may provide potential systemic treatment options for Xuan Wei lung cancer patients.

Material and method

Scanning Electron Microscopy (SEM), Diffraction of x-rays (XRD), X-ray fluorescence spectrometry (XRF) and Particle Size Distribution (PSD) were utilized to characterize the low-temperature coal ash (LTA).

Transmission Electron Microscope (TEM) was performed to validate that LTA enters the cells and lung tissue. Changes in human bronchial epithelial(B2B) cells after C1 and C9 LTA exposure were investigated by XTT assay, colony formation assay and 3D colony formation assay. Immunoblotting, and immunofluorescence staining were also employed for functional studies.

Result and discussion

Our XRD analysis indicates that chamosite is contained in C1 and C9 LTA, not in C1 and C9 high-temperature ash (HTA). The XRF results showed C1 LTA has higher iron content than C9 LTA. The analysis of BEAS-2B cells with TEM demonstrated that the mitochondria were subcellular targets of LTA. LTA was also found in the lung tissue of mice by TEM. Histopathological analysis of lung sections using H&E staining demonstrated that LTA treatment for 3 months caused more severe injury and fibrosis than the mice in the control group.

Additionally, EGFR and KRAS genes were over-expressed both in vivo and in vitro.

Conclusion

Our study indicates that long-term exposure of C1 and C9 LTA may lead to malignant transformation of normal cells as well as alterations in the lung tissue of mice. The deeper mechanisms will be addressed in further work.

⁵*University of Jyväskylä & Welbeing service county*

of Central Finland, Department of Biology and environmental science & Central Finland Biobank, Jyväskylä, Finland

Introduction

Systemic metabolism affects cellular processes and can modulate the tissue microenvironment in complex ways, potentially impacting cancer initiation processes. In Lynch syndrome, a condition characterized by carriers of pathogenic mutations in DNA mismatch repair genes (path_MMR genes), genetic background significantly increases cancer risk. However, not all carriers develop cancer. Various lifestyle factors can influence Lynch syndrome cancer risk, with lifestyle choices actively shaping systemic metabolism, serving as the mechanistic link between lifestyle and cancer risk. In this study, we explore systemic metabolism at different omics levels, including the circulating metabolome, proteome, and enzymatic profiles of Lynch syndrome carriers.

Material and method

This study comprises a two-group cross-sectional analysis to compare the circulating metabolome, proteome, and enzymatic levels of cancer-free Lynch syndrome carriers with healthy non-carrier controls. We correlate these results with clinical parameters and path_MMR status to discern the metabolic distinctions attributable to genetic differences.

Result and discussion

Our analysis detected elevated levels of circulating cholesterol, lipids, and lipoproteins in Lynch syndrome carriers. Furthermore, significant alterations were observed in circulating amino acid and ketone body profiles when compared to healthy non-carriers, suggesting a distinct systemic energy metabolism in Lynch syndrome carriers. These findings highlight a unique metabolic landscape in cancer-free Lynch syndrome carriers, which may contribute to their varied cancer risk.

Conclusion

This study provides valuable insights into the systemic metabolic landscape of individuals with Lynch syndrome, enhancing our understanding of how energy metabolism is linked to cancer risk. The metabolic signatures identified could serve as potential biomarkers for early detection and risk assessment in Lynch syndrome.

Sociodemographic and clinicopathologic features associated with rapid relapse in triple-negative breast cancer: A Swedish nationwide registry-based study

S. Sarathchandra¹, E. Grönberg², Z. Einbeigi¹, K. Helou¹, A. Kovács³, S. Janeva⁴, P. Karlsson¹, T. Parris¹

¹*University of Gothenburg, Department of Oncology, Gothenburg, Sweden*

²*Sahlgrenska University Hospital, Department of Oncology, Gothenburg, Sweden*

³*Sahlgrenska University Hospital, Department of Clinical Pathology, Gothenburg, Sweden*

⁴*Sahlgrenska University Hospital, Department of Surgery, Gothenburg, Sweden*

Introduction

Triple-negative breast cancer (TNBC) is associated with high recurrence rates within the first three years of diagnosis. Here, we identify sociodemographic and clinicopathologic factors associated with rapid relapse or death in TNBC using Swedish population-based registry data.

Material and method

Data were retrospectively collected from national registries for 9262 women diagnosed with primary invasive TNBC in Sweden between 2007 and 2021. Eligible patients ($n = 8338$) were categorized into three relapse groups: rapid relapse or death within 2 years (rrTNBC), late relapse or death after 2 years (lrTNBC), and non-rapid relapse for <5 years follow-up and no survival event (non-rrTNBC). Multivariable logistic regression and nomogram modeling were employed to assess predictive factors for relapse.

Result and discussion

Of the 8338 eligible patients, 15% experienced rapid relapse. Rapid relapse was associated with advanced age (71 years vs. 61 years in lrTNBC), larger tumor size (30 mm vs. 20 mm in lrTNBC), and advanced stage at diagnosis (19% Stage III in rrTNBC vs. 4% in lrTNBC) and after surgery (rrTNBC 29% vs. lrTNBC 7%).

Compared to the lrTNBC group, the rrTNBC group frequently received neoadjuvant chemotherapy (NACT), but were less likely to receive breast-conserving surgery combined with adjuvant radiotherapy. Although pathologic complete response (2.6%) was generally poor for those undergoing NACT, regional residual disease was more common in the rrTNBC group (67% vs. 40% in lrTNBC). Furthermore, rrTNBC patients had parents born outside of Sweden, lower education levels, lower income, and a higher proportion of widowed individuals. Logistic regression identified age, tumor size, tumor grade, nodal status, and Charlson comorbidity index as key predictors of relapse risk. The predictive model achieved an AUC of 70%, indicating moderate accuracy.

Conclusion

Taken together, rapid relapse in TNBC is strongly linked to advanced age, tumor characteristics, and socio-economic status. The predictive model provides a valuable tool for identifying high-risk TNBC patients in need of personalized treatment strategies.

EACR25-1850

Exploring the role of monoallelic pathogenic MUTYH variants in colorectal cancer risk: Clinical implications and genetic findings in Serbian population

V. Karadžić¹, M. Djordjić Crnogorac¹, A. Krivokuća¹

¹*Institute for Oncology and Radiology of Serbia, Genetic Counseling Department, Belgrade, Serbia*

Introduction

MUTYH is a crucial gene in the base excision repair pathway that encodes the A/G-specific adenine DNA glycosylase, also known as hMYH. This enzyme is essential for maintaining genomic integrity by removing adenine residues mispaired with 8-oxoguanine, a product of oxidative DNA damage. Biallelic pathogenic variants

in this gene cause autosomal recessive MUTYH-associated polyposis (MAP). Individuals with MAP have a 70%–90% absolute risk of developing colorectal cancer (CRC) if polyposis is left untreated, with the disease most commonly diagnosed between the ages of 45 and 59. However, the cancer risk associated with germline variants in individuals carrying a single defective MUTYH allele remains a topic of debate.

Material and method

Using Next-Generation Sequencing (NGS), the Institute for Oncology and Radiology of Serbia (IORS) has been performing screening for hereditary CRC since 2018. Patients are selected based on early-onset cancer, personal and/or family history of colorectal cancer. In total, 116 individuals meeting criteria for genetic testing for hereditary colorectal cancer were analyzed using the Illumina TruSight Hereditary Cancer Panel at the Genetic Counseling Department at IORS.

Result and discussion

In 6 of 116 patients (5.17%), three different monoallelic pathogenic germline variants in the MUTYH gene were detected (c.1353_1355delGGA, c.1103G>A, c.650G>A). Five of them were diagnosed with colon polyposis and/or CRC between the ages of 29 and 49, with one of these patients developing three primary colon cancers due to many polyps. Four of these five patients have a family history of colorectal, endometrial, and/or breast cancer. The sixth patient carrying the pathogenic MUTYH variant, aged 57, has a long-established history of gastric polyposis and no family history. While some population-based analyses of monoallelic MUTYH P/LP variant carriers suggest that these variants do not significantly increase CRC risk, emerging evidence indicates that even heterozygous pathogenic variants may contribute to a heightened risk of malignancies, particularly CRC and other types of cancer. One proposed mechanism is that MUTYH deficiency in heterozygosity can promote tumorigenesis through Loss of Heterozygosity (LOH) of the functional allele.

Conclusion

According to the 2024 NCCN Guidelines, individuals with a single defective MUTYH allele do not have an increased risk of developing CRC, but individuals with a personal or family history of polyposis are advised to have increased screening compared to the general population. The results of several studies are contradictory and range from no increased risk to a slight or moderate increased lifetime risk of developing colorectal, endometrial, or breast cancer. These findings highlight the need for further research to better define the role of monoallelic MUTYH variants and improve clinical practice in genetic counseling and cancer prevention.

EACR25-1883

Uncovering Missing Heritability in Prostate Cancer: A Functional Genomics Approach Using Allele-Specific Expression

A. Besouro-Duarte^{1,2}, N. Martins¹, L. Leite¹, A. Maia^{1,2,3}, J. Xavier^{1,3}

¹Rise-Health, Universidade do Algarve, Faro, Portugal

²Faculdade de Medicina e Ciências Biomédicas,

Universidade do Algarve, Faro, Portugal

³Centro de Ciências do Mar, Universidade do Algarve, Faro, Portugal

Introduction

Prostate cancer (PC) has an estimated heritability of approximately fifty eight percent and less than half of its genetic contribution has been elucidated. Identifying target genes and understanding their functional consequences remain major challenges, requiring novel approaches. Since most identified risk loci lie outside protein-coding regions and often act through cis-regulatory mechanisms, we hypothesize that much of PC's missing heritability is attributable to unidentified cis-regulatory variants. We propose an innovative framework to genetic association studies by leveraging differential allelic expression (AE) as a quantifiable readout of cis-regulatory variant effects. This method effectively controls for trans effects using an internal reference within each sample. A similar strategy successfully identified new breast cancer (BC) risk loci and, given evidence of shared regulatory variants between BC and PC, pleiotropy will also be assessed.

Material and method

We analyzed RNA-seq data from prostate tissue of healthy individuals (GTEx n = 116) and tumor-matched normal prostate from individuals with PC (TCGA n = 51). RNA-seq was mapped to a reference genome using STAR and variant calling was performed using GATK. For TCGA samples, genotype data were imputed from microarrays. Case-control association studies will be conducted using allelic expression fraction. daeQTL and functional analyses will be performed on loci of interest to elucidate regulatory mechanisms and pinpoint causal variants.

Result and discussion

The analysed samples include a diverse ancestry, with a predominant european background. The AE analysis pipeline allowed the standardization and cross-comparison between RNA-seq data from two independent datasets. Sample-wise mean AE fraction at heterozygous sites is around 0.5, indicating an overall balanced allelic expression. Ongoing statistical analysis, including effect size estimation, aim to identify variants whose AE levels are associated with PC risk modulation. Variants exhibiting significant associations after multiple test correction will be compared to those identified in breast cancer using the same methodology, as well as to previously reported GWAS.

Conclusion

By applying this approach that enhances case-control studies, we are able to leverage allele-specific expression as a quantitative phenotype and improve the identification of genetic risk factors in PC. The focus on cis-regulatory variants, allows this approach to refine risk prediction and uncover novel mechanisms underlying PC susceptibility.

⁹Bristol Medical School, Translational Health Sciences, Bristol, United Kingdom

Introduction

Recent research has identified a potential protective effect of higher numbers of circulating lymphocytes on colorectal cancer (CRC) development. However, the importance of different lymphocyte subtypes and activation states in CRC development remains poorly understood and warrants further investigation. CD4+ T cells, a highly dynamic lymphocyte subtype, undergo remodelling upon activation to induce the expression of genes critical for their effector function. Previous studies investigating their role in CRC risk have used bulk tissue, limiting our current understanding of the role of these cells to static, non-dynamic relationships only.

Material and method

Here, we combined two genetic epidemiological methods – Mendelian randomisation (MR) and genetic colocalisation – to evaluate evidence for causal relationships of gene expression on CRC risk in multiple CD4+ T cell subtypes and stages of activation. Genetic proxies were obtained from single-cell transcriptomic data, allowing us to investigate the causal effect of expression of 1,805 genes across five CD4+ T cell activation states on CRC risk (78,473 cases; 107,143 controls). We repeated analyses stratified by CRC anatomical subsites and sex, and performed a sensitivity analysis to evaluate whether the observed effect estimates were likely to be CD4+ T cell-specific.

Result and discussion

We identified six genes with evidence ($FDR-P < 0.05$ in MR analyses and $H4 > 0.8$ in genetic colocalisation analyses) for a causal role of CD4+ T cell expression in CRC development – FADS2, FHL3, HLA-DRB1, HLA-DRB5, RPL28, and TMEM258. We observed differences

in causal estimates of gene expression on CRC risk across different CD4+ T cell subtypes and activation timepoints, as well as CRC anatomical subsites and sex. However, our sensitivity analysis revealed that the genetic proxies used to instrument gene expression in CD4+ T cells also act as eQTLs in other tissues, highlighting the challenges of using genetic proxies to instrument tissue-specific expression changes.

Conclusion

Our study demonstrates the importance of capturing the dynamic nature of CD4+ T cells in understanding disease risk, and prioritises genes for further investigation in cancer prevention research.

EACR25-2243**Subtyping Xeroderma Pigmentosum in Tanzania through blood whole-exome sequencing**

M. Parmentier¹, D. Mavura², S. Msuya², L. Kini², J. Farhat³, A. Sablon³, L. Devis³, P. Jaen⁴, M. Tarabichi³, I. Pastushenko³

¹Université Libre de Bruxelles, IRIBHM - Jacques E. Dumont Institut Interdisciplinaire en biologie humaine et moléculaire, Bruxelles, Belgium

²Kilimanjaro Christian Medical University College, Moshi, Tanzania

³Université Libre de Bruxelles, Bruxelles, Belgium

⁴Hospital Universitario Ramón y Cajal, Madrid, Spain

Introduction

Xeroderma Pigmentosum (XP) is a rare inherited disease caused by mutations in a group of 9 DNA repair genes (XPA, ERCC3, XPC, ERCC2, DDB2, ERCC4, ERCC5, ERCC1, POLH). XP patients develop an extreme sensitivity to ultraviolet radiation and exhibit a high risk of developing skin cancer and serious skin disease due to sun rays extreme sensitivity. The incidence of XP in Tanzania is much higher than in Europe due to consanguineous marriages and the genetic landscape of XP patients in Tanzania remains unknown. Since 2017 we initiated an XP outreach program aiming at providing awareness of the damaging effects of UV radiation and early cancer detection, treatment and follow-up clinic every 2 months. This study aims to determine the genetic subtypes of XP in Tanzania and its correlation with clinical presentation. As genetic profiling has a high cost and it is not affordable to perform it in a routine manner in Tanzania, this study should allow us to predict the genotype, and the risk of complications based on the early symptoms and thus to improve the management of these patients.

Material and method

We performed a whole-exome sequencing on 156 blood samples from patients and parents. To detect variants across samples, we used HaplotypeCaller, a software specifically designed to call germline single nucleotide polymorphisms and indels. Variants were next annotated for pathogenicity with GeneBe. Additionally, we performed bulk RNA sequencing on keratinocyte samples from 40 patients in our cohort.

Result and discussion

We detected 17 variants classified as pathogenic, likely and predicted pathogenic in XP genes. We detected

homozygous and double-hit heterozygous pathogenic mutations in four XP subtypes: XPC, XPA, XPF and XPG. A known XPC splice-site variant was detected in 130 of the 156 individuals. To correlate the emergence of this XP hotspot with consanguinity, we carried out an inbreeding analysis with Automap to identify runs of homozygosity (ROH), i.e. genomic regions that are identical by descent. As expected, we found an enrichment of ROH in the region harbouring the XPC gene in XPC patients compared to parents. This highlights how consanguinity leads to high frequency of XP in this population where the known XPC hotspot is a low-frequency polymorphism.

Conclusion

In this study, we identified four XP subtypes, with XPC being the most prevalent. XPC is primarily caused by a hotspot mutation, which is a splice site variant and mainly results from consanguinity. These findings highlight the genetic basis of XPC and its underlying mutational mechanisms.

EACR25-2528

Changing epidemiology and trends in incidence of childhood acute lymphoblastic leukaemia in Scotland: An analysis of the national cancer registration data, 1971-2020

G. Al-Najjar¹, A. Memon¹

¹Brighton and Sussex Medical School, Primary Care and Public Health, Brighton, United Kingdom

Introduction

Acute lymphoblastic leukaemia (ALL) is the most common haematological malignancy in children (aged 0-14 years), accounting for about 25% of all childhood cancers. The highest incidence is observed in developed countries in Europe, North America and Oceania. The disease is relatively more common in males than females, with a M:F ratio of about 1.3-1.5:1. The aetiology of ALL is not well understood – this includes genetic (e.g. Down's syndrome) and environmental (e.g. exposure to high levels of ionizing radiation) factors and 'delayed infection hypothesis'. We conducted a retrospective population-based cohort study to examine whether there have been changes in the epidemiology of ALL in Scotland during the past five decades.

Material and method

Individual-level, national (population-based) cancer registration data for patients diagnosed with childhood (age 0-14 years) ALL (ICD-10 code, C91.0) in Scotland from 1970-2020 were obtained from the Scottish Cancer Registry, Public Health Scotland. Average annual incidence rates were calculated by gender during the 10 five-year time periods (1971-75 to 2016-20). The percentage (%) change in the incidence rates in each gender was calculated as the change in the average annual incidence rate from the first (1971-75) to the last time period (2016-20). The average annual percentage change (i.e. year-on-year increase in incidence rates during 1971-2020) was estimated using the slope of the linear trend line fitted to the incidence rates by year of diagnosis.

Result and discussion

During the 50-year study period (1971-2020), a total of 2,951 new cases of childhood (age, 0-14 years) ALL were registered in Scotland (56.5% males, 43.5% females). The average annual incidence rates increased by about 56% in males (from 2.7/100,000 children in 1971-75 to 4.2/100,000 in 2016-20), and about 95% in females (from 2.1/100,000 in 1970-75 to 4.1/100,000 in 2016-20). The average annual percentage change in incidence rate was 1.2% in males and 1.6% in females.

Conclusion

It appears that there has been a small but steady increase in the incidence of childhood ALL in Scotland during the past 5 decades. Some of this increase may be due to the improvement in diagnostic procedures during this period. Although generally the disease is more common in males, our study showed that the incidence rates in recent years have become similar in both genders (4.2/100,000 vs. 4.1/100,000). There was also a much higher increase in the incidence rates in females than in males (95% vs. 56%) over the study period. This unexpected relatively greater increase in incidence in female children needs further investigation.

Prevention and Early Detection

EACR25-0059

A 8-miRNA risk score-based prediction model for liver cancer rupture

Y. Xu¹, T. Feng¹

¹Chongqing University Cancer Hospital, General Department, Chongqing, China

Introduction

Approximately 700,000 people die of Hepatocellular Carcinoma (HCC) each year worldwide, making it the third leading cause of cancer related deaths. Rupture is a potentially life-threatening complication of HCC. Spontaneous rupture is the third most common cause of death due to HCC after tumor progression and liver failure.

Material and method

Here, we derived a 8-microRNA risk score (8-miRNA RS)-based model with better performance in the prediction of liver cancer rupture in 755 advanced liver cancer patients (273, 265, and 217 in the training, internal, and external validation sets, respectively). This model, presented as a nomogram, included four parameters: the 8-miRNA RS, TNM stage, primary tumor size, and volume transfer constant (Ktrans).

Result and discussion

Favorable calibration and discrimination of 8-miRNA RS-based model with areas under the curve (AUC) of 0.865, 0.811, and 0.804 were shown in the training, internal, and external validation sets, respectively. Patients who have higher nomogram score (>92.2) would have higher liver rupture rate ($P = 0.004$).

Conclusion

In summary, our data showed the 8-miRNA RS-based model could precisely identify more patients who are likely to develop tumor nodule rupture, which may help clinicians formulate the initial prevention and diagnosis

strategy and consequently achieves better clinical prognosis for patients with liver cancer.

EACR25-0066

Implementing cancer prevention strategies in the occupational setting: the Cancer Prevention at Work (CPW) study protocol

G. Collatuzzo¹, R. Gan², A. Godono³, A. Tardon⁴, E. Fabianova⁵, G. Fiorini⁶, D. Mates⁷, P. Boffetta^{1,6,7} on behalf of CPW Working Group

²IUOPA, University of Oviedo and Health Research Institute of Asturias (ISPA), Oviedo, Spain

³University of Torino, Department of Public Health and Pediatrics, Torino, Italy

⁴University of Oviedo, Health Research Institute of Asturias, Oviedo, Spain

⁵Regional Authority of Public Health, Banská Bystrica, Occupational Health Department, Banská Bystrica, Slovakia

⁶University of Bologna, Cardiovascular Medicine Unit, Heart, Chest, and Vascular Departments, Bologna, Italy

⁷National Institute of Public Health, Environmental Health, Bucharest, Romania

Introduction

Chronic infections account for 13% of human cancer. Helicobacter pylori (Hp), Hepatitis C Virus (HCV) and Human Papilloma Virus (HPV) are responsible together for 75% of this burden. The adoption of evidence-based preventive interventions is suboptimal. The occupational health surveillance (OHS) would be a suitable framework for implementing health promotion activities, given the structured medical examination program. The aims of Cancer Prevention at Work (CPW) are (i) to conduct pilot protocols for prevention of cancers caused by Hp, HCV and HPV among workers; (ii) to estimate the cost-effectiveness of these interventions and compare them with no intervention scenario; (iii) to develop plans for the large-scale implementation of such interventions and engage stakeholders; (iv) to identify barriers and facilitators of occupational-based interventions; (v) to provide data on prevalence of infection and of adherence to cancer prevention strategies in different types of workers.

Material and method

CPW is held in four European Countries with a high prevalence of cancer-related infections: Italy, Spain, Romania and Slovakia. Population involved include healthcare, retail, finance, metal and manufacture workers. Three interventions - Hp test; HCV test; HPV vaccination - will be implemented during the OHS as a prospective pilot study involving at least 1000 workers in each center. The recruitment started in summer 2024 and will continue for 12-18 months. Anonymized data will be collected electronically and centralized. Workers who tested positive for Hp and HCV and their family members (FMs) will be followed up through confirmatory diagnostic tests and eventual treatment. HPV vaccination will be offered to eligible workers and

their FMs. A 6-month follow-up questionnaire will be administered to the participants.

Result and discussion

The project is expected to identify cost-effectiveness advantages from using OHS to implement interventions that are broader in scope than occupational disease prevention. If such advantages are identified, the project has a significant potential to influence future research efforts and practical initiatives within the OHS that prevent all (including non-occupational) cancer. The project will also describe the determinants of the cost-effectiveness of the interventions, providing a robust evidence base for decision makers to draw conclusions on the potential benefits from replicating the interventions in other sectors and countries.

Conclusion

OHS represents an innovative context for cancer prevention implementation and might offer an effective contribution to cancer control, reaching heterogeneous populations and sensitizing to cancer prevention.

This work is supported by the European Union Horizon Europe Research and Innovation Programme under the CPW Grant Agreement No. 101104716.

EACR25-0067

Helicobacter pylori screening integrated to occupational health surveillance – the HPOS Study

G. Collatuzzo¹, G. Fiorini¹, R. Gan², M. Pavoni¹, D. Vaira¹, P. Boffetta¹

¹University of bologna, Medical and Surgical Sciences, Bologna, Italy

²IUOPA, University of Oviedo and Health Research Institute of Asturias (ISPA), Oviedo, Spain

Introduction

Eradication of Helicobacter pylori (Hp) infection can prevent cancer development¹⁻⁵. However, there are still no standardized screening protocols⁶. We aimed at testing an occupational-based Hp screening in a population of Italian healthcare workers (HCW).

Material and method

The study, approved by the Ethical Committee, started in January 2023 and will be completed in March 2025. The population includes HCW employed at the S.Orsola University Hospital, Bologna, aged 40-65. Detailed occupational, lifestyle and clinical information were collected through a written questionnaire. Hp infection was tested with stool antigen test (SAT). Hp positives were referred to the general practitioner (GP) for treatment; they were followed-up at 3 months by phone interview on health status, management of the infection and feedback around the implemented screening.

Result and discussion

Up to July 2024, 567 HCW were contacted, 379 agreed to participate and 278 returned the SAT for analyses. Of these, 213 (76.9%) were women and 64 (23.1%) were men, mean age 51 years old. Overall, 46 (16.6%) were Hp positive and 232 (83.4%) Hp negative. Family history of Hp infection was reported by 46 HCW (17.1%), while 152 (56.5%) did not report any history and 71 (26.4%) did not know; 34 HCW (12.7%) reported family history of gastric cancer. Most participants were nurses (N =

123, 45.4%), and worked in medical units ($N = 107$, 42.7%); 118 (43.5%) performed invasive practices during their activity; 36 (13.3%) worked in gastroenterology units; 115 HCW (42.9%) reported gastritis and 110 (41.5%) abdominal pain; 91 (34.0%) had undergone upper endoscopy. Surprisingly, 16 HCW (5.9%) reported to have no knowledge on Hp infection. To date, 39 of the 46 Hp positives were followed-up: 25 contacted the GP, 11 referred to another physician, the remaining did not report any contact. Of the 36 referring to a doctor, 30 were prescribed antibiotics (14: 10-day sequential; 12: 10-day concomitant therapy; 3: 14-day triple therapy; 1: triple therapy modified; 2: not prescribed any therapy). Feedback on the study were very good: 27 HCW would suggest this screening to their families; 18 HCW involved their families in Hp screening; 22 HCW reported 9-10 points at the experience quality score.

Conclusion

We implemented an occupational-based Hp screening program for gastric cancer prevention within HCW in Italy obtaining good compliance and feedback.

Prevalence of infection was lower than expected. Replication in other populations of workers is needed.

EACR25-0146

Characterize the spatial biology of HPV infection in tissue with multiplexing

M. Mathieu¹, K. Tian², J. Coleman²

¹*Enzo, Sales Support, Lausen, Switzerland*

²*Enzo, R&D, Farmingdale, United States*

Introduction

Human papillomavirus (HPV) infection is associated with a variety of clinical conditions that range from innocuous lesions to cancer. Cervical cancer is the most common cancer caused by HPV. Other less common cancers affecting both men and women include anal, vulvar, vaginal, mouth/throat, and penile cancers. More than 200 types of HPV have been identified and classified as high-risk and low-risk. Among the high-risk HPV types, HPV 16 and HPV 18 are responsible for most HPV-related cancers.

Material and method

We developed a multiplex method of nucleic acid and protein detection by combining *in situ* hybridization (ISH) application with AMPIVIEW® RNA probes and immunohistochemistry (IHC) applications. Powered by Enzo's LoopRNATM ISH technology, AMPIVIEW® RNA probes are uniquely designed with the precision of targeted, sequence-specific RNA, to deliver superior sensitivity for the detection and the expression analysis of key biomarkers in cells and tissue including formalin-fixed, paraffin-embedded (FFPE) tissue specimen.

Result and discussion

In the progression of cervical lesions to cancer, expression of key markers of proliferation and check-point control such as Ki-67 and p16 can be dysregulated at the transcriptional and protein levels. In this study, we used IHC to detect the expression pattern of these key markers, as well as RNA ISH with AMPIVIEW® HPV RNA probes to spot integrated HPV DNA as well as HPV RNA.

Conclusion

Changes can be assessed between different infection

levels and the severity and extent of marker gene dysregulation, thereby providing a proof of principle for AMPIVIEW®-based multiplexing as a tool to assist tracking the progression of cancer cells due to HPV infection.

⁵*Bhabha Atomic Research Centre, Molecular Biology Division, Mumbai, India*

⁶*Homi Bhabha National Institute (HBNI), Mumbai, India*

Introduction

Inflammatory bowel disease (IBD), such as ulcerative colitis (UC) and Crohn's disease (CD), causes chronic inflammation induced tissue damage and repair, that predisposes colitis-associated colorectal cancer (CACRC), the third most prevalent cancer globally. Recently IBD is more common in India than in other Asian countries. The nucleotide-binding domain leucine-rich repeat containing (NLR) proteins are crucial for innate immunity and intestinal tissue repair/renewal and its dysregulation is prime cause of IBD. Fruits of Aegle marmelos, commonly known as "Bael," is a natural immune modulator to treat gastrointestinal (GI) disorders. This study was aimed to evaluate immunomodulatory, anti-inflammatory and anti-cancer activity of Aegle marmelos fruit extract (AME) using preclinical models of inflammation-associated colon cancer.

Material and method

AME chemo prevention were investigated using *in vitro* IBD model of colon cancer cell line (Colo 205) exposed to dextran sodium sulfate (DSS). AME binding affinity to α -tubulin was determined using surface plasmon resonance (SPR) and confocal imaging techniques. The cyto compatibility of AME on peripheral blood lymphocytes was assessed through the CCk-8 assay. DSS-colitis (BALB/c) mice model and HT-29 xenograft tumor model were used to assess anti-cancer and immunomodulatory effects of the AME. Disease activity index (DAI) and hematoxylin-eosin (H&E) staining and immunohistochemical analysis of NLRP3 inflammasome markers were employed to assess its therapeutic effect.

Result and discussion

AME exhibited dose-dependent affinity for α -tubulin protein, obstructed tubulin polymerization, and impaired microtubule formation. AME altered HT-29 cell morphology by disrupting mitochondrial disintegration and impairing membrane integrity. DSS treatment showed a time/dose-dependent effect on Colo-205 cells. DSS (0.5 to 10 μ g/ml) induced hormesis effect and increased vitality of colo-205 cells, while AME treatment decreased cell viability. AME treatment improved DAI scores and pathological damage due to DSS induced colitis in mice. Delayed tumor growth was observed with AME treated HT29 xenograft transplanted mice. AME treatment suppressed levels of NLRP3 inflammasome pathway molecules such as NLRP3, GSDMD, IL-18, TIM-3, and AIM-2 inflammatory factors both in DSS colitis and xenograft tumor models.

Conclusion

These results validated AME as immune regulatory and chemo prevention in colon cancer under inflammatory conditions by targeting NLRP3 inflammasome mediated immune signal. Also, provides insight into AME's potential therapeutic benefits and supporting the use of natural compounds in cancer prevention and highlights the importance of exploring alternative approaches to traditional therapies in the quest for effective treatments.

EACR25-0251

G-Protein coupled Estrogen Receptor 1 (GPER1): A Novel Target for Chemoprevention of Prostate Cancer

⁷*Seth G.S. Medical College and King Edward Memorial Hospital, Department of Urology, Mumbai, India*

⁸*Tata Memorial Hospital (TMH), Department of Uro-oncology, Mumbai, India*

Introduction

The pathogenesis of Prostate Cancer (PCa), the 2nd most common cancer in men, is preceded by a long latency period. G-Protein coupled Estrogen Receptor 1 (GPER1); a plasma membrane localized receptor, is reported to have cell-context dependent role in progression of tumors of various organs. Existing data suggest that GPER1 has a tumor suppressive role in PCa. However, GPER1 has not been explored for its chemopreventive potential for PCa.

Material and method

Publicly available human datasets were screened for prostatic GPER1 expression. Human PCa and Benign Prostatic Hyperplasia (BPH) tissues and prostatic tissues at different stages during PCa progression in TRAMP (Transgenic Adenocarcinoma of Mouse Prostate) model were assessed for GPER1 expression using qRT-PCR or flow-cytometry. Pyrosequencing was carried out to study GPER1 promoter methylation. TRAMP mice subcutaneously administered G1 (GPER1 agonist) alone or in combination with G15 (GPER1 antagonist) were assessed for tumour progression. Stable GPER1-silenced clones of RWPE-1, LNCaP and PC3 cells were assessed for their proliferative, invasive and migratory abilities in the presence and absence of G1. RT2 profiler, qRT-PCR and zymography assays were carried out to identify GPER1-regulated molecules.

Result and discussion

The frequency of GPER1-positive cells was found to be significantly reduced in high-grade human PCa compared to BPH tissues. A similar observation was concluded by the analysis of public datasets for prostate tumours. In the TRAMP mice, GPER1 expression and GPER1-positive cell frequency was found to be significantly higher at the HGPIN (High-Grade Intraepithelial Neoplasia) stage and decreased at the well differentiated carcinoma (WDC) stage, compared to respective age-matched controls animals. Methylation analysis revealed an increase in the percent methylation at the 5 CpG sites spanning the GPER1 promoter in TRAMP mice displaying HGPIN followed by a decrease in the animals displaying WDC, compared to respective age-matched control mice. Pharmacological activation of GPER1 with G1 alone, not when co-administered with G15, inhibited progression of HGPIN to PCa in TRAMP mice. GPER1-silencing in LNCaP, PC3 and RWPE-1 led to an increase in migration and invasion while G1-treatment led to a decrease in proliferation and invasion in vitro. GPER1 mediated epithelial to mesenchymal transition (EMT) was found to be regulated through miR200a-ZEB2-E-Cadherin loop and other metastasis-associated genes.

Conclusion

GPER1 silencing in prostate epithelial cells favored EMT while GPER1 activation inhibited EMT. GPER1 activation by G1 prevented progression of HGPIN to PCa in TRAMP mice. Overall, these observations highlight the potential of GPER1 as a promising target for chemoprevention and warrant clinical studies to test GPER1 agonists for their role in PCa chemoprevention in humans.

EACR25-0302

Personalized Initial Screening Ages for Colorectal Cancer Based on Detailed Family History in Western Europe

T. Seum¹, M. Hoffmeister¹, H. Brenner¹

¹*German Cancer Research Center (DKFZ), Division of Clinical Epidemiology and Aging Research, Heidelberg, Germany*

Introduction

Individuals with a family history of colorectal cancer (CRC) face varying levels of increased risk, influenced

by the number of affected relatives, their relatedness, and age at diagnosis. Early detection through timely screening is crucial. Current guidelines often provide broad age ranges for screening and lack precision to account for these risk variations. This study aims to derive risk-adapted starting ages for CRC screening based on varying family history characteristics in Western European countries, where CRC incidence is rising among younger populations.

Material and method

We determined 5-year cumulative risks of CRC for ages 30 to 50 for selected Western European countries (Germany, France, The Netherlands, and Belgium) using the GLOBOCAN 2022 database. Risk estimates were derived from a comprehensive meta-analysis of 20 cohort studies, where relative risks for CRC ranged from 1.09 (95% CI, 1.03–1.15) for individuals with a second-degree relative (SDR) diagnosed with CRC to 3.26 (95% CI, 2.82–3.77) for those with a first-degree relative (FDR) diagnosed before age 50. We then identified the ages at which individuals with different family history characteristics reach the same CRC risk as the average-risk population at age 50 (aCR50), the most common starting age for screening in Europe.

Result and discussion

Those with at least one FDR diagnosed with CRC at or after age 50 reached the aCR50 threshold at ages 45–46 across the four countries. For those with two or more FDRs diagnosed with CRC, aCR50 was reached at age 41 (95% CI, 39–44) in France and at ages 43–44 in the other countries. When an FDR was diagnosed before age 50, the aCR50 threshold was reached earlier, ranging from age 39 (95% CI, 38–40) in France to age 42 (95% CI, 41–43) in the Netherlands. In cases where individuals had at least one SDR with CRC, the aCR50 threshold was consistently reached at 49 years across all included countries. These findings highlight discrepancies between calculated risk-adapted starting ages and current screening guidelines.

Conclusion

This study underscores the need and potential of a tailored approach to CRC screening for individuals with a family history and provides an empirical basis for refining risk-adapted starting ages of CRC screening for people with a CRC family history in the analysed European countries.

EACR25-0311

Assessment of a Fiber-rich Diet in Post-treatment Breast Cancer Survivors

G. Moll¹, L. Tennen², J. Ponce¹, C. Hanson¹, M. Timmerman¹, R. Lietka³, M. Jackson¹

¹UNMC, Medical Nutrition, Omaha, United States

²UNMC, Oncology/Hematology, Omaha, United States

³UNMC, Medical Nutrition, Kearney, United States

Introduction

Breast cancer survivors are living longer post-cancer diagnosis and thus are experiencing continued impacts of cancer treatment. Cancer treatments may alter diet intake, including fiber-rich foods; thus, it is important to understand survivors' dietary patterns to inform targeted interventions that may reduce recurrence and improve outcomes. This study aimed to characterize dietary

patterns among breast cancer survivors and compare intake among those receiving chemotherapy, radiation, and surgery.

Material and method

This was an observational secondary analysis of female breast cancer survivors seen at a Midwestern, USA Cancer Center Survivorship Clinic. The Diet History Questionnaire III was used to collect dietary intake, including total fiber, fiber-rich foods and used to score diet quality (Healthy Eating Index-2015 score; HEI-2015). Participants also self-reported fiber and probiotic supplements and treatment history was collected from the medical record. Mann Whitney U-test, Kruskal-Wallis, and Fisher's Exact test examined differences in dietary intake between treatment groups.

Result and discussion

The population (N = 17) were 88% white women (n = 15), with a median (IQR) age of 62 (16). Most were diagnosed with stage 1 cancer (76.5%, n = 13). All participants received surgical treatment, where 59% (n = 10) received radiation and surgical treatment, and only 29% (n = 5) received chemotherapy as a part of any treatment plan. Median daily fiber intake was 13.0 (18) g, meeting 43% of the American Institute for Cancer Research (AICR) goal of 30 g fiber/day, with a median HEI-2015 of 69.9 (10) out of 100. The median daily intake of whole grains was 0.66 (1) ounces, comprising only 24% of median total grain consumption. Participants ate a median of 1.8 (2.3) cups of fruit, 1.5 (1.4) cups of vegetables, and 0.8 (1.5) ounces of nuts, seeds, and legumes, where 41% (n = 7) used probiotics, and 24% (n = 4) used fiber supplements. No significant differences in total fiber, fiber-rich foods, or use of fiber and probiotic supplements were found between breast cancer survivors by treatment type.

Conclusion

When compared to established recommendations of dietary fiber and fiber-rich foods, no treatment groups met the AICR guidelines. There is a need for practical nutrition interventions and education to increase dietary fiber intake among breast cancer survivors.

⁴Centre Léon Bérard, -, Lyon, France

⁵Centre Léon Bérard, Département Prévention Cancer Environnement ; Université Lyon 1, Lyon, France

⁶Imperial College London, Cancer Epidemiology and Prevention Research Unit, Department of Epidemiology and Biostatistics, School of Public Health, London, United Kingdom

Introduction

This pilot study aimed to test the feasibility and optimize

the fieldwork procedures of a lifestyle intervention in French hospital settings for the implementation of the large-scale randomized control trial LIFE-SCREEN [1] that aims to provide evidence-based diet and lifestyle advice for cancer prevention at colorectal cancer screening.

Material and method

A total of 40 patients were recruited at two hospitals, Centre Léon Bérard and Hôpital Edward Herriot in Lyon, France. The intervention material comprised cancer prevention recommendations including recipes, nutrition and physical activity tips, advice on behavioural change, and a logbook to support goal setting, tracking and achievement. Patients received the intervention material in pre- or post-colonoscopy visits and were asked to complete questionnaires at baseline and after at least one month of using the material. They also received a pedometer. Self-administered biospecimens collections (urine, feces, capillary blood collections) and venous blood (collected at hospital) were optional to enable patients to participate while refusing one or more biospecimens. Focus group meetings were organised with patients and then with hospital staff to obtain clear information and understanding regarding their perspective on the intervention.

Result and discussion

Out of the 40 participants enrolled (20 men & 20 women; mean age of 56.7 ± 8.1 years), 65% and 30% responded to the self-administered questionnaires at one-week and one-month post-recruitment, respectively. The collection of biospecimens was generally rated as acceptable to very acceptable by the patients, with the exception of capillary blood collection. Patients participating in the two-focus group meetings were positive about the quality of the intervention folder and material and found the monitoring sheets useful to help them reach their different goals. Hospital staff suggested to simplify the material while referring to more detailed online information to reduce the time needed to explain the intervention material to the patient during the visit. Venous blood collection and following up the participants to arrange self-administered biospecimens collection and transportation was deemed burdensome by hospital staff.

Conclusion

To optimize the feasibility of the LIFE-SCREEN trial, several modifications were made to the intervention material and protocol to improve efficacy and meet the diversified patients' needs while reducing the burden on hospital staff. More specifically, a simplification of the material was performed and supplementary resources online (including short videos) were developed. In addition, biospecimens collections were removed from the protocol (due to logistical challenges).

Predictors of colorectal neoplasia among individuals with a family history of CRC aged 40 to 54 years: Objective Risk vs. Perceived Risk

J. Hibbert¹, M. Hoffmeister¹, H. Brenner¹

¹*German Cancer Research Center (DKFZ), Division of Clinical Epidemiology and Aging Research, Heidelberg, Germany*

Introduction

Individuals with a family history of colorectal cancer (CRC) are at increased risk of CRC and recommended to start screening earlier than the average-risk population. Current recommendations are exclusively based family history and genetic predisposition and do not consider lifestyle-related risk factors. This study aimed to evaluate risk factors for CRC precursors and predictors of risk perception among first-degree relatives (FDRs) of CRC patients aged 40–54 in Germany.

Material and method

Data from 922 participants with a family history of CRC in an FDR were analyzed in a multi-center cross-sectional study. Participants completed questionnaires on sociodemographic factors, lifestyle choices, medical history, and perceived CRC risk. Colonoscopy reports were obtained, and participants were categorized according to the most advanced finding at colonoscopy (advanced neoplasia, non-advanced neoplasia, or no neoplasia). Multivariable logistic regression models were used to assess predictors of both presence of neoplasms and perceived CRC risk.

Result and discussion

Two hundred twenty (23.9%) participants were found to have colorectal neoplasia, including 63 (6.8%) with advanced lesions. Strong associations with advanced neoplasia presence were observed for obesity ($BMI > 30$: aOR 2.44, 95% CI 1.12–5.22), smoking (aOR 1.47, 95% CI 1.14–1.88 per 10-pack-years), and physical inactivity (<45 minutes/day; aOR 2.51, 95% CI 1.11–5.25). However, these factors did not match the lifestyle predictors of perceived risk. Instead, alcohol consumption and fruit and vegetable intake were the lifestyle factors most strongly related to people's sense of their own risk.

Conclusion

This study assessed and compared objective risk factors for advanced neoplasia and key predictors of CRC risk perception among individuals with a family history of CRC. Our results show a significant disconnect between objective risk factors and participants' risk perceptions. Individuals with a family history of CRC may benefit from effective risk communication and personalized CRC screening strategies incorporating lifestyle factors.

EACR25-0998

Participant-related risk factors for false positive faecal occult blood test results in screening for colorectal cancer – a systematic review and meta-analysis

W. Poulsen¹, W. Xu², K. Bendixen¹, L. Loekkegaard³, E. Theodoratou², X. Li⁴, S. Lin⁴, M. Timofeeva⁵

⁴Zhejiang University School of Medicine, Department of Big Data in Health Science, Hangzhou, China

⁵University of Southern Denmark, Department of Public Health, Odense, Denmark

Introduction

Colorectal cancer (CRC) screening using faecal occult blood tests (FOBT) reduces CRC-related mortality, but both guaiac FOBT (gFOBT) and faecal immunochemical tests (FIT) have undesirably high rates of false positives (FP). There is evidence that the number of FP differs by sex, and multiple studies have investigated the effects of sex-specific FIT cut-offs. However, it remains unclear whether other factors are also relevant. We identified participant-related factors associated with the risk of FP results.

Material and method

We systematically searched MEDLINE, EMBASE, Cochrane Central, MedRxiv.org and BioRxiv.org up to April 2022, screened the reference lists of relevant systematic reviews, and tracked citations of included studies through Web of Science. An updated search primo January 2025 is in progress. Eligible studies included average-risk or symptomatic populations aged 18 years or older who were screened with either of the FOBT. We screened full texts in duplicate and assessed the risk of bias using the Joanna Briggs Institute's critical appraisal tools. We calculated relative risks (RR) of false positive rates (FPR) and RR of positive predictive values (PPV) of available risk factors. For each risk factor reported in at least two studies, we estimated the summary effects and corresponding 95% confidence intervals using random-effects models (Prospero CRD42022315767).

Result and discussion

We included 90 studies with 17,728,741 participants. Males had higher FPR [FPR (95%CI): 1.32 (1.23, 1.41) for gFOBT and 1.32 (1.15, 1.48) for FIT] and PPV [PPV (95%CI): 1.79 (1.56, 2.02) for gFOBT and 1.44 (1.35, 1.53) for FIT] than females. In populations tested with gFOBT, age groups were found to differ in PPVs, e.g., the PPV for 65–69-year-olds was 2.16 (95%CI: 1.47, 2.86) times the PPV for 50–54-year-olds. Populations tested with FIT had significantly different FPRs when comparing age groups, use of antiplatelet agents, use of antithrombotic agents, and presence of hypertension. For instance, the FPR for 65–69-year-olds was 1.69 (95%CI: 1.17, 2.22) times the FPR for 50–54-year-olds. When considering PPVs, the results showed differences across age groups, use of aspirin, use of proton pump inhibitors (PPI), alcohol intake, smoking, diabetes mellitus, metabolic syndrome, and diarrhea, e.g., users of PPI had a lower PPV than non-users [PPV (95%CI): 0.75 (0.68, 0.83)]. Most comparisons showed high heterogeneity.

Conclusion

Several participant-related factors are associated with the risk of FP. These observations could be due to differences in cancer incidence between the groups as well as true associations with FP. Despite this uncertainty, the evidence from this study supports the need to optimize screening across subgroups. We suggest further research to assess whether the identified risk factors can be used to tailor screening programs to their intended populations.

EACR25-1004

Effect of TiO₂, as food additive E171 or nanoparticles, on colorectal carcinogenesis and colibactin-producing *Escherichia coli* virulence

C. Juban¹, T. Sauvaitre¹, A. Devaux¹, G. Roche¹, C. Ledieu¹, O. Awitor², N. Barnich¹, C. Massard², M. Bonnet¹, D. Boucher¹

¹*Microbes, Intestin, Inflammation et Susceptibilité de l'Hôte (M2iSH) unit, UMR 1071 Inserm/Université Clermont Auvergne, USC INRAE 1382, Clermont-Ferrand, France*

²*CNRS/IN2P3, Laboratoire de Physique de Clermont (LPC+), UMR 6533, Université Clermont Auvergne, Clermont-Ferrand, France*

Introduction

Colorectal cancer (CRC) is the third most common cancer worldwide and the second leading cause of cancer mortality. Genetic, host susceptibility, immunological, and environmental factors contribute to its initiation, development, and/or clinical expression. Among the environmental contaminants, titanium dioxide (TiO₂) particles are of particular concern given their potential carcinogenic effects and ubiquity in everyday consumer products, especially as a food additive (E171). TiO₂ nanoparticles may interact with the intestinal microbiota and facilitate the emergence of pathobionts such as colibactin-producing *Escherichia coli* (CoPEC), which abnormally colonise the colonic mucosa of CRC patients. This project aims to investigate the impact of TiO₂ on colorectal carcinogenesis, with a particular focus on its effects on the interactions between intestinal epithelial cells (IEC) and the gut microbiota, including CoPEC.

Material and method

The growth of five CoPEC strains was monitored after a 24-hour exposure to TiO₂ doses equivalent to those reaching the intestine (0.1 and 1 mg·kg⁻¹). Their ability to interact with human intestinal epithelial HT-29 cells was then measured. Interactions with nanoparticles were observed using scanning electron microscopy (SEM) coupled with energy dispersive spectroscopy (EDS). APCmin/+ mice predisposed to develop CRC were exposed to a human equivalent dose of E171 (10 mg·kg⁻¹ of body weight) twice a week for 27 days. A co-exposure scenario was tested in which mice were infected with the 11G5 CoPEC strain and exposed five times a week for 50 days to E171. Macroscopic, histological, and colonic mucosa-associated microbiota analyses were performed.

Result and discussion

In vitro, the doubling time of each CoPEC strain was reduced after TiO₂ exposure. Adsorption of TiO₂ particles was observed on the surface of the 11G5 strain by SEM-EDS. An increase in the ability of 11G5 to adhere and persist in HT-29 was shown along with structural pili modifications. In vivo, after 27 days, some of the E171-exposed individuals exhibited more advanced tumour development than the control group (number and total volume of polyps) and were defined as E171-sensitive group. Occludin gene expression was significantly reduced in this group. These sensitive mice also showed a greater dysbiosis than the E171 non-sensitive and unexposed ones with several over-

represented taxa that are also more abundant in CRC. Additionally, E171 exposure led to an increased colonisation and persistence of the 11G5 strain in the colon and its translocation to the liver and spleen.

Conclusion

Collectively, these results suggest that, in sensitive individuals, exposure to TiO₂ may contribute to CRC aetiology by altering the structure and function of the intestinal microbial ecosystem and the host intestinal barrier. This could promote the emergence of pathobionts such as CoPEC, in addition to inducing changes that enhance their colonisation.

EACR25-1018

Investigating how Mitochondrial Dysfunction Promotes Breast Carcinogenesis in a Stiff Extracellular Matrix

F. Tennant¹, A. Gilmore¹, K. Brennan¹, J. Swift², C. Kirwan¹

¹*University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom*

²*University of Manchester, Division of Cell Matrix Biology and Regenerative Medicine, Manchester, United Kingdom*

Introduction

High mammographic density (HMD) is one of the highest independent risk factors for breast cancer, yet the mechanisms by which HMD promotes breast carcinogenesis are not understood. HMD is associated with increased mechanical stiffness of the extracellular matrix in breast tissue. Metabolic reprogramming is a key hallmark acquired by cancer cells to support their survival and progression in the tumour microenvironment (TME). TME stiffening has been shown to drive metabolic changes in various cancer types. However, less is known about the importance of metabolic rewiring in breast carcinogenesis, particularly with respect to HMD. Here we use a mechanically tuneable 3D model to investigate how metabolic changes in a stiff matrix may drive the oncogenesis of normal mammary epithelial cell lines.

Material and method

MCF10A cells were cultured in Matrigel for 14 days to allow the formation of mature, polarised mammary acini. Live acini were then extracted and transferred into soft (0.25 kPa) or stiff (10 kPa) Matrigel-alginate hydrogels, the latter of which were generated by crosslinking alginate polymers with 24 mM Ca²⁺. After 7 days acini were extracted from hydrogels and processed for downstream analysis.

Result and discussion

Global proteomics revealed that GO pathways associated with oxidative phosphorylation (OXPHOS) are down-regulated in MCF10A acini cultured in a stiff 3D matrix. Mitochondrial morphology is an indicator of mitochondrial function, where highly interconnected mitochondrial networks generate ATP through increased OXPHOS. Consistently, confocal imaging showed that mitochondrial networks are dense and elongated in a soft matrix, while those in stiff are fragmented and sparse. Mitochondrial DNA (mtDNA) copy number is reduced

by 20% in stiff, suggesting that mitochondrial biogenesis and/or clearance change in response to increased matrix stiffness. Subcellular fractionation revealed that mitochondria in a stiff matrix are partially depleted of the mitochondrial transcription factor TFAM, which maintains the stability, replication and transcription of mtDNA. Moreover, TFAM is enriched in the cytoplasmic fraction of acini in stiff. The reduction in mitochondrial TFAM may be responsible for mtDNA depletion and impaired OXPHOS in a stiff matrix. Ongoing work aims to understand if there is defective import of TFAM into mitochondria in stiff, or if TFAM is released into the cytosol through partial mitochondrial permeabilization.

Conclusion

We show that non-cancerous mammary acini cultured in a stiff 3D matrix exhibit mitochondrial dysfunction, characterised by increased mitochondrial fragmentation, reduced mitochondrial TFAM and a decreased OXPHOS signature. Future work will investigate whether this mitochondrial dysfunction promotes breast carcinogenesis in a stiff matrix, with the hope to identify targetable pathways for the early detection and prevention of breast cancer in women with HMD.

OUTLIVE-CRC "Improving prognosis and quality of life of young CRC patients: Tertiary prevention through multi-marker models and nutritional interventions"

O. Consortium¹, L. Almeida¹, E. Dazert-Klebsattel¹, D. Vondran¹, M. Kirstein¹, J. Pochhammer², S. Sebens², N. von Bubnoff¹, S. Derer-Petersen¹

¹*UKSH Lübeck, Lübeck, Germany*

²*UKSH Kiel, Kiel, Germany*

Introduction

Colorectal cancer (CRC) is increasing in younger individuals and depicts an overall five-year survival rate reaching 65% with a recurrence rate about 10–40%. It is known that lifestyle factors such as physical activity and nutrition are important risk factors. A divergence between chronological and biological age (BA) constitutes an adverse prognostic factor for young adults, especially for those having a metabolic syndrome. The overriding goal of OUTLIVE-CRC is the early detection and prevention of recurrences to improve prognosis and quality of life of early-onset CRC patients (<50 years) by combining functional omics data and nutritional interventions.

Material and method

We develop a biological age (BA) based multimarker risk panel encompassing clinical parameters as well as multi-omics data (metabolomics, proteomics, genomics, epigenomics, microbiomics) using blood and stool samples. Liquid biopsy techniques will be applied to detect recurrence at early stage and/or to identify patients with a high risk of recurrence, and will be combined with BA markers, using artificial intelligence methods. Patient-derived colonic organoid cultures will be implemented to study the individual risk of malignant transformation and to train liquid biopsy marker panels. Microfluidic automation strategies will be used to translate the identified

multi-marker panel into a point-of-care microfluidic platform. Personalized nutritional interventions will be developed based on identified liquid biopsy markers. Patient representatives are integrated in all parts of the study.

Result and discussion

OUTLIVE-CRC is a multi-center study funded in the course of the The National Decade against Cancer by the German Federal Ministry of Education and Research between the years 2022 and 2030. OUTLIVE-CRC will provide a new tertiary prevention concept for early-onset CRC patients by combining liquid biopsy testing with personalized nutritional interventions. The consortium is supported by active patient integration.

Conclusion

The OUTLIVE-CRC study will implement a novel tertiary prevention strategy to improve prognosis and quality of life of early-onset CRC patients.

EACR25-1559

Effects of Immediate Breast Reconstruction on Psychosocial and Sexual Well-Being in Women with Breast Cancer: The Mediating Role of Breast Satisfaction

P. Gil-Olarte¹, R. Guil¹, M. Gil-Olarte², M. Baena¹, R. Gómez-Molinero¹

¹*Universidad de Cádiz, Psicología, Cádiz, Spain*

²*Hospital Universitario Virgen Macarena, Sevilla, Spain*

Introduction

Breast cancer is the most common cancer in women, and its treatment can have a significant impact on quality of life, particularly psychosocial and sexual aspects.

Immediate breast reconstruction (IBR) has emerged as a solution to improve body image and overall well-being. This study examines the relationship between breast satisfaction, psychosocial well-being and sexual well-being in patients undergoing IBR.

Material and method

A prospective study involving 36 women undergoing IBR. The BREAST-Q questionnaire assessed the quality of life in psychosocial, physical and sexual dimensions, as well as breast satisfaction, and data were analysed using correlations and mediation models. Additionally, differences in results were explored based on the surgical technique and the reason for surgery.

Result and discussion

Participants reported the highest quality of life in the psychosocial and sexual dimensions. No significant differences in these indicators were found based on surgical technique or reason for surgery. Psychosocial well-being and breast satisfaction explained 56.16% of the variability in sexual well-being, with 44.67% attributable to psychosocial well-being. Breast satisfaction acts as a mediator between psychosocial and sexual well-being, independent of physical well-being. These findings suggest that IBR may improve patients' well-being by preserving body image and reducing psychological morbidity.

Conclusion

IBR is a key strategy for improving the quality of life in breast cancer patients, particularly by positively

influencing psychosocial and sexual well-being.

Satisfaction with breast reconstruction is a crucial factor in this improvement, acting as a mediator in the relationship between psychosocial and sexual well-being. These findings highlight the importance of incorporating psychological support and reconstruction information into breast cancer treatment to help patients make informed decisions and improve their long-term well-being.

EACR25-1682

Overview of ovarian cancer risk prediction models evaluating their performance and utility: a systematic review

A. Ardasheva¹, K. Atha¹, I. Mohamed², K. Gaitskell¹, C. Kartsonaki³

¹*University of Oxford, Oxford, United Kingdom*

²*University of Leicester, Leicester, United Kingdom*

³*University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom*

Introduction

Ovarian cancer is the deadliest gynecological malignancy and most cases are diagnosed at an advanced stage. There is no population-wide screening and some women with known genetic risk are offered surveillance or prophylactic strategies. Models for predicting risk of ovarian cancer could be useful in decreasing mortality. We provide the first comprehensive overview of ovarian cancer risk prediction models and assess their performance, quality, and applicability.

Material and method

We conducted a systematic literature search through MEDLINE and Embase for articles on ovarian cancer risk prediction models and validation studies. The Prediction model Risk of Bias Assessment Tool (PROBAST) was used to assess model quality.

Result and discussion

We identified twenty-eight studies representing twenty-one ovarian cancer risk prediction models. Fourteen risk prediction models were developed in the general population, while six were developed for high-risk populations, defined by family history, and one for patients with endometriosis. The number of study participants ranged from 80 to 4,943,765 women aged between 18–89 years old. There were eight internally and four externally validated models. Two models had both internal and external validation. Twenty-three studies that reported discrimination and/or calibration had moderate-to-good performance. Risk prediction models with the best predictive ability, both developed in the primary care setting, reported an area under the receiver-operating characteristic curve (AUC) of 0.86 (95% confidence interval (CI) 0.84–0.87) for 2-year and an AUC of 0.77 (95% CI 0.76–0.78) for 10-year ovarian cancer risk in the general population. For women with higher ovarian cancer risk, the 10-year risk predictive ability of the best-performing risk prediction model had a good discrimination with a C-index of 0.77 (95% CI 0.73–0.82) and a good calibration with an expected to observed ratio of 0.87 (95% CI 0.70–1.08). Overall, predictive ability

was strongest in short-term ovarian cancer risk prediction models.

Conclusion

Several models for predicting short- and long-term risk of ovarian cancer have been published, of which a few have been validated in other populations. Their predictive ability varies but is generally moderate-to-good, and some models may be suitable for use in primary care or specialty clinics; however, assessment of their utility and validation in diverse cohorts is warranted.

EACR25-1690

Prevalence and Clinical Characteristics of High-Risk HPV in Women from Underserved and Remote Regions of Colombia

R. Parra-Medina¹, C. Piedrahita¹, G. Cardenas¹, C. Corredor¹, Y. Salgado¹, A. Mosquera-Zamudio¹, G. Rivera¹, A. Combita¹, J. Riaño¹, C. Wiesner¹

¹Instituto Nacional de Cancerología, Colombia

Introduction

Human papillomavirus (HPV) is the leading risk factor for cervical cancer, the most common malignancy among Colombian women. Colombia is a genetically diverse country, with Indigenous, Afro-descendant, and mixed-ancestry populations residing in different regions.

Despite advancements in screening and vaccination, disparities in prevention and early detection persist, particularly among women in remote and underserved areas with limited healthcare access. HR-HPV prevalence and clinical impact may vary by ancestry due to genetic, immunological, and environmental factors. This study evaluates HR-HPV prevalence and cytological findings in women from low-resource regions with restricted healthcare coverage with diverse ancestral backgrounds.

Material and method

A co-testing approach (HPV testing and cytology) was conducted in four Colombian regions with limited healthcare access: Soacha, Buenaventura, Ciénaga de Oro, and Mitú. The study included women from diverse ancestral backgrounds, including Indigenous, Afro-descendant, and migrant populations. Liquid-based cytology was performed using the ThinPrep system, while HPV genotyping was conducted with the Cobas HPV test, detecting HPV 16, HPV 18, and other high-risk genotypes.

Result and discussion

A total of 561 women were included in the study, with a mean age of 46 years. HR-HPV was detected in 15% of the participants. Among them, 63 women tested positive for other high-risk genotypes, while HPV 16 and HPV 18 were each identified in 5 cases. The prevalence of HR-HPV varied across different regions: Buenaventura (15.3%), Ciénaga de Oro (13.5%), Mitú (12.9%), and Soacha (10%). Cytological abnormalities among HR-HPV-positive women: ASC-US: 16 cases (30.8%). LSIL (CIN I): 8 cases (15.4%). HSIL (CIN II, III, carcinoma in situ): 2 cases (3.8%). ASC-H: 2 cases (3.8%).

Conclusion

These preliminary results show an HR-HPV prevalence of 15%, with regional variations (10%–15.3%), reflecting

global disparities linked to socioeconomic and ancestral factors. HPV 16 and 18 were detected in 1.8% of cases, while other high-risk genotypes (12%) highlight the need for broad-spectrum screening. Cytological abnormalities were present in 53.8% of HR-HPV-positive women, with ASC-US (30.8%) as the most frequent. These findings underscore the need for expanded vaccination, targeted screening, and improved healthcare access to reduce cervical cancer risk in vulnerable populations.

Dietary differences exist among rural and urban cancer survivors

M. Jackson¹, R. Johnson Beller², G. Tlusty³, R. Schmidt⁴, V. Tran⁵, K. Brassil⁵, J. Loftis⁵, R. Lally⁶

¹UNMC, Medical Nutrition, Omaha, United States

²UNMC, Niedfelt Nursing Research Center, Omaha, United States

³MD Anderson, Department of Nursing, Texas, United States

⁴Nebraska Medicine, Survivorship and Cancer Risk and Prevention Program, Omaha, United States

⁵Pack Health, Birmingham, United States

⁶UNMC, Nursing, Omaha, United States

Introduction

The United States ranks fourth globally in cancer rates, with obesity as a major risk factor affecting survivorship outcomes. The American Institute for Cancer Research and World Cancer Research Fund (AICR/WCRF) emphasize maintaining a healthy weight, physical activity, and a plant-based diet. However, addressing obesity also requires understanding social determinants like socioeconomic and geographic factors. This analysis of a randomized control trial aims to assess health factors of cancer survivors and their relationship to these social determinants.

Material and method

Cancer survivors ≥19 years, following completion of primary treatment were enrolled in a multi-site trial. At baseline, self-reported diet (Diet History Questionnaire III), demographic, clinical, and wearable physical activity data (Fitbit) were collected. Healthy Eating Index-2015 (HEI) was used to evaluate diet quality. Those with complete diet data (>600 calories) were analyzed via Chi-square, t-test, one-way ANOVA (Bonferroni correction), and linear regression to examine the relationship between health factors (diet, BMI, physical activity) and social determinants of rural–urban commuting area (RUCA) codes and Area Deprivation Index (ADI).

Result and discussion

Of 79 evaluable participants at a Midwestern site, the majority were non-Hispanic White (95%, n = 75) females (99%, n = 78), with stage 1 breast cancer (55%, n = 42). At baseline, most were overweight or obese (BMI ≥ 25; 75%, n = 59), 19% (n = 15) live in either a large rural city (“micropolitan”) or rural area and 18% (n = 14) live in an area of socioeconomic disadvantage. The average (SD) age was 54.6 (11.7) years old and mean physical activity was 43.4 (30.9) minutes per week. The average HEI score was 65.5 (11.0) out of 100, with a mean daily intake of 15.7 (8.1) g of fiber, 1.2 (1.1) cups of fruit, 1.6 (0.9) cups of vegetables, 39 (29.9) g of added sugar,

1.5 (1.3) oz red and processed meat, and 81% of grain intake from refined grains. HEI scores were significantly lower among those in more rural areas (66.8 vs. 60.1, $p = 0.03$). Those in the micropolitan areas ate significantly higher red and processed meats compared to metropolitan residents (3.1 vs 1.3 oz/day, $p < 0.001$) and rural residents (3.1 vs 1.6 oz/day, $p = 0.04$). On average, micropolitan residents ate 1.75 oz more red and processed meats compared to metropolitan and rural residents, after adjustment of age and calories (β : 1.75, $p < 0.001$). There was no significant relationship between ADI and diet, obesity or activity.

Conclusion

Cancer survivors' health factors fall short of AICR/WCRF recommendations for physical activity, body weight, added sugar, fiber, fruit, vegetables, and whole grains. Those in more rural areas may be at higher risk of adverse diet intake. Identifying at-risk populations early on enables targeted interventions and personalized strategies to reduce obesity among cancer survivors, supported by inter-professional collaboration.

⁴University Hospital Schleswig-Holstein, Section for Translational Surgical Oncology and Biobanking, Department of Surgery, Lübeck, Germany

⁵www.outlive-crc.uni-luebeck.de/projekte, Lübeck, Germany

Introduction

The incidence of early-onset colorectal cancer (EOCRC) is increasing globally, influenced by divergence between chronological (CA) and biological age (BA). Lifestyle choices, such as diet, are the main factors to promote diet-related intestinal inflammation and thereby influence the divergence of CA and BA, resulting in an increased risk of EOCRC. Another sign of advanced BA is immunosenescence, a gradual decline in function of the immune system, which is associated with the development of many age-related diseases, like cancer. Searching for a stable biomarker for EOCRC detection, we focused on the functions of intestinal plasma cells, which play an important role in maintaining tissue homeostasis and protection against invading organisms, mostly via secretion of immunoglobulin A (IgA).

Material and method

Human and murine fecal IgA levels were determined by ELISA. Telomer length was measured in blood leukocytes via qPCR and serum metabolites were quantified via NMR. As experimental mouse models we used (i) acute Dextran Sodium Sulfate (DSS)-induced

colitis, by adding DSS into the drinking water for 7 days and (ii) colitis-associated colorectal cancer (CAC), by administering of two treatment cycles of i.p. azoxy-methane (AOM) and oral DSS, over the course of 5 weeks. As part of a nutritional intervention, these mice were fed a diet high in fat and sugar, that resembles modern western diet (WD), for 20 weeks. Fecal samples were collected at several time points for quantification of IgA and mesenteric lymph nodes (mLN) as well as Peyer's Patches (PP) were analyzed by flow cytometry. Finally, colon tissues were collected and analyzed by mass spectrometry-based proteomics.

Result and discussion

In humans, fecal IgA levels decline with CA and strongly correlate with BA, using telomer length of leukocytes as an indirect measure. Metabolomic analysis revealed increased serum LDL lipoprotein levels with CA, with serum LDL levels negatively correlating with fecal IgA levels. Of note, LDL levels were already enhanced in EOCRC patients, compared to age-matched normal controls. In a mouse model of acute DSS-induced colitis we observed that, in contrast to old mice, young mice respond to DSS with IgA secretion into the lumen. In line with that, proteomic analysis identified old mice to down-regulate colonic IGHα level, while up-regulating IGG2B and IGHM in comparison to young mice.

Conversely, female mice do not alter IGHα expression during aging. Finally, in a CAC model, young male mice fed a WD displayed the lowest survival rate, while the percentage of IgA+ cells in the mLN and PP correlated with survival rate under WD amongst all four groups.

Conclusion

Our data suggest that IgA secretion is reduced in old individuals, especially in those with higher risk to develop CRC, and could potentially be used as a non-invasive biomarker for the detection of divergent BA and hence increased risk to develop EOCRC.

EACR25-1888

Menarche, menopause, and female breast cancer risk in China and the UK: comparative findings from three large cohorts

X. Li¹, L. Yang¹, C. Kartsonaki¹, G. Reeves¹

¹University of Oxford, Nuffield Department of Population Health, Oxfordshire, United Kingdom

Introduction

Breast cancer incidence differs significantly between Western and Eastern populations, exemplified by the UK and China. Age at menarche and menopause, well-established risk factors for breast cancer, also exhibit distinct characteristics across these populations. This study aims to compare their distributions and associations with breast cancer risk in the UK and China.

Material and method

We used data from three large prospective cohort studies: the China Kadoorie Biobank (CKB), which included 300,824 women aged 30–79 recruited between 2004 and 2008 across 10 diverse regions in China; the Million Women Study (MWS), comprising 1.3 million women aged 48–91 recruited between 1996 and 2001 in England and Scotland; and the UK Biobank (UKB), with 273,402

women aged 40–69 recruited between 2006 and 2010 in England, Wales, and Scotland. Together, these cohorts covered over 1.8 million women and ~100,000 breast cancer cases (ICD-10: C50). Reproductive data were collected via questionnaires. Cox proportional hazards models were used to estimate hazard ratios (HRs) for menarche, menopause, menopausal status, and reproductive duration, adjusting for potential confounders.

Result and discussion

Breast cancer incidence was 4–5 times higher in the UK (3.93 per 1,000 person-years in MWS; 3.19 in UKB) than in China (0.82 in CKB). On average, Chinese women had later menarche (mean: 15.44 years [SD 1.97] in CKB) than UK women (12.97 [1.62] in UKB; 13.00 [1.60] in MWS), while menopause timing was similar (48.22 [4.41] in CKB vs. 49.74 [5.09] in UKB and 47.53 [5.80] in MWS). Menarche at age 15 or older, compared to below age 12, was more protective in Chinese women (HR 0.81, 95% CI 0.60–0.81) than in UK women (HR 0.91, 95% CI 0.86–0.98 in UKB; HR 0.94, 95% CI 0.92–0.96 in MWS). Later menopause was associated with higher breast cancer risk, with a greater magnitude in Chinese women (HR 1.56, 95% CI 1.30–1.88) than in UK women (HR 1.18, 95% CI 1.08–1.30 in UKB; HR 1.27, 95% CI 1.22–1.31 in MWS).

Conclusion

Differences in reproductive characteristics and in their associations with breast cancer risk between UK and Chinese women may partially explain the disparities in breast cancer incidence between the two populations.

EACR25-2167

Association between area-based socioeconomic status and colorectal cancer mortality in England

E. Taylor-Gallardo¹, A. Memon¹, N. Islam²

¹*Brighton and Sussex Medical School, Primary Care and Public Health, Brighton, United Kingdom*

²*University of Southampton, Faculty of Medicine, Southampton, United Kingdom*

Introduction

Colorectal cancer (CRC) remains one of the leading causes of cancer-related mortality worldwide. While advances in screening, early detection, and treatment have significantly improved survival rates, disparities in outcomes persist. Socioeconomic disparities play a crucial role in influencing CRC mortality – affecting access to healthcare, engagement with screening programmes, early diagnosis, treatment adherence, and overall survival. We conducted a population-based retrospective cohort study to examine the association between area-based socioeconomic status and CRC mortality, by age and sex in England for the period 2011–20.

Material and method

Individual-level anonymised CRC mortality data (ICD-10 codes: C18–20) for 151,050 patients were obtained from the Office for National Statistics. Each patient was assigned to one of five area-based socioeconomic groups using the Index of Multiple Deprivation (IMD quintile 1, most deprived; IMD quintile 5, least deprived). Age- and sex-specific mortality rates and age-standardised

mortality rates (standardised to the 2013 European Standard Population) were calculated. CRC mortality rates (per 100,000 population) were calculated for each year of death (2011 to 2020) by age, sex and area-based socioeconomic group (IMD quintiles 1–5). Poisson regression models were constructed to examine the differences in CRC mortality rates between the most and least deprived socioeconomic groups/area.

Result and discussion

Overall, colorectal cancer patients from the most deprived socioeconomic group/area (IMD quintile 1) experienced 21–28% higher mortality rates than those in the least deprived socioeconomic group/area (IMD quintile 5). This excess risk of mortality in patients from the most deprived socioeconomic group/area was significantly greater (i.e. more than double) for males (29–46%) compared with females (9–20%).

Conclusion

The association between socioeconomic status and CRC mortality is driven by a complex interplay of higher burden of behavioural risk factors (e.g. unhealthy diet, obesity, smoking, physical inactivity), comorbidities (e.g. diabetes) low uptake of CRC screening (43% vs 57%), delayed diagnosis, and disparities in treatment adherence. The excess CRC mortality in males is attributed to relatively high CRC incidence and enhanced burden of these factors compared to females. By understanding these connections and addressing the social determinants of health, it is possible to reduce this disparity in CRC mortality and improve survival rates in all patients, regardless of their gender and socioeconomic status.

EACR25-2300

Melanoma and health inequity in the UK

S. Robertson¹, P. Lapitan², B. Morgan³, S. Merriel¹

¹*University of Manchester, Primary Care, Manchester, United Kingdom*

²*University of Manchester, Medical School, Manchester, United Kingdom*

³*Manchester Foundation Trust, NHS, Manchester, United Kingdom*

Introduction

Melanoma is the 5th most common form of cancer in the UK, with incidence rates rising significantly by 147% since the 1990s and a projected ongoing rise of 9% by 2040. A global burden of disease study identified incidence rates to be the second highest in Western Europe. Early diagnosis improves outcomes for patients; however, health inequity can significantly impact the journey to receiving appropriate care. In England, socio-economically deprived areas have been shown to have the lowest levels of cancer symptom awareness and greatest barriers to seeking medical review.

Material and method

In accordance with the PRISMA guidelines, a systematic review was performed. Databases Ovid MEDLINE, Embase, CINAHL, Cochrane were searched. Articles were included if participants were aged over 18+ with a diagnosis of cutaneous melanoma and any source of health inequity as defined by WHO: employment status, income level, gender, ethnicity, sexual orientation. Data was exported to Raayan, both reviewers performing

article selection independently.

Result and discussion

[table on article selection, mortality and incidence plus T-test/aNOVA to compare mean time to diagnosis to be inserted here on poster] Studies across Europe and America have shown an increased incidence but reduced mortality of cutaneous melanoma in groups which have a higher economic status. Those from economically deprived areas, skin of colour and male have worse outcomes measured by mortality and stage at diagnosis. This is reflected in the findings of studies across the UK, North America and Europe which identify the greatest incidence of melanoma in socioeconomically advantaged Caucasian populations to a significant degree, yet worse outcomes are recorded for people with skin of colour and those living in areas of higher economic deprivation. Across age groups this trend continues, as although melanoma is a cancer associated predominantly with increasing age, it is also one of the most common cancers in young adults aged 20–39 in very high regions on the Human Development Index (HDI). Despite this, young adults in low HDI settings have a five times greater case fatality rate compared to their high HDI counterparts. Acral lentiginous melanoma commonly impact people of colour; a study in North America determined that most patients present later, with worse outcomes and that black male patients are disproportionately burdened by health inequity in diagnosis. There were no large scale studies in the UK, with regional data echoing global trends, in particular the impact of COVID-19 on melanoma stage 4 diagnosis has been shown to have increased from 7% in 2019 to 21% in 2020 in the most deprived populations.

Conclusion

There are no large scale studies on the impact of health inequity on melanoma diagnosis and survivorship in the UK. This is significant as understanding regional trends in melanoma is vital for informing policy, healthcare service planning and public health interventions.

EACR25-2393

The role of diet and dietary patterns on colorectal cancer risk, progression and outcomes

M. Melo Moreira¹, A. Salgado², P. Napoleão¹, C. Sousa Guerreiro³, I. Santos³, A. Santos Almeida⁴

¹Gulbenkian Institute for Molecular Medicine, Lisboa, Portugal

²Gulbenkian Institute for Molecular Medicine, Lisbon, Portugal

³Faculdade de Medicina, Universidade de Lisboa ; Instituto de Saúde Ambiental (ISAMB), Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal

⁴Gulbenkian Institute for Molecular Medicine ; Faculdade de Medicina, Universidade de Lisboa, Portugal

Introduction

Colorectal cancer (CRC) accounts for nearly 2 million new cases and 1 million deaths annually. Around 50% of CRC cases are preventable through lifestyle changes, with diet playing a key role. Adherence to dietary patterns such as the Mediterranean Diet (MD) and Plant-Based Diets (PBD) has been associated with lower CRC risk, while the Western Diet (WD) has been associated

with a higher risk. Understanding how dietary patterns and specific nutrients are associated with CRC risk and its outcomes (e.g. disease-free progression and survival) is crucial to guide future prospective research and the development of public health initiatives.

Material and method

This multicenter, cross-sectional observational study is part of the GUTBIOME-PT study (NCT06741293) and aims to recruit 5,000 participants aged 40–74 from partner hospitals. Eligible participants include individuals undergoing screening colonoscopy or newly diagnosed with CRC (pre-treatment). Participants are categorised into four groups based on clinical diagnosis: healthy controls, low-risk polyps (LRP), high-risk polyps (HRP), and CRC. Socio-demographic and anthropometric data (weight and height) are collected via self-administered questionnaires. Dietary intake is assessed using two non-consecutive 24-hour dietary recalls, and data is converted into nutrients using the Portuguese Food Composition Table. Additionally, adherence to the MD and PBD is evaluated using validated tools such as the Mediterranean Diet Adherence Score and the Plant-Based Dietary Index. Principal component analysis identifies and characterises dietary patterns while correlation analyses explores associations between dietary intake and CRC risk, disease-free progression and overall survival. Multi-variable models, including linear or logistic regression, adjust for potential confounders such as age, sex, and BMI to ensure robust associations [1].

Result and discussion

Recruitment began in November 2023 and is expected to be completed by late 2029. Currently, 206 participants have been recruited with dietary data collected from 119 participants. Among these, approximately 57% are female and 43% are male with a mean age of 54 years. Regarding group distribution, 55% are controls, 30% have LRP, and 15% have HRP. Adherence to MD is moderate in 53% of participants, high in 30% and low in 17%. By the time of the poster presentation, we anticipate showcasing analyses based on data from 200 participants, providing insights into the relationship between dietary intake and patterns and CRC.

Conclusion

This study will establish a foundational framework for identifying dietary patterns that are associated with a decreased CRC risk and mortality and an increased disease-free progression, contributing to tailored nutritional recommendations and public health strategies aimed at improving CRC prevention and treatment.

EACR25-2420

Capacity for detection of tumor markers in Sierra Leone: a snapshot assessment

B. Lawal¹, F. Faye², I. Wurie³, B. Duduyemi³, O. Sankoh³, M. Afolabi⁴

¹University of Sierra Leone, Laboratory Medicine and Diagnostics, Kambia, Sierra Leone

²London School of Hygiene and Tropical Medicine, Clinical Research, Kambia, Sierra Leone

³University of Sierra Leone, Laboratory Medicine and Diagnostics, Freetown, Sierra Leone

⁴*London School of Hygiene and Tropical Medicine, Clinical Research, London, United Kingdom*

Introduction

Introduction The International Agency for Research on Cancer (IARC) reported that in 2022, there were 1,918 new cancer cases and 1,334 deaths due to cancer in Sierra Leone. Early diagnosis and treatment can taper down these alarming figures. Tumor markers, when used together with imaging and other examinations, are vital diagnostic tools that are critical for early cancer diagnosis and management. This preliminary snapshot assesses the tumor markers testing capacity and accessibility in Sierra Leone.

Material and method

We performed a snapshot review of the testing capacity of 15 secondary to tertiary laboratories – public and private laboratories across Sierra Leone, purposefully selected to represent the regions. The assessment was done by making phone calls and or reviewing the laboratories' websites and extracting information on their testing capacities. We reviewed the laboratories' capacities for the quantitative measurement of common tumor markers such as Cancer Antigen 15-3 (CA 15-3), CA-125, CA 19-9, and prostate-specific antigen (PSA) for diagnosing breast, ovarian, pancreatic, and prostate cancers respectively, and Alpha-fetoprotein (AFP) – a marker that suggests liver, ovarian, or testicular cancer. The availability of equipment and competent staff for tumor markers tests was also reviewed.

Result and discussion

Of the 15 facilities assessed, only 4 (26.7%) had testing capacity for tumor markers. One (1) of these (25%) was a public tertiary hospital-based laboratory. All 4 laboratories with cancer markers testing capacities were located in Freetown, the capital city. There is a research laboratory located in the Kambia district, which is a study site for the Human Papillomavirus global burden estimation study. Among the laboratories that were not providing the services, two had the equipment and knowledgeable staff that could perform the analysis. Our findings confirm a huge gap in cancer diagnosis and research in Sierra Leone. Based on the demographic data, only 16% of the country's population (8.461 million (2023) live in Freetown, the capital city. This means only this fraction can access tumor markers testing services, while the others living in provinces will have to travel to access the service. The above explains the high cancer incidence and cancer mortality rates, and minimal cancer research in Sierra Leone.

Conclusion

There is a gap in cancer diagnosis and research capacity in Sierra Leone. The government, stakeholders, and researchers should commit more resources in the forms of capacity building and public-private partnerships for establishing fit-for-purpose facilities so as to prevent the alarming cases of preventable deaths due to cancer. The strategic objectives documented in the National Policy and Strategy for the Elimination of Cervical Cancer 2023-2028 should be pursued rigorously.

EACR25-2514

The Impact of Emotional Intelligence on Mental Health: A Protective Factor in Breast Cancer Survivors

R. Guil¹, P. Gil-Olarte¹, L. Ordoñez², M. Gill-Olarte³, L. Morales-Sánchez⁴, P. Ruiz-González⁵, M. Baena¹

¹*Universidad de Cádiz, Cádiz, Spain*

²*Universidad Santiago de Cali, Cali, Colombia*

³*Hospital Universitario Virgen Macarena, Sevilla, Spain*

⁴*Universidad de CádizCádiz, Cádiz, Spain*

⁵*Universidad de Cádiz, Cádiz, Spain*

Introduction

Breast cancer (BC) is the most common neoplasm among women worldwide. Although survival rates have improved, the disease continues to negatively affect patients' mental health, with a high prevalence of depression. Emotional competencies have been identified as protective factors against affective disorders, but the specific mechanisms of their influence on the mental health of breast cancer survivors (BCS) remain unclear. This study analyzes the relationship between survival experience and depression, considering the mediating role of perceived emotional intelligence (PEI).

Material and method

A cross-sectional study was conducted with 237 women divided into two groups: 56 BCS and 181 healthy controls. The Trait Meta-Mood Scale 24 (TMMS-24) was used to assess PEI, and the Hospital Anxiety and Depression Scale (HADS) was applied to measure depression. Mediation analyses were conducted to examine the effect of PEI dimensions (emotional attention, emotional clarity, and emotional repair) on the relationship between BC and depression. Additionally, age was included as a covariate in the analyses.

Result and discussion

The results showed that survival and PEI explained 37.8% of the variance in depression, with 11.7% attributed to the direct or indirect effects of PEI dimensions. Emotional attention was positively associated with depressive symptoms, while emotional clarity and emotional repair had a protective effect. It was found that BCS exhibited lower levels of emotional clarity and higher levels of emotional repair compared to healthy controls. Additionally, reduced emotional clarity mediated the increase in depressive symptoms in BCS, while emotional repair acted as a protective factor.

Conclusion

Emotional clarity and emotional repair play a key role in regulating depressive symptoms in BCS. Interventions improving these emotional competencies may promote better psychological adjustment in this population. It is recommended to develop psycho-oncology intervention programs that strengthen emotional regulation in breast cancer survivors to reduce the risk of depression and improve their quality of life.

Dissecting ovarian cancer cellular responses to radioimmunotherapy with β - particle and ultra-short range conversion and Auger electron-emitting radionuclides

T. Todorov¹, P. Grundler¹, A. Moiseeva¹, N. van der Meulen², J. Grünberg¹, R. Schibli³, M. Behe¹, M. Grzmil¹

¹PSI-Center for Life Sciences, Center for Radiopharmaceutical Sciences, Villigen-PSI, Switzerland

²PSI-Center for Nuclear Engineering and Sciences, Laboratory of Radiochemistry, Villigen-PSI, Switzerland

³ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich, Switzerland

Introduction

The cell surface glycoprotein L1 cell adhesion molecule (L1CAM) plays a key role in cancer stemness, promoting carcinogenesis and therapy resistance in various malignancies. Our previous study demonstrated the selectivity of anti-L1CAM radioimmunotherapy (RIT) and identified L1CAM as a potential therapeutic target in high-grade serous ovarian cancer (HGSOC) models. In targeted radionuclide therapy, terbium-161 has emerged as a promising alternative to the clinically established lutetium-177. While both radionuclides emit β - particle radiation with comparable energy, Tb-161 additionally emits short-range conversion and Auger electrons (CE/AE), which significantly enhance cytotoxicity. Despite this advantage, the radiobiological effects of CE/AE at molecular level remain poorly understood. This study provides a comparative analysis of signaling network alterations in response to ovarian cancer anti-L1CAM RIT with Tb-161 vs. Lu-177.

Material and method

The anti-L1CAM chimeric mAb chCE7 was functionalized with a DOTA bifunctional chelator, followed by radiolabeling, to produce 177Lu-DOTA-chCE7 and 161Tb-DOTA-chCE7 radioimmunoconjugates (RICs). In vitro assays confirmed the L1CAM-specificity and efficacy of the RICs. Tandem mass tagging (TMT)-based integrated phosphoproteomics and proteomics quantified 22,101 phosphopeptides and 7484 proteins, respectively. Comparative bioinformatics analyzed signaling network alterations in response to 177Lu-DOTA-chCE7 and 161Tb-DOTA-chCE7 in L1CAM-expressing ovarian cancer OVCAR8 cells.

Result and discussion

Both 177Lu-DOTA-chCE7 and 161Tb-DOTA-chCE7 treatments induced pathways involved in DNA damage response (DDR) and repair, signal transduction (including EGFR, VEGFR, and mTOR signaling), mRNA processing, cell cycle and cytoskeleton regulation, translation, apoptosis, and glycogen metabolism. Both treatments induced DNA double-strand breaks and cellular response via ATM (fold enrichment 5.3 ($P = 4.1\text{E-}06$) for 177Lu-DOTA-chCE7, and 6.2 ($P = 6.6\text{E-}08$) for 161Tb-DOTA-chCE7), and ATR pathways

(fold enrichment 3.9, ($P = 5.4\text{E-}05$) for 177Lu-DOTA-chCE7, and 5.3 ($P = 9.0\text{E-}09$) for 161Tb-DOTA-chCE7). While most alterations were common to both treatments, the phosphorylation of a few proteins associated with chromatin methylation, GTPase activation, and chromosome structure was either uniquely induced or significantly more pronounced with 161Tb-DOTA-chCE7 compared to 177Lu-DOTA-chCE7. Further bioinformatics analysis and validation studies are currently underway.

Conclusion

This study highlights signaling networks activated by Tb-161 and Lu-177, advancing the understanding of radiobiology related to β - and CE/AE emitters. In addition, these findings provide insights into potential radiation-induced molecular targets for the development of adjuvant radiosensitization strategies aimed at improving L1CAM-targeted RIT for ovarian cancer.

EACR25-0197

Experimental alpha-radioimmunotherapy for tumors that have acquired resistance to antibody therapy

H. Li¹, S. Hasegawa¹

¹National Institutes for Quantum Science and Technology, Charged particle therapy research, Chiba, Japan

Introduction

Recent progress on radioisotope production accelerates targeted radionuclide therapy or radioimmunotherapy (RIT) for the management of cancer. A radionuclide astatine-211 emits alpha-particles in the process of its decay and has potential for cancer treatment. Uterine serous carcinoma (USC) is a rare but aggressive uterine cancer and overexpression of HER2 protein is seen in about one-third of the patients. Trastuzumab, an antibody drug reacting to HER2 protein, has been proposed as a drug against HER2-positive USC; however, the therapeutic effect is limited because of acquired resistance to trastuzumab. The aim of this study is to investigate the therapeutic potential of alpha-RIT using astatine-211-armed trastuzumab (At-211-Tras) against trastuzumab-resistant USC that metastasized into peritoneal cavity (USC-PM) in a mouse model.

Material and method

Animal experiments were carried out with permission and under the regulations of the Institutional Animal Care and Use Committee of Experimental Animals of National Institutes for Quantum Science and Technology, Japan. A mouse model of USC-PM was generated by a transplantation of luciferase genes-introduced human USC cells into peritoneal cavity of immunodeficiency mice. Tumor growth was monitored by *in vivo* chemiluminescence imaging. After generating the USC-PM mouse model and confirming tumor growth in the peritoneal cavity, antibody therapy (400 μg of trastuzumab per mouse by intraperitoneal injection, twice a week for 5 weeks) was performed. After confirming subsequent regrowth of USC cells in peritoneal cavities, a single dose of At-211-Tras (1 MBq) was administered into the peritoneal cavities. The authors declare no conflicts of interest associated with this presentation.

Result and discussion

Tumor changes were approximately 600, 500, 400, and 200 % from the initial tumor sizes at 2 weeks after treatment of PBS only, Tras, 1 MBq of At-211-HuIgG, or 1 MBq of At-211-Tras, respectively. These data suggest that a single dose of At-211-Tras suppressed the tumor growth of HER2 positive USC-PM in mice compared to other control groups. At-211-Tras showed a transient reduction of white blood cell count at 1 week after the administration, but a comparable level of white blood cell count compared to those of other groups at 4 weeks after the administration.

Conclusion

Alpha-RIT using alpha-emitting trastuzumab may be an effective treatment option for USC resistant to trastuzumab therapy.

EACR25-0206

Evaluating the role of ATM inhibitors in enhancing the efficacy of radiotherapy and their potential to improve the immunosuppressive microenvironment of glioblastoma

T. Liao¹, Y. Chen¹, Y. Chang², M. Chan³, H. Tu¹, F. Hsu⁴

¹*National Yang Ming Chiao Tung University, Department of Dentistry, Taipei, Taiwan*

²*Taipei Medical University-Shuang Ho Hospital Ministry of Health and Welfare, Department of Medical Imaging, New Taipei, Taiwan*

³*National Yang Ming Chiao Tung University, Department of Biomedical Imaging and Radiological Science, Taipei, Taiwan*

⁴*National Central University, Department of Life Science, Taoyuan, Taiwan*

Introduction

Glioblastoma (GBM) is an aggressive primary brain tumor with limited treatment options. Standard therapies include surgery, chemotherapy, immunotherapy, and radiation therapy (RT); however, GBM's infiltrative nature makes complete surgical removal nearly impossible, positioning RT as a key treatment modality. Although RT induces DNA damage, the efficiency of repair mechanisms – particularly those mediated by ataxia telangiectasia mutated (ATM) kinase – often limits its effectiveness. ATM inhibitors (ATMi) can disrupt the repair of radiation-induced DNA double-strand breaks and interfere with cell cycle progression, thereby enhancing the effects of RT and chemotherapy.

Nonetheless, the radiosensitizing effects of ATMi on GBM and their impact on the tumor immune microenvironment remain unclear. This study aims to enhance DNA damage while inhibiting repair mechanisms and to assess the combined treatment's impact on immunosuppressive cells (MDSCs, Tregs, and M2 macrophages) as well as on immune-activated cells (cytotoxic and memory T cells).

Material and method

To evaluate the therapeutic potential of ATM inhibitors (ATMi), we conducted both in vitro and in vivo experiments. In vitro, cell viability was assessed using the MTT assay to determine the impact of ATMi on RT-induced cytotoxicity, while colony formation assays

evaluated post-irradiation survival and proliferation. Flow cytometry was employed to analyze DNA damage markers (p-ATM, p-CHK2), cell cycle distribution, and immune cell populations within the tumor microenvironment. In vivo studies monitored tumor growth and immune responses following combined ATMi and RT treatment.

Result and discussion

The combination of ATMi with RT significantly impaired DNA repair and enhanced radiosensitivity. In vitro, ATMi-treated cells exhibited increased DNA damage accumulation, cell cycle arrest, and apoptosis following radiation exposure. Western blot and flow cytometry analyses confirmed a reduction in the expression of DNA repair-related proteins. In vivo, ATMi and RT co-treatment suppressed tumor growth and favorably modulated the immune microenvironment, evidenced by a decrease in immunosuppressive cells (MDSCs, Tregs, and M2 macrophages) and an increase in cytotoxic T cell activation. These results indicate that ATMi enhances RT efficacy by modulating immune responses.

Conclusion

This study demonstrates that ATMi enhances GBM radiosensitivity by disrupting DNA repair and regulating the tumor immune microenvironment. The observed reduction in immunosuppressive cells and the activation of cytotoxic T cells underscore ATMi's therapeutic potential, suggesting it as a promising radiosensitizer for future clinical application.

Personalized Tumor Models for Precision RadioTheranostics of Glioblastoma

F. Mendes¹, C. Pinto², A. Fonseca³, A. Abrunhosa³, D. Grosshans⁴

¹*Instituto Superior Técnico, Universidade de Lisboa, C2TN – Centro de Ciências e Tecnologias Nucleares, DECN – Departamento de Engenharia e Ciências Nucleares, Lisboa, Portugal*

²*Instituto Superior Técnico, Universidade de Lisboa, C2TN – Centro de Ciências e Tecnologias Nucleares, Lisboa, Portugal*

³*Instituto de Ciências Nucleares Aplicadas à Saúde, Universidade de Coimbra, CIBIT/ICNAS, Coimbra, Portugal*

⁴*MD Anderson Cancer Center, The University of Texas, Texas, Departments of Radiation Oncology and Experimental Radiation Oncology, Texas, United States*

Introduction

Based on metabolic or targeted radiopharmaceuticals, targeted radionuclide therapy (TRT) allows for the specific irradiation of localized and disseminated disease with potentially fewer side effects than external beam radiotherapy (EBRT) (1). This may play an important role in the treatment of the most common and lethal brain tumor – glioblastoma (GBM) where despite EBRT treatment nearly 100% of patients will experience a local recurrence. The use of relevant cellular models, that can better replicate the in vivo conditions of the tumor, to investigate the biological effects of ionizing radiation is of crucial importance, namely the molecular and cellular

mechanisms involved in the radiation response in GBM. We have previously demonstrated in multicellular 3D spheroids derived from GBM cell lines that the simple theranostic radiopharmaceutical, [64Cu]CuCl₂ is able to significantly reduce spheroids' growth and viability, while also affecting cells' proliferation capacity (2).

Material and method

This work aims to provide further preclinical insights into TRT by evaluating the translational potential of [64Cu] CuCl₂ in advanced 3D culture models of GBM, in a precision therapy approach. The 3D models used were developed by the Brain Tumor Center of MDACC and are derived from patients, being classified as glioma stem-like cells (GSCs), representative of 3 of the main subtypes of GBM, according to the Cancer Genome Atlas Project: classical, proneural and mesenchymal (3). The radionuclide uptake was evaluated, as well as its cytotoxic and anti-proliferative effects on the GSCs models.

Result and discussion

Our results revealed that even though GSCs from the proneural subtype had the lowest uptake of [64Cu]CuCl₂, they also had the lowest viability and proliferative capacity after treatment, revealing a higher sensitivity of this GBM subtype to TRT. In contrast, mesenchymal GSCs exhibited the highest uptake and the most resistance to treatment.

Conclusion

Overall, this work validates the use of GBM patient-derived models, in a personalized medicine approach, benchmarking their future application for the translational evaluation and validation of new target-specific radiopharmaceuticals.

Radiobiology of Image-Guided Radiotherapy: in vitro Impact of Computed Tomography on the Radiosensitivity of Lung Cancer

R. El-Hassan¹, C. Feghaly², H. Bou Hadir², R. Challita¹, V. Manouguian³, T. Eid², W. Abou-Kheir¹, L. Bodgi²

¹American University of Beirut, Anatomy, Cell Biology and Physiological Sciences, Beirut, Lebanon

²American University of Beirut Medical Center, Radiation Oncology, Beirut, Lebanon

³American University of Beirut, Radiation Oncology, Beirut, Lebanon

Introduction

Lung cancer remains a leading cause of cancer-related mortality, with nearly two million cases in 2022. Approximately 76% of lung cancer patients are recommended to undergo radiotherapy (RT). The integration of image-guided RT and adaptive RT in modern treatment machines involves daily computed tomography (CT) scans before each RT session, allowing real-time adjustments to treatment plans based on changes in tumor size or patient anatomy. However, the radiobiological effect of low-dose exposure from CT followed by a high-dose RT is still not well documented.

Material and method

Two human lung cancer and one normal skin fibroblast cell lines were exposed to (a) single low doses (0.1 or 0.2 Gy) of radiation at low ([i] 50 kV, 2 mA, dose rate (DR) = 3 cGy/minute; [ii] 50 kV, 20 mA, DR = 30 cGy/minute); or [iii] high (225 kV, 13.3 mA, DR = 260 cGy/minute) energies, (b) a single high dose of 2 Gy at high energy, and (c) combinations of a single low dose followed by 2 Gy separated by time intervals ranging from 1 to 20 minutes. DNA double-strand break (DSB) repair kinetics were analyzed for each condition using immunofluorescence, focusing on key protein markers including pATM and γH2AX at pre- and post-irradiation. Cellular radiosensitivity was assessed using the clonogenic and micronuclei (MN) assays.

Result and discussion

Cells exposed to low-dose irradiation had a significant number of unrepaired DNA DSB 24 hours post-irradiation. The combination of a low dose followed by 2 Gy with a 1-minute interval resulted in significantly more γH2AX foci 24 hours post-irradiation than 2 Gy or the sum of separate doses. Similarly, the formation of MN significantly increased 24 hours post-irradiation whether at single low or high doses or combination doses. Cells treated with combination doses exhibited a decrease in the number of pATM foci 10 minutes and 1 hour after irradiation. This suggests that CT exposure can decrease the efficiency of DNA DSB repair mechanisms. These results were confirmed by the clonogenic cell survival assay. Cells exposed to a low dose followed by a high dose had a significantly lower surviving fraction than the sum of the separate single doses, suggesting that sequential irradiation has a stronger effect on survival than an additive response, with the time interval between exposures potentially influencing this response.

Conclusion

Our findings show that a low dose before a high dose can influence the DNA damage response depending on the time interval between exposures. This suggests clinical implications for adaptive RT, particularly when performed daily. This highlights the need to consider the impact of imaging exposure and time interval when planning radiotherapy.

Introduction

Glioblastoma (GBM) is the most frequent form of malignant primary brain tumor, having an extremely poor prognosis. It is characterized by an increased cell proliferation associated with erratic neovascularization, that leads to the development of hypoxic regions, known to have higher concentrations of Cu (1). Interestingly, Cu has several radioisotopes that can be incorporated into radiopharmaceuticals. Among them, ^{64}Cu has attracted interest due to its theranostic potential for PET imaging and therapy due to β^+ and β^- emissions respectively. Clinical studies with the ^{64}Cu radiopharmaceutical, $[^{64}\text{Cu}]\text{CuCl}_2$, reported its selective accumulation in GBM (2). Considering this, we aim to study the therapeutic effects of $[^{64}\text{Cu}]\text{CuCl}_2$ in GBM, also comparing them to Cu's standard therapeutic radionuclide pair, ^{67}Cu , using advanced culture models that can better replicate *in vivo* tumors. In particular, spheroids are 3D models expected to recreate crucial tumoral environmental cues and phenotypes such as the establishment of O₂, nutrients, and metabolite gradients, developing hypoxic and proliferative regions (3).

Material and method

After establishing and characterizing spheroids derived from 3 genetically and phenotypically distinct GBM cell lines (U373, U87, and T98G), we studied the uptake and distribution of ^{64}Cu within the spheroids, through autoradiography. Then we evaluated the changes in the growth, viability, production of reactive oxygen species (ROS), and the population of cancer stem-like cells (CSCs) in spheroids incubated with $[^{64}\text{Cu}]\text{CuCl}_2$. Finally, we compared the survival capacity of spheroids that were incubated with $[^{64}\text{Cu}]\text{CuCl}_2$ and $[^{67}\text{Cu}]\text{CuCl}_2$.

Result and discussion

The results revealed that ^{64}Cu is capable of penetrating spheroids from all cell lines, being able to affect spheroids' growth and viability while increasing the concentration of ROS in the most affected spheroids. Additionally, $[^{64}\text{Cu}]\text{CuCl}_2$ therapy modulated the expression of CSCs markers, particularly CD44 and CD15. Furthermore, the anti-proliferative capacity of ^{64}Cu in GBM spheroid-derived cells was relevant and comparable to the one observed in spheroids treated with ^{67}Cu .

Conclusion

Overall, our results highlighted the therapeutic potential of the simple radiopharmaceutical $[^{64}\text{Cu}]\text{CuCl}_2$, through the evaluation of its effects in advanced culture models, supporting its application as a theranostic agent for GBM.

Ro 90-7501 Enhances The Radio-Sensitivity of Breast Cancer Cells by Impairing DNA Double-Strand Break Repair Mechanisms

C. Feghaly¹, H. Bou Hadir¹, S. Hussayni², E. Estephan¹, W. Chebli¹, R. Challita³, R. El Hassan³, L. Bodgi¹

¹American University of Beirut Medical Center, Department of Radiation Oncology, Beirut, Lebanon

²American University of Beirut, Department of Anatomy, Cell Biology and Physiological Sciences, Beirut, Lebanon

³American University of Beirut, Department of Anatomy, Cell Biology and Physiological Sciences, Beirut, Lebanon

Introduction

Recent studies have shown that Ro 90-7501, a drug initially developed to inhibit amyloid β 42 fibril formation in Alzheimer's disease, can sensitize cervical cancer cells to radiation, likely by impairing DNA double-strand break (DSB) repair. This study aims to assess the radio-sensitizing potential of Ro 90-7501 in breast cancer and normal fibroblast cell lines, focusing on its impact on DNA DSB repair to optimize radiotherapy (RT) efficacy.

Material and method

Two breast cancer cell lines (MDA-MB-231, MCF7) and one normal skin fibroblast cell line (GM03652) were used in this study. Cells were treated with Ro 90-7501 (1, 3 and 10 μM), with or without 2 Gy of ionizing radiation. Cell viability, proliferation, and cytotoxicity were evaluated using MTT and Trypan Blue assays. DNA damage and repair were analyzed by quantifying γ H2AX and pATM foci at 0, 10 minutes, 1 hour, 4 hours, and 24 hours post-irradiation using immunofluorescence. Clonogenic assay was conducted to assess cell survival.

Result and discussion

Ro 90-7501 reduced viability and proliferation in breast cancer cells (p -value < 0.01) without affecting normal fibroblasts (p -value > 0.05). Following 2 Gy irradiation, Ro 90-7501 induced an increase in residual γ H2AX foci at 24 hours post-treatment (p -value < 0.001) and significantly reduced pATM foci at 10 minutes and 1 hour (p -value < 0.01) in both cancer cell lines. Clonogenic assay revealed a significant reduction in colony formation in MCF-7 cells with 3 μM and 10 μM of Ro 90-7501 (p -value < 0.01), while no effect was observed in MDA-MB-231 cells or normal fibroblasts (p -value > 0.05).

Conclusion

In conclusion, Ro 90-7501 exhibits radio-sensitizing effects on breast cancer cell lines at both the molecular and cellular levels, with minimal impact on normal cells. These findings suggest that Ro 90-7501 has potential as a

radio-sensitizer, capable of enhancing tumor response while minimizing effects on normal tissue.

EACR25-0536

Impact of Lamin Mutations on Radiation Response in Lung Cancer

J. Janetzko¹, J. Weissbon¹, A. Schramm¹

¹West German Cancer Center, Medical Oncology, Essen, Germany

Introduction

Lamins are intermediate filament proteins that provide structural support to the nucleus by forming a meshwork of polymerized lamins. Depolymerization is induced by phosphorylation enabling cell cycle progression and cell division. Lamins also play critical roles in maintaining nuclear integrity by regulating nuclear stability.

Additionally, they have been reported to impact the DNA damage response and the organization of chromatin structure. Overall, changes in lamin expression are frequently observed, whereas lamin mutations are relatively rare in cancer. These expression changes can result in chromosomal and genomic instability, which are hallmarks of cancer. We hypothesize that the nuclear envelope network is linked to DNA damage response and cell cycle regulation upon irradiation in lung cancer cells and thus represents an important cell-autonomous mediator of radiosensitivity.

Material and method

CRISPR/Cas9-mediated approaches using site-directed gRNAs and homology-directed repair generated lamin phosphorylation mutations mimicking unfeasible or persistent phosphorylation in non-small cell lung cancer cell lines. Selection of single clones enabled further investigation of lamin function by analyzing proliferation and subcellular localization of lamins and their mutated variants using immunofluorescence. Furthermore, colony formation assays and γH2AX-stainings were performed to assess the impact of lamin mutations on nuclear stability and the DNA damage response.

Result and discussion

In total, mutations at three prominent lamin phosphorylation sites were generated and validated by sequencing. Growth differences in lamin A/C S22 mutated A549 cells indicated clonal effects independent from the mutation. Radiosensitivity of these clones was subsequently assessed by colony formation assay, which confirmed that lamin A/C S22 mutated clones exhibit increased radiosensitivity, though to varying extents. Additionally, S22D mutant cells that mimic persistent phosphorylation present altered lamin A/C localization and aberrant nuclear morphology and structure compared to the parental cells. These results confirm that phosphorylation of lamin A/C at S22 plays a crucial role for nuclear division in non-small cell lung cancer cell lines.

Conclusion

Studying the interplay between wildtype and mutant lamins and their clonal differences may provide insight into the role of the cancer-specific lamin network in the cellular damage response upon irradiation.

Radioresistance of colorectal cancer cells is driven by GPX4 and ferroptosis resistance

R. Jehay¹, L. Montero-Ruiz¹, C. Pottier², P. Foidart², A. Noël¹, A. Heuskin³, N. Souanni¹

¹University of Liege, Laboratory of tumor biology and development (LBTD), Liege, Belgium

²Liege University Hospital, Medical Oncology, Liege, Belgium

³University of Namur, Nuclear reaction analysis laboratory (LARN), Namur, Belgium

Introduction

Radiotherapy is widely used for the treatment of many cancers, including rectal cancer. Despite advances in the field of radiotherapy (RT), innate and acquired radio-resistance remain the main issues leading to treatment failure and relapse. Only about 10% of rectal cancer patients fully respond to neoadjuvant treatment (RT/ chemotherapy), highlighting the need to improve treatment efficacy through novel drug combinations. Ionizing radiation (IR) delivered during treatment generates reactive oxygen species (ROS) which oxidize DNA, proteins, and lipids. Lipid peroxide accumulation at the plasma membrane triggers ferroptosis, an iron-dependent cell death. Leveraging IR-induced ferroptosis may overcome radioresistance.

Material and method

Radioresistant cells (HCT-116RR, HT-29RR) were generated through daily sublethal doses of IR (0.5 to 2Gy/day). The radioresistance of colorectal cancer cells was confirmed by cell death assay using FACS (7-AAD probe) and clonogenic assay. ROS and lipid peroxide levels were respectively measured using the CELLROX and BODIPY C11 581/591 dyes. Lipid droplets were visualized and quantified using holo-tomographic microscopy (CX-A, Nanolive). Western blot and RT-qPCR were used to confirm RNA-sequencing data performed on parental and resistant cells. CRISPR screen was performed in parental cells irradiated or not with 2Gy using a gRNA library (Addgene #191535). Sequencing of gRNA amplicons was performed by VectorBuilder.

Result and discussion

HCT116 and HT29 accumulate lipid peroxides 24 hours post-IR, a trend also observed in triple-negative breast cancer cells. HT29 cells showed less sensitivity to IR and showed lower lipid peroxide accumulation when compared to the IR-sensitive HCT116 cells. After irradiation, we observed a significant level of lipid droplets in both cell lines, which might be an adaptation response to IR. HCT116RR cells also showed resistance to GPX4 inhibitor (RSL3) when compared to parental cells. Moreover, GPX4 expression in radioresistant cells was higher. This has led us to hypothesize that a combination of RSL3 + IR before the onset of resistance to IR could improve patient response. Ongoing RNA-sequencing analysis on HCT116RR and parental cells, along with a CRISPR screen of lipid and ferroptosis-related genes in cells treated with IR will help decipher anti-ferroptotic targets driving radioresistance in colorectal cancer.

Conclusion

Taken together, our results suggest that cancer cells rely on ferroptosis resistance pathway to acquire radio-resistance. Considering this dependency of cancer cells, combining ferroptosis inducers with radiotherapy may be a promising way of improving neoadjuvant treatment efficacy for rectal cancer patients.

Tumour Volume Dynamics of Glioblastoma During Radiotherapy on 1.5T Magnetic Resonance Imaging-Linear Accelerator

S. Ng¹, K. Jamora¹, D. Mathieu², S. Fong³, M. Wada¹, R. Khor¹, M. Tacey¹, H. Gan¹, B. Harris¹, A. Scott¹

¹Austin Health, Melbourne, Australia

²CHU de Québec, Quebec, Canada

³Olivia Newton-John Cancer Research Institute, Melbourne, Australia

Introduction

Glioblastoma (GBM) treatment response is typically assessed using pre- and post-treatment magnetic resonance imaging (MRI), as frequent imaging can be logistically challenging and costly. MRI-guided radiation therapy (MRgRT) enables real-time high-frequency monitoring of tumour dynamics throughout treatment. Here, we quantify the daily interfraction variations in tumour volume in GBM treated on an MRI-linear accelerator (MR-linac).

Material and method

GBM patients suitable for chemoradiation using a 1.5T MR-linac were enrolled in a prospective study. T2/FLAIR hyperintensity regions were contoured at baseline and succeeding fractions. Tumour dynamics were assessed using absolute volume, percentage change in volume relative to fraction 0 (V%), and migration distance representing the linear displacement of volume relative to fraction 0. Tumour changes were compared between patients with early progression (defined as progression within 6 months post-treatment) and those without early progression, as well as between methylated and unmethylated/unknown MGMT promoter status groups.

Result and discussion

Among 26 patients, 10 received 4005 cGy/15 fractions, and 16 received 6000 cGy/30 fractions of chemo-radiation. The mean absolute volumes at Fx0, Fx1, Fx10, Fx15, Fx20, and Fx30 were 60.5 cm³, 62.1 cm³, 60.2 cm³, 57.1 cm³, 61.2 cm³, and 65.9 cm³. The corresponding mean V% at Fx1, Fx10, Fx15, Fx20, and Fx30 were 3.9%, 8.6%, 8.6%, 17.1%, and 39.2%. In early progressors, V% at these fractions were 7.8%, 22.8%, 31.4%, 57.6%, and 108.6%, while in non-early progressors, values were 3.0%, 3.1%, -1.6%, -11.0%, and -10.7%. Among methylated tumours, V% were 7.7%, 9.6%, 0.9%, -11.4%, and -7.7%, while unmethylated/unknown tumours had 1.6%, 7.9%, 13.4%, 30.1%, and 60.6%. The mean migration distances at Fx1, Fx10, Fx15, Fx20, and Fx30 were 1.0 mm, 3.3 mm, 4.9 mm, 7.1 mm, and 7.7 mm. In early progressors, migration distances were 0.9 mm, 2.7 mm, 4.4 mm, 5.0 mm, and

6.0 mm, while in non-early progressors, values were 0.9 mm, 3.5 mm, 5.1 mm, 9.5 mm, and 9.8 mm.

Conclusion

Tumour dynamics during chemoradiation may vary based on MGMT methylation status and could potentially serve as an indicator of early post-treatment progression. Early progressors showed greater volume increases, particularly after Fx10, while treatment responders had stable or decreasing volumes. Methylated tumours showed a trend toward volume stability or reduction, whereas unmethylated/unknown tumours exhibited progressive growth. Migration distance was greater in treatment responders, suggesting possible tumour deformation, while early progressors had lower migration, possibly due to continuous expansion. These findings suggest distinct tumour evolution patterns, with potential implications for treatment adaptation and response monitoring.

EACR25-0748

Activation of the E2F Pathway as a Contributor to Radioresistance in Atypical Teratoid Rhabdoid Tumor

L. Giang^{1,2}, T. Wong^{3,4}, C. Chang^{1,5,3}

¹Taipei Medical University, International Ph.D. Program for Translational Science, College of Medical Science and Technology, Taipei, Taiwan

²Hai Phong University of Medicine and Pharmacy, Department of Biology and Genetics, Hai Phong, Vietnam

³Taipei Medical University Hospital, Neuroscience Research Center, Taipei, Taiwan

⁴Taipei Medical University, Pediatric Brain Tumor Program, Taipei Cancer Center, Taipei, Taiwan

⁵Taipei Medical University, TMU Research Center for Cancer Translational Medicine, Taipei, Taiwan

Introduction

Atypical teratoid rhabdoid tumor (ATRT) is a highly aggressive pediatric central nervous system (CNS) tumor with no standardized treatment and poor prognosis. The current multimodal regimen involves surgery, chemotherapy, and radiation therapy (RT). However, those approaches pose risks such as severe side effects and long-term cognitive impairments. Recently, radiation therapy has played a crucial role in the success of multimodal treatment for ATRT. However, the contentious treatment may contribute to resistance in pediatric cases. A deeper understanding of the mechanisms involved in radiation therapy could help minimize radiation doses and provide strategies to overcome resistance and recurrence in ATRT cases.

Material and method

We established a clinical protocol to generate radiation-resistant ATRT cells. Then, we examined the molecular profiles of ATRT patients and treated cells to pinpoint the specific signaling pathways impacted by radiation therapy. In-silico analysis findings were validated using cell function assays, qPCR, and western blot analysis.

Result and discussion

Our results revealed significant upregulation of HALLMARK_E2F_Targets in radiation-resistant (RES) cells, which contrasts with the findings in the single

radiation exposure. Further RNA-seq analysis of recurrent ATRT cases in our cohort who received radiation therapy also demonstrated the enrichment of E2F and cell cycle pathways, suggesting that repeated radiation cycles induce distinct gene expression profiles. Functional assays confirmed that E2F activation enhances cell proliferation and migration in RES cells. Given that E2F transcription factors regulate DNA replication and cell cycle progression, their dysregulation likely contributes to ATRT recurrence and therapy resistance.

Conclusion

Our findings highlight the critical role of E2F signaling in ATRT recurrence and radiation resistance. The repeated radiation-induced upregulation of E2F_Targets suggests that inhibiting the E2F pathway could enhance ATRT radiosensitivity, offering a potential strategy to improve ATRT treatment outcomes and survival when combined with current therapies.

EACR25-0757

Ephrin B3 as a Therapeutic Target and Radiosensitizer in Glioblastoma: New Insights

T. Kolenc Milavec^{1,2}, P. Hågg³, A. Caceres Verschae³,

N. Agarwal³, B. Breznik¹, K. Viktorsson³, M. Novak¹

¹*National Institute of Biology, Department of Genetic Toxicology and Cancer Biology, Ljubljana, Slovenia*

²*Jožef Stefan International Postgraduate School,*

Ljubljana, Slovenia

³*Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden*

Introduction

Glioblastoma (GB) is the most common primary brain tumour with poor overall survival despite aggressive treatment. To improve patients' response to treatment, signalling pathways, linked with therapy resistance, could be targeted. It is known that Ephrin and Eph signaling pathways are important in tumor signaling; Ephrin B3 promotes GB invasion and tumour growth, whereas EphA2 is upregulated in GB and its phosphorylation atnS897 drives progression and invasion of GB. The aim of the study was to explore the role of Ephrin B3 and EphA2 S897 signalling in GB radioresistance.

Material and method

Patient-derived GB cell lines were established from fresh tumour tissue biopsies. Clonogenic potential and cell proliferation were studied after a single dose of 10 Gy or fractionated RT with 4 x 2.5 Gy. Differences in Ephrin B3 and EphA2 S897 expression and localisation were analysed by western blot (WB) and immunofluorescence, respectively. Ephrin B3 was silenced using siRNA, following standard Lipofectamine protocol; WB analysis was done to confirm silencing. After combining siEphrinB3 with 2 Gy RT, the effect of co-therapy on clonogenic capacity of GB cells was studied.

Result and discussion

Our results showed that RT decreased clonogenic potential of GB cells in dose-dependent manner, leading to reduced number and size of colonies in RT-treated samples. Analysis of Ephrin B3 and EphA2.S897 showed that both proteins were present in GB cells prior and post RT in both RT procedures. No major difference in

expression of Ephrin B3 or EphA2.S897 was observed between irradiated and control samples in case of single dose RT, however, 2.5-fold upregulation of Ephrin B3 expression and 4-times higher levels of EphA2.S897 were detected after fractionated RT. We next silenced Ephrin B3 using siRNA. We observed that after Ephrin B3 was knocked-down, cell proliferation decreased by half, and cell morphology changed in response to treatment. Cells formed more protrusions, in which Ephrin B3 and EphA2 S897 were present in high levels. Clonogenic assay showed that plating efficiency of siEphrinB3-treated cells decreased by 40 % compared to non-target siRNA-treated cells. To reveal if Ephrin B3 silencing sensitizes GB cells to RT, we combined both treatments. After Ephrin B3 silencing in GB cells, we exposed cells to 2 Gy RT. WB analysis revealed 50 % reduction of Ephrin B3 levels after its silencing, but the effect was less prominent when combining siRNA and RT (only 20 % reduction). Clonogenic assay showed that Ephrin B3 silencing or 2 Gy RT itself reduced plating efficiency of GB cells, however, plating efficiency decreased for another 50 % when cells were exposed to the combination of siEphrinB3 and RT.

Conclusion

Our results suggest that Ephrin B3 diminishes the responsiveness of GB cells to radiation therapy, suggesting that targeting Ephrin B3 could enhance radiosensitivity in GB.

EACR25-0957

Targeting immune signaling to overcome radioresistance by increasing DNA damage in breast cancer cells

S. Classen¹, A. Moustafa^{1,2}, K. Hintelmann³, N. Zhafirah¹, M. Vogt¹, H. Schlüter², H. Pospiech^{4,5,6}, K. Rothkamm¹, C. Petersen³, K. Borgmann¹

³*University Medical Center Hamburg-Eppendorf, Department of Radiotherapy and Radiation Oncology, Hamburg, Germany*

⁴*University Hospital Düsseldorf, Research Laboratory of the Clinic for Gynecology and Obstetrics, Düsseldorf, Germany*

⁵*Leibniz Institute on Aging - Fritz Lipmann Institute, Project Group Biochemistry, Jena, Germany*

⁶*University of Oulu, Faculty of Biochemistry and Molecular Medicine, Oulu, Finland*

Introduction

Around 70% of breast cancer (BC) patients receive radiotherapy (RT). However, development of resistance is a frequent cause for therapy failure. One promising strategy to overcome radiation resistance is the use of DNA damage response inhibitors to modulate the immune response and thereby increase the efficacy of immune checkpoint inhibitors in BC. Therefore, this project aims to understand how immune pathways, like cGAS/STING, can be exploited as target to overcome radioresistance by increasing DNA damage.

Material and method

Bottom-up quantitative proteomics of BRCA1-mutated MCF7 cells was performed using liquid chromatography tandem mass spectrometry. Cellular survival after irradiation (IR) and ATR inhibition (ATRi) by AZD6738 was assessed by colony formation assay. Protein expression was determined by Western Blot. PD-L1 surface expression was measured by flow cytometry. Changes in the secreted chemo- and cytokines were analyzed by real-time PCR. DNA repair capacity was analyzed by γ H2AX foci formation. cGAS positive micronuclei and IRF3 translocation were analyzed by immunofluorescence.

Result and discussion

Proteomic profiling revealed significant upregulation of interferon (IFN) alpha/gamma signaling pathway in radiosensitive compared to radioresistant BRCA1-mutated cell lines. Notably, only upon addition of ATRi, IFN signaling was upregulated in resistant cells, which was accompanied by a radiosensitizing effect. STAT1 was detected to be among the top candidates of the IFN signaling pathway, which was further confirmed by Western Blotting. STAT1 activation led to significantly increased expression of IFN-stimulated genes (IFIT1, IFIT3, OAS3 and ISG15) after IR in sensitive cell lines, whereas in resistant cells, this effect was observed only after combined IR and ATRi treatment. A similar trend was observed for several chemo- and cytokines (IFN β 1, CXCL10 and CCL5). Further, PD-L1 surface expression was upregulated after IR, however reduced after ATRi in all cell lines. Previous studies have described a CHK1-dependant PD-L1 upregulation, and our results indicate that by ATRi this might be disrupted. To identify how addition of ATRi led to an increased immune signaling in radioresistant cells, cGAS/STING activation due to increased DNA damage was investigated. γ H2AX foci revealed an increase in DNA damage in the resistant cells after combined treatment. Correspondingly, the number of cGAS-positive micronuclei and IRF3 translocation were both enhanced.

Conclusion

These results show that immune signaling was enhanced by DNA damage-induced activation of cGAS/STING signaling after combined treatment of IR and ATRi in radioresistant, BRCA1-mutated BC cells. This consequently led to a radiosensitizing effect, which may open up new avenues for the treatment of patients that developed a resistance to RT.

EACR25-1059

Evaluation of Therapeutic Efficacy of Magnolol Combined with Radiation in Non-small Cell Lung Cancer

D. Wang¹, B. Chen², D. Dong², F. Hsu², I. Chiang³, Y. Liu³

¹*China Medical University, Graduate Institute of Biomedical Sciences, Taichung, Taiwan*

²*China Medical University, Biomedical Sciences and Technology, Taichung, Taiwan*

³*Show Chwan Memorial Hospital, Radiation Oncology, Changhua, Taiwan*

Introduction

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related death worldwide, and radiotherapy is a common treatment for NSCLC; however, it is often hampered by drug and radiation resistance. Magnolol is a polyphenol compound extracted from *Magnolia officinalis* bark and has multiple biological activities. Nevertheless, its specific role and mechanism in enhancing the effect of radiotherapy for NSCLC remain unclear. This study aimed to explore the synergistic effect of magnolol combined with radiotherapy in non-small cell lung cancer and its mechanism.

Material and method

CL1-5-F4 and HCC827 were treated with 15 μ M magnolol and a radiation dose of 4 Gy. Cell viability was assessed using the MTT assay, while proliferation ability was evaluated through colony formation assays. Apoptosis and DNA damage repair were analyzed using flow cytometry. Additionally, Western blotting was employed to detect the expression of apoptosis-related proteins.

Result and discussion

MTT assays demonstrated that magnolol inhibited NSCLC cell proliferation, with 15 μ M reducing cell viability. Colony formation assays revealed that the combination of magnolol and 4 Gy radiation significantly reduced colony formation compared to single treatments. Apoptosis analysis confirmed enhanced activation of caspase-3, -8, and -9, indicating the induction of both intrinsic and extrinsic apoptotic pathways. Annexin V staining showed increased early and late apoptosis in the combined treatment group. Elevated mitochondrial membrane potential loss suggested that magnolol exacerbates radiation-induced damage through mitochondrial dysfunction. Furthermore, magnolol modulated the ATM-CHK2 pathway, enhancing sensitivity to DNA damage. Western blot analysis revealed increased expression of pro-apoptotic proteins (BIM, BAK, BAX, and BID) in the combined treatment group. These findings indicate that magnolol enhances radiotherapy efficacy by promoting apoptosis and disrupting DNA repair, offering a promising strategy for NSCLC treatment.

Conclusion

Magnolol significantly enhances the sensitivity of NSCLC cells to radiotherapy. Its mechanisms likely involve the inhibition of DNA damage repair and induction of apoptosis. These results provide strong evidence supporting the potential of magnolol as a radiosensitizer in NSCLC treatment.

EACR25-1098

Upconversion Nanoparticle-Mediated Neutron Capture Therapy Lu-177 Treatment in Head and Neck Squamous Cell Carcinoma via the c-MET Signaling Pathway

K. Lin¹, C. Wu¹, Y. Chang¹, M. Chan¹

¹*National Yang Ming Chiao Tung University, Department of Biomedical Imaging and Radiological Sciences, Taipei, Taiwan*

Introduction

Oral cancer has a poor prognosis due to late diagnosis

and limited treatments. Overexpressed c-Met promotes tumor progression, making it a key therapeutic target. This study developed cMApt-UCNPs, dual-functional nanoparticles for targeted theranostics. Neutron-activated UCNPs emit β radiation for therapy and γ rays for SPECT imaging while displaying upconversion fluorescence. c-Met aptamer functionalization enables selective oral cancer targeting, offering a novel precision treatment approach.

Material and method

Cell Culture FaDu and OMF cells were cultured in DMEM with 10% FBS and 1% penicillin-streptomycin at 37°C, 5% CO₂, and passaged every 2–3 days. UCNPs Synthesis and Characterization NaLuF₄:Yb,Tm@NaLuF₄ UCNPs were synthesized via high-temperature coprecipitation and characterized by XRD, TEM, UV-Vis, PL spectroscopy, FTIR, DLS, and zeta potential. DNA electrophoresis confirmed c-Met aptamer conjugation. Neutron Activation UCNPs were neutron-irradiated at THOR (10¹¹–10¹² neutrons/cm²·s, 60–120 min) to convert Lu-176 into Lu-177 for β therapy and γ SPECT imaging. Cytotoxicity and Cellular Studies Alamar Blue: Assessed UCNP cytotoxicity. Western Blot: Analyzed c-Met and apoptosis markers. Confocal Microscopy: Visualized UCNP uptake. Flow Cytometry: Measured uptake and apoptosis. Colony Formation: Evaluated long-term proliferation effects. In Vivo Imaging IVIS bioluminescence and 980 nm NIR fluorescence imaging assessed cMApt-UCNP biodistribution and theranostic potential in FaDu tumor-bearing mice.

Result and discussion

This study synthesized NaLuF₄:Yb,Tm@NaLuF₄ UCNPs for theranostics. Characterization confirmed crystallinity (XRD), morphology (TEM, 65 nm), composition (EDX), and biocompatibility (PEG, FTIR). c-Met aptamer conjugation (DNA electrophoresis) enabled tumor targeting. DLS showed sizes (210.4–241.4 nm) with stable zeta potential (-13.8 to -14.3 mV). UCNPs fluoresced at 475, 650, and 700 nm (980 nm excitation). Neutron irradiation converted Lu-176 into Lu-177, confirmed by gamma spectrum (67, 117, 206 keV), releasing β particles for therapy and γ rays for SPECT imaging. cMApt-UCNPs showed 80% biocompatibility in FaDu cells (48 hr, 1000 μ g/mL). Confocal microscopy and flow cytometry verified aptamer uptake, while Western blot showed 75% c-Met reduction (72 hr). Neutron-activated cMApt-UCNPs (1000 μ g/mL, ~100 μ Ci) reduced FaDu viability to 49%, inhibited colony formation, and induced apoptosis. IVIS imaging confirmed tumor accumulation, demonstrating strong theranostic potential.

Conclusion

This study developed cMApt-UCNPs for targeted cancer theranostics. PEG ensured biocompatibility, while c-Met aptamer enabled tumor-specific delivery. Neutron activation produced Lu-177 for therapy and imaging. In vitro and in vivo results confirmed targeting, cytotoxicity, and tumor regression, demonstrating their potential for precision cancer treatment.

Treatment of Orthotopic Human GBM Tumours in Mice Using Auger Electron-Emitting 197Hg-Gold Nanoparticles Administered by Convection-Enhanced Delivery

M. Brown¹, Z. Cai¹, Y. Ganga-Sah², V. Radchenko², R. Reilly^{1,3}

¹*University of Toronto, Department of Pharmaceutical Sciences, Toronto, Canada*

²*University of British Columbia, TRIUMF, Vancouver, Canada*

³*University Health Network, Princess Margaret Cancer Centre, Toronto, Canada*

Introduction

Glioblastoma multiforme (GBM) is the most common and lethal primary brain cancer. Current treatments have not improved survival, due to recurrence in almost all patients. Our group has developed a radiation nanomedicine composed of the Auger electron (AE) and γ -photon emitter, 197Hg incorporated into gold nanoparticles (AuNPs) that could be infused into GBM tumours by convection-enhanced delivery (CED) to prevent and treat recurrent disease.

Material and method

197Hg-AuNPs were produced by incorporating 197Hg into AuNPs by forming a stable mercury-gold amalgam. 197 Hg-AuNPs were modified with panitumumab to target epidermal growth factor receptors (EGFR) on GBM cells and internalize and route 197Hg-AuNPs to the cell nucleus where the AEs are most damaging to DNA. A human GBM tumor xenograft model was established by stereotaxic inoculation of U251-Luc cells into the right cerebral hemisphere in NRG mice. Two weeks later, mice were treated by stereotaxic CED of EGFR-targeted or non-targeted 197Hg-AuNPs (0.7 MBq; 7 x 10¹⁰ AuNPs; 5 μ L). SPECT/CT images were obtained up to 7 d post-infusion (p.i.) and the time integrated activity from 0 h to 7 d p.i. was determined at the intratumoural infusion site to estimate radiation absorbed doses. A dose-volume histogram (DVH) was constructed for CED of 1.0 MBq. Acute toxicity was assessed at 14 d p.i. by complete blood cell counts (CBC), blood biochemistry and monitoring body weight in mice infused with EGFR-targeted or non-targeted 197Hg-AuNPs (1.9 MBq; 9.8 x 10¹¹ AuNPs; 5 μ L). A therapy study is in progress comparing the survival of mice receiving EGFR-targeted or non-targeted 197Hg-AuNPs vs. control mice treated with non-radioactive AuNPs or normal saline.

Result and discussion

SPECT/CT images showed strong retention at the site of infusion for EGFR-targeted and non-targeted 197Hg-AuNPs, but non-targeted 197Hg-AuNPs showed greater diffusion than EGFR-targeted 197Hg-AuNPs. The DVH revealed that 60% of the tumour received >190 Gy after CED of EGFR-targeted 197Hg-AuNPs, but only 1% of the tumour received this dose for non-targeted 197Hg-AuNPs. Both EGFR-targeted and non-targeted 197Hg-AuNPs delivered >50 Gy to 95% of the tumour. Doses were highly conformal decreasing to <1 Gy at 3 mm from the infusion site, greatly minimizing irradiation of normal

brain. No significant differences in CBC and blood biochemistry or weight loss was found in treated vs. control mice indicating no general toxicity. Results of the on-going therapy study will be reported including assessment of therapeutic response by Kaplan-Meier survival and assessment of adverse effects on the brain by histopathology and T2-weighted MRI.

Conclusion

We report here for the first time that 197Hg-AuNPs were safely infused by CED into U251-Luc human GBM tumours in the brain of NRG mice and were strongly retained depositing high and conformal radiation absorbed doses in the tumour that are anticipated to be therapeutic.

EACR25-1160

Radiosensitivity and DNA Damage Response in Human Sarcoma: p53-Dependent and Independent Mechanisms Under Alpha-Particle Radiation

A. Sheikh¹, A. Altaras¹, D. Goloe¹, I. Tsarfaty¹, T. Cooks², M. Gerlic¹, I. Kelson³, Y. Keisari¹

³Tel Aviv University, School of Physics and Astronomy, Sackler Faculty of Exact Sciences, Tel Aviv, Israel

Introduction

Intra-tumoral Diffusing Alpha-emitters Radiation Therapy (DaRT) harnesses high-linear energy transfer (LET) alpha particles for potent cytotoxicity and systemic antitumor immunity. Yet, the response of sarcomas, often driven by p53 mutations, remains unpredictable, marked by radiation resistance and treatment-induced adaptability. Defining how p53 status influences radiosensitivity and post-radiation plasticity is critical for optimizing DaRT's therapeutic potential. This study defines how alpha radiation differentially modulates survival, proliferation, and adaptability across p53-variant sarcoma models, revealing key mechanistic drivers of resistance and potential therapeutic vulnerabilities.

Material and method

Five sarcoma cell lines – U2OS (wild-type p53), SAOS2 (p53-null), RD18 (mutated p53, rhabdomyosarcoma), A673 (mutated p53, Ewing sarcoma), and SK-LMS (mutated p53, leiomyosarcoma) – were irradiated with alpha particles from a sealed Americium-241 (Am-241) source (0–4.2 Gy). Colony formation assays determined survival fractions (SF) and D_0 values, Incucyte live-cell imaging tracked proliferation, γ -H2AX immuno-fluorescence staining assessed double-strand break (DSB) repair kinetics, and wound healing assays evaluated

Result and discussion

Radiosensitivity followed a p53-dependent hierarchy, with the wild-type p53 model demonstrating higher sensitivity, while p53-deficient sarcomas exhibited progressive resistance, requiring greater exposure for comparable cytotoxicity. Notably, A673 and SK-LMS

required nearly three times the radiation dose for similar survival reduction, reinforcing p53 dysfunction as a key driver of radioresistance. Proliferation assays showed dose-dependent suppression, yet p53-deficient models like RD-18 maintained growth at intermediate doses, suggesting stress-induced survival tied to p53 dysfunction. DSB repair dynamics varied significantly, revealing distinct genomic stress responses across sarcoma subtypes. Additionally, low-dose irradiation (0.35–0.7 Gy) enhanced motility in A673 and RD18, suggesting radiation-induced cytoskeletal remodeling, while SAOS2 exhibited a paradoxical response, motility inhibition at 1.4 Gy but recovery at 4.2 Gy, indicating nonlinear stress adaptation.

Conclusion

These findings highlight the paradox of alpha radiation in p53-deficient sarcomas, inducing lethal DNA damage while simultaneously driving adaptive survival responses. The implications for DaRT therapy extend beyond direct tumor eradication, highlighting the need to consider radiation-induced motility and DNA repair capacity when optimizing treatment strategies. Future studies will explore p53 restoration as a potential strategy to enhance radiosensitivity and limit radiation-driven adaptability in resistant sarcoma subtypes.

⁵Szent-Györgyi Albert Clinical Center, Oncotherapy Clinic, Szeged, Hungary

Introduction

Radiotherapy causes severe side effects in 5–10% of patients. Radiation-Induced Lymphocyte Apoptosis (RILA) appears to be a promising clinical method for detecting radiosensitivity. Threshold values can vary by patient group, that's why our goal is to establish the method's threshold, improve workflow efficiency, and clinically validate it in cervical cancer patients. We investigated the impact of different incubation times on RILA values. We also tested the necessity of the CO₂ addition during the culturing step. We are also testing the elimination of the pre-irradiation time to reduce the total test duration from 4 days to 3 days, making the method more practical for clinical use. Furthermore, we examined the possibility of replacing irradiation with

bleomycin to eliminate the need of an irradiator, which is typically the linear accelerator used to treat the patients.

Material and method

We collect blood from patients before radiotherapy and at 3 months, 1 year, and 2 years after treatment completion. At these time points, we assess side effects using EMBRACE II, EORTC-QoL-C30, and EORTC-Cx24 questionnaires. We quantify gastrointestinal side effects with citrulline measurements. We mix the blood with RPMI (20% FBS) and irradiate it with 8 Gy, 100 MU/minute, 6MV radiation. Two days later, we label lymphocytes with CD8-FITC and CD4-eFluor506 antibodies. After erythrolysis, we treat the samples with propidium iodide and RNase, then analyze them using flow cytometry.

Result and discussion

We measured radiation-induced apoptosis levels (8 Gy) in CD8+ and CD4+ lymphocytes in samples from 147 patients scheduled for definitive radiochemotherapy. Our current threshold values for CD8+ and CD4+ lymphocytes are 5.78% and 3.86%, respectively. The pre-irradiation time, post-irradiation time, and increase in FACS lag affect the RILA values. However, this can be resolved if the samples are always irradiated and the processing is initiated at the same time. In the case of CD8+ lymphocytes we demonstrated that the use of CO₂ during culturing can be omitted. We are currently testing the removal of the pre-irradiation time, reducing the entire test from 4 days to 3 days. Our initial results show similar outcomes as historical controls (7.4% CD8+ RILA), but validation against side effects is still needed. We examined the replacement of radiation using bleomycin. The addition of 70 and 80 µg/ml bleomycin to the samples for 5 hours, 24 hours before flow cytometry measurements, provided values most similar to irradiation.

Conclusion

We have successfully established the threshold for the RILA method in cervical cancer patients at our center, but validation against side effects is still required. Further development of the method is ongoing to improve workflow efficiency and facilitate its introduction into clinical practice.

Introduction

Locally advanced head and neck squamous cell carcinomas (HNSCC) are commonly treated with radio-chemotherapy, but improving treatment efficacy and patient quality of life remains a challenge. Reliable preclinical models are essential for testing new therapeutic strategies, biomarkers and understanding radiation response. In this work, we utilized histopathological imaging and unsupervised learning techniques to cluster histopathological slides of 10 HNSCC xenograft models, and assessed how the results correlate with radiosensitivity data from previous in-house experiments.

Material and method

In prior experiments, athymic nude mice were xenotransplanted with ten HNSCC tumor models of varying radiosensitivity. These models, ordered from radiosensitive to radioresistant based on tumor control dose 50% (TCD50) values obtained from fractionated radiotherapy, include: XF354, UT-SCC45, SAT, UT-SCC14, UT-SCC8, UT-SCC15, CAL-33, FaDu, SAS and UT-SCC5. A total of 71 hematoxylin and eosin (H&E) whole slide images (WSI) were obtained from excised untreated control tumors (4-10 slides per model). For each WSI, we considered the entire tissue area, from a resolution of 0.44 µm x 0.44 µm, to extract tiles of size 224x224. A publicly available deep-learning model pretrained on large histopathological datasets (UNI) was used to extract 1024 deep features from each tile. The features were standardized using Z-score normalization.

Dimensionality reduction was then performed using principal component analysis (PCA). The reduced features were subsequently clustered using Gaussian Mixture Models (GMM) into five clusters, a number determined empirically. We calculated the percentage of each cluster within individual slides to compare the clustering distribution across the tumor models, and assessed the correlation with the TCD50 values to examine how they align with radiosensitivity.

Result and discussion

Clustering results showed a relatively good visual separation of the clusters in the 2-dimensional space (PCA), in addition to similar cluster distribution within the slides of each tumor model. Visual inspection of the tiles revealed that one cluster likely represents necrotic and stromal areas, while another corresponds to keratin presence in the tissue. The remaining clusters represent tumor regions, though no definitive distinctions were made. Notably, the median percentage of the keratin cluster in each model showed a negative correlation with the TCD50 values, with a Spearman coefficient of -0.75 (p-value = 0.01).

Conclusion

Unsupervised clustering shows promise for HNSCC xenograft models profiling, offering a potential complement to the TCD50 information. Future work will investigate feature interpretability, and undergo further validation and clinical relevance assessment.

Introduction

Predictive biomarkers have a significant role in developing personalized treatment in head and neck squamous cell carcinomas (HNSCC) patients. Despite recent advances, there is still a crucial need for reliable biomarkers for radiosensitivity. Therefore, we investigated combining hypoxia and stem cell markers with predictive scores derived from a deep learning (DL) model based on hematoxylin and eosin (H&E) stained images for classifying the radiosensitivity of HNSCC xenograft models.

Material and method

In prior in-house experiments, athymic nude mice were xenotransplanted with 10 HNSCC tumor models of varying radiosensitivity. These models can be classified into radiosensitive: XF354, UT-SCC45, SAT, UT-SCC14, UT-SCC8 and radioresistant UT-SCC15, CAL33, FaDu, SAS, UT-SCC5, according to the tumor control dose 50% (TCD50) values obtained from fractionated radiotherapy. In parallel to radiotherapy, slices of untreated control tumors were stained with hematoxylin and eosin (H&E), hypoxia markers (Pimonidazole, CAIX and CD31) and stem cell markers (CD44, CD98 and CD31). H&E and immunofluorescence (IF) images were obtained for a total of 63 mice (4 to 8 per model). IF images were analyzed using QuPath software to derive marker scores, defined as the percentage of positive cells for each marker and for each sample. The percentages of double positive cells for CAIX-Pimonidazole and CD44-CD98 were considered as additional scores. For modeling, we considered a binary classification approach. A DL model based on an open source feature extractor (CtransPath) and attention-based multiple instance learning was trained on H&E slides. A logistic regression with l2 regularization was trained using the marker scores. We combined both models (A) using the DL model output as a feature in logistic regression, and (B) averaging the probabilities from both methods. 5 repetitions of 5-fold validation were performed, where in each iteration a different combination of one radioresistant and one radiosensitive xenograft model was held out.

Result and discussion

Across 5 repetitions, the DL model achieved averages of 0.80 and 0.82, while the logistic regression achieved 0.77 and 0.80, for accuracy and F1-score, respectively.

Combining the two models led to an improved performance, with an average accuracy and F1-score of 0.82 and 0.85 in (A), and 0.84 and 0.87 in (B). Pearson correlation was calculated between the deep learning scores derived from the validation sets and the marker scores. The strongest correlation was observed for the CD44-CD98 score with an average coefficient of -0.50 (p-value < 0.05 across 5 repetitions).

Conclusion

Integrating biomarkers related to hypoxia and stemness with H&E-trained models improves radiosensitivity prediction in HNSCC xenograft models, suggesting a potential path towards more personalized treatment for patients.

EACR25-1384**Novel biomarkers for Radiotherapy response in Small Cell Lung Cancer**

Introduction

Thoracic radiotherapy (TRT) has been widely used in the treatment of extensive-stage small cell lung cancer (ES-SCLC). However, phase III trials evaluating chemotherapy (CT) + anti-PD-L1 in the first-line setting excluded this treatment approach. More recently, the use of TRT as a means of boosting the anti-tumour immune response through the activation of innate immune DNA/RNA sensors has been reported. However, what role TRT in combination with CT plays in switching SCLC to immune-responsive type remains unclear. Here, we characterised multiple omics data in SCLC cell lines and peripheral immune cells from SCLC patients undergoing TRT treatment with respect to rare germline variants and the transcriptional profile following treatment with RT alone or in combination with CT.

Material and method

We enrolled patients with a diagnosis of SCLC receiving one of the following treatments: chemotherapy (cisplatin) and/or TRT. Within 2 h of blood draw, PBMCs were isolated by using gradient centrifugation. NGS analysis, alignment and filtering analysis were performed. We then performed an analysis of germline variants which led to loss of function (LoF). We performed GSEA on RNAseq data obtained from n=6 SCLC cell lines before and after treatment with CT (cisplatin 0.5 uM) and/or RT (4 Gy) for 72h and from PBMCs of SCLC patients before and after receiving TRT treatment. Innate immune biomarkers expression in SCLC cells was explored by immunofluorescence, flow cytometry and western blot to validate transcriptomic data.

Result and discussion

GSEA revealed that RT-treated SCLC cells were enriched for DNA Damage Repair (DDR) gene sets (BRCA1, BRCA2, ATM) and Notch gene sets in the RT-treated SCLC cells compared to CT. EMT genes were significantly downregulated in the RT SCLC cells compared to CT. The combination of RT+CT resulted in enrichment of cell adhesion molecules (CAMS) and upregulation of type I Interferon (IFN) gene sets compared to CT alone in SCLC cells, suggesting a concomitant reduction of EMT features and increase of immune-responsive phenotype. Furthermore, CT+RT combination treatment affected SCLC transcriptomic profile by decreasing EMT, glycolysis, oxidative phosphorylation, stemness and lung cancer poor survival gene sets compared to CT alone. The NE marker ASCL1 was also significantly downregulated in SCLC cells after RT+CT treatment. In parallel, in vitro analysis of innate immune markers in PBMCs from SCLC patients undergoing TRT showed an activation of STING preferentially in post-RT setting.

Conclusion

Taken together, these data suggest a potential pro-immune role for TRT in chemotherapy-treated ES-SCLC patients.

EACR25-1594**Investigating the Synergistic Effects of HDAC and ABC Efflux Transporter Inhibitors in Radiation-Resistant Triple Negative Breast Cancer**

A. Prajapati¹, D. Uppal^{2,3}, D. Agarwal¹

¹*Amity University, Noida, AIMMSCR, Uttar Pradesh, India*

²*Bhabha Atomic Research Centre, Molecular Biology Department, Trombay, Mumbai, India*

³*Homi Bhabha National Institute, Anushakti Nagar, Mumbai, India*

Introduction

Triple Negative Breast Cancer (TNBC), an aggressive subtype of breast cancer, accounts for approximately 15% of cases. Radiation resistance remains a major therapeutic challenge, necessitating a deeper understanding of its underlying mechanism. The present study investigates the synergistic therapeutic potential of a FDA approved histone deacetylase inhibitor (HDACi), Romidepsin, an epigenetic modulator, in combination with the ABC drug efflux inhibitor, Verapamil, in radioresistant TNBC cells, aiming to elucidate their mechanism of action.

Material and method

Radiation resistant TNBC cells (RR) were generated by exposing MDA-MB-468 cells to a clinical fractionated radiation dose of 40 Gray. These cells were characterized using colony-forming, migration scratch assay and FACS analysis. Cell viability assay was performed to generate dose response matrices and synergy score plot for RR cells in combination with romidepsin and verapamil. qRT-PCR and immunoblotting assays confirms the mechanistic insights into the radiation resistance and mode of drug action were analysed through apoptotic assays, FACS based assays.

Result and discussion

RR cells exhibited increased radiation resistance, proliferation, and migration potential. Among the tested HDACis, (Romidepsin, SAHA, Belinostat), Romidepsin displayed a promising cytotoxic effect but was less effective in RR cells as compared to the parent radiation-sensitive (RS) cells. Gene expression analysis demonstrated upregulation of Endothelial to Mesenchymal Transition (EndMT) markers (N-Cad, ZEB1, TWIST, FIBRONECTIN), Cancer Stemness regulatory markers (OCT4, SOX2, NANOG) and ABC efflux transporters (ABCC1, ABCC2, ABCG2) in the RR cells. Hoechst efflux assays confirmed increased transporter activity in TNBC-RR cells. Romidepsin treatment alone did not significantly alter H3K9ac/K27ac acetylation levels in RR cells. However, Inhibition of efflux transporters by verapamil lowered romidepsin efflux, restored H3K9/K27 acetylation, and resensitized RR cells to Romidepsin. The combination of Romidepsin and Verapamil inhibited cell viability of TNBC-RR in a dose dependent synergistic manner. Additionally, an increase in the sub-G1 population upon combinatorial treatment

indicated activation of cell death pathways in TNBC-RR cells. Ongoing *in vivo* studies aim to validate these findings in mouse models of radiation-resistant TNBC.

Conclusion

The synergistic effect of Romidepsin and Verapamil shows promising cytotoxic response in radiation-resistant TNBC cells, highlighting the potential of ABC transporter efflux inhibitors to overcome HDACi resistance. This study suggests a promising therapeutic strategy for improving treatment outcomes in radiation-resistant TNBC.

⁴Linkoping University, Department of Health, Medicine and Caring Sciences (HMV), Linkoping, Sweden

Introduction

Radiotherapy is used to treat over 50% of cancer patients and is used in combination with surgery, chemotherapy, and immunotherapy, for cancers of the breast, lung, oesophagus, and rectum [1-3]. Ionising radiation exerts its anti-cancer effect through both direct DNA damage and indirectly through the production of reactive oxygen species via water radiolysis. This DNA damage is made permanent in the presence of molecular oxygen; however, it is reversible under hypoxia [4]. Therefore, hypoxia confers significant radiotherapy resistance and given that it is a common feature of most solid tumours it offers a unique tumour vulnerability to exploit to improve radiotherapy efficacy. To address this, we have developed a biocompatible, oxygenating perfluorocarbon nanoemulsion with imaging capacity (NanOx) that has potential to increase the radiosensitivity of hypoxic oesophageal adenocarcinoma (OAC) cells with acquired radioresistance.

Material and method

NanOx biocompatibility was assessed *in vitro* using 2D and 3D HepG2 cells, and *in vivo* using zebrafish embryos. NanOx oxygen delivery kinetics were assessed using the Seahorse bioanalyzer and via HIF-1α expression by Western immunoblot. Radiosensitisation efficacy studies were conducted using an isogenic model of acquired radioresistance in OAC and included colony forming assays, DNA damage and repair via 53BP1 foci immunofluorescence, cell cycle kinetics, and apoptosis.

Result and discussion

NanOx was biocompatible across *in vitro* and *in vivo* model systems, and significantly increased supernatant oxygen levels and significantly reduced HIF-1α

expression with 30 min treatment. NanOx, in combination with radiotherapy, significantly reduced the surviving fraction of hypoxic OAC cells with acquired radioresistance with a sensitiser enhancement ratio of 2.22. Combining NanOx with radiotherapy did not alter the level of DNA damage but significantly impaired the repair of this DNA damage, evident through increased 53BP1 foci persistence. NanOx combined with radiotherapy significantly increased the number of radioresistant OAC cells in G2/M and the number of apoptotic cells, in comparison with either treatment alone.

Conclusion

Hypoxia is a common feature of solid malignancies and significantly impairs treatment efficacy, particularly radiotherapy. We have invented a novel oxygenating perfluorocarbon nanoemulsion with imaging potential which can significantly improve response to radiotherapy in hypoxic OAC cells with acquired radioresistance.

EACR25-1929

Hypoxic tumor cells acquire a cellular quiescence phenotype that protects them against radiation-induced cell death

Introduction

Previously, with the use of a lineage-tracing hypoxia reporter system we showed that pre-treatment hypoxic cells enrich in the regrowing spheroids and xenograft tumors following irradiation (IR). Here, we aim to understand how hypoxic tumor cells evade radiation-induced cell death.

Material and method

The lung AdenoCa H1299, head and neck SCC FaDu and the murine GBM LA6 cell lines originally carrying the hypoxia lineage tracing reporter (UnaG) (1), were transduced with the Fluorescent Ubiquitination-base cell cycle reporters (Fucci) to visualize the different cell cycle phases. Colony forming assays were performed in normoxic, chronic hypoxic or reoxygenated prior to IR conditions. To estimate the DNA repair capacity of the cells at different conditions, immunofluorescent staining for DNA damage response (DDR) proteins was performed and subsequently, the 53BP1 protein was endogenously tagged with a Halo tag to visualize the radiation-induced DNA double-strand breaks (DSBs) by means of live cell imaging.

Result and discussion

Tumor cells cultured in 1% O₂ atmosphere are progressively arrested in the G1/G0 phase of the cell cycle and display higher radioresistance compared to normoxic cells. Interestingly, hypoxic cells that were re-oxygenated prior to IR (3h) remain radioresistant despite the fact that induction of DNA damage in terms of nuclear foci is not different. Sorting FUCCI cells based on the cell cycle profile revealed that cells in the G1-arrested state are more radioresistant compared to S and G2 phase cells upon re-oxygenation, suggesting that the hypoxia-induced quiescence is a protective mechanism. In live cell imaging, irradiated re-oxygenated cells displayed slower progression to the cell cycle, less catastrophic events and less chromosomal miss-aggregations during mitosis compared to normoxic cells. To link clearance of DNA damage with cell cycle progression and the retention of cellular fitness in a single cell level we tagged endogenously 53BP1 and we are currently performing live-cell imaging. In 3D spheroids, hypoxic tumor cells are in a quiescence state and upon irradiation exhibit a survival advantage and enrich in regrowing spheroids. Irradiated hypoxic cells remain in a non-proliferative state for prolonged period, before they acquire a proliferative profile and contribute to spheroid regrowth. Importantly, splitting the total radiation dose and re-irradiate at the regrowing phase of the sphere led to higher spheroid control probability by irradiation, suggesting that re-irradiation at the time that hypoxic cells exit their quiescent state might be an appealing novel therapeutic strategy.

Conclusion

Our data suggests that hypoxic tumor cells acquire a quiescent state and this is linked with higher capacity to maintain cellular fitness upon radiation-induced damage even upon re-oxygenation.

Introduction

Combination therapies targeting cancer metabolic vulnerabilities and enhancing radiosensitivity offer promising strategies to improve treatment efficacy. L-asparaginase (L-ASNase) is a clinically established chemotherapy agent used to treat acute lymphoblastic leukemia (ALL): the treatment strategy is to exploit asparagine auxotrophy of cancer cells, by depriving them of asparagine (Asn) and glutamine (Gln). However, its possible application in solid tumors remains under-explored. This study investigates the combined effects of L-asparaginase II (EcAII) and ionizing radiation (IR) across selected solid tumor *in vitro* models, focusing on quantitative synergy assessments, building on preliminary findings demonstrating EcAII's efficacy in reducing proliferation in adenocarcinomas and triple-negative breast cancer (TBNC) cell lines.

Material and method

In vitro models included adenocarcinoma (A549 lung, 786-O renal, Caco-2 colorectal) and TNBC (BT549) cell lines, which were treated with EcAII (0.05–3 U/ml) and/or X-rays (1–5 Gy). Synergy was quantified using two complementary approaches: short-term proliferation (72-h growth assays) and long-term survival (colony formation assays). Dose-response curves for monotherapies (EcAII or X-rays only) were generated investigating clinically relevant doses centered on IC₅₀ values for each agent; data were fitted via Hill's equation. Synergy was assessed using the Bliss Independence model, generating Combination Indexes (CI, where CI < 1 indicates synergy) across effect levels. Secondary analyses included cell cycle profiling and mTOR pathway modulation.

Result and discussion

Bliss analysis revealed context-dependent interactions. Caco2 colorectal cells exhibited significant synergy (CI < 0.68) at low EcAII concentrations (0.05–0.1 U/mL) and moderate IR doses (3–5 Gy). In contrast, A549 and 786-O models showed additive effects (CI ≈ 1). TNBC models displayed cytostatic responses to EcAII monotherapy, characterized by G1-S arrest and mTOR pathway suppression, though the combination with IR yielded variable effects. These findings underscore the interest of tumor-specific context in designing combination regimens. While the Caco2 synergy highlights therapeutic potential of metabolic targeting in colorectal adenocarcinoma, variability in other models emphasizes the need for precision-based approaches.

Conclusion

This study provides a quantitative framework for evaluating the possible synergy for combined EcAII-IR treatments, identifying colorectal cancer as a promising candidate for metabolic radiosensitization. Limitations include *in vitro* model constraints and CI threshold interpretation; ongoing work employs 3D/organoid models to refine the predictive framework. These insights advance quantitative synergy evaluation in combined chemo-radiotherapy, offering strategies for optimizing combination therapies in solid tumors.

⁵*UMONS, Department of Human Biology and Toxicology, Mons, Belgium*

Introduction

Head and neck cancers (HNC) rank as the seventh most common malignancy worldwide, contributing

significantly to cancer-related mortality. In 2022, more than 940.000 cases of HNC were reported and more than 480.000 deaths were recorded. In locally advanced stages (III and non-metastatic IV), radiochemotherapy is the standard treatment, administered either alone or as an adjuvant therapy following surgery. Despite advances in radiotherapy, HNC remain challenging due to the complexity of the anatomical region. In this context, iron oxide nanoparticles (IONPs) have been explored as potential radiosensitizers for HNC treatment, aiming to enhance radiotherapy efficacy while minimizing damage to surrounding healthy tissues. These nanoparticles are hypothesized to amplify cancer cell radiosensitivity by increasing reactive oxygen species (ROS) production and decreasing antioxidant defences. Furthermore, erasin, a known ferroptosis inducer, has been investigated in combination with IONPs to enhance the antitumor effects through oxidative stress generation.

Material and method

In this study, IONPs coated with 3-(triethoxysilyl)propyl succinic anhydride (TEPSA) were used. Experiments using radiotherapy were performed using a 6 MeV beam. Clonogenic assays were conducted to assess the impact of IONPs on cell survival following exposure to various doses of radiation (2–8 Gy) and pre-treatment or not with nanoparticles. ROS generation, glutathione depletion, and thioredoxin reductase (TrxR) enzyme activity were measured to evaluate oxidative stress dynamics.

Additionally, the effects of erasin were also evaluated alone and in combination with IONPs regarding cell viability, ROS production, and ferroptosis induction.

Result and discussion

Results indicate that IONPs alone do not significantly reduce cell viability or enhance ROS production, though they are efficiently internalized across all tested HNC cell lines. The radiosensitizing effects of IONPs appear to be variable depending on the cell line and experimental conditions, and their overall impact remains insufficient. Interestingly, the combination of IONPs with erasin – at doses that are non-toxic when used separately – induces a marked decrease in cell viability and a concomitant reduction in ROS levels, suggesting a potential ferroptotic mechanism.

Conclusion

These findings highlight the promising role of IONPs and erasin in HNC treatment. Further investigations integrating radiotherapy are necessary to confirm their radiosensitizing potential and to elucidate the underlying molecular pathways, particularly ferroptosis induction.

Introduction

Radium-223 dichloride ($^{223}\text{RaCl}_2$) is an alpha-emitting radiopharmaceutical approved for the treatment of metastatic castration-resistant prostate cancer (mCRPC) with bone metastases. While its primary therapeutic effect is through targeted bone deposition and induction of DNA damage in tumor cells, emerging evidence suggests potential effects beyond the bone micro-environment, including modulation of tumor cell migration, invasion, and angiogenesis. However, these effects remain poorly understood. This study aimed to investigate the effects of $^{223}\text{RaCl}_2$ on cancer cell

migration, invasion, and angiogenesis using 2D and 3D *in vitro* models.

Material and method

To investigate the impact of $^{223}\text{RaCl}_2$ on tumor progression *in vitro*, we used PC3 prostate cancer cells as 2D monolayers and 3D spheroids, plus mouse aortic rings for angiogenesis studies. Cell models were exposed to $^{223}\text{RaCl}_2$ at doses of 0.88–110.66 mGy (24 h irradiation) or 0.3–3.1 mGy (10-minute irradiation). Migration was assessed in monolayers (scratch assay) and spheroids (in extracellular matrix assay), while invasion was evaluated in spheroids (after 5 and 7 days). Angiogenesis was measured using aortic ring assay. Gene expression of migration and invasion regulators was analyzed in spheroid mRNA (after 8 d).

Result and discussion

Our long-term results indicated that $^{223}\text{RaCl}_2$ significantly reduced PC3 cell migration and invasion in a dose-dependent manner, both in monolayer and spheroid models. The migration area, compared to control (5 days post-irradiation), was significantly reduced in scratch assay as well as the migration distance in spheroid migration assay when exposed to 55.33 and 110.66 mGy. PC3 spheroid invasion capacity (maximum invasion distance and sprout density) was significantly reduced when evaluated in the same endpoint after exposure to equal doses of $^{223}\text{RaCl}_2$. Short-term exposure to $^{223}\text{RaCl}_2$ significantly impaired angiogenesis by significantly reduced sprout distance (48 h post-irradiation) and mean migration distance (5 d post-irradiation). A significant downregulation of migration-related genes, especially integrin- β 1 were determined after exposure to 0.88, 55.33, and 110.66 mGy.

Conclusion

These findings showed that $^{223}\text{RaCl}_2$ suppressed metastatic potential by inhibiting cellular migration, invasion, and angiogenesis in prostate cancer models. Even short-term exposure reduced sprouting and vascular network formation, highlighting its broader impact on the tumor microenvironment and potential role beyond targeting bone metastases.

EACR25-2337

Targeting Protein Disulfide Isomerases for Radiation Sensitization in Prostate Cancer

O. Nuta¹, M. Bertrand², M. Garrido², A. Parizadeh², A. Chauchereau²

¹*Nazarbayev University, Biology, Astana, Kazakhstan*

²*INSERM UMR981, Gustave Roussy, Paris-Saclay University, Villejuif, France*

Introduction

Prostate cancer frequently managed with radiotherapy faces challenges from radioresistance, leading to recurrence and poor prognosis. Mechanisms contributing to radiation resistance include antiapoptotic pathways, enhanced DNA repair, cancer stem cell maintenance, hypoxia, and ROS detoxification. Antioxidants have been implicated in radioresistance with varying degrees of emphasis. Protein disulfide isomerases (PDI) are chaperone proteins regulating cell viability and oxidative

stress by modulating cellular redox balance. Increased PDI levels occur in multiple cancers, including prostate cancer. This study investigates PDI inhibitors as radiation sensitizers in prostate cancer models with different radiation sensitivity profiles.

Material and method

We evaluated pan-PDI inhibitors (PACMA31, 35G8, E64FC26) alone and combined with ionizing radiation (2 Gy) in four prostate cancer cell lines (IGR-CaP1, 22rv1, PC3, and DU145) representing varied radiation sensitivity. Cell viability was assessed using WST-1 assays, and proliferation was monitored by real-time IncuCyte imaging. Sequence-dependent effects were examined by administering PDI inhibitors either before or after radiation treatment.

Result and discussion

PACMA31 demonstrated potent anti-proliferative activity across all prostate cancer cell lines with nanomolar EC₅₀ values (10–250 nM). Efficacy and optimal timing were cell-line dependent. In radioresistant cell lines (PC3 and DU145), PACMA31 before radiation showed enhanced growth inhibition compared to post-radiation administration. In radiosensitive 22rv1 cells, PACMA31 demonstrated synergy when given after radiation, reducing proliferation to near-complete inhibition. 35G8 showed particular efficacy in radio-sensitive cells. For IGR-CaP1 cells, PACMA31 showed significant efficacy both before and after radiation, with stronger inhibition in post-radiation protocols. Importantly, PDI inhibitors remained effective against chemoresistant prostate cancer cells, suggesting potential applications in both chemotherapy-naïve and chemoresistant disease settings.

Conclusion

PDI inhibitors, particularly PACMA31, can effectively enhance radiation response in prostate cancer cells, with optimal timing dependent on intrinsic radioresistance profiles. Radioresistant models benefit from PDI inhibition before radiation, while radiosensitive models respond better when PACMA31 follows radiation. Results also suggest PDI may influence cells' ability to resist oxidative stress through interaction with glutathione systems, thioredoxin, and antioxidant enzymes, thus constituting an interesting Achilles heel to target radioresistant cells. Tailored personalized administration sequence of PDI inhibition and radiation therapy based on tumor radioresistance characteristics could significantly improve treatment outcomes in prostate cancer.

EACR25-2419

111In-Radioconjugates Carrying DNA Intercalators and PSMA Inhibitors for Improved Auger Electron Therapy of Prostate Cancer

P. Raposo¹, J. Santos², C. Silva², M. Andorinha², C. Fernandes¹, F. Mendes¹, A. Belchior¹, A. Paulo¹

¹*Instituto Superior Técnico, Universidade de Lisboa, DECN/C2TN, Lisboa, Portugal*

²*Instituto Superior Técnico, Universidade de Lisboa, C2TN, Lisboa, Portugal*

Introduction

Prostate specific membrane antigen (PSMA) has emerged as one of the most promising molecular targets for prostate cancer (PCa), which motivated the study of PSMA inhibitors radiolabeled with different imaging and/or therapeutic radionuclides in PCa theranostics. In particular, Auger electron (AE) emitters, such as ^{111}In , are attractive tools in targeted radionuclide therapy to selectively irradiate tumour cells while sparing healthy tissues [1]. However, short range AEs must be emitted close to radiosensitive organelles to obtain efficient therapeutic effect [2]. Considering that nuclear DNA is the canonical target for biological damage induced by AEs, we have synthesized and proceeded with the pre-clinical evaluation of dual-targeted ^{111}In -complexes carrying a PSMA inhibitor and an acridine orange (AO) DNA intercalator. The designed dual-target radio-complexes were expected to undergo a selective uptake by PSMA(+) PCa cells with potential accumulation of the radionuclide in the nucleus (Figure 1).

Material and method

DOTA-based chelators bearing a PSMA inhibitor with the Glu-urea-Lys binding motif and AO groups were synthesized and labeled with ^{111}In . The preclinical evaluation of the resulting radioconjugates included cellular uptake and internalization, PSMA-blocking assays and nuclear uptake in cell lines expressing different levels of PSMA, as well as the evaluation of radiobiological effects (e.g., clonogenic survival, cell viability and g-H2AX assays) in the same cell lines. It also comprised the evaluation of biodistribution and pharmacokinetics of ^{111}In -labeled conjugates in healthy female mice. The study was done in comparison with single-targeted congeners carrying uniquely the PSMA inhibitor or AO group.

Result and discussion

The ^{111}In -complexes were obtained with high radiochemical yield, purity and in vitro stability. The single- and dual-targeted radiocomplexes carrying the PSMA inhibitor displayed high and PSMA-specific cell uptake and internalization in the PSMA(+) PC3 PIP cells while presenting a negligible uptake and internalization in the PSMA(-) PC3 flu cells. The radiobiological studies indicated that the dual-targeted radiocomplexes compromise cell viability and survival in a dose-dependent manner, being more efficient to induce DNA double-strand break formation than the single-targeted congeners. The animal studies demonstrated a high in vivo stability and favourable pharmacokinetic profile for dual-targeted complexes.

Conclusion

The dual-targeted ^{111}In -complexes exhibited high and specific internalization in PSMA(+) PCa cells and extensive radiotoxicity in the same cell lines revealing their potential for Auger therapy of PCa cancer.

Normal Human Epithelial-Fibroblast 3D Spheroid Cultures for Modeling Radiation-induced Lung Injury

L. Stasch¹, M. Buchholzki¹, Z. Sevindik¹, B. Budeus², D. Klein¹

¹*Institute of Cell Biology (Cancer Research), Essen, Germany*

²*Institute of Cell Biology (Cancer Research), Genomics & Transcriptomics Facility, Essen, Germany*

Introduction

Lungs are among the most sensitive organs to ionizing radiation, and this high intrinsic sensitivity is dose-limiting for thoracic radiotherapy (RT). RT-induced lung injury (RILI) includes acute inflammation and repair, which can develop into chronic inflammation and fibrosis. The classically used mouse model of RT-induced pneumopathy –like other animal models- only inadequately reflect clinically relevant dose sensitivities and characteristics of human RILI. We investigated direct spheroidal co-cultures of epithelial cells and fibroblasts, which can be considered as an *in vivo*-approximated culture method, and analyzed the cell-type specific RT response in combination with potential radioprotective strategies.

Material and method

Spheroidal co-cultures of human epithelial cells and HS5 fibroblasts were optimized concerning cell numbers and culture conditions. The RT response was further investigated (growth/retardation and cell fate e.g., viability, cell cycle, cell death and senescence) with or without co-applied modifier treatment (Src inhibitor Dasatinib; antidiabetic drug metformin).

Result and discussion

After irradiation, the growth of spheroids decreases while the cells remain viable. In these cultures, a rather low induction of apoptosis of 10% can be observed post RT, but an induction of senescence (to approx. 35%) can be observed, which is equally distributed between epithelial and fibroblastic cells. Purely epithelial spheroids show neither a reduction in growth after RT nor an induction of apoptosis and senescence, which on the one hand reflects an inherently resistant character and on the other hand shows that co-cultured fibroblasts influence the cell fate of the epithelial cells. A co-applied metformin treatment seems to lower the growth in general with no further decrease post RT, while no effects on the cell-type specific apoptosis and senescence level could be observed. A co-applied Dasatinib treatment lowers the spheroid growth significantly under non-irradiated conditions with no (further) impact post RT. growth in general but especially in combination with RT, while no effects on the cell-type specific apoptosis and senescence level could be observed. The degree of RT-induced senescence was not affected but apoptosis induction was limited in fibroblasts following Dasatinib co-treatment while increased in respective HBEC cells.

Conclusion

Using normal bronchial epithelial cells together with fibroblasts resulted in complex lung structures consisting of different epithelial and mesenchymal lung cell types. Differential cell fates post RT revealed the fibroblasts being more sensitive and fostering senescence of co-cultured epithelial cells. Currently we are validating respective findings using different epithelial-fibroblast pairs. Supported by grants of BMBF (16LW0293) and by the DFG RTG2762.

EACR25-2473**Exploiting replication stress as a novel therapeutic target in CIC-rearranged sarcomas**

W. Waisi¹, C. Roukoz¹, R. Masson¹, V. Perrin¹, M. Brahmi¹, F. Tirode¹

¹*Cancer Research Center of Lyon, Genetic, Epigenetic and biology of sarcoma, Lyon, France*

Introduction

CIC rearranged sarcomas are a relatively recently recognized, aggressive round cell sarcoma that are distinct from Ewing Sarcoma. While there is no consensus standard of care approach, the treatment for newly diagnosed CIC rearranged sarcomas usually consists of multimodal therapy including neoadjuvant and/or adjuvant polychemotherapy, in combination with surgery and often radiotherapy. Nevertheless, the prognosis remains very poor with a high rate of relapse/progression. ATR (Ataxia Telangiectasia Mutated and Rad-3 Related protein kinase) is activated by single-stranded DNA such as can be produced during replication stress, double-strand break (DSB) resection, or DNA cross-links. Cerelastib (AZD6738) is an ATP competitive, commercially available ATR inhibitor (ATRi) that blocks phosphorylation of CHK1 proteins disrupting DNA replication, inducing DNA damage, and preventing DNA repair, finally leading to cell death. We hypothesized that CIC rearranged sarcomas with high levels of replication stress may therefore be sensitive to ATR inhibition and would be radiosensitized by ATRi.

Material and method

A comparative transcriptional analysis was performed between cell lines (RSP7-C1, TE-441.T and IB120) harbouring an oncogenic CIC::DUX4 fusion and their counterpart with siRNA based CIC::DUX4 knock down. Differential genes expression and enrichment analysis were performed. Each line was treated, with increasing concentration of ATRi (AZD 6738 : 10 nM-5 µM) and/or RT (2 Gy-4 Gy). Tumoroids were then tested with increasing concentration of AZD 6738 (100 nM-2 µM) and/or radiation therapy (2 Gy-4 Gy).

Result and discussion

Enrichment analysis showed that terms involved in replication and cell cycle were related to CIC::DUX4 fusion. All cell lines demonstrate sensitivity to AZD6738 with IC50 of 490 nM (IC95 : 410-590 nM), 510 nM (IC95 : 480-540 nM) and 980 nM (IC95 : 820-1200 nM) for RSP7-C1, TE-441.T and IB120 respectively. Radiosensitization with AZD6738 was consistent between all cell lines and non cytotoxic concentration of AZD6738 showed a significant radiosensitization effect.

Conclusion

CIC::DUX4 oncogenic fusion induce transcription of genes involved in replication stress. To the best of our knowledge, this is the first study showing a cytotoxic effect of ATR inhibition in CIC::DUX4 sarcoma in vitro, particularly in three tumoroid models. Moreover, non cytotoxic concentration of ATRi showed a significant radiosensitization effect in both monolayer and tumoroid models. These data supports the importance of targeting replication and DNA damage pathways in CIC rearranged sarcomas. Further investigation is required to

determine the potential mechanisms of differential sensitivity, and determine the efficacy in vivo.

EACR25-2516**Response of non-small lung cancer cells to irradiation with helium ions**

V. Petkovic¹, O. Keta¹, F. Cammarata², M. Djordjevic¹, G. Petringa³, P. Cirrone³

¹*Vinca Institute of Nuclear Sciences, Belgrade, Serbia*

²*Istituto di Bioimmagini e Fisiologia Molecolare ging and Physiology, CNR-IBFM, Cefalu, Italy*

³*Istituto Nazionale di Fisica Nucleare, INFN-LNS, Catania, Italy*

Introduction

Radiotherapy is an important treatment option for oncologic patients. Compared to conventionally used photon irradiation, hadron beam radiotherapy (hadron-therapy) has emerged as a more promising treatment approach due to its improved precision and better sparing of the surrounding tumor tissue, also causing fewer side effects. Radiotherapy with protons or carbon ions, already used in clinical settings, is proven to maximize the dose delivered to the tumor within the Bragg peak region. Helium ion beams are considered another promising alternative for radiation therapy, especially for the treatment of deep-seated and pediatric tumors, due to their favorable physical and biological properties over protons and carbon ions. This study aimed to examine the effects of helium ion radiation on radioresistant lung cancer cells, as well as to compare the efficiency of helium ion with the previously obtained proton irradiation.

Material and method

Human non-small lung cancer cell line HTB177 was irradiated with 62 MeV/u helium ions, with the irradiation position in the middle of the Spread-Out Bragg Peak. Clonogenic cell survival analysis was performed to detect changes in cellular radiosensitivity concerning different radiation doses applied. The dynamics of DNA double-strand break (DSB) repair was estimated by γ-H2AX foci analysis. The irradiation-induced changes in the cell cycle by helium ion beams were analyzed as well.

Result and discussion

Radiobiological data showed that HTB177 cells are more radiosensitive to helium ion irradiation compared to the corresponding data obtained following proton irradiation. The analysis of γ-H2AX foci showed that helium ions induced a comparable number of DSB as proton irradiation, which does not entirely correlate with the cell survival data. These results could be explained by complex DNA damages that may arise following helium ion irradiation, which reduce the cellular clonogenic potential. According to the obtained profile of cell cycle distribution, an increase in the subG1 cell cycle phase was more prominent for cells irradiated with helium ions compared to protons. These results point to stronger lethal effects of helium ions than protons, which is in agreement with the analysis of cell survival data. To further elucidate the cellular response to helium irradiation, an in-depth analysis of the complexity of the DNA lesions and DNA damage response will be performed.

Conclusion

Due to the growing interest in finding novel and more effective approaches in hadrontherapy, the study outlined here will enable prospective in vitro studies to be carried out on radioresistant cancer cells, such as pancreatic cancer cells, using helium and lithium-ion beams of different energies.

EACR25-2519

Therapeutic antitumor potential of brachytherapy combined with TLR7 agonist imiquimod

M. Jarosz-Biej¹, R. Smolarczyk¹, D. Sprus-Lipka¹, P. Wojcieszek², M. Szlag², Z. Urbaś², J. Czapla¹, J. Cieplak¹, E. Pilny¹, T. Cichoni¹

¹*Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice Branch, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland*

²*Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice Branch, Brachytherapy Department, Gliwice, Poland*

Introduction

Brachytherapy (BR, contact radiotherapy) is one of the radiation methods of treating patients with cancer. It destroys cancer cells and also affects the tumor microenvironment (tumor blood vessels and immune cells). A dose of 10Gy acts as an "in situ" vaccination leading to the development of a robust antitumor immune response. Late effect after radiation is characterized by arise of numerous areas of underoxygenation (hypoxia) which weakens the anticancer effect of RT. Imiquimod (IMQ), the toll-like receptor 7 (TLR7) agonist, acts as an immunostimulant and vascular normalizing agent. In this study, we evaluated the effect of IMQ on the long-term antitumor response of BR in a mouse model of melanoma. The combination of IMQ with BR should elicit synergistic effect in cancer treatment.

Material and method

Mice with well-developed B16-F10 melanoma tumors were treated with IMQ and 5 days later with BR. IMQ was administered subcutaneously at a vascular normalized dose of 50 µg. BR was used at dose of 10Gy. The dose was planned using CT scans on the dedicated commercial platform. Irradiation was performed in the shielded therapeutic room with a high-dose rate after-loader equipped with an iridium-192 radioactive source (Microselectron, Nucletron). The dose per fraction was planned to be specified 2–3 mm from the applicator surface. The time of fraction delivery was adjusted depending on the source activity (3–10 Ci).

Result and discussion

Therapeutic anticancer effect of IMQ and BR combination was studied. We observed 70% tumor growth inhibition following monotherapy with the use of IMQ or 10Gy dose radiotherapy at 22th day of therapy. Combined therapy (IMQ with BR) inhibited tumor growth the most effectively compared to the other groups (tumor growth inhibition was 90% to control group and 70% to monotherapies). In a long-term observation we noticed tumor progression after IMQ treatment and large necrosis areas in tumors treated with BR. In mice treated

with combination of IMQ+BR we observed prolonged tumor growth inhibition. We also checked the therapy's impact on the hematological system parameters. Combined therapy decreased the number of lymphocytes with increase of granulocytes and eosinophils share in blood of treated mice. The proportion of eosinophils in peripheral blood was 10-times higher after combined therapy, compared to the other groups.

Conclusion

The combination of the vasculature normalizing dose of IMQ with BR elicit synergistic antitumor effect in melanoma treatment. Eosinophils mediated anticancer immunity after combined therapy may be essential for the therapeutic antitumor effect. Our data indicate that it is reasonable to use a drug that will prevent the changes occurring in the tumor microenvironment in combination with radiotherapy.

⁴*Univ Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO), Institute of Biophysics, Faculty of Medicine; Univ Coimbra, Center for Innovative Biomedicine and Biotechnology (CIBB); Clinical Academic Center of Coimbra (CACC); Unidade Local de Saúde (ULS) de Coimbra, Centro Hospitalar e Universitário de Coimbra (CHUC), General Surgery Department, Coimbra, Portugal*

Introduction

Pancreatic cancer (PanC) is one of the most lethal types of cancer worldwide, with a 5-year survival rate of approximately 5%, requiring novel and more effective treatment approaches. Poly(ADP-ribose) Polymerase inhibitors (PARPi) can prevent cancer cells from repairing their damaged DNA. Therefore, the combination of PARPi with external beam radiation therapy can trigger an accumulation of DNA damage that surpasses the repair mechanisms of cancer cells, enhancing treatment effectiveness. This study aimed to investigate the combination of external beam radiation

therapy with PARPi to improve PanC treatment outcomes.

Material and method

Olaparib (OLA), a PARPi, was combined at a fixed non-cytotoxic concentration (1 μ M) with 6 MV X-rays in the MIA PaCa-2, PANC-1, and Hs 766T pancreatic cancer cell lines. The clonogenic assay was used to evaluate cell survival and calculate survival parameters, such as dose to achieve 10% or 50% of the survival fraction (D10 or D50), as well as the survival fraction at 2Gy (SF2) and the mean inactivation dose (MID). The radiosensitization effect of OLA was quantified by the sensitization enhancement ratio at D10 (SERD10), D50 (SERD50), SF2 (SERSF2), and MID (SERMID). Genotoxicity was also evaluated 72 hours after treatment using the Cytokinesis-Block Micronucleus assay. Additionally, the presence of DNA double-strand breaks (DSBs) was evaluated using the gamma-H2AX foci assay at 2, 4, 8, 12, and 24 hours after treatment.

Result and discussion

OLA combined with X-rays showed a synergistic effect in all cell lines, with all the survival parameters evaluated being lower in the OLA and X-rays combination compared to X-rays alone. Overall, OLA demonstrated a radiosensitizing effect in the three pancreatic cancer cell lines, with SER values ranging from 1.2 to 1.4. Notably, this radiosensitizing effect was observed regardless of the tumor origin or cell line radioresistance. Furthermore, an increase in the percentage of binucleated cells with micronuclei was observed with the combined treatment, indicating that it induced more DNA damage than the isolated treatments. Preliminary results also showed a slight increase in the number of gamma-H2AX foci per nucleus in the combined treatment, 24 hours post-treatment in the PANC-1 cell line, suggesting an increase in DSBs.

Conclusion

This study demonstrates the potential of combining OLA with X-rays as a future therapeutic approach for PanC, representing an alternative to the therapeutic options currently used in clinical practice. The induction of DNA damage by X-rays with the consequent inhibition of their repair by OLA may help explain the synergistic and radiosensitizing effects observed.

⁴*University of Veterinary Medicine and Pharmacology in Košice, Department of Food Hygiene, Technology and Safety, Košice, Slovakia*

Introduction

The scientific community is concerned with the quality and safety of the raw materials and the content of bioactive substances beneficial to health. Coffee contains more than a thousand chemical compounds, some of them have bioactive potential, such as polyphenols known for antioxidant and anti-inflammatory effects. The fatty acid composition of coffees Burgundy processed by fermentation was previously described. The main risk factor for colorectal cancer has always been diet. The focus of our research was monitoring the effect of different methodological approaches of roasted coffee and green coffee on colon cancer tumor cells and compared to fibroblasts in vitro. We focused on monitoring the anti-proliferative effect of the extracts and profiling individual signaling pathways due to the influence of the extracts used.

Material and method

Cell cultures were used for Label-Free Protein Quantification analysis consisting of BJ-5ta healthy human cells and HCT116 colon cancer cells. The effect of coffee extract from naturally roasted coffee, anaerobically roasted coffee, naturally unroasted coffee, and anaerobically unroasted coffee was investigated. Determination of the proteins was characterized by UHPLC/MS analysis and then searched against the Uniprot database, followed by PCA and heatmap analysis and Gene Set Enrichment Analysis. We examined proliferation capacity, response to therapy and signaling pathway.

Result and discussion

In total, 1371 proteins were identified and quantified in BJ-5ta cells and 1528 in HCT116 cells. The differentially expressed genes (DEGs) obtained among the control (C), coffee natural roasted (CNR), coffee anaerobic roasted (CAR), coffee natural unroasted (CNU), and coffee anaerobic unroasted (CAU) showed that 989 proteins in BJ-5ta cells and 51 in HCT116 cells showed significant changes. Fibroblast cells exhibited significant differences between the CNR group and groups (C, CAR, and CAU). The significant was an decrease in the proliferation capacity. qRT-PCR analysis revealed the changes in the expression of genes associated with the inhibition of proliferation.

Conclusion

This study provides a comprehensive overview of the effect of coffee extracts after different preparations (roasted and unroasted) on tumor tissue and the effect on healthy cells. The key pathway enrichment of the gene sets across the C, CNR, CAR, CNU, and CAU groups in BJ-5ta and HCT116 cell cultures was examined using GSEA in the KEGG database. Our study demonstrates that the most significant pathways across all groups were the Pentose phosphate pathway and the Ribosome pathway. The Gap junction pathway was found to be downregulated in BJ-5ta cells.

SoxC transcription factors are oncoembryonic regulators of colon development and cancer

T. Dalessi¹, T. Valenta¹, G. Moro¹, M. Brügger¹, A. Meij², S. Lampart¹, R. Platt², M. Scharl³, I. Arnold⁴, H. Fazilaty¹

¹University of Zurich, Department of Molecular Life Sciences, Zurich, Switzerland

²ETH, D-BSSE, Basel, Switzerland

³University Hospital Zurich, Department of Gastroenterology and Hepatology, Zurich, Switzerland

⁴University of Zurich, Institute of Experimental Immunology, Zurich, Switzerland

Introduction

Colorectal cancer is a leading cause of death worldwide and thus a major unmet medical need. The standard of care upon diagnosis consists of surgical removal and chemotherapy. Existing targeted therapies are suitable only for a small subset of patients with specific molecular features. Therefore, the identification of new genes and proteins involved in tumor progression as potential targets is necessary to improve therapeutic outcome. Recently, the reactivation of embryonic programs in tumors has emerged as a mechanism used by cancer cells to acquire malignant features. Understanding this reactivation at the molecular level may allow to identify new targets to attack cancer-specific features, avoiding toxicity to healthy cells.

Material and method

Colorectal tumors, healthy adult colon and developing colon of the mouse were compared at the transcriptional level, to identify “oncoembryonic” programs active during development and in cancer but not in homeostasis. Using a combination of scRNAseq, ATACseq and ChIPseq, the genetic networks and hierarchies inside these oncoembryonic programs were defined. The results were then validated in colon development using knock-out mouse models and in colorectal cancer using a colonoscopy-based injection of genetically modified and control cancer organoids. The clinical relevance of the results was assessed by analyzing human tumor data and comparing the expression of oncoembryonic genes and survival rates.

Result and discussion

We identified the family of SoxC transcription factors as critical regulators within these oncoembryonic programs. Indeed, developing colons depleted of SoxC displayed an impaired phenotype. The genetic network regulated by SoxC during colon development included genes such as Mdk, Tead2, and Klf4. In the murine colorectal cancer model, depletion of SoxC hindered tumor growth and affected similar downstream target genes as during development. The expression of SoxC transcription factors and their downstream target genes also correlated with poor survival in human colorectal cancer patients, underscoring the therapeutic potential of targeting SoxC-

regulated pathways in colorectal cancer treatment.

Conclusion

SoxC transcription factors emerged as key regulators of oncoembryonic programs in colon development and colorectal cancer. Targeting SoxC-regulated pathways in colorectal cancer may therefore be an innovative approach to hit cancer cells without harming healthy adult cells. More broadly, systematically comparing development and cancer thus emerged as a powerful framework to identify new molecular vulnerabilities in cancer cells with a strong translational potential.

EACR25-0135

Structural characterization of ligand binding to stabilin-2, the Hyaluronic Acid Receptor for Endocytosis (Stab2/HARE)

A. Twarda-Clapa¹

¹Lodz University of Technology, Institute of Molecular and Industrial Biotechnology, Lodz, Poland

Introduction

Studies of the past decades have demonstrated that endothelium lining the blood vessels in the liver, spleen, pancreas, and other organs and tissues plays an important scavenging role and acts as a gatekeeper of immunity. The function of one of the scavenger receptors, stabilin-2 (Stab2) or Hyaluronic Acid Receptor for Endocytosis (HARE), seems to be especially important in these processes, as well as in other physiological and pathologic states, including cancer. Stab2 is expressed by sinusoidal endothelium and other types of cells, including macrophages, acting as a scavenger receptor of more than 10 ligands. In terms of its importance in cancer, blocking Stab2 function effectively opposed cancer metastasis in mice. The decreased level of metastasis of melanoma cancer cells in the Stab2 knock-out mice was demonstrated, accompanied by a dramatic increase in the circulating HA level. A similar effect was observed after the administration of monoclonal antibodies, which suggests that blocking Stab2 function provides an interesting strategy to prevent metastasis. Moreover, the homotypic interaction of Stab2 plays a critical role in lymph node metastasis of tongue cancer, and the lack of expression of Stab2 in endothelial cells in peritumorous tissues was correlated with increased patient survival. Apart from HA, Stab2 is also a receptor for Advanced Glycation End-products (AGEs). AGEs constitute a non-homogenous, chemically diverse group of compounds formed either exogenously or endogenously on the course of various pathways in the human body. They gained the scientific community's interest due to the increasing evidence of their involvement in many pathophysiological processes and diseases, such as cancer, diabetes, aging, cardiovascular and neuro-degenerative diseases. The negative impact of the accumulation of excessive AGE levels is connected with inflammation and oxidative stress.

Material and method

Stab2 fragments were expressed and purified in bacterial or baculovirus system. The structure of the recombinant Fas1 Stab2 domain was solved by X-ray crystallography. Molecular modelling (homology modelling, docking) was used for ligand-receptor interaction characterization.

Result and discussion

I hereby present the high-resolution (1.48 Å) crystal structure of the seventh FAS1 domain of Stab2, which provided the first and only experimental information about the three-dimensional fold of a fragment of this receptor. Molecular models of putative HA and AGEs binding sites at Stab2 are also proposed.

Conclusion

The deciphering of the structural aspects of Stab2-ligand (HA, AGEs) interactions could facilitate the understanding of the signalling pathways triggered by this receptor and potentially serve as a novel protein target in anticancer strategy.

Receptor-like Tyrosine Kinase as a Promising Therapeutic Target in Pancreatic Cancer: Counteracting Wnt/β-catenin and Sonic Hedgehog/GLI1 Signaling

K. Yadav¹, P. Chaudhary¹, K. Ghimire¹, B. Jeong¹, J. Kim¹

¹Yeungnam University, College of Pharmacy, Gyeongsan, Korea (Republic of)

Introduction:

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with an exceptionally poor prognosis, as reflected in a 5-year survival rate of less than 8%. The complex molecular landscape underlying PDAC aggressiveness, which is characterized by genetic alterations, hyperactivation of receptor tyrosine kinases (RTKs), and dysregulated embryonic developmental signaling, poses a significant challenge to single-targeted therapies. Targeting key regulators of tumor signaling networks is essential for effective PDAC therapy.

Material and method

Cell viability was assessed using the MTT assay. A phospho-receptor tyrosine kinase (p-RTK) array assay was conducted to profile basal RTK activity and evaluate drug effects in pancreatic cancer cells. Co-immunoprecipitation assays were performed to examine the interaction between receptor-like tyrosine kinase (RYK) and EGFR. Small interfering RNA (siRNA) transfection was utilized to achieve RYK knockdown. The therapeutic efficacy of the treatment was evaluated in a pancreatic cancer xenograft mouse model.

Result and discussion

In the PANC-1 PDAC cell line, p-RTK array revealed that phosphorylated EGFR exhibited the highest basal activity, followed by IGF-1R and RYK. Co-immunoprecipitation assays demonstrated that RYK was cross-phosphorylated by EGFR. RYK knockdown led to increased phosphorylation of glycogen synthase kinase-3 beta (GSK3β) at serine 9 (S9), an inhibitory modification, without altering phosphorylated β-catenin levels. In addition, RYK silencing promoted nuclear translocation of GLI1, a key effector of the Sonic Hedgehog (Shh) signaling. Targeting the RYK-GSK3β axis with a 2,4-dimethylpyridin-3-ol analog of the multi-RTK inhibitor sunitinib induced cancer cell-selective cytotoxicity and exhibited potent antitumor efficacy in PDAC xenograft mouse model. Notably, unlike other multi-RTK inhibitors

such as sunitinib and gefitinib, especially the latter of which inhibited both EGFR and RYK, the sunitinib analog only suppressed Sonic Hedgehog (Shh)/GLI1 signaling. Moreover, this modulation reprogrammed macrophage polarization toward M1 phenotype, thereby enhancing cancer cell death in the tumor microenvironment.

Conclusion

Our study identifies RYK as a novel EGFR cross-phosphorylation target and functions as an upstream regulator of GSK3β. The RYK-GSK3β axis plays a critical role in counterbalancing both canonical Wnt signaling and RTK-mediated non-canonical Wnt/β-catenin signaling, as well as canonical and KRAS-driven non-canonical GLI1 activity. Pharmacological inhibition of the RYK-GSK3β using a 2,4-dimethylpyridin-3-ol analog of sunitinib effectively suppressed tumor growth, reprogrammed macrophage phenotypes, and inhibited metastasis, underscoring its potential as a promising therapeutic strategy against PDAC.

⁴University College Dublin, UCD School of Medicine, Dublin, Ireland

⁵St. Vincent's University Hospital, Department of Urology, Dublin, Ireland

⁶University College Dublin, UCD School of Biomolecular and Biomedical Science, Dublin, Ireland

Introduction

The five-year survival rate for metastatic prostate cancer (PCa) is only 30%. While androgen deprivation therapy, the standard of care treatment, initially proves effective, inevitable development of castration resistance renders the disease incurable. Therefore, novel therapeutic approaches are urgently needed to improve treatment options & outcomes for aggressive PCa. Cannabinoids have shown promising anticancer properties & potential to enhance efficacy of existing therapies. Cannabidiol (CBD), a major non-psychotropic cannabinoid, reduces PCa cell viability & alters expression of key cell cycle proteins. However, the mechanism by which CBD enters PCa cells remains unclear. This study aims to identify receptors involved in modulating CBD activity in PCa cells.

Material and method

mRNA expression of cannabinoid receptor 1 (CNR1), CNR2, transient receptor potential vanilloid 1 ion channel (TRPV1), TRPV2, G protein-coupled receptor 55 (GPR55), GPR18, GPR19, TRP ankyrin 1 (TRPA1), TRP melastatin 8 (TRPM8), peroxisome proliferator-activated receptor gamma (PPARG), & fatty acid amide

hydrolase (FAAH) in 7 prostate cell lines (6 cancerous; DU145, PC-3, LNCaP, 22Rv-1, C4, LNCaP Abl, and 1 non-cancerous; PWR1E) was established via RT-qPCR. DU145 cells were seeded in a 6-well plate & transfected with 10 nM non-targeting pool (control) or PPARG siRNA for 24hr. After 24hr, cells were trypsinised & re-seeded in a 96-well plate. Cells were treated with the vehicle (DMSO) or CBD IC₅₀ value (11.07 μM). After 72hr treatment, cell viability was measured using the MTT assay.

Result and discussion

CNR1, CNR2, GPR55, & GPR18 were not expressed in any cell lines. TRPV1 & TRPV2 were expressed across all cell lines at low-to-medium levels ($5 < \Delta Ct < 20$). TRPM8 was expressed exclusively in androgen receptor (AR)-positive PCa cell lines (LNCaP, 22Rv-1, C4, & LNCaP Abl) at low levels ($10 < \Delta Ct < 20$). TRPA1 was solely expressed in the non-cancerous cell line ($\Delta Ct = 12.22$). GPR19 & FAAH were expressed to varying extents across all cell lines. Finally, PPARG was widely expressed at medium-to-high levels ($4 < \Delta Ct < 10$), with AR-negative cell lines (DU145 & PC-3) having the highest expression ($\Delta Ct = 7.61$ & 4.54 respectively). siRNA-knockdown of PPARG had no effect on the efficacy of 72hr CBD treatment on DU145 cells.

Conclusion

Having established gene expression levels of 2 known & 5 novel cannabinoid receptors in PCa cells, the receptors will be systematically knocked down & treated with CBD to assess the role of receptors in the mechanism of action of CBD. Results indicate that PPARG is not involved in CBD's mechanism of action in DU145 cells. Receptors may be knocked down in pairs &/or groups depending on results of individual knockdown experiments. These findings provide a foundation for further investigation into receptors mediating CBD's effect on PCa cells, which may ultimately inform the development of targeted therapeutic strategies for advanced prostate cancer.

EACR25-0404

Role of intracrine VEGFA-VEGFR1 signaling in BRAF mutated melanoma

V. Sarlo¹, A. Gualandris¹, S. Parab¹, L. Palmiotto¹, S. Capellero², G. Villari¹, F. Bussolino¹, V. Comunanza¹

¹*University of Turin, Department of Oncology, Turin, Italy*

²*University of Turin, Department of Veterinary Science, Turin, Italy*

Introduction:

Despite recent advances in prevention and treatment, melanoma remains an aggressive and deadly malignancy. Moreover, therapy-driven resistance is still a major obstacle in the clinical management of the metastatic disease. These findings highlight the need to further elucidate mechanisms underlying melanoma growth and progression. VEGF/VEGF receptors axis represents an attractive target for combinatorial cancer therapy. It has been demonstrated that its role is not limited to angiogenesis and immuno-suppression, but VEGFA mediated signalling may also occur in tumour cells. However, how VEGF receptors contribute to tumorigenesis and tumor progression remains largely unclear. Here we

investigated the biological role of VEGF receptor 1 (VEGFR1) in melanoma cells.

Material and method

VEGFR1 loss-of-functions strategy was based on gene silencing (shRNA) in BRAF-mutated melanoma cell lines D4M, YUMM 3.3 and A2058. Cell proliferation was assessed by CellTiter Glo assay. Individual cell migration was investigated using time-lapse video microscopy. Tumor spheroids were produced according to the hanging drop methods. In situ proximity ligation assay (PLA) was executed with Duolink® Detection Reagents kit (Merck). VEGFR1 localization was assessed by Subcellular protein fractionation kit (Thermo).

Result and discussion

We observed that VEGFR1 was highly expressed in different melanoma cell lines and its silencing reduced in vitro growth and motility in 2D culture, independently of exogenous VEGFA stimulation. We demonstrated that VEGFR1 was needed for fast and directional cancer cell migration, through actin re-organization. In addition, we observed that VEGFR1 silencing altered melanoma invasive activity in 3D spheroids, decreasing cell protrusions into the extracellular matrix. Furthermore, PLA confirmed the intracellular VEGFA-VEGFR1 association and cell fractionation showed a nuclear localization of VEGFR1. These results suggested that VEGFR1 may be involved in gene expression regulation. Then, we performed RNA-seq that validated the role of VEGFR1 in the control of cell proliferation and cell migration. Moreover, RNA-seq revealed also the involvement of VEGFR1 in the amino acids metabolism. In particular, VEGFR1 silencing impaired the expression of genes involved in serine and proline metabolism (PYCR1, ALDH18A1, PHGDH, PSPH). Interestingly, both the pathways are mainly regulated by ATF4 (activating transcriptional factor 4) that we found expressed in close proximity to VEGFR1, also in the nucleus.

Conclusion

Collectively, these findings suggest that VEGFR1 is involved in growth, spreading and metabolism of tumor cells. Since melanoma cells were never treated with recombinant exogenous VEGFA, we suggest that VEGFR1 is activated by VEGFA in an autocrine fashion. Furthermore, the nuclear expression of VEGFR1 and its colocalization with ATF4 indicates a possible role of VEGFR1 as a coactivator of transcriptional program.

EACR25-0405

Self-antigen presentation drives T-cell leukemia development in a TCR transgenic mouse model

M. C. Baessa¹, N. R. dos Santos¹

¹*i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal*

Introduction

T cell acute lymphoblastic leukemia (T-ALL) is a malignant disorder characterized by development arrest of immature T cells, followed by their rapid proliferation and dissemination. The T cell receptor (TCR), plays an essential role in T cell development, since its interaction with MHC-bound self-antigens defines T cell fate during

positive and negative selection in the thymus. Since many T-ALL cases exhibit TCR on their leukemic cells, we aimed to understand the TCR role in leukemia development, and the impact of leukemic cell antigenic stimulation.

Material and method

A cohort of Rag2^{-/-} mice expressing transgenic TCR OT-I, which is responsive to the SIINFEKL ovalbumin peptide (OVA), were generated and followed for 12–14 months. Leukemic cells underwent immunophenotypic analysis by flow cytometry and, to confirm their malignant nature, OT-I leukemic cells were injected into Rag2^{-/-} recipient mice. Both leukemic and non-leukemic OT-I T cells were stimulated *in vitro* with OVA to activate the TCR pathway. Activation of the TCR pathway was also achieved through PMA/Ionomycin and anti-CD3 monoclonal antibody. Activation status was assessed by induction of T cell activation marker CD69 by flow cytometry.

Result and discussion

Around 60% of TCR OT-I mice developed a T-ALL-like disease, characterized mainly by thymic lymphoma, increase of white cells in the blood and dissemination to lymphoid and non-lymphoid organs. This malignant transformation occurred through basal TCR signaling, since the ablation of this interaction by β2-microglobulin gene knockout impaired disease development. Malignant cells were found to express CD90, CD4, CD8, CD24, CD5 and TCRβ, confirming the development of a T cell leukemia. When injected in recipient mice, these cells led to a rapid development of fatal leukemia. Surprisingly, when treated with OVA, most OT-I leukemic cells did not upregulate CD69 and those that did had low levels compared to healthy OT-I lymphocytes. The responsiveness patterns were similar when the TCR pathway was activated by anti-CD3 or PMA/Ionomycin.

Conclusion

These findings show that transgenic TCR OT-I leads to T cell leukemia through basal TCR signaling by presentation of self-peptides to the receptor. However, upon malignant transformation, the TCR is less responsive to antigenic stimulation. Further research is needed to understand why leukemic cells do not upregulated CD69 when OT-I TCR is stimulated.

EACR25-0443

Novel interactions of Mixed-Lineage Kinase 4: identifying key binding partners in breast cancer

V. Truong¹, D. Mehlich¹, D. Dymerska-Zaremba¹, A. Marusiak¹

¹*The International Institute of Molecular Mechanisms and Machines Polish Academy of Sciences, The Laboratory of Molecular OncoSignalling, Warsaw, Poland*

Introduction

Mixed-Lineage Kinase 4 (MLK4) is frequently over-expressed in various cancer types and linked to poor prognosis. MLK4 can enhance migration, invasiveness, DNA damage response, and chemoresistance in triple-negative breast cancer (TNBC). Despite growing evidence implicating MLK4 kinase in tumorigenesis, the

underlying molecular mechanisms of MLK4 signaling in cancer progression remain largely unexplored, emphasizing the necessity for further investigation. Hence, this study aims to investigate the MLK4 interactome to uncover its molecular mechanisms driving cancer advancement and aid therapy development.

Material and method

To achieve this goal, we employ coimmunoprecipitation (co-IP) coupled with mass spectrometry to investigate the MLK4 interactome in TNBC cells – HCC1806. Then, the candidates are validated by co-IP followed by immunoblotting, immunofluorescent and fractionation experiments. An *in vitro* kinase assay using inactive GST-MLK4β kinase domain is applied to determine whether any candidates are MLK4 direct substrates. Moreover, phenotypic assays such as colony formation, migration and comet assay are conducted to elucidate the functional implications of these interactions in cancer cells.

Result and discussion

The 54 new interactors of MLK4 were identified. They were involved in cell cycle, PI3K/Akt and MAPK signaling. These hits were mostly present in cytosol, nucleus or plasma membrane in cellular component terms. Afterward, 14-3-3 – the anchored protein, GNL3 – a nucleolar protein, MLK1 – another MLKs member, RAN – a RAS-related nuclear protein and MYBBP1A - a transcriptional regulator, were validated as potential MLK4 binding partners. MYBBP1A is chosen for further validation because it modulates p65 (NF-κB) activity, which is regulated by MLK4 in DNA damage and chemoresistance in TNBC cells (Marusiak 2019, Mehlich 2021). The interaction of MLK4 and MYBBP1A localizes in the nuclei, which was confirmed by co-staining and fractionation experiments. Interestingly, silencing of MLK4 decreased the binding of MYBBP1A and p65, suggesting that MLK4 may act as a molecular anchor, bridging this interaction. Notably, this interaction is disrupted under doxorubicin treatment, indicating a dynamic regulatory response to chemotherapy.

Conclusion

The interaction of MLK4-MYBBP1A was selected for deeper validation to understand the molecular mechanisms of MLK4 signaling promoting cancer progression. We confirmed the interaction between MLK4 and MYBBP1A in the nuclei under basal conditions. We also observed that MLK4 enhanced the interaction of MYBBP1A and p65. Moreover, this interaction may be interrupted upon therapeutic treatment. Further study will investigate the functional roles of this network in DNA damage response through p65 signaling and the novel nuclear function of MLK4 in regulating cancer cell behaviors.

EACR25-0621

H19 Non-Coding RNA expression in Bladder Cancer Tissue as a marker of progression and therapy resistance

H. Piekarczyk¹, T. Konecki², Z. Jabłonowski², A. Zmysłowska¹, E. Borkowska¹

¹*Medical University of Lodz, Department of Clinical Genetics, Lodz, Poland*

²Medical University of Lodz, 1st Clinic of Urology, Lodz, Poland

Introduction

Bladder cancer (BC) is one of the most common urological malignancies, with high recurrence and progression rates. Long non-coding RNAs (lncRNAs) have emerged as key regulators of cancer development, with H19 being one of the most studied lncRNAs in various cancers, including BC. H19 is implicated in tumor proliferation, invasion, and drug resistance. This study aims to evaluate the expression levels of H19 in bladder cancer tissues using the real-time PCR (qPCR) method and assess its potential role as a biomarker for BC.

Material and method

Bladder cancer tissue samples and adjacent normal tissues were collected from patients undergoing surgical resection. Total RNA was extracted, and cDNA synthesis was performed. The expression of H19 was quantified using real-time PCR with specific primers and normalized to housekeeping genes. Statistical analyses were conducted to determine the correlation between H19 expression and clinicopathological characteristics.

Result and discussion

H19 was significantly upregulated in bladder cancer tissues compared to adjacent normal tissues. H19 expression correlated with higher tumor grade, advanced stage, and progression ($p = 0.0117$), but not with the increased risk of recurrence ($p = 0.05$). It was confirmed that survival predictions are significantly different in the groups of patients with high-grade and low-grade cancers ($p = 0.02101$). The real-time PCR method provided highly sensitive and reproducible quantification of H19 expression levels.

Conclusion

In summary, lncRNA H19 could be a critical factor in bladder cancer progression and therapy resistance. Understanding its mechanisms offers avenues for developing targeted therapies to improve treatment efficacy. Real-time PCR is a reliable method for detecting H19 expression, highlighting its potential application in BC diagnosis and prognosis. Further studies are needed to explore the functional role of H19 and its therapeutic implications in bladder cancer.

EACR25-0665

APRIL-induced feedback loop regulating BCMA expression in Multiple Myeloma

M. Faber¹, S. Stotz¹, K. Irlinger¹, A. Augsburger¹, C. Klement², R. Rad^{2,3}, M. Schmidt-Supplian^{4,3}, L. Rieger¹, F. Bassermann^{1,5,6}

¹TranslaTUM, Klinik und Poliklinik für Innere Medizin III, Munich, Germany

²TranslaTUM, Institute of Molecular Oncology and Functional Genomics, Munich, Germany

³Translational Cancer Research, Heidelberg, Germany,

⁴TranslaTUM, Institute of Experimental Hematology, Munich, Germany

⁵German Cancer Consortium of Translational Cancer Research, Heidelberg, Germany, BZKF

⁶Bavarian Center for Cancer Research, Munich, Germany,

Introduction

The B-cell maturation antigen (BCMA; TNFRSF17), primarily expressed on both healthy and malignant plasma cells, has become a prominent target for immune cell therapies in B-cell malignancies and diseases such as multiple myeloma (MM) and certain autoimmune diseases. These therapies include chimeric antigen receptor (CAR) T cells and bispecific T cell engagers (BiTEs) targeting BCMA. MM growth and survival are mediated by APRIL (A proliferation-inducing ligand) binding to BCMA, triggering NF-κB signaling. Here, we investigate a potential feedback mechanism in MM that enhances BCMA expression via APRIL-induced NF-κB activation.

Material and method

To investigate the functional relationship between NF-κB activity and BCMA expression, NF-κB activation and suppression were modulated using either cytokines and APRIL or small-molecule inhibitors and doxy-inducible shRNA knockdown (KD). The analysis was performed at both the mRNA and protein levels using quantitative PCR (qPCR) and immunoblotting, respectively. To visualize APRIL-mediated NF-κB signaling, we examined nuclear translocation through cellular fractionation followed by immunoblotting and complemented this with immunofluorescence (IF) analysis. Genomic analysis was performed to identify potential NF-κB binding motifs in regions regulating TNFRSF17 transcription. Chromatin immunoprecipitation (ChIP) in MM cells in response to APRIL stimulation was used to investigate binding of NF-κB to the selected regions of BCMA. NF-κB binding to targeted genomic regions was quantified by q-PCR.

Result and discussion

We observed that enhanced NF-κB activity was associated with increased BCMA mRNA and protein levels, while suppression of NF-κB resulted in a corresponding decrease in MM cells. Notably, APRIL-induced activation of NF-κB and its subsequent nuclear translocation led to significant upregulation of BCMA protein levels, an effect abolished by either pharmacological inhibition of NF-κB or tet-on shRNA-mediated KD of RELA (NF-κB, p65). ChIP experiments revealed that NF-κB regulates TNFRSF17 transcription, a process enhanced upon APRIL stimulation.

Conclusion

Here, we identify a previously unexplored positive feedback loop in which BCMA promotes its own expression through APRIL-induced NF-κB activation. These findings suggest that this specific feedback mechanism and its interplay with the bone marrow niche may contribute to MM progression and survival.

EACR25-0694

Decipher the Roles of IL-6 Signaling in CTPS Filament-mediated Cancer Progression

C. Wang¹, L. Pai^{1,2}

¹Graduate Institute of Biomedical Sciences, Chang-Gung University, Taoyuan, Taiwan

²Department of Biochemistry, Chang-Gung University, Taoyuan, Taiwan

Introduction

CTP synthase (CTPS) filament forms in cancer cells, which reprograms nucleotide metabolism for stress adaptation under glutamine (Gln) deprivation. While research on the physiological effects of CTPS filament is developing, only a few regulators of CTPS filament formation have been identified. Here, we propose that IL-6, a extracellular protein overproduced by HEp-2 cancer cell under Gln-free (Gln(-)) and serum-free (S(-)) conditions, served as an external signal to enhance the CTPS filament formation. IL-6 is a pro-tumor cytokine that remodels the activities and differentiation of immune cells, but few studies discuss its influence on the protein compartmentalization.

Material and method

We performed a screen by comparing the extracellular proteins secreted by the cells cultured in the Gln(-)S(-) conditions with those in the Gln(+)S(+) conditions, and identified IL-6 as a top elevated protein. We used IL-6 antibodies to block effects of IL-6 signaling in the HEp-2 and HCT116 cancer cells and examined their CTPS filament formation. We also added exogenous recombinant human IL-6 into the conditional medium to enhance IL-6 signals. Small molecule inhibitors targeting IL-6 downstream pathways were used to determine the critical signals regulating CTPS filament formation.

Result and discussion

We identified a role of IL-6 in enhancing, but not inducing, CTPS filament formation in HEp-2 and HCT116 under Gln(-)S(-), and it is mediated by IL-6 downstream signaling pathway. Our data indicate that IL-6 is a critical factor to regulate CTPS filament formation, therefore we are currently dissecting its molecular mechanism by investigating the connection between CTPS filament-associated proteins and ERK downstream signatures.

Conclusion

Here we demonstrate that the IL-6-downstream signaling axis regulates CTPS filament formation, which may facilitate the adaptation of cancer cells in nutritional stress. The value of therapeutic strategy by hindering CTPS filament formation is brought out with its universally-conserved feature in different types of cancer cell. We will further decipher the detailed molecular mechanism and to provide a widely-effective anti-cancer therapeutic strategy combining CTPS filament formation and IL-6 signaling.

EACR25-0838

SRF fusions act as hyperactivated transcription factors in pediatric tumors

C. Pirson¹, A. Sablon¹, J. Demoulin¹

¹de Duve Institute, Brussels, Belgium

Introduction

Soft tissue tumors expressing muscle markers, including perivascular tumors, myofibroma, and rhabdomyosarcoma, have been associated with chromosomal translocations leading to SRF fusion genes. The Serum Response Factor (SRF) is a transcription factor that regulates muscle development via TCF or MRTF cofactors. We characterized four SRF fusion genes: SRF::RELA, SRF::FOXO1, SRF::ICA1L, and SRF::

PDGFRB, to assess their molecular mechanisms and oncogenic potential.

Material and method

To investigate the properties of SRF fusion proteins, we transfected their constructs into mammalian cells and analyzed their subcellular localization using fluorescence microscopy. Their transcriptional activity was evaluated through luciferase reporter assays, while co-immunoprecipitation assays assessed dimerization. To study their oncogenic potential, we performed cell proliferation assays and tested their sensitivity to imatinib. Muscle differentiation was studied by fluorescence microscopy, examining the expression of differentiation markers. Transcriptomic analyses were conducted to compare gene expression profiles between cell lines and tumor samples carrying SRF fusions. Additionally, BioID experiments were performed to identify protein interaction partners of the fusion proteins.

Result and discussion

All SRF fusion proteins localized to the nucleus and exhibited constitutive transcriptional activity, independent of MRTF or TCF cofactors, unlike wild-type SRF. This required the SRF MADS box for DNA binding and the partner transactivation domain. Interestingly, we identified a cryptic transactivation domain in the cytosolic protein ICA1L. In contrast, SRF::PDGFRB functioned differently, relying on its tyrosine kinase domain for activity. It transformed Ba/F3 cells, demonstrating oncogenic potential, and was inhibited by imatinib, suggesting therapeutic relevance. Most SRF fusions increased cell proliferation and altered muscle differentiation genes, except SRF::PDGFRB, which induced STAT1 signaling and an interferon-like response. We observed a correlation in gene expression between cell line and tumors bearing the same SRF fusion.

Conclusion

Most SRF fusions act as hyperactivated transcription factors, driving oncogenesis in myoid soft tissue tumors by deregulating muscle differentiation and increasing cell proliferation. The MADS box is crucial for dimerization and transcriptional activity. SRF::PDGFRB, acting as a tyrosine kinase-driven oncogene, is sensitive to imatinib. Gene expression similarities between cell models and tumors highlight their biological relevance.

EACR25-0963

The Serine/Threonine phosphatase POPX2 and its effects on cell mechano-sensing

C. Theng Xuan¹, Z. Song Jing¹, K. Cheng Gee¹

¹Nanyang Technological University, Singapore, Singapore

Introduction

POPX2 is a serine/threonine phosphatase from the PP2C family. It has been reported that POPX2 levels positively correlate to the invasiveness and motility of cancer cells. POPX2 dephosphorylates and downregulates p21-activated kinase (PAK) activity. Through POPX2's interaction with the PAK-interacting guanine nucleotide exchange factor (PIX), it is thought to participate in the maintenance of focal adhesions (FAs) and actin stress fibers (SFs). FAs are formed from the recruitment of FA

proteins (FAPs) to the cell surface membrane upon the interaction of integrin receptors with the extracellular matrix (ECM). Actin SFs which are linked to the FAPs allow cells to exert pulling forces on the ECM. The physical characteristics of the ECM are then fed back to the cells through the FAs in a process known as mechano-sensing. In this study, we investigated the effects of POPX2 on mechano-sensing.

Material and method

Control (ctrl-3T3) and POPX2-overexpressing NIH3T3 (X2-3T3) mouse embryonic fibroblasts were seeded onto fibronectin-coated polyacrylamide gels of 4 different rigidities: 6kPa, 14kPa, 31kPa, and 61kPa. Changes in cell morphology, FA, and SF formation were observed using immunofluorescence microscopy. Traction force microscopy was performed to measure changes in cell-generated traction stress. Cell lysates were prepared for Western blot analysis to identify changes in pathways implicated in mechano-sensing.

Result and discussion

Our results show that X2-3T3 cells display higher cell spreading area, actin intensity, FA area, and FA number compared to ctrl-3T3 cells across all substrate rigidities. We also confirmed that cells plated on stiffer ECM are more well spread and contain more FAs. X2-3T3 cells were found to generate greater traction stress compared to ctrl-3T3 cells across a range of substrate rigidities. Our data suggest that POPX2 could facilitate rigidity sensing. We are now in the process of exploring different mechanosensors which may be regulated by POPX2 signalling.

Conclusion

In this study, we found that NIH3T3 cells expressing high levels of POPX2 exhibit a more well spread morphology, more robust actin SFs and contain more FAs. Our observations also suggest that POPX2 could promote rigidity sensing.

EACR25-0964

IL-6/STAT3 Regulates Solid Stress Enhanced Migration and Invasion in Breast Cancer Cells

R. Sheriff¹, F. Azizan¹, C. Koh¹

¹Nanyang Technological University, School of Biological Sciences, Singapore, Singapore

Introduction

While tumour cells are known to respond to biochemical signals, the influence of physical and mechanical cues is increasingly more recognised. Solid stress compression, a prevalent biomechanical force in the tumour micro-environment that accumulates alongside tumour growth, has been associated with enhanced invasive and metastatic phenotypes in various cancer cells. When a tumour mass rapidly expands within the body, it pushes on surrounding tissues, which in turn exerts an equal and opposite force on the tumour. This phenomenon is known as solid stress compression. In this study, we investigated the effects of solid stress compression on breast cancer cells.

Material and method

We applied solid stress compression on MBA-MD-231 breast cancer cells using a 2D in-vitro compression setup.

To mimic the varying solid stress pressures experienced by cells at the periphery of the tumour mass, three incremental solid stress compressions were applied: 386.5 Pascal (Pa), 773.0 Pa (the estimated breast tumour microenvironment pressure), and 1546.0 Pa. The cells were plated on transwell insert membrane of 0.4 μm pore size. The compression weights are cushioned with 2% agarose disks of ~3mm thickness to ensure even pressure on the cell monolayers. After 16 hours of compression, the cells were harvested for further experiments. Cell lysates were prepared for western analysis and RNA was extracted for RNA-sequencing. Migration assays were also conducted to monitor the effects of compression on cell migration.

Result and discussion

Our findings revealed that MDA-MB-231 cells under incremental solid stress compression exhibited enhanced migration and followed a biphasic trend. Migratory and invasive capacities were elevated at 386.5 Pa, peaked at 773.0 Pa, and reduced but remained elevated at 1546.0 Pa as compared to uncompressed control cells. Global transcriptome analysis found upregulation of many genes, including Interleukin-6 (IL-6), a vital cytokine in breast cancer progression and metastasis. Western blot analysis demonstrated that solid stress upregulated protein levels of IL-6 and SNAI1, as well as IL-6 secretion. STAT3, the main transducer of IL-6 signalling, also showed elevated phosphorylation status with increasing solid stress. Our data suggest solid stress compression leads to the activation of the IL-6/IL-6 receptor/STAT3 signalling pathway.

Conclusion

This study, for the first time, links solid stress compression to the upregulation of IL-6. In the context of breast cancer, solid stress appears to elicit a more aggressive phenotype through the upregulation of genes such as IL-6 and SNAI1. Solid stress compression also leads to increased secretion of IL-6, which might act in autocrine and paracrine manners to activate IL-6 signalling and upregulate downstream gene targets such as SNAI1.

Characterizing the Transition from Well-Differentiated to Anaplastic Thyroid Cancer Using Digital Spatial Profiling

B. Donati¹, F. Torricelli¹, C. Ascione¹, V. Manicardi¹, S. Piana¹, D. De Biase², G. Tallini^{3,4}, A. Ciarrocchi¹, G. Manzotti⁵

¹Azienda USL - IRCCS di Reggio Emilia, Translational Research Laboratory, Reggio Emilia, Italy

³University of Bologna, Dipartimento di Scienze Mediche e Chirurgiche (DIMEC), Bologna, Italy

⁴IRCCS Azienda Ospedaliero-Universitaria Policlinico S. Orsola di Bologna, Laboratorio Interaziendale di Patologia Molecolare dei Tumori Solidi, Bologna, Italy

⁵Translational Research Laboratory, Translational Research Laboratory, Reggio Emilia, Italy

Introduction

Anaplastic thyroid cancer (ATC) is a rare, aggressive form of thyroid cancer with a mortality rate exceeding 80%. Unlike differentiated thyroid cancers (DTC), ATC are refractory to standard therapies. Research suggests that ATC typically develops from pre-existing DTC, accumulating molecular alterations and becoming undifferentiated and aggressive. The mechanisms driving this transition are poorly understood, and further investigation is crucial for developing targeted therapies and personalized prognostic tools. Recent studies, including some of our own, have identified potential drivers of ATC development, but a comprehensive understanding of their interconnected roles remains elusive.

Material and method

We leveraged the GeoMx™ Digital Spatial Profiler, enabling us to precisely separate and analyze the ATC and DTC components within the same biphasic samples with high spatial resolution. Using PanCK and TTF1 as distinguishing markers, we identified 203 regions of interest (ROIs) across seven samples and sequenced the transcriptome of each ROI using the Whole Transcriptome Atlas panel. We performed RNA-seq on a larger, independent cohort of FFPE samples from pure DTC and pure ATC to validate these findings.

Differential analyses were performed to identify relevant altered pathways while, to investigate the TFs driving the transcriptional program, we used different motif search algorithms. The biological role of these putative drivers will be validated using knockdown (KD) techniques to mimic the observed alterations. Specifically, TFs upregulated or associated with ATC will be silenced in ATC cell lines to assess whether KD can mitigate aggressiveness. Conversely, TFs upregulated or associated with DTC will be silenced in DTC cells to determine if KD can induce dedifferentiation and increase aggressiveness.

Result and discussion

Differential analysis comparing DTC and ATC ROIs identified 2193 differentially expressed genes (DEGs) in ATC, with 1339 UP-regulated and 854 DOWN-regulated. Gene Ontology analysis revealed five key pathway clusters altered in the transition, providing insight into the underlying biological processes: EMT, cell cycle, thyroid hormone-related processes, immune system, and metabolism. We also focused on the TFs driving the transcriptional program underlying this transition. We considered both TFs present in the DEGs list and TFs upstream of these DEGs, identified through a bioinformatics approach. Following manual and literature-based curation of these two lists, we generated a shortlist of 20 candidate TFs, equally divided between TFs associated with UP-DEGs and those associated with DOWN-DEGs.

Conclusion

This study will provide a detailed characterization of the DTC-ATC transition by identifying all relevant interconnected pathways and the TFs most likely to play a pivotal role in the transition, thus also revealing potential therapeutic targets for restraining ATC aggressiveness.

EACR25-1023

Histone deacetylase inhibitors (HDACi) downregulate HER2 protein expression in gastric cancer, leading to pronounced HDACi sensitivity in tumor cells with high basal HER2 expression

T. Zenz¹, H. Borchardt¹, R. Jenke¹, T. Büch¹, A. Aigner¹

¹Leipzig University, Rudolf-Boehm-Institute for Pharmacology and Toxicology, Clinical Pharmacology, Leipzig, Germany

Introduction

Gastric carcinoma represents a major cause of cancer-associated deaths. Cytoreductive chemotherapeutic drugs and targeted therapeutics established for this entity usually show only rather unsatisfactory effects and the use of immunotherapeutics is only promising in a small proportion of patients. In gastric carcinoma with HER2 overexpression (about 10–20% of cases), the use of HER2 inhibiting therapeutics has shown some effectiveness, although resistance almost always occurs during the course of the disease. The present study aimed at investigating the effect of histone deacetylase inhibitors (HDACi) on the expression and signal transduction of HER2 in gastric carcinoma and elucidating differences in susceptibility to HDACi in gastric carcinomas with high vs. low HER2 expression.

Material and method

Basal or HDACi-altered HER2 expression was investigated in a panel of human gastric carcinoma cells and in tissue slice cultures of cell line- and patient-derived xenografts. The phosphorylation of AKT and the expression of p21 were recorded as downstream signaling pathways. The antitumor effect of HDACi was delineated by formazan-based WST assays, colony forming assays, cell cycle analyses and annexin V/PI staining.

Result and discussion

Treatment with HDACi led to a significant reduction in HER2 protein levels in the investigated cells. In line with this reduced HER2 protein expression, a reduction in AKT phosphorylation and p21 induction was observed as well. Interestingly, the proliferation/cytotoxicity assays showed that cell lines with a high basal HER2 expression (before treatment with HDACi) were significantly more sensitive to HDACi than cell lines with a low basal HER2 level.

Conclusion

The HER2 expression level of gastric cancer cells represents a factor affecting the susceptibility against HDACi. Of note, previous clinical trials (which were unsuccessful) on the efficacy of HDACi in gastric cancer patients did not include patients with high HER2 expression in the tumor tissue; this strategy may have excluded those patients who could in particular benefit from HDACi due to their additional HER2 inhibitory action.

EACR25-1066

Uncovering the paraspeckle-dependent and independent role of NONO in transcriptional regulation in Multiple

Myeloma

D. Ronchetti¹, A. Devecchi², I. Silvestris¹, V. Traini¹, G. Fabbiano³, I. Craparotta⁴, L. Agnelli², F. Passamonti³, N. Bollì¹, E. Taiana³

¹University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Diagnostic Innovation, Milan, Italy

³IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Hematology, Milan, Italy

⁴Mario Negri IRCCS, Computational Oncology Unit, Oncology Department, Milan, Italy

Introduction

Multiple myeloma (MM) is a malignant disease of bone marrow plasma cells (PCs) with variable outcomes. Despite advances in treatment, MM remains incurable. LncRNA NEAT1, a scaffold for the paraspeckle (PS) organelle, plays a critical role in DNA repair and cell survival in MM. NONO, a protein involved in NEAT1 stability and PS, is upregulated in MM and correlates with poor overall survival and progression free survival. Besides its role in PSs, NONO may have independent functions in MM cells. We plan to investigate NONO's role in modulating the transcriptome of MM PCs through NGS and assess its contribution within and independently of PSs.

Material and method

RNA was extracted from NONO-KD, NEAT1-KD, and scramble AMO1 and LP1 human MM cell lines (HMCLs). RNA-seq libraries were prepared using Illumina's Stranded TotalRNA PrepLigation protocol. Sequencing was done on an Illumina Novaseq. CoMMpass data were retrieved from the Interim Analysis 15a.

Result and discussion

RNA-seq data from NONO-KD or NEAT1-KD AMO1 and LP1 HMCLs were compared to identify overlapping pathways. Significant downregulation was observed in gene sets associated with chromatin modifications, WNT/β-catenin, and NOTCH signalling in NEAT1 and NONO silenced cells. RNA-seq data from AMO1 HMCL over-expressing NEAT1 and PSs confirmed a significant and positive modulation of the same pathways. Further validation was obtained by stratifying samples from the CoMMpass dataset based on NONO expression levels, comparing the expression profiles between the two extreme quartiles, and conducting GSEA on the list of differentially expressed coding genes. Since NONO is essential for protecting NEAT1 from degradation, its silencing results in a marked downregulation of NEAT1 expression levels, thereby impacting the transcriptome of NONO-silenced cells in a NEAT1-dependent manner, making it impossible to distinguish NONO's effects independent of PSs. However, the analysis of data from the extreme quartile of NONO in CoMMpass dataset enabled the identification of NONO specific pathways not shared with NEAT1-KD HMCLs, which may suggest pathways that NONO regulates independently of PS in MM cells. This analysis revealed NONO's involvement in RNA splicing or maturation, cellular RNA trafficking to the cytoplasm, as well as its role in mitochondrial biogenesis and cell-matrix adhesion.

Conclusion

NONO plays complex transcriptional roles in MM, influencing pathways critical for disease progression. The in-silico validation further supports the clinical relevance of these findings, highlighting the value of the HMCLs model in advancing our understanding of MM.

EACR25-1199

Protective Role of Thymosin Beta 4 Against Sarcopenia via Regulation of PI3K/Akt/mTOR and NLRP3 Signaling Pathways in C2C12 Myotubes

J. Choi¹, J. Kwon¹

¹Jeonbuk National University, College of Veterinary Medicine, Iksan-si, Korea (Republic of)

Introduction

Sarcopenia, characterized by progressive skeletal muscle loss and functional decline, is a major health concern associated with aging and chronic diseases such as diabetes. Oxidative stress and glucocorticoid exposure are known contributors to muscle atrophy. Thymosin beta 4 (Tβ4), a multifunctional peptide with anti-inflammatory and cytoprotective properties, has shown potential as a therapeutic agent; however, its role in sarcopenia remains unclear. This study aimed to evaluate the protective effects of Tβ4 against D-galactose- and dexamethasone-induced muscle atrophy in C2C12 myotubes and to elucidate the underlying molecular mechanisms.

Material and method

C2C12 myoblasts were differentiated into myotubes over six days and treated with Tβ4 (0.1, 0.4, and 1.6 μg/mL) for 24 hours. Sarcopenia-like conditions were induced using D-galactose (50 mM) and dexamethasone (100 μM) for an additional 24 hours. Gene and protein expressions were analyzed via RT-PCR and Western blotting to assess myogenic factors (MyoD, Myogenin, Myo1D), atrophy-related genes (MuRF1, Atrogin-1), autophagy markers (p62, LC3A/B, Atg3), and components of the PI3K/Akt/mTOR pathway. The involvement of the NLRP3 inflammasome (NLRP3, IL-1β, IL-18, TNF-α), apoptotic regulators (Caspase-1, Bax, Bcl-2), and IGF-1 was also examined.

Result and discussion

Tβ4 treatment significantly alleviated muscle atrophy in C2C12 myotubes. It restored the expression of MyoD and Myogenin while reducing MuRF1 and Atrogin-1 levels. Tβ4 modulated autophagy by decreasing p62 accumulation and LC3A/B ratios and suppressed NLRP3 inflammasome activation, as evidenced by decreased levels of NLRP3, IL-1β, and IL-18. Additionally, Tβ4 reduced pro-apoptotic markers Bax and Caspase-1 and increased anti-apoptotic Bcl-2 expression. IGF-1 levels were also enhanced, suggesting improved anabolic signaling and muscle regeneration. These results indicate that Tβ4 protects muscle cells from atrophy through coordinated regulation of protein degradation, inflammation, and apoptosis.

Conclusion

In conclusion, Tβ4 demonstrates protective effects against sarcopenia-like stress in C2C12 myotubes by modulating key signaling pathways, including PI3K/

Akt/mTOR, autophagy, and the NLRP3 inflammasome. These findings support further *in vivo* studies to explore Tβ4's therapeutic potential in diabetic sarcopenia and other muscle-wasting conditions, highlighting its promise as a novel intervention for age-related muscle degeneration.

EACR25-1266

A novel regulator of Hedgehog signaling and stemness in prostate cancer

C. Yen¹, L. Cheng², C. Chui³, K. Tsai²

¹Taipei Medical University, Laboratory of Advanced Molecular Therapeutics, Taipei, Taiwan

²Taipei Medical University, Laboratory of Advanced Molecular Therapeutics, Taipei, Taiwan

³National Health Research Institutes, Institute of Cellular and System Medicine, Miaoli, Taiwan

Introduction

The disruption of tissue organization is a major contributing factor of the malignant transformation of glandular epithelium, including prostate glands. Physiologically relevant models of tissue organization, specifically three-dimensional organotypic cultures, have led to the discovery of molecular mechanisms underlying malignant progression. Through our screening, we identified ACTL6A as a potential oncoprotein in prostate cancer (PCa). To further investigate its role, we employed patient-derived organoid (PDO) models and PCa cell lines to evaluate its expression and functional significance.

Material and method

This study uses MicroWestern Array analysis to screen for ACTL6A as a potential oncoprotein of PCa. IB and co-IP analysis alone with Quantitative reserve transcription PCR (qRT-PCR) analysis were used to evaluate ACTL6A expression and its association with GLI-1 in PDO models of normal and malignant prostate epithelium, as well as in PCa cell line. Bioinformatics analysis was conducted to interrogate public datasets for the expression of ACTL6A in benign and malignant prostate tissues. Orthotopic mouse model of PCa was also used to assess the expression of ACTL6A in tumor tissues.

Result and discussion

The protein abundance level of ACTL6A is upregulated in disorganized prostate epithelial organoids and PCa cells compared to its expression in normal prostate cells and organoids. Echoing this finding, the expression of ACTL6A is upregulated in human PCa compared to normal prostate and is correlated with poor clinical prognosis. At the functional level, small hairpin RNA (shRNA)-mediated knockdown of the expression of ACTL6A in PCa cells attenuated stemness and tumorigenesis *in vitro* and *in vivo* in an orthotopic mouse model of PCa progression. To gain mechanistic insights into how ACTL6A regulates PCa oncogenesis, we screened several development-associated signaling pathways for their reporter activities in ACTL6A-deficient PCa cells and thereby uncovered the Hedgehog (Hh) pathway whose activity was affected by the loss of ACTL6A expression. Consistently, ACTL6A deficiency led to the reduced expressions of Hh-pathway target genes in PCa cells. We identified the marked reduction in the protein

abundance level of GLI1, the key transcriptional factor in Hh-pathway, in ACTL6A-deficient PCa cells, implicating its potential role as a downstream mediator of ACTL6A-regulated Hh-pathway activity. We continue exploring the in-depth molecular and biochemical mechanisms behind the effect of ACTL6A on GLI1 expression.

Conclusion

In conclusion, our study illuminated a novel oncogenic mechanism mediated by the ACTL6A-GLI1-Hh signaling axis that contributes to PCa progression, which may have diagnostic and therapeutic implications.

EACR25-1276

Elevated temperatures induce PDCD1 expression via HSF1 activation

A. Toma-Jonik¹, P. Janus¹, K. Mrowiec¹, K. Sarkowicz¹, N. Vydra¹, M. Bar¹, J. Mirek¹, M. Olbryt¹, W. Fidyk², W. Widlak¹

¹Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice Branch, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland

²Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice Branch, Department of Bone Marrow Transplantation and Oncohematology, Gliwice, Poland

Introduction

Elevated body temperatures (regardless of the cause) lead to the activation of HSF1 (heat shock factor 1), which is a major mediator of transcriptional responses to proteotoxic stress (including heat stress), frequently overexpressed in cancer. PDCD1 (Programmed cell death protein 1) is a cell surface receptor that inhibits the excessive response of antigen-activated T cells to prevent autoimmune tissue damage. Thus, the PDCD1 has been named an “immune checkpoint”, referring to its role as a gatekeeper of immune responses. In chronic infections or cancer, lasting antigen exposure leads to permanent PDCD1 expression that can limit immune-mediated clearance of pathogens or degenerated cells.

Consequently, blocking PDCD1 can enhance T cell function, which is the basis of cancer immune checkpoint therapy.

Material and method

The effect of proteotoxic stress (heat shock, bortezomib) on PDCD1 expression was studied in various human cell lines, peripheral blood mononuclear cells (PBMC), and mouse tissues by RT-qPCR, western blot, or flow cytometry. HSF1 binding to chromatin was studied by chromatin immunoprecipitation. Functional HSF1 knockout was obtained using the CRISPR/Cas9 editing system.

Result and discussion

PDCD1 expression can increase as early as a few hours after temperature elevation. We observed this at the mRNA and protein levels in human leukemic and lymphoblastoid cell lines (such as Jurkat, THP1, HL-60, and GM07062). Transcriptional upregulation of the PDCD1 gene was associated with the binding of heat shock factor 1, HSF1, to the promoter. In contrast, HSF1 knockout in HL-60 cells resulted in the inhibition of PDCD1 activation. Although PDCD1 transcript levels increased in the thymus and spleen of heat-shocked mice,

PDCD1 mRNA did not increase in human PBMC and NK-92 (natural killers cell line). Nevertheless, we observed a heat shock-dependent increase in glycosylated (and therefore active) PDCD1 protein levels also in these cells. This is associated with PDCD1 exposure on the cell membrane and may lead to the loss of cytotoxic properties of NK-92 cells. We propose different mechanisms of heat-induced up-regulation of PDCD1 in cancer and normal cells: at the transcriptional and post-transcriptional levels.

Conclusion

Our observation suggests that the immune response could be attenuated in various physiological conditions accompanied by increased temperatures (infection, heat stroke, etc.). For this reason, fever (as well as pharmacological fever reduction) can have unexpected consequences depending on the disease state. This observation may have clinical implications, and therefore, further research is warranted to understand the importance of fever and PDCD1 in various disease states, as well as their interaction with treatment.

EACR25-1289

Generation of an In Vitro Model for the Study of the Aryl Hydrocarbon Receptor Pathway in Adrenocortical Carcinoma Cell

A. Schiavon¹, L. Saba¹, C. Evaristo¹, J. Petiti², Y. Pignochino¹, S. Puglisi¹, P. Perotti¹, M. Terzolo¹, M. Lo Iacono¹

¹*University of Turin, Department of Clinical and Biological Sciences, Turin, Italy*

²*Istituto Nazionale di Ricerca Metrologica (INRIM), Division of Advanced Materials Metrology and Life Sciences, Turin, Italy*

Introduction

The Aryl Hydrocarbon Receptor (AhR) is a sensor of environmental stimuli and a mediator of their harmful effects on health. It recognizes specific sequences known as Xenobiotic Responsive Elements (XRE), through which it controls a wide set of genes, such as the CYP450 cytochrome family. Despite its role in xenobiotics metabolism, AhR has many pathophysiological functions, including a role in cancer, where it exerts pro-oncogenic or onco-suppressive properties depending on the tumor type. Adrenocortical carcinoma (ACC) is a rare and aggressive tumor, for which mitotane, a derivative of DDT pesticide, is the only approved drug. Of note, compounds similar to these insecticides can modulate AhR. Furthermore, a connection with mitotane-based therapy is highlighted in our recent work, where we observed that mitotane activates both the AhR molecular pathway and the endoplasmic reticulum stress via ATF4. Interestingly, ATF4 pathway activation and related cellular stress are listed as one of the AhR-mediated tumor suppressor mechanisms. Given this evidence and the lack of pharmacological alternatives to mitotane, we generated and validated an in vitro model to elucidate the involvement of AhR pathway in ACC and its possible use as future therapeutic target.

Material and method

To generate our in vitro tool, all components of the AhR-mediated transcription modulation were integrated with

lentiviral transduction into the H295R cell line, the cell model of choice for ACC. We obtained stable H295R clones expressing Firefly-luciferase under the control of xRE (5x 5'-TTGCGTGASAA-3'), with different basal luciferase expression levels. To validate the model, cell clones were treated with some AhR modulators, and the receptor activity was evaluated with luciferase assay and, at transcriptional level, with qPCR experiments.

Result and discussion

To validate our in vitro model, we correlated the experimental luciferase results with the expression of CYP1A1, a gene commonly used as an indicator of AhR activation. Our results showed the congruence between CYP1A1 expression and reporter gene activation, with a fold change $>\pm 1$. Our model can respond to AhR activation/inhibition mediated by modulators of this receptor. We measured an increase in luciferase production compatible with the activation of AhR after treatment with agonists and a decrease with antagonists. Of note, the different behavior of some compounds compared to literature could suggest a tissue or cell type dependent effect, underlining the complexity of this pathway.

Conclusion

Our cell model serves as a tool to explore AhR role in ACC, independently and in conjunction with other molecular pathways. Our system enables a rapid observation of changes induced by various pathophysiological or pharmacological stimuli, facilitating the identification of novel molecular pathways for diagnostic or therapeutic applications.

EACR25-1393

FOSL1 controls chromosomal instability in non-small cell lung cancer (NSCLC) via the β -catenin/TCF4 complex

F. Pedrini¹, S. Graf¹, C. De La Torre González², P. Schirmacher¹, K. Breuhahn¹

¹*Institute of Pathology, Heidelberg University Hospital, Heidelberg, Germany*

²*NGS Core Facility, Medical Faculty of Mannheim, Heidelberg University, Mannheim, Germany*

Introduction

Chromosomal instability (CIN) is a hallmark of cancer, characterized by a high rate of chromosomal alterations associated with tumor heterogeneity and cancer progression. In non-small cell lung cancer (NSCLC), CIN is associated with poor prognosis and immune evasion. Transcription factors play a crucial role in regulating genomic stability by modulating key pathways involved in cell division. However, the underlying mechanisms of CIN induction in NSCLC cells remain unclear, and tools for CIN detection are missing.

Material and method

To investigate the role of individual transcriptional regulators, inhibition of AP1 constituents (FOSL1, JUN, JUND) and WNT signaling (β -catenin and TCF4) in A549 cells was followed by next-generation sequencing (NGS). The perturbation of AP1 activity and the β -catenin/TCF4 complex was achieved using gene-specific siRNAs or inhibitors (SR11302 and iCRT3, respectively). Quantitative PCR (qPCR), Western blotting, and

chromatin immunoprecipitation were utilized to confirm the transcriptional regulation of genes. A CIN gene signature served as an indicator for the presence of CIN. TCGA expression data from NSCLC patients was analyzed, and immunohistochemical staining of NSCLC tissue microarrays was performed for FOSL1 and pH2AX.

Result and discussion

FOSL1 and the β -catenin/TCF4 complex regulate gene expression relevant to mitosis and associated with CIN. In contrast, JUN and JUND do not yield similar results. Notably, FOSL1 significantly induces β -catenin expression and interacts with the β -catenin/TCF4 complex, suggesting that FOSL1 may affect β -catenin/TCF4 complex activity in a bimodal manner. In NSCLC tissues, a significant correlation between nuclear FOSL1 and the CIN marker pH2AX was observed, suggesting a relationship between FOSL1 activity and CIN in lung cancer development. Lastly, NGS reanalysis identified long non-coding RNAs (lncRNAs) regulated by FOSL1 and TCF4, which may be biomarkers for CIN activity in NSCLC. The association between a lncRNA signature and the expression of CIN-associated genes can be validated by data from NSCLC patients.

Conclusion

This study suggests an essential role of the FOSL1/ β -catenin/TCF4 axis in regulating CIN in NSCLC. Moreover, we identified a FOSL1/ β -catenin/TCF4-driven lncRNA signature as a potential biomarker for CIN. Thus, monitoring this lncRNA signature may offer new diagnostic tools for NSCLC patients. Future studies will investigate whether lncRNA signatures can be detected in the serum of NSCLC patients with FOSL1/ β -catenin/TCF4 activation and CIN.

EACR25-1568

Decoding EGFR-Driven Transcriptional Networks in NSCLC

D. Goodall¹, M. Trauernicht², J. Neto², R. Bernards², B. van Steensel²

¹*Netherlands Cancer Institute, Amsterdam, Netherlands*

²*Amsterdam, Amsterdam, Netherlands*

Introduction

The Epidermal Growth Factor Receptor (EGFR) signalling pathway activates multiple downstream sub-pathways which are frequently mutated in non-small cell lung cancer (NSCLC). While these cytoplasmic sub-pathways have been extensively characterized, our understanding of how each node along a given sub-pathway regulates transcription factors (TFs) and their target genes remains incomplete. Previous research has identified a limited subset of TFs (such as AP1, ELK1, and STAT3) downstream of EGFR, however activity-based evidence is lacking, with most conclusions being drawn from abundance-based assays. Moreover, the relative impact of how multiple nodes influence TF activity is largely unknown.

Material and method

We have developed and validated a multiplexed reporter system which simultaneously measures 100 TF activities in a single experiment. Each reporter consists of a TF-specific response element driving expression of a barcoded mRNA, optimized through testing 36,000

different designs across multiple cell types and conditions. We will apply this system to NSCLC cell lines with diverse genetic backgrounds (including EGFR and KRAS constitutively activate mutants). We will systematically perturb nodes within a given sub-pathway using clinically relevant inhibitors, to identify the differential TF activity downstream of the EGFR signalling pathway.

Result and discussion

Initial data reveal a distinct and overlapping sets of TFs controlled by each node within a single sub-pathway. For example, by treating EGFR constitutively active cells with an EGFR inhibitor (Osimertinib) or MEK inhibitor (Trametinib) revealed unique TF activity profiles, despite the often-linear representation. These observations are consistent across KRAS driven cells, despite the driver mutation differences.

Conclusion

This comprehensive mapping of EGFR-driven transcriptional networks will enhance our understanding of resistance mechanisms, identify novel drug targets beyond kinase inhibitors, and may inform rational drug repurposing strategies. Future applications include exploring tissue-specific variations in EGFR-TF networks across cancer types and crosstalk between receptors.

³*University Hospital Bonn, Department of Neuropathology, Bonn, Germany*

⁴*University Hospital Bonn, Department of Neurooncology, Center for Neurology, Bonn, Germany*

Introduction

Intercellular communication is a significant factor in chemotherapy resistance in malignant brain tumors. Connexin-43 (Cx43)-based gap junctions (GJs) facilitate this communication by allowing intercellular ion transfer and small molecule exchange. The impact of GJs in medulloblastoma as the most common malignant pediatric brain tumor is unknown. In the present study, we analyzed the potential of GJs as a putative novel therapeutic target in medulloblastoma. Here, we utilized meclofenamate (MFA), an FDA-approved drug with gap junction-inhibitory properties, which had never been used in medulloblastoma research before.

Material and method

Immunofluorescence and Western blot analysis for Cx43 were used to evaluate intercellular GJ expression in human group 3 and 4 medulloblastoma cell lines. A CRISPR/Cas9 gene knockdown of Cx43 was used to explore cellular effects related to the inhibition of GJs. Realtime-imaging fluorescence-guided measurements of GJ-mediated cell-to-cell cytoplasm transfer was

performed for the CRISPR/Cas9 Cx43 knockdown model and MFA treatment. We used RNA-sequencing to study downstream signalling cascades in response to GJ inhibition. DNA-fragmentation served as readout for cell death and was assessed by flow cytometric analysis of propidium iodide-stained nuclei.

Result and discussion

All medulloblastoma group 3 and 4 cell lines showed an expression of intercellular Cx43-based GJs. We observed a significant reduction of intercellular cytoplasm transfer via GJs in both the CRISPR/Cas9 Cx43 knockdown model and in MFA-treated medulloblastoma cells. MFA-mediated inhibition of GJs profoundly rendered medulloblastoma cells susceptible for lomustine-mediated cell death. Cytotoxic effects were similar to those observed in CRISPR/Cas9 Cx43 cells. In RNA sequencing, we observed not only an upregulation of programmed cell death pathways but also a significant upregulation of wound healing pathways when MFA was combined with lomustine treatment.

Conclusion

This study suggests that inhibiting intercellular connectivity makes medulloblastoma cells more susceptible to lomustine-induced cytotoxic effects. This disruption of tumor networks can be compared to the initial phase of wound healing, where the cellular network is broken apart. Understanding these processes provides insight into therapeutic strategies that target both the destruction and regrowth phases of tumor cell networks. Consequently, gap junction-targeted approaches might offer a novel treatment strategy for this malignant pediatric brain tumor.

⁶University Hospital Bonn, Department of Neurooncology, Center for Neurology, Bonn, Germany

Introduction

Several discoveries both on the morphological and functional cellular level have fundamentally changed our understanding of glioblastoma biology over the last years. Most notably, tumor microtubes (TMs) as ultralong membrane protrusions enable glioblastoma cells to assemble to a syncytial microinvasive communicating network. TM-supported neurogliomatous synapses (NGS) have been shown to integrate glioblastoma cells into neural circuits which foster malignant

growth and cellular invasiveness. The authors speculate to what extent these novel insights into the malignant network might impact future standard of care and attempt to conceive a multimodal treatment regime based on current translational efforts and ongoing clinical trials.

Material and method

A therapeutic outlook was conceptualized with regard to the following basic principals deduced from above-mentioned discoveries: 1) Morphological isolation on the single cell level via inhibition of TM-based spatial network architectures. 2) Functional isolation on the single cell level via inhibition of TM-mediated intercellular cytosolic exchange and inhibition of NGS activation. 3) Greatest possible removal of the micro-invasive tumor cell front far beyond MRI-detectable abnormalities.

Result and discussion

Three multicenter clinical trials in the light of above-mentioned principles are being designed, are recruiting or are at the stage of initiation: The MeCmeth/NOA-24 phase I/II trial evaluates meclofenamate (MFA) as a potential TM-targeted drug. MFA has recently been shown to exert a morphological and functional breakdown within TM-based glioblastoma networks by an inhibition of TM outgrowth and TM-mediated intercellular cytosolic traffic. The PERSURGE trial will analyze the effects of perampanel as a NGS-inhibitory drug regarding functional connectivity and radiological tumor growth kinetics. The ATLAS/NOA-29 trial is designed as the first prospective trial to evaluate supramarginal resection for a potential survival benefit compared to a gross-total resection regime in temporal glioblastoma.

Conclusion

Reminiscent of the Alcatraz Federal Penitentiary, where inmates had to face 1) a spatial isolation in single cells, 2) a functional isolation by the ban of interpersonal communication and 3) a safety-margin to the mainland by the sea as an insuperable barrier, the authors propose the Alcatraz-Strategy as a multimodal therapeutic approach – aimed at fighting glioblastoma’s long-distance connectivity and microinvasive capacity.

Hypericum alpestre phytochemicals and L-NAME downregulate PI3K/AKT/mTOR signaling and activate apoptosis in A549 lung adenocarcinoma cells

N. Avtandilyan¹, H. Javrusyan², T. Harutyunyan², M. Ginovyan², A. Maloyan³

¹Yerevan State University, Research Institute of Biology, Yerevan, Armenia

²Yerevan State University, Yerevan, Armenia

³OHSU, Oregon, Portland, United States

Introduction

Lung adenocarcinoma remains one of the most aggressive cancer types, often exhibiting resistance to conventional therapies. The PI3K/AKT pathway is crucial in promoting tumor survival, angiogenesis, metastasis, and inflammation. Natural compounds with inhibitory effects on this pathway may provide new

therapeutic opportunities. *Hypericum alpestre* (HA), a medicinal plant rich in bioactive polyphenols, has demonstrated anticancer potential. When combined with L-NAME, a nitric oxide synthase (NOS) inhibitor, its efficacy may be further enhanced. This study aimed to investigate the effects of HA extract, phytochemicals and L-NAME (combined and separately) on PI3K/AKT/mTOR signaling and associated inflammatory and angiogenic mediators in A549 lung adenocarcinoma cells and in breast cancer rat models.

Material and method

The cytotoxic effects of HA and L-NAME were assessed via MTT assay. ELISA, ICC/IF and Western blot analyses were conducted to evaluate the expression levels of key signaling molecules, including PI3K, AKT, mTOR, TNF α , VEGF α , COX-2, and MMP-2. Apoptosis induction was confirmed through Caspase-3 activity assays and Hoechst 33258 nuclear staining.

Result and discussion

HA extract and its combination with L-NAME reduced the mTOR, total and phosphorylated forms of PI3K and AKT, reducing TNF α and VEGF α levels, thereby limiting inflammation and angiogenesis. The combination of HA with L-NAME resulted in a more pronounced suppression of COX-2 and MMP-2, which are key mediators of tumor progression and metastasis. Furthermore, Caspase-3 activation and apoptotic cell death were significantly enhanced, suggesting that HA and L-NAME exert their effects through both signaling inhibition and apoptosis induction. Notably, this combination therapy exhibited superior efficacy compared to 5-Fluorouracil and Dactolisib (PI3K/AKT inhibitor). To further clarify the potential anti-metastatic effect of the proposed therapeutic model, *in vivo* studies were conducted in rats with 7,12-dimethylbenzanthracene (DMBA)-induced breast cancer, focusing on the VEGF α /MMP-2 axis in lung tissue. Consistent with findings in A549 cells, the results demonstrated inhibition of VEGF α /Akt/MMP-2 signaling in the lung tissue of rats with breast cancer. Additionally, histological analysis revealed the cessation of lung cancer-associated changes, further supporting the anti-metastatic and anti-angiogenic efficacy of the HA and L-NAME combination therapy.

Conclusion

These findings suggest that the strong effects of HA extract and L-NAME on the PI3K/AKT/mTOR signaling pathway and downstream targets hold promise for developing novel more effective therapeutic strategies against cancer.

Science, Scranton, United States

⁴Touro College of Osteopathic Medicine, Department of Preclinical Education, Middletown, United States

⁵UPMC Magee-Womens Hospital, Pittsburgh, United States

Introduction

Glucocorticoid (GC) plays an important role in human pathophysiology as an anti-inflammatory and ubiquitous stress-activated steroid hormone. Clinically, it is commonly used as a co-treatment for cancer therapies with high efficacy in inducing apoptosis of leukemia and lymphoma. However, in breast cancer treatments, GC can sometimes produce controversial effects that induce drug resistance to chemotherapy and even promote breast cancer recurrence. To understand underlying mechanisms, we focused on investigating the specificity of GC signaling in different subtypes of breast cancer cells in this study.

Material and method

Triple negative breast cancer (TNBC) cell line MDA-MB-231 and lumina A subtype breast cancer cell line MCF-7 were used in this study. Dexamethasone (Dex, a synthetic GC) was used for treatments with optimized conditions. Quantitative Western blotting was carried out to analyze protein expression, and breast cancer specific qRT-PCR array (RT² Profiler™ PCR Array, Qiagen) was used to quantify the expression of target genes. CRISPR technique was utilized to down-regulate gene expression, and the real-time label-free technique (ECIS, Applied Biophysics) was employed to measure cell migration.

Result and discussion

When MDA-MB-231 and MCF-7 cells were treated by Dex, in addition to inducing apoptosis slightly, GC regulated cell migration more sensitively in MDA-MB-231 cell than in MCF7 cell. Gene expression profiling by qRT-PCR array revealed that the GC/GC receptor (GR) signaling regulated gene expression differently between these two breast cancer cells; MDA-MB-231 cell showed more genes up- or down-regulated than MCF7 cell, among which Snai2/Slug (a transcriptional factor involved in EMT) was identified to be highly activated in both cell lines. Western blotting analysis confirmed that MDA-MB-231 cells had higher levels of Snai2 than MCF-7 cells upon Dex treatment. GR response elements (GREs) were also identified in the promoter region of Snai2 bioinformatically, thus confirming Snai2 as a new target gene of GR in breast cancer. When Snai2 was knocked out by CRISPR, it was found that the migration rates were decreased in both cell lines, indicating Snai2 as a mediator to regulate breast cancer cell migration in response to GC/GR signaling.

Conclusion

The findings from this study shed new light on the differential use of GC in breast cancer therapies depending on different subtypes of breast cancer, wherein TNBC should be precautionary.

The extracellular matrix produced by VEGFR2R1032Q altered melanoma cells modifies adhesive and migratory characteristics of endothelial cells

M. Domenichini¹, M. Corsini¹, M. Menotta², C. Ravelli¹, A. Ricci², H. Gerhardt³, J. Kraxner³, E. Grillo¹, S. Mitola¹

¹*University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy*

²*University of Urbino, Department of Biomolecular Sciences, Urbino, Italy*

³*Max Delbrück Center (MDC), Integrative Vascular Biology, Berlin, Germany*

Introduction

The VEGF/VEGFR2 axis is frequently altered in cancer where it regulates cell metabolism, proliferation, motility, and stemness. Recent pan-cancer mutational analysis identified the alteration VEGFR2R1032Q as the most frequent point mutation in VEGFR2. Although this mutation reduces the kinase activity of VEGFR2, its expression in melanoma cell lines (SK-MEL-31) promotes tumor growth and vascularization. Preliminary functional data and transcriptomic analysis suggested an alteration in extracellular matrix (ECM) organization. In cancer, continuous ECM remodelling affects tumor cell-ECM and cell-cell interactions. Altered ECM may also influence tumor vasculature by modulating endothelial cells (ECs)-ECM interactions.

Material and method

To dissect the effects of tumor-derived ECM, an in vitro decellularization protocol was established. Decellularized matrices (d-ECM) were characterized by mass spectrometry and used for functional assays. In particular ECs seeded onto VEGFR2WT SK-MEL-31 and VEGFR2R1032Q -SK-MEL-31-(d-ECM) were assessed in static culture conditions and in response to unidirectional laminar flow (6 dyne/cm² for 24 h) by high resolution microscopy. Also FLIM/FRET biosensors were used for the characterization of mechano-transduction signaling.

Result and discussion

Mass spectrometry analysis revealed significant alterations in VEGFR2R1032Q -SK-MEL-31-d-ECM, which exhibited higher haptotactic activity on ECs. ECs plated on VEGFR2R1032Q-derived matrix displayed impaired spreading, increased number and dimension of focal adhesions (FAs) compared to EC plated onto VEGFR2WT-SK-MEL-31-dECM. Also, FLIM/FRET-based FAT-FAK sensor highlighted a reduced FAK activity in FAs in ECs plated onto VEGFR2R1032Q -SK-MEL-31-derived matrix. According to this, adhesion on VEGFR2R1032Q -SK-MEL-31-dECM increased intracellular traction forces in FAs as demonstrated by VinTS -based mechano-sensor and reduced the amount of primary cilia, a structural mechano-sensor. These tensile and adhesive features were coupled with an increased expression of genes involved in the endothelial to mesenchymal transition. Under laminar flow conditions, ECs seeded on VEGFR2WT SK-MEL-31-derived matrix elongated and polarized in response to shear stress. In contrast, ECs on VEGFR2R1032Q-derived ECM exhibited a delayed polarization and a reduced sensitivity to shear stress, as confirmed by cytoskeletal organization analyses. Time-lapse imaging over 24h further validated these findings under flow conditions and highlighted a reduction in the fluidity of cell monolayer.

Conclusion

These findings suggest that differences in tumoral ECM composition and organization impact EC behavior, mechano-transduction, and shear stress responses. Understanding these mechanisms could unveil novel therapeutic targets providing advancements in cancer treatment.

EACR25-1763

Downregulation of Frizzled-5 in Gastric Cancer: Tumor Suppressor Potential and the Role of Fibroblast-Derived WNT5A

S. Zimmer¹, W. Hu¹, I. Rompen¹, H. Nienhäuser¹

¹*Heidelberg University Hospital, Department of General, Visceral and Transplantation Surgery, Heidelberg, Germany*

Introduction

The Wingless (Wnt) signaling pathway is involved in gastric carcinogenesis originating from gastric cancer stem cells. Frizzled-5 (FZD5), the Wnt-receptor mediating non-canonical WNT5A activity, seems to be involved in this process and the WNT5A-FZD5 signaling axis is crucial in gastric inflammation and regeneration. Studies suggest that increased FZD5 expression indicates tumor-suppressing effects, while targeted deletion inhibits stem cell activity in alveolar epithelial cells. Within the tumor microenvironment (TME) of gastric cancer both cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs) are known as key pro-tumor mediators and discussed as WNT5A source. This study aims to identify FZD5- and WNT5A-expressing cells in the stomach and their role in human gastric carcinogenesis.

Material and method

Tissue samples of 50 gastric cancer patients were analyzed. Immunohistochemistry and RT-qPCR were used to assess the expression of FZD5, ATP4A for parietal cells, and PGA5 for chief cells. To investigate the role of WNT5A expressing cells in gastric cancer, we isolated fibroblasts from both healthy gastric tissue and gastric tumor tissue obtained from surgical resections. M2 macrophages, polarized from THP-1 cells using IL-4, were co-cultured with the isolated fibroblasts. WNT5A expression levels were assessed by RT-qPCR.

Additionally, the levels of WNT5A in the co-culture supernatant were measured by ELISA (Enzyme-Linked Immunosorbent Assay).

Result and discussion

We show that FZD5 is the highest expressed receptor in human gastric tissue in healthy mucosa as well as in tumor tissue. FZD5 is expressed by ATP4A-positive parietal cells but not by chief cells (PGA5) in the normal gastric epithelium. In gastric cancer tissue, FZD5 expression is significantly reduced and the expression of ATP4A and PGA5 is lost. Further investigation is necessary to clarify the molecular mechanisms underlying the selective loss of parietal cells while preserving FZD5-positive cell populations in the tumor.

Investigating this pathway, we were able to identify human fibroblasts isolated from fresh mucosa and tumor tissue as a source of WNT5A and confirmed by RT-qPCR that WNT5A is one of the most relevant ligands in

human gastric tissue. Additionally, an *in vivo* gastric cancer model using *Helicobacter*-infected Wnt5a knock-out mice revealed progressive loss of parietal cells and chief cells, as well as a reduced expression of Fzd5 with persisting infection.

Conclusion

These findings suggest that a loss of FZD5-positive cells is one of the drivers in gastric carcinogenesis, mediated by WNT5A. We conduct further experiments, including scRNA sequencing and more comprehensive *in vivo* studies, to gain deeper insights into the development and progression of gastric cancer and the role of the WNT5A-FZD5 signaling cascade in this process. Modulating this pathway could potentially serve as a treatment option in gastric cancer therapy.

EACR25-1775

The Impact of IK Deficiency on Cancer-Related Signaling Pathways: Insights from Zebrafish and Cellular Models

J. Jang¹, E. Jeon¹, H. Ka², M. Kim¹

¹*Sookmyung Women's University, Department of Biological Sciences, Seoul, Korea (Republic of)*

²*Sookmyung Women's University, Research Institute of Women's Health, Seoul, Korea (Republic of)*

Introduction

IK is a splicing factor that facilitates spliceosome activation and plays a crucial role in the assembly and catalytic activation of the spliceosome during pre-mRNA splicing. Loss of IK in cells is known to halt cell division, leading to apoptosis in cancer cells, and causes genetic instability by impairing the splicing of DNA damage repair genes. Consequently, IK deficiency is likely to influence cancer development; however, the specific genes and mechanisms involved remain largely unknown. This study aims to explain the impact of IK deficiency on cancer-related gene expression and the underlying mechanisms by analyzing transcriptome data from IK-deficient zebrafish embryos.

Material and method

To investigate the molecular consequences of IK deficiency, we performed real-time PCR (RT-PCR) to analyze the mRNA expression of genes associated with GTPase activity, EGFR signaling, and GPCR activity. mRNA sequencing was conducted on RNA extracted from wild-type and IK-deficient zebrafish embryos. Additionally, Western blot analysis was carried out to assess protein expression levels relevant to the correlation between IK deficiency and cancer. To further elucidate the role of IK in cancer pathways, alternative splicing mechanism differences across cancer types were compared using human cancer cell lines.

Result and discussion

mRNA sequencing of IK-deficient zebrafish embryos revealed altered regulatory mechanisms of transcriptome related to GTPase activity, EGFR signaling, and GPCR activity, suggesting a role for IK in cancer-related pathways. Changes in alternative splicing mechanisms involved in cell proliferation, survival, and apoptosis indicate that IK deficiency may contribute to the regulatory mechanism of multiple steps in cancer initiation and progression. Western blot analysis confirmed protein-level changes consistent with

alternative splicing variation, supporting IK's influence on transcriptional and post-transcriptional regulation. *In vivo* experiments using zebrafish embryos further demonstrated disruptions in key signaling pathways, reinforcing the link between IK deficiency and cancer progression. These findings suggest that IK plays a critical role in tumorigenesis by affecting transcriptional regulatory mechanisms driving cancer growth.

Conclusion

This research demonstrates that IK plays an essential role in the regulation of alternative splicing through cancer-related signaling pathways, influencing cell proliferation, survival, and apoptosis. Further studies are needed to validate candidate genes and investigate the potential of IK as a therapeutic target in cancer progression.

EACR25-1825

The Androgen Receptor-Serum Response Factor Network As a Pharmacological Target in Castration Resistant Prostate Cancer

K. Zitzmann¹, J. Campbell¹, K. Wynne², M. Prencipe¹

¹*University College Dublin, School of Biomolecular and Biomedical Science, Dublin, Ireland*

²*University College Dublin, Systems Biology Ireland, Dublin, Ireland*

Introduction

Prostate cancer (PCa) is one of the most common cancers in men worldwide. Current treatments focus on targeting the Androgen Receptor (AR) with androgen deprivation therapies (ADT) such as enzalutamide. Although initially effective, ADT's create a selection pressure resulting in treatment resistance in a form of advanced PCa called castration resistant prostate cancer (CRPC). This emphasises the need for alternative therapeutic approaches that will bypass this resistant mechanism, continue to disrupt AR signalling without targeting AR itself. One such method includes targeting co-regulators in the AR signalling network such as the Serum Response Factor (SRF), which has been identified as being crucial to PCa progression. Previous co-immunoprecipitation studies combined with mass spectrometry have identified common interactors between AR and SRF intracellular network, including HSP70, HSP90 and members of the PI3K/Akt pathway. Our research focuses on targeting the co-regulators within the AR-SRF network as a pharmacological approach for patients with CRPC.

Material and method

We investigated targeting the AR-SRF interactome in four PCa cell lines: LNCaP (ADT-sensitive), LNCaP Abl and C4 (ADT-resistant), 22Rv1 (ADT-resistant and ARv7 positive) and in a non-cancerous prostate cell line (PWR1E). Small molecule inhibitors include SRF inhibitors (CCG1423, Lestaurtinib), AR/ARv7 inhibitors (Enzalutamide, EPI7170) and common co-factor inhibitors (VER-15508, JG-98, Ganetespib, Ipatasertib, Alpelisib). MTT assays and IncuCyte proliferation analysis were performed for single and combination treatments, with CompuSyn software analyzing combination profiles for antagonism, additivity, or

synergy. Western blotting assessed phosphoproteomic changes after treatment.

Result and discussion

We have shown that inhibiting AR, SRF and common co-factors, singly and in combination, decreases cell viability and proliferation in the PCa cell line panel. Furthermore, we show that the following combinations are synergistic, even at IC₁₀ concentrations: Lestaurtinib+Ipatasertib, CCG1423+EPI7170, EPI7170+Ipatasertib and EPI7170+Lestaurtinib. Lestaurtinib and Ipatasertib were shown to alter the global phosphorylation landscape in 22Rv1. To better understand the molecular mechanisms behind the synergy, proteomic and phosphoproteomic analysis are currently ongoing.

Conclusion

To conclude, our results indicate that targeting the AR-SRF intracellular network holds promise as a treatment option for patients with CRPC. Combination treatments were shown to bypass resistance mechanisms in our CRPC cell line models and are synergistic at lower concentrations. Furthermore, by studying the proteomic and phosphor-proteomic landscape before and after treatments, we can further understand disease and resistance mechanisms in PCa as well as find potential novel targets which can be used for the disease.

EACR25-1864

SP1 Downregulates ADAMTS-8 mRNA Expression in Colorectal Cancer Model

M. Alper¹, Y. Keleş², F. Sav², F. Köçkar²

¹Dokuz Eylül University, Institute of Oncology,
Department of Translational Oncology, İzmir, Turkey
²Balıkesir University, Department of Molecular Biology
and Genetics, Balıkesir, Turkey

Introduction

A Disintegrin and Metalloproteinase with Thrombospondin Motifs (ADAMTS) proteases play a crucial role in forming and remodeling the extracellular matrix (ECM). The ADAMTS family, consisting of 19 members, is involved in key biological processes such as angiogenesis, migration, proliferation, and cancer progression. ADAMTS-8, an anti-angiogenic member of this family, is frequently downregulated in various cancers and is a potential tumor suppressor in colorectal cancer (CRC). Specificity Protein 1 (SP1), a zinc finger transcription factor that binds to GC-rich sequences, is highly expressed in human CRC tissues. This suggests that SP1-regulated genes may contribute to CRC progression and metastasis. This study aims to investigate the transcriptional regulation of ADAMTS-8 by SP1 in CRC.

Material and method

The promoter region of the ADAMTS-8 gene was analyzed using the PROMO TF Search program. Bioinformatic analysis identified multiple SP1 binding motifs within the ADAMTS-8 promoter, which were mapped and visualized. To evaluate the effect of SP1 on the transcriptional regulation of ADAMTS-8, SP1 was overexpressed in SW480 cells. The impact of SP1 on ADAMTS-8 mRNA expression was analyzed using a qRT-PCR-based strategy.

Result and discussion

Multiple SP1 binding sites were identified within the ADAMTS-8 promoter. Ectopic expression of SP1 decreased ADAMTS-8 mRNA expression in SW480 cells.

Conclusion

These findings indicated that SP1 negatively regulates ADAMTS-8 expression in the SW480 CRC model. Further research is required to elucidate the precise mechanisms underlying this regulatory interaction and the potential contribution of SP1-mediated ADAMTS-8 downregulation to CRC progression.

EACR25-2097

11q Loss Meets 17q Gain: Molecular Insights into Neuroblastoma Treatment Resistance

*T. Gradowski Farias da Costa do Nascimento¹,
J. de Faria Poloni², S. Andrade Marques¹, M. Oliveira
Thomazini¹, B. Feltes², S. Elifio Esposito¹*

¹Pontifícia Universidade Católica do Paraná, Graduate
Program in Health Sciences, Curitiba, Brazil

²Federal University of Rio Grande do Sul, Department of
Biophysics, Porto Alegre, Brazil

Introduction

Neuroblastoma (NB) is the most common solid tumor in early childhood, responsible for around 15% of cancer deaths in this age group. NB tumors are highly heterogeneous, and segmental chromosomal alterations are related to the more aggressive cases. MYCN amplification is the most significant alteration in 40% of high-risk tumors. In addition, 35–40% of primary tumors have an 11q deletion, which is strongly related to refractory recurrences. This study aims to identify copy number alterations (CNAs) in NB tumor samples to identify alterations associated with tumor resistance and recurrence.

Material and method

A retrospective study used data and tumor samples from pediatric patients diagnosed with NB and treated at the Pequeno Príncipe Pediatric Hospital (HPP), Curitiba, Brazil, between 2004 and 2014 [1]. DNA was isolated from FFPE samples, and CNA analysis was performed using an oligonucleotide a-CGH platform (SurePrint G3 Human CGH Microarray 8x60K; Agilent Technologies Inc.). CNA was defined as Agilent Cytogenomics guidelines. The number of calls and affected cytobands were obtained from the generated aberration interval base reports (Agilent Cytogenomics v. 5.0). The list of the genes from the affected cytobands were used to create pre- and post-CT protein-protein integration (PPI) networks for each patient using the STRINGdb R package.

Result and discussion

Out of 76 patients initially included in the study, three cases had paired pre- and post-CT FFPE samples and presented 11q deletion. Systems biology analysis revealed that the PPI networks in the post-CT samples showed fewer connections than the pre-CT networks. Five genes in the post-CT networks were common in all patient samples, which may be related to treatment resistance: BIRC5, BRCA1, PRKCA, SUMO2, and GPS1, all located in the 17q region. Gains in 17q are

common on NB tumors and are associated with poor disease prognosis. Also, The PPI analysis showed that BIRC5 acts as a Bottleneck and Switch, suggesting it may be a central gene for different molecular pathways such as DNA damage repair, apoptosis, and chromatin remodeling.

Conclusion

This study reinforces the importance of BIRC5 as a key gene in cancer progression and highlights its impact on the most resistant tumors. This work opens the perspective of the validation of BIRC5 as a biomarker in high-risk neuroblastoma.

[1] This study was approved by the institution's ethics committee (approval number 33.573.221).

Tissue factor augments TGF β signaling in cancer cells by modulating receptors dynamics and plasma membrane tension

A. Metelli¹, F. Di Modugno¹, A. Tocci², P. Nistico¹, J. Wrangle³

¹IRCCS Regina Elena National Cancer Institute, Rome, Italy

²IRCCS Regina Elena National Cancer Institute, Italy

³Medical University of South Carolina, Charleston, United States

Introduction

Tissue Factor (TF) is a protein mediator of platelet-cancer cross talk: it is indeed the key activator of blood coagulation, while it is highly expressed on human aggressive malignancies. Tumor growth factor beta (TGF β) is the most abundant biomolecule secreted by platelets and the most potent promoter of the epithelial to mesenchymal transition (EMT). Distribution analysis of TF on human lung cancer biopsies reveals that it is predominantly expressed on the epithelial edge of aggressive tumors, indicating that TF expression correlates with cell invasion and migration. Based on these initial observations, we sought to determine the role played by TF in the intracellular TGF β signaling and cell phenotype.

Material and method

CRISPR/Cas9-mediated TF knocked out in human non-small cell lung carcinoma PC9 cells was performed and EMT indicators such as cell shape and size were evaluated by confocal microscopy and protein analysis. To investigate TGF β signaling, Smad protein phosphorylation was evaluated by luciferase reporter system and TGF β phosphoarray was performed. TGF β receptor 1 and 2 expression and function were analyzed by flow cytometry and Proximity Ligation Assay (PLA). Spectrophotometry analysis followed by in silico simulation, were employed to gain insight into the interactome of TF. Finally, Flipper-TR associated with confocal live cell imaging was employed to study how TF modulates membrane tension.

Result and discussion

Depletion of TF resulted in acquired epithelial features such as smaller size, round shape, reduced Smad2/3 phosphorylation and augmented E-Cadherin expression. The ability of TF-depleted cells to produce and activate TGF β is unaltered. Although TGF β receptors 1,2 and 3 transcripts remain unchanged, our data show that TF

supports their surface expression and activity. Moreover, PLA assays show reduced TGF β receptors tetrameric structure formation. The spectrometry analysis unveils that TF interacts with Ezrin and in silico studies suggest that the intracellular TF domain stabilizes Ezrin dimer and inhibits its phosphorylation. Finally, we observed that TF Knocked out cells display a reduced plasma membrane tension, which might explain the affected TGF β receptors dynamics.

Conclusion

Taken together, these data suggest that TF enhances TGF β signaling by augmenting the availability and dynamics of TGF β receptors. Ezrin, the master regulator of plasma membrane architecture and tension, is one of the candidate to orchestrate such an underlying mechanism. The role of TF in the modulation on plasma membrane tension and TGF β signaling transduction, is a novel concept and more studies are needed to investigate its function in receptors dynamics. Moreover, like TGF β receptors, the scenario that TF/Ezrin interaction might control the expression and dynamics of multiple cancer-related surface proteins is under investigation and may highlight novel mechanisms for drug resistance.

EACR25-2184

The effects of 17 β -estradiol on the expression and functionality of large-conductance voltage- and Ca $^{2+}$ -activated potassium channels in human glioblastoma cells

A. Lalik¹, B. Dworakowska², A. Sekrecka-Belińska², K. Skutnik¹, W. Piecha¹, J. Misala¹, M. Szyszka¹, A. Wiszkony¹, A. Wawrzkiewicz-Jałowiecka¹

¹Silesian University of Technology, Gliwice, Poland

²Warsaw University of Life Sciences, Warsaw, Poland

Introduction

Gliomas are a type of brain tumor that is more common in men than in women suggesting that sex hormone levels, including estrogens, are important for glioma-gensis. However, the mechanism of estrogen action on the metabolism and pathogenesis of gliomas is not yet fully understood. In our work, we focused on the effects of 17 β -estradiol (E2) on the expression and functioning of large-conductance voltage- and Ca $^{2+}$ -activated potassium channels (gBK) present in human U87-MG cell line. gBK channels can contribute to cell growth and extensive migration in glioblastoma. Moreover, these channels are overexpressed in malignant gliomas in comparison to nonmalignant cortical tissues, and their expression level correlates positively with the malignancy grade of the tumor. Thus, changing gBK expression levels or altering their activity should significantly affect cancer cell behavior.

Material and method

U-87 MG cells were treated with various concentrations (from ng/ml to μ g/ml) of E2 for 24 or 48h. Then we determined cell viability using the CCK-8 assay and evaluated the expression levels of α and β (1-4) subunits of gBK channels using the RT-qPCR technique. The promoter regions of the genes under study were analyzed for E2 response elements using the online program AliBaba2.1. We examined the gBK channels

functionality based on the single-channel patch-clamp recordings obtained at two E2 concentrations (i.e., a physiological-like 0.0018 µg/ml and pharmaceutical 1,8 µg/ml) and the appropriate controls. Membrane potentials were fixed at -50 mV, -25 mV, +25 mV, +50 mV, +75 mV.

Result and discussion

The results showed that the expression of both β3 and β4 subunits of gBK channels depends on the E2 concentration, with the most significant increase observed for the β3 stimulated by physiological-like concentration of E2. The observed changes suggest that at least some of the estrogen response elements present in genes encoding gBK subunits are functional. E2-induced changes in the expression of gBK subunits can result in differences in their protein levels, which can affect the gBK channel functionality and can shape their functional hormone-dependent hallmarks in glioblastoma. The patch-clamp results indicated the decrease of the open-state probability (pop) of gBK channel (inhibition) as a consequence of E2 administration. The observed decrease of pop depended on E2 concentration and applied voltage, with the well-pronounced effects at membrane depolarization (e.g. at 50 mV, control: pop = 0.45 ± 0.06, E2physiol.: pop = 0.11 ± 0.03 and E2pharm.: pop = 0.14 ± 0.03). E2 stimulation resulted in a decrease of U87-MG viability.

Conclusion

E2 is an effective functional inhibitor of gBK channel activity and a potent expression regulator of its subunits in glioblastoma U-87 MG cells. Moreover, E2 affects the viability of these cells. This study reveals the novel aspects of glioblastoma biology which enlighten the role of K⁺ channels modulation by E2.

EACR25-2185

The effects of progesterone on the expression and functionality of large-conductance voltage- and Ca²⁺-activated potassium channels in human glioblastoma cells

A. Lalik¹, B. Dworakowska², A. Sekrecka-Belniak², K. Skutnik¹, W. Piecha¹, J. Misala¹, M. Szyszka¹, A. Wiszkony¹, A. Wawrzkiewicz-Jałowiecka¹

¹Silesian University of Technology, Gliwice, Poland

²Warsaw University of Life Sciences, Warszawa, Poland

Introduction

Progesterone (P) is a steroid hormone involved in the regulation of many cellular processes. It can act via the classical and non-classical pathways by binding to the progesterone receptor. In glial cells, progesterone affects proliferation, migration, and the cell cycle. Progesterone levels are also associated with cancer development, but the exact mechanism of action is not yet understood. In our study, we examined the effect of P levels on the expression and functioning of large-conductance voltage- and Ca²⁺-activated potassium channels (gBK) in the human U87-MG cells, and its effects on cell viability. The gBK can regulate cell growth and extensive migration in glioblastoma. Therefore, changing gBK

expression levels or altering their activity should significantly influence cancer cell biology.

Material and method

We treated U87 cells with various concentrations (from ng/ml to µg/ml) of progesterone for 24 or 48h. We then determined cell viability using the CCK-8 assay and determined the expression levels of α and β subunits of gBK channels using the RT-qPCR technique. The promoter regions of the genes under study were analyzed for progesterone response elements using the online program AliBaba2.1. For functional gBK channel analysis, the single-channel patch-clamp recordings were obtained at two P concentrations (i.e., 0.025 µg/ml and 25 µg/ml) at membrane potentials ranging from -50 mV to +75 mV with 25 mV step.

Result and discussion

The expression of the gBK channel subunits depends on the P concentration, with the highest effects observed for β3 and β4 subunits. The changes in relative expression levels of regulatory subunits in E2-stimulated cells can result in differences in their protein levels, which can affect the gBK channel functionality (activation, inactivation, Ca²⁺-sensitivity), and consequently shape their functional hormone-dependent hallmarks in glioblastoma. The patch-clamp results indicated the decrease of the open-state probability (pop) of the gBK channel (inhibition) as a consequence of the P administration. The pop decrease depended on P concentration and applied voltage, with the well-pronounced effects at membrane depolarization (e.g. at 50 mV, control: pop = 0.45 ± 0.06, P0.025 µg/ml: pop = 0.07 ± 0.03 and P25 µg/ml: pop = 0.08 ± 0.03). P stimulation resulted in a decrease of U87-MG viability, with a nonlinear dose-dependent relation (it ranged from 0.65 ± 0.01 to 0.91 ± 0.03 for the examined P concentrations).

Conclusion

Progesterone is an effective functional inhibitor of gBK channel activity and a potent expression regulator of its subunits in glioblastoma U-87 MG cells. It also changes the viability of these cells. This study reveals novel aspects of glioblastoma biology which enlighten the role of K⁺ channels modulation by sex-hormones.

EACR25-2200

Unveiling the Molecular Mechanisms of KCa3.1 in Pancreatic Cancer Development

V. Carpanese¹, S. Sadeghi¹, L. Todesca¹, C. Paoli¹, V. Checchetto¹, I. Szabó¹

¹University of Padova, Department of Biology, Padova, Italy

Introduction

Ion channels mediating ion flux across biological membranes are gaining attention as potential oncology targets, as their aberrant expression and function contribute to multiple cancer hallmarks. Ion channels play crucial roles in cancer progression, not only by mediating ion flux but also by modulating intracellular signalling pathways. The intermediate conductance Ca²⁺-activated potassium channel (KCa3.1) is highly expressed in various cancers, including pancreatic ductal adenocarcinoma (PDAC) where its dysregulation

correlates with poor prognosis underscoring its significance in pancreatic malignancy. However, the molecular mechanisms linking KCa3.1 to pancreatic cancer remain incompletely understood. To investigate its role, we characterized a PDAC cell line lacking KCa3.1 and applied TurboID-based proximity labeling to map its interactome, identifying key interactors and pathways associated with KCa3.1 channel activity.

Material and method

To demonstrate the involvement of KCa3.1 in tumorigenesis through its participation in signaling complexes, we first investigated its interactome using TurboID proximity labeling in KPC intact cells. To further establish the relevance of KCa3.1 in tumorigenesis, we generated a CRISPR/Cas9 knock-out (KO) KPC cell line and characterized it both *in vitro* and *in vivo*.

Result and discussion

TurboID analysis revealed that the KCa3.1 channel interacts with several cancer-related signal transduction pathways including those associated with integrins and WNT/β-catenin signaling. We next validated these functional interactions with some of the identified partners, taking advantage of KCa3.1 KO pancreatic cancer cells, which exhibited remodeled gene expression, reduced proliferation *in vitro*, and formed significantly smaller tumors *in vivo*.

Conclusion

The analysis of the interactome of KCa3.1 using TurboID proximity labeling has, for the first time, allowed us to identify novel putative interacting proteins of the channel in the context of pancreatic cancer. These interactions may explain the channel's ability to modulate specific signaling pathways involved in cancer-promoting mechanisms. In conclusion, our findings provide new insights into the molecular landscape of KCa3.1 in pancreatic cancer and highlight its potential as a therapeutic target.

EACR25-2232

Regulation of MBD4 expression and cell-cycle mediated Interactions with the DNA Mismatch Repair (MMR) pathway

A. Kahn¹, A. Bortolini Silveira², A. Houy², A. Le Ven², M. Rodrigues², M. Stern²

¹*Duke Health, Duke University School of Medicine, Durham, United States*

²*Institut Curie, Inserm U1339 UMR3666, DNA Repair and Uveal Melanoma (D.R.U.M.) team, Paris, France*

Introduction

Uveal melanoma (UM) is an ocular neoplasm that predominately affects those of European origin. Loss of MBD4 is implicated in UM. Germline mutations in MBD4 also predispose to cancer syndromes such as Lynch Syndrome, which commonly results from germline mutations in DNA mismatch repair (MMR) genes. MBD4 and TDG encode base excision repair (BER) glycosylases responsible for the repair of G:T mismatches caused by spontaneous deamination of 5-methylcytosine. MBD4 deficiency has been associated with an increase in tumor mutational burden. Here, we aim to understand MBD4 regulation and characterize physical interactions throughout the cell cycle.

Material and method

To evaluate potential regulatory sensors affecting MBD4 expression, the ratio between mature and nascent MBD4 RNA was determined using quantitative PCR (qPCR) and RNA-seq data in isogenic HAP1 cell lines wild-type or knockout for MBD4. Protein expression of BER glycosylases (MBD4 and TDG) and MMR components (MLH1, MSH2, MSH6 and PMS2) was evaluated by western blotting in RPE1 or HAP1 cell lines. Cells in different phases of the cell cycle were sorted based on fluorescent cell cycle indicators (FUCCI) or by DNA content. We aim to establish the interaction between BER and MMR proteins during the G1 and S phases of the cell cycle by co-immunoprecipitation, using epitope-tagged MBD4 as bait.

Result and discussion

Through qPCR and RNA-seq analysis on HAP1 cell lines, MBD4 loss-of-function mutations showed minimal effect on MBD4 transcription. This either indicates a weak effect of nonsense-mediated decay or transcriptional upregulation. The proportion of immature relative to mature MBD4 transcripts was higher in MBD4-mutated cell lines. However, our work found no evidence to support increased expression of unspliced transcripts as the cause. Evaluation of protein levels in the context of the cell cycle revealed that MBD4 protein levels were not cycle-regulated, although we observed strong reduction of TDG levels in S-phase cells. Current literature suggests that MLH1 and PMS2 physically interact with MBD4, suggesting a role of non-canonical MMR in 5mC deamination repair. Here, we will aim to clarify if this interaction is cell cycle-regulated.

Conclusion

Our work demonstrates some key features of MBD4 gene and protein regulation that have not been previously characterized. In MBD4 deficient cell lines, we demonstrated that increased expression of MBD4 is not the result of increased expression of immature MBD4 transcripts. Furthermore, MBD4 protein level is not cell cycle-regulated. Our ongoing work seeks to build on this knowledge to clarify the interplay between BER and MMR pathways.

EACR25-2315

SUPT5H influences Cell Identity in Pancreatic Ductal Adenocarcinoma

M. Dittrich¹, T. Ekstrom^{1,2}, M. Manjunath¹, R. Rosok¹, N. Schacherer¹, W. Ge¹, S. Johnsen¹

¹*Robert Bosch Center for Tumor Diseases, Molecular Cancer Epigenetics, Stuttgart, Germany*

²*Mayo Clinic Graduate School of Biomedical Sciences, Rochester, United States*

Introduction

Approximately 85% of pancreatic ductal adenocarcinoma (PDAC) patients are diagnosed at a locally advanced stage, eventually developing chemotherapy resistance during the course of treatment in most cases. The intrinsic ability of PDAC to develop therapy resistance is likely attributable to the tremendous phenotypic plasticity of PDAC tumor cells, in combination with the transition of the classical to the basal PDAC subtype, where the classical subtype exhibits better response to standard chemotherapy treatment compared to the basal subtype.

Since the subtypes exhibit only minor differences at the genomic level, their distinctions appear to be primarily driven by epigenetic factors, such as transcriptional regulation and chromatin modulation. Therefore, understanding the epigenetic mechanisms that govern the molecular identity of PDAC subtypes is crucial for identifying novel therapeutic targets, potentially enhancing treatment outcomes. In PDAC, cell identity is governed by gene expression, where RNA Polymerase II (Pol II) regulation and enhancer-promoter interactions shape subtype-specific transcription in a context-dependent manner. The release of promoter-proximal Pol II pausing, an essential checkpoint in gene expression, plays a crucial role in regulating classical subtype-specific genes. Within this transcriptional regulatory network, SUPT5H, a key subunit of the DRB Sensitivity-Inducing Factor (DSIF) complex, is a central player in controlling Pol II pausing. In this study, we investigate if SUPT5H governs PDAC subtype identity and therapeutic responsiveness by modulating promoter-proximal Pol II pause release and transcriptional elongation.

Material and method

We employed siRNA-mediated knockdown of SUPT5H followed by mRNA sequencing and Chromatin Immunoprecipitation sequencing (ChIP-seq) for SUPT5H, Pol II, GATA6, p63 and relevant chromatin marks.

Result and discussion

Results of this study indicate that siRNA-mediated depletion of SUPT5H in basal-like PDAC specifically results in downregulation of basal-specific genes, including KRT5, FAT2, MIR205HG and TP63. ChIP-seq analysis after SUPT5H depletion revealed a global reduction in Pol II occupancy across downregulated genes, while at unregulated and upregulated genes, Pol II levels decreased at the transcription start site but accumulated in the 5' downstream region. Further ChIP-seq analysis of subtype-specific active distal regions could unravel SUPT5H's potential role in subtype-specific enhancer regulation, in turn influencing subtype-specific gene expression in PDAC potentially.

Conclusion

The results of this study suggest that SUPT5H depletion alters Pol II distribution, potentially leading to transcriptional dysregulation in a gene-specific manner.

⁴*Universidad de Barcelona, Barcelona, Spain*

⁵*Catalan Institute of Oncology, Oncology Data Analytics Program, L'Hospitalet de Llobregat, Spain*

Introduction

Lynch Syndrome (LS) is the most common inherited cancer syndrome, characterized by development of mainly right-sided colorectal cancers (CRC), among other types of tumors. It is caused by germline pathogenic variants in mismatch repair (MMR) genes. In tumors and preneoplastic lesions, loss of MMR system associates with high neoantigen burden that is recognized by the immune system. A distinctive immune microenvironment has been recently described in normal colonic mucosa from healthy LS carriers. The aim of this study is to provide novel insights on the early molecular events in normal colonic mucosa that underlie LS colon cancer predisposition.

Material and method

39 LS carriers (13 survivors – with previous CRC or advanced adenomas – and 26 previvors – without previous CRC or advanced adenoma) and 10 healthy non-LS individuals were included. Fresh-frozen biopsies of normal appearing mucosa were obtained from left and right colon during routine surveillance colonoscopies. RNA was extracted and mRNA stranded libraries were sequenced on a NovaSeq 6000 (Illumina) in paired-end mode, with a read length of 2x151 bp. Differential gene expression, gene set enrichment and cell type deconvolution analyses were assessed according to the anatomical localization of the analyzed sample and the germline mutated MMR gene.

Result and discussion

Normal colonic mucosa from LS individuals showed a distinct transcriptomic profile compared to non-LS individuals, with 2774 differentially expressed genes (DEG) (p adjusted value (p_{adj}) < 0.05), of which 24 with a $|FC| > 2$. The most enriched biological processes in LS samples were related to metabolism, cellular respiration and T cell activation. Sharp differences in gene expression were observed between right and left colon mucosa samples in both control (1593 DEG, $p_{adj} < 0.05$) and LS (7053 DEG, $p_{adj} < 0.05$) groups, mainly related to B cell activation and antimicrobial response in colon. The most enriched biological processes in the right colon from LS compared to controls were related to metabolism, cellular respiration and T cell activation whereas in the left colon additional pathways were observed such as DNA replication and proliferation. Specific immune cell types (CD4, CD8, Treg and dendritic cells) were particularly abundant in the right colon in LS previvors. Distinct transcriptomic profiles according to the MMR germline mutated gene were also identified.

Conclusion

Differentially expressed genes and pathways have been identified in both right and left normal colonic mucosa from LS carriers. Enhanced immunosurveillance is enriched in the right colon of LS previvors, which may play a role in elimination of (pre)malignant cells. Our findings suggest a novel role of the MMR system in metabolic processes.

EACR25-2432**Coordinated Changes in Midkine Expression and Its Receptor Network in Gliomas***R. Zagożdżon¹, K. Zieliński¹, A. Góźdz², P. Szpak³,**I. Kalaszczyńska³, M. Lachota⁴**¹Medical University of Warsaw, Laboratory of Cellular and Genetic Therapies, Warsaw, Poland**²Medical University of Warsaw, Department of Histology and Embryology, Warsaw, Poland**³Medical University of Warsaw, Department of Histology and Embryology, Warsaw, Poland**⁴Children's Memorial Health Institute, Department of Ophthalmology, Warsaw, Poland***Introduction**

The diverse functions of midkine (MDK) are harnessed in cancer to support tumor development and invasion. However, despite previous reports of MDK presence in gliomas, its specific roles and the significance of each of its receptors remains inadequately understood.

Material and method

To investigate the role of MDK, we integrated four bulk RNA-Seq datasets to create a comprehensive glioma dataset comprising over a thousand adult gliomas. Next, we collected fresh human glioblastoma tumor samples and established glioblastoma stem cell cultures to examine MDK expression and secretion patterns as well as surface expression of MDK receptors. Furthermore, we correlated MDK serum levels with its mRNA expression in primary tumors. Finally, we conducted an in-depth cell-cell communication analysis using single-cell RNA-Seq data from 44 tissue fragments of different grade glioma tumors.

Result and discussion

We identified divergent MDK expression patterns in IDH1wt and IDH1mut gliomas. MDK was associated with negative prognostic value which was more pronounced in IDH1wt gliomas compared to IDH1mut tumors. Integrated bulk, single-cell RNA-seq and proteomic data indicate that malignant glioma cells are the primary source of MDK in the glioma micro-environment with MDK exerting multidirectional protumorigenic effects. While the mechanisms responsible for high MDK expression in gliomas remain unknown, cell-cell communication analysis and flow cytometry profiling of MDK receptors has allowed for improved understanding of the role of the MDK's complex receptor network.

Conclusion

Collectively, these findings provide novel insights into the role of MDK and its receptor network in glioma, allowing for informed targeting of MDK and its signaling in MDK-high subset of gliomas.

EACR25-2551**Novel insights into CDH1 non-coding regulatory elements: effects on E-Cadherin expression, metastasis, and patient outcomes***R. Barbosa-Matos¹, C. São José¹, S. Lobo¹, M. Ferreira¹, N. Martins¹, I. Gullo¹, J. Senz², J. Bessa³, S. Mundlos⁴,**C. Oliveira⁵**¹i3S, Expression Regulation in Cancer, Porto, Portugal**²University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada**³i3S, Vertebrate Development and Regeneration, Porto, Portugal**⁴Max Planck Institute for Molecular Genetics, RG Development & Disease, Berlin, Germany**⁵i3S, Porto, Portugal***Introduction**

Regulation of CDH1 expression relies on regulatory elements (RE) located between the 5'-UTR and intron 2. However, the effects of disrupting these RE in cancer cells, and their link to patients' outcomes remain poorly defined. Here, we explore the consequences of single and combined disruptions of non-coding RE at the CDH1 locus, assessing both local and global gene expression changes.

Material and method

METABRIC tumor samples (n=2085) were classified based on intron 2 deletions or amplifications, examining clinical-pathological features and disease-specific survival. The regulatory potential of coding exon 2, REa, and REb was assessed by luciferase assays, zebrafish enhancer detection, and lacZ reporter assays in mice. Their functional impact was evaluated by CRISPR/Cas9 perturbation, RNA-seq, ATAC-seq, 4C-seq with a viewpoint at the CDH1 promoter, as well as lung colonization assays via mice tail vein injections. Gene ontology analysis from differentially expressed genes (DEG) was integrated with ATAC-seq to identify key genes and relevant pathways. KMPlotter was used as an independent cohort to explore candidate genes expression in metastasis-free survival.

Result and discussion

Breast cancer patients with homozygous deletions spanning CDH1 intron 2 RE showed better outcomes and lower tumor grades compared to other tumors, including those with intron 2 amplification. Intronic REa, REb and Exon2 showed regulatory properties. Combined disruption of REa and REb led to CDH1 loss of function, producing the strongest impact on transcriptome and global chromatin accessibility profiles, but cells were not able to colonize the lung. Cells with REb disruption alone displayed half CDH1 expression, and less ability to colonize the lung than Exon2 deletion or wild-type cells, highlighting an hypomorphic nature. Cells with combined disruption of REa and REb revealed DEG impairing extravasation, supporting their lack of lung colonization. Reduced expression of two candidate genes associated with extravasation and colonization correlated with better patient's outcomes in an independent cohort.

Conclusion

Impairment of intron 2 RE induces global changes in 3D-chromatin architecture, accessibility and expression profiles that prevent cell extravasation, hampering lung colonization. This mechanism supports the favorable outcomes of breast cancer patients with homozygous CDH1 RE deletions, despite E-cadherin loss.

³St. Anne's University Hospital and Faculty of Medicine, First Department of Orthopedic Surgery, Brno, Czech Republic

⁴St. Anne's University Hospital and Faculty of Medicine, First Pathology Department, Brno, Czech Republic

Introduction

Giant cell tumor of bone (GCTB) is a benign but locally aggressive osteolytic tumor that typically originates in the epimetaphyseal region of long bones. It is characterized by a high recurrence rate and contains multinucleated osteoclast-like giant cells and neoplastic mononuclear stromal cells. To minimize the risk of recurrence, various adjunctive therapies have been employed, including cryosurgery, phenol, bone cement, and argon beam therapy. Systemic treatments such as bisphosphonates, interferon alpha, and denosumab are also used. Denosumab, a human monoclonal antibody, inhibits the activity of osteoclast-like giant cells, but it does not affect the neoplastic mononuclear stromal cells. Therefore, there is a need for new therapies targeting the neoplastic stromal cells to reduce recurrence and improve patient outcomes.

Material and method

A phospho-protein array was used to detect phosphorylation of 49 RTKs in tumor tissues obtained from diagnostic biopsies or post-treatment surgery.

Subsequently, protein expression was verified on tumor tissue samples and derived stromal cell lines by western blotting. Based on those results, we have identified druggable molecular targets involved in RTK signaling. Selected FDA-approved low-molecular weight inhibitors were used to test their in vitro effects on cell viability and cell cycle.

Result and discussion

After denosumab treatment, phosphorylation of specific RTKs, including EGFR, PDGFR α , PDGFR β , and IGF-IR, was detected in tumor tissues. A similar profile was observed in tumor-derived cell lines. MTT assay and live cell imaging demonstrated a significant dose-dependent effect on cell viability in vitro after the use of specific RTK inhibitors (e.g., sunitinib, axitinib, crizotinib, ceritinib, and trametinib). In addition, flow-cytometric analysis demonstrated induction of cell death as indicated by an increase in the sub-G1 peak. Among the tested inhibitors, trametinib, a specific MEK1/2 kinase inhibitor, showed the best effect in all stromal cell lines used.

Conclusion

These findings suggest that RTK signaling plays a crucial role in promoting stromal cell proliferation within GCTB tumors. Targeted therapy with inhibitors of specific

RTKs or downstream signaling proteins could serve as a valuable addition to current GCTB treatment strategies.

This study was supported by project no. NU22-10-00054 from the Ministry of Healthcare of the Czech Republic and by the project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102)—Funded by the European Union—Next Generation EU.

Introduction

Clustering of type-II tumour necrosis factor receptors (TNFRs) is required to induce intracellular signaling. Current methods for receptor clustering lack precise control over ligand valency and spatial organization, potentially limiting optimal TNFR activation, biological insight, and therapeutic efficacy. DNA nanostructures provide nanometer-precise control over molecular arrangement, allowing control of both ligand spacing and valency.

Material and method

Here, we produce a DNA nanostructure decorated with controlled numbers of engineered single-chain TNF-related apoptosis-inducing ligand (sc-TRAIL) trimers. These trimers cluster death receptor 5 (DR5), enabling investigation of the geometric parameters influencing apoptotic pathway activation.

Result and discussion

We show that cell killing is affected by both valency and separation of sc-TRAIL trimers, which can be utilized to induce cell killing in human primary pancreatic and colorectal cancer organoids.

Conclusion

Together, our data shows that precise control of receptor clustering through spacing and valency enhances our understanding of receptor activation mechanisms and informs the development of more effective cancer therapies.

Introduction

Breast cancer is the most frequently diagnosed cancer in women worldwide. Triple negative tumors (TNBC) are deficient for well-defined molecular targets making chemotherapy, which is non-specific and cytotoxic, the most common treatment option. Patients with TNBC tend to develop metastasis and recurrence after treatment as well as lower survival compared to patients with other subtypes of breast cancer. Hence, there is a need for innovative therapeutic interventions to help women with breast tumors. Cannabinoids are products of Cannabis sativa. They were first introduced as palliative medicinal products, aiding in reducing emesis resulting from chemotherapy for cancer patients. Cannabinoids possess anti-tumoral activity in breast cancer cell lines. In this study, to elucidate the role of CBD and CBDA (Cannabis oils extracted by cannabis inflorescence) in tumor growth progression in TNBC, we performed in vitro studies on MDA-MB231 cells, and in vivo studies on heterotopic mice of TNBC.

Material and method

In vitro assays were performed on triple-negative MDA-MB-231 cells treated with CBD and CBDA, alone and in combination. The effects of CBD and CBDA on viability were determined by wound healing and MTT assays, cell migration was assessed by transwell migration and in vitro apoptosis by flow cytometry. Xenograft mouse model of TNBC was generated by a subcutaneously injection of MBA.MB231 cells into the right-side flank area of BALB/c mice (n total = 24 mice). After the randomization mice were divided into 3 groups according to the different types of treatment: 1) Normal Saline (vehicle); 2) CBD and 3) CBDA injected peri-tumorally every day for 3 weeks. The animals were sacrificed 2 weeks later. Half of the tumor tissue was formalin-fixed and paraffin-embedded for immunohistochemistry for CD31, for immunofluorescence localization of Ki67 protein, and routine H&E staining. Western blotting analysis was performed according to standard protocols on protein extracted from breast tumor tissues to detect the expression of proteins P53 and Bcl2.

Result and discussion

We demonstrated that both CBD and CBDA, can inhibit cell proliferation of MDA MB 231 cells by enhancing the apoptosis. In vivo studies performed on xenograft mouse model of TNBC, revealed that tumors of mice treated with CBD and CBDA are smaller than those observed in the controls. CBD Modifies the Expression of Tumor

Development Markers Ki67, Bcl2 and P53. Our results suggest that CBD and CBDA, can be viewed as promising agents for inhibiting TNBC progression, which has scarce therapeutic options and is featured by inauspicious prognosis and low survival rates.

Conclusion

Our results suggest that phytocannabinoids, CBD, and CBDA, can be viewed as promising agents for inhibiting TNBC progression.

EACR25-0074

Natural stilbenes in prostate cancer targeted interception and therapy: pre-clinical studies

A. Levenson¹

¹College of Veterinary Medicine, Long Island University, Biomedical Sciences, Brookville, United States

Introduction

Nutritional chemoprevention and interception are a particularly promising approach for prostate cancer due to its slow progression and predominance in elderly men. Plant-derived stilbenoids are a class of natural polyphenols with multiple positive pharmacological properties including antioxidant, anti-inflammatory, and pro-apoptotic effects. Metastasis-associated protein 1 (MTA1), a master transcriptional co-regulator and chromatin modifier, is strongly associated with prostate cancer progression and metastasis. The importance of MTA1-targeted interventions to block prostate cancer progression will be discussed.

Material and method

We established multiple MTA1 loss-of-function prostate cancer cell lines for mechanistic studies and developed various preclinical models of prostate cancer, including xenografts and unique transgenic mouse models reflecting different stages of prostate cancer to test the anti-inflammatory and anticancer effects of resveratrol, pterostilbene, and Gnetin C by different routes of administration. Immunohistochemistry, real-time PCR, western blot analysis, colony formation, wound healing, ELISA, to mention some, were used for evaluating MTA1 signaling (PTEN, p53, pAkt/Akt, mTOR, Cyclin D1, Notch2, Ets2, E-cadherin, IL-1 β) targeting results.

Result and discussion

Our in-dept in vitro and in vivo experiments demonstrated remarkable interceptive/therapeutic potential for stilbenes, specifically for the most potent dimer-resveratrol Gnetin C, in constraining MTA1 signaling and blocking progression of prostate cancer in preclinical models. Stilbene-supplemented diets diminished the progression of prostate cancer in transgenic mice by reducing inflammation, cell proliferation, angiogenesis and inducing apoptosis. Combination of natural compounds with clinically approved drugs showed promising results in combating castrate-resistant prostate cancer. Challenges in combinatorial approaches using natural compounds with approved drugs will be discussed.

Conclusion

Due to known reasonable safety, natural stilbenes may become the most promising MTA1-targeted strategy for prostate cancer chemoprevention, interception, and therapy. Well-controlled clinical trials are needed to

confirm novel nutritional intervention for untreated patients under active surveillance and novel combined therapy for more advanced disease.

Introduction

The prognostic relevance of heart-rate variability (HRV) among cancer patients has stimulated scientific exploration into its therapeutic utility. This prospective interventional phase III randomised clinical trial with open-label approach aims to assess the therapeutic efficacy of the HRV biofeedback intervention (HRV BI) in patients with solid tumors as a supplementary therapeutic approach. The trial aims to evaluate the impact of HRV BI on various clinical and psychosocial parameters compared to standard of care (SOC) alone.

Material and method

Trial design Participants in the intervention group will receive the SOC treatment along with HRV BI, involving four sessions led by a trainer. They will learn about the prognostic significance of the vagal nerve in cancer, as well as techniques for reducing distress and pain through deep paced breathing with HRV monitoring. Subsequently, they will perform daily HRV BI sessions for three months with online monitoring and support. The participants in the non-interventional group will receive the SOC alone. Cohort A- patients with pathologically confirmed breast cancer diagnosis planned for neo-adjuvant chemotherapy +/- targeted therapy +/- immunotherapy approach defined by standard of care in current European Society for Medical Oncology (ESMO) guideline. Cohort B- includes patients with pathologically confirmed colon cancer diagnosis planned for adjuvant chemotherapy +/- targeted therapy +/- immunotherapy defined by standard of care in current ESMO guideline. The study's primary endpoints include the effect of HRV biofeedback on inflammation (IL-6, Tumor necrosis factor α , IL-10 and Tumour Infiltrating Lymphocytes), QoL (measured by EORTCQLQ-C30), executive functions (measured by Stroop task test), effect on stress relief (measured by salivary cortisol slopes), sleep quality (measured by actigraphy and self-report data), HRV (indexed by the root mean square of successive differences between heartbeats – RMSSD) and working memory (measured by digit span test score). The study's secondary endpoints include evaluation of the Relapse-free Survival (RFS), Overall survival (OS), Serious Adverse Events (SAE) and the rates of

Pathologic Complete Response (pCR) and Residual Cancer Burden (RCB) in the cohort A.

Result and discussion

Clinical trial identification NCT06281145

CT Scan Identified Sarcopenia and MST and AND/ASPEN Malnutrition Guidelines in Gastrointestinal Cancer Patients

S. Dieckmann¹, J. Ponce², M. Jackson², L. Tenner³, K. Bailey², C. Hanson²

¹UNMC, Medical Nutrition, Salt Lake City, United States

²UNMC, Medical Nutrition, Omaha, United States

³UNMC, Oncology & Hematology, Omaha, United States

Introduction

Sarcopenia, a debilitating muscle-loss disorder, worsens quality of life and raises morbidity and mortality, particularly in gastrointestinal (GI) cancer patients. Although up to 89% of cancer patients have sarcopenia, no clear consensus exists on risk screening, including the use of malnutrition tools. While Computed Tomography (CT) is considered the gold standard for diagnosing sarcopenia and is routinely performed in GI cancer care, there is currently limited utilization of CT scans for sarcopenia, clinically. This study used routine CT scans to assess how well the Malnutrition Screening Tool (MST) and the Academy of Nutrition and Dietetics and American Society for Parenteral and Enteral Nutrition (AND/ASPEN) malnutrition guidelines detect sarcopenia in a GI cancer population.

Material and method

In this retrospective chart review, CT scans were used to diagnose sarcopenia utilizing ImageJ software. Demographic, MST scores, and malnutrition data were collected from the subjects' medical record at their initial oncology visit. GI cancers evaluated included colon, rectal, small bowel, gastric, esophageal, and pancreatic. Fisher's exact tests, independent t-tests, receiver operating characteristic curves, and logistic regression were used to examine the relationship between the two tools and sarcopenic and non-sarcopenic groups.

Result and discussion

At baseline, 50 participants were included in the study. The population was 56% (n = 28) male, 92% (n = 46) white, and the median age of the group was 65.5 (IQR = 16.0) years old. Of GI cancers, 48% (n = 24) had colon or rectal cancers, with pancreatic cancer being the next most prevalent (28%, n = 14). The median body mass index (BMI) of the group was 26.9 kg/m² (IQR = 6.8). 50% (n = 25) of participants were identified as sarcopenic. Baseline demographics were not statistically different between groups. The odds of being diagnosed with sarcopenia increased by 153% for each one unit increase in the MST (OR 1.53, 95% CI: 1.00, 2.33; p-value = 0.050). There was no statistically significant relationship when comparing malnutrition status using the AND/ASPEN guidelines with CT diagnosed sarcopenia.

Conclusion

CT scans identified sarcopenia in half of the population, offering additional clinical utility of routinely accessible

scans. There may be a relationship between MST and sarcopenia, showing potential as a clinical prediction tool of sarcopenia risk. Given the small sample size, further larger powered studies are needed to confirm the relationships between more commonly used nutrition assessment tools and their predictive value in identifying sarcopenia.

EACR25-0342

Treatment response and survival of patients with early-onset compared to older-onset colorectal cancer in the Netherlands

L. Borghuis¹, S. van Hooff¹, L. Vermeulen¹, T. Buffart²

¹*Amsterdam UMC, Laboratory of Experimental Oncology and Radiobiology, Amsterdam, Netherlands*

²*Amsterdam UMC, Medical Oncology, Amsterdam, Netherlands*

Introduction

The incidence of patients with early-onset colorectal cancer (eoCRC) (<50 years) is rising. The aim of this study is to investigate response to current treatment and survival in patients with eoCRC compared to older-onset CRC.

Material and method

Clinicopathological data, including treatment response and survival of patients diagnosed between 2016 and 2022 were requested from the Netherlands Cancer Registry. EoCRC patients were compared to patients 50-70 and ≥70 years of age. Additionally, eoCRC patients were matched with patients 50-70 and ≥70 years based on tumor stage, RAS/BRAF mutations, tumor sidedness and therapy. To compare groups, two sided X2 and Fisher's exact tests were used. Overall survival (OS) was analyzed with Kaplan Meier and median survival times were compared with the log-rank test (R software). P-values < 0.05 were considered significant.

Result and discussion

Between 2016 and 2022, 81,769 patients were diagnosed with CRC, including 3,948, 34,918, and 42,930 patients <50, 50-70 and ≥70 year, respectively. Patients <50 and ≥70 years had worse OS compared to patients aged 50-70 years ($p < 0.001$; HR, 1.14 (95% CI, 1.07-1.21); HR, 2.06 (95% CI, 2.06-2.11)) with a 5-year OS of 69%, and 54%, compared to 73%, respectively. EoCRC patients with high risk stage II CRC (T4N0) have a similar OS compared to patients 50-70 years, but better than patients ≥70 years ($p = 0.02$; HR, 2.19 (95% CI, 1.15-4.16); $p = 0.03$; HR, 1.46 (95% CI, 1.04-2.05), respectively). EoCRC patients with high-risk stage III (T4 and/or N2), have worse OS compared to patients 50-70 years ($p = 0.03$; HR, 0.81 (95% CI, 0.67-0.98)), while OS in low-risk stage III (T1-3/N1) was similar. Patients ≥70 years have worse OS compared to patients 50-70 years in both high- and low risk stage III CRC ($p < 0.001$; HR, 1.41 (95% CI, 1.28-1.55), $p < 0.001$; HR, 1.80 (95% CI, 1.58-2.06), respectively). EoCRC patients with pMMR stage IV disease at diagnosis have better OS, while patients ≥70 years of age have worse OS compared to patients 50-70 years ($p < 0.001$; HR, 0.56 (95% CI, 0.79-0.93), $p < 0.001$; HR, 1.55 (95% CI, 1.47-1.64), respectively). EoCRC patients more often received triple therapy

(fluoropyrimidine + oxaliplatin + irinotecan +/- bevacizumab) in first line compared to older patients, (20%, 10% and 3% for patients <50, 50-70 and ≥70 years, respectively). Patients ≥70 years more often received fluoropyrimidine monotherapy +/- bevacizumab (8%, 14% and 40%, respectively). After matching no significant difference in OS was observed between eoCRC patients and patients 50-70 years. OS of patients ≥70 years remained worse.

Conclusion

OS of eoCRC patients with high-risk stage II and low risk stage III was similar to patients 50-70 years, but OS was worse in high-risk stage III eoCRC. EoCRC patients with pMMR stage IV CRC have better OS but also receive more intense systemic therapy. OS difference between eoCRC and patients 50-70 years disappeared after matching. Survival of patients ≥70 years remained worse.

⁴*Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Genetic Predisposition to Gastrointestinal Cancer, Barcelona, Spain*

⁵*The Netherlands Cancer Institute, Department of Pathology, Amsterdam, Netherlands*

Introduction

Rectal cancer biobank (RCB) is the first human-sample, research-based repository in Serbia established by following highly controlled internationally approved biobanking criteria at the Institute for Oncology and Radiology of Serbia (IORS). The World Health Organization reported 42,000 new cancer cases in Serbia in 2022, which provides a rationale for further expansion of the IORS biobank with collections of other tumor types and locations besides rectal cancer. To implement best practices for effective strategic planning and management, we performed a SWOT analysis to address possible challenges in the process of IORS biobank development.

Material and method

A comprehensive evaluation of internal and external determinants that may impact the future growth and performance of the IORS biobank has been performed.

Result and discussion

Accessibility of patients with different tumor types, good logistic management between clinicians and biobank staff and a well-integrated bioethical framework at IORS,

allow extensive collecting strategy. Those advantages together with biobank team members who hold advanced knowledge and skills for various methodologies in processing of biospecimens and data annotation are major strengths that biobank growth can rely on. On the other hand, weaknesses include currently limited storage and working space that could not be easily improved considering project-based funding and a lack of legal clauses for implementation of a self-sustainability plan, considering the four dimensions of sustainability: operational, financial, social and environmental. Being the first official cancer biobank at the national level and also tightly collaborating with several international scientific groups and international biobanks, make opportunities for IORS biobank to take a significant place in contributing to cancer research in the region and beyond. However, the major threats to IORS biobank prosperity are lack of knowledge about biobanking from layman population, researchers and clinicians, deficiencies of national legislative regulations regarding the development of non-transplant tissue biobanks, national accreditation path, and the obstacles to enroll additional administrative and laboratory personnel without IORS executive department consent.

Conclusion

The results of the conducted SWOT analysis serve as a valuable foundation for development planning, assisted us to establish priorities, and challenge risky assumptions that could lead to misconceptions and failure of IORS biobank objectives. Complementary tools related to business planning and data management planning will be crucial to achieving excellence in national biobanking.

[1] The RCB was established within STEPUPIORS Horizon Europe project No 101079217 according to guidelines recommended by international expert institutions (ISBER, BBMRI, ERIC).

EACR25-0423

Cardiac Remodelling and Incident Cardiovascular Risk in Haematological Cancer Survivors from the UK Biobank

G. Andriamiadana¹, J. Cooper¹, L. Szabo^{2,1}, D. Condurache¹, C. Maldonado-Garcia¹, S. Petersen¹, Z. Raisi-Estabragh¹

¹*Queen Mary University of London, William Harvey Research Institute, London, United Kingdom*

²*Semmelweis University, Heart and Vascular Centre, Budapest, Hungary*

Introduction

Haematological cancer survivors are at increased risk of cardiovascular disease (CVD) due to cancer-related biological processes and cardiotoxic cancer therapies. Cardiovascular magnetic resonance (CMR) provides detailed organ-level information about cardiovascular health. However, population-level studies examining long-term cardiovascular health in this population are limited. This study integrates clinical and CMR data from the UK Biobank to define the excess risk of specific CVDs and cardiovascular remodelling patterns in survivors of haematological cancer.

Material and method

Participants with a record of haematological malignancy prior to baseline recruitment were identified using linked

hospitalisation and cancer registry data. Each cancer-exposed participant was propensity score matched to two non-cancer controls on an extensive range of socio-demographic, lifestyle, baseline morbidity, and clinical biomarker variables. Missing covariate data were imputed using predictive mean matching. Cox regression was used to calculate hazard ratios for the following CVD outcomes: chronic ischaemic heart disease, non-ischaemic cardiomyopathy, heart failure, myocardial infarction, atrial fibrillation, pericardial disease, and venous thromboembolism. Incident outcomes were prospectively ascertained from linked hospital and death registry records over a median of 13.6 years. In participants with CMR data available, linear regression was used to examine the association of cancer exposure with CMR-derived metrics of cardiovascular structure and function, and myocardial tissue character. These included ventricular and atrial volumes and function, arterial stiffness strain, and myocardial T1.

Result and discussion

A total of 2,166 haematological cancer survivors [median age 61, (IQR: 53–65) years; 56% women] and 4,331 controls were included in the analysis. Cancer survivors demonstrated a significantly increased incident risk for all selected CVDs, with the highest risks observed in relation to pericardial disease [HR = 6.38, 95% CI: 3.18–12.83]. Participants with haematological cancer had significantly large left ventricular volumes with poorer function (lower ejection fraction, worse global longitudinal strain), and pronounced myocardial fibrosis (higher T1).

Conclusion

Haematological cancer survivors have a significantly elevated risk of a range of incident CVDs. CMR analysis reveals adverse cardiac remodelling, comprising larger and poorer functioning left ventricle with greater myocardial fibrosis in haematological cancer survivors, compared to matched controls. These findings highlight the excess long-term cardiovascular risk of this cohort and the potential role of imaging biomarkers in risk stratification and understanding underlying mechanisms.

EACR25-0479

Genomic Profiling of Colloid Carcinoma of the Pancreas

M. Bevere¹, A. Mafficini¹, A. Scarpa¹, C. Luchini¹

¹*University of Verona, ARC-NET Applied Research on Cancer Center, Verona, Italy*

Introduction

Colloid carcinoma (CC) of the pancreas is a rare and distinct subtype of pancreatic cancer (PDAC), representing only 1–3% of all pancreatic tumors. Unlike the more common PDAC, CC is distinguished by the abundant extracellular mucin produced by tumor cells. CC often arises from intraductal papillary mucinous neoplasms (IPMNs), particularly of the intestinal subtype. While CC shares similarities with other pancreatic tumors in terms of symptoms, diagnosis, and treatment, it has a significantly better prognosis than PDAC. At the molecular level, CCs are associated with frequent

mutations in GNAS, followed by mutations in KRAS and TP53, with MSI cases typically being KRAS wild-type. However, most molecular studies focus primarily on PDAC, with relatively few cases of CC. The reasons behind its improved prognosis remain unclear, highlighting the need for further research to uncover potential therapeutic targets.

Material and method

We used DNA-targeted sequencing (174 genes) and immunohistochemistry (IHC) analyses to profile this cohort.

Result and discussion

This study analyzed 46 patients, including 27 with IPMN-associated CC (1 with intraductal oncocytic papillary neoplasm, IOPN; 26 with IPMN) and 19 with CC alone. Histological grading was performed based on immunophenotypic classification to characterize these tumors. The IHC analyses confirmed that IPMNs are mostly high-grade intestinal lesions, while the IOPN exhibited only high-grade dysplasia. Among the invasive tumors, 31 out of 46 (67%) were classified as mucinous and low-grade tumors, whereas 15 out of 46 (33%) displayed an infiltrative glandular component and high-grade tumors. DNA sequencing revealed that the most common genetic variations affected KRAS (48%), GNAS (46%), TP53 (35%), ATM (22%), RNF43 (17%), CDKN2A/SMAD4 (15%). Interestingly, 4 out of 9 ATM mutations were germline, as confirmed by Sanger sequencing. In addition to these germline mutations, one patient had a CHEK2 mutation, and another carried two different germline mutations affecting NF1 and ATM. Two patients of 46 showed microsatellite instability (MSI) with high tumor mutational burden (TMB). Lastly, it was found patients harboring amplification in CCND1 (1/46), CCND2 (4/46), CCND3 (1/46), CCNE1 (1/46), and IDH2 (1/46), which may be sensitive to targeted therapies (CDK4/6 inhibitors, CDK2 inhibitor or IDH2 Inhibitors). Overall, this study emphasizes the value of genomic profiling to identify patients with 1) potentially druggable mutations, gene amplifications or MSI; and 2) germline mutations sensitive to platinum-based therapies and/or PARP inhibitors.

Conclusion

To date, this study includes the largest cohort of patients with CC. This may help shed light on the factors contributing to the improved outcomes of CC compared to PDAC.

EACR25-0500

Breast cancer immunotherapy using magnetised oncolytic virus

F. Howard¹, H. Al-Janabi¹, J. Conner², M. Muthana¹

¹*University of Sheffield, Division Clinical Medicine, Sheffield, United Kingdom*

²*Invisis, Glasgow, United Kingdom*

Introduction

Oncolytic viruses (OV) are encouraging new immunotherapies for cancer. OV, replicate in cancer cells inducing immunogenic cell death (ICD) and activating antitumour immunity. To date, clinical use has focused on intratumoural delivery due to concerns over inadequate tumour targeting following systemic administration. We hypothesize that magnetising OV

and magnetic guidance strategies will improve systemic delivery by protecting the viruses from inactivating immune mechanisms and non-specific adsorption.

Material and method

To investigate this, we magnetised oncolytic viruses and delivered these to tumours *in vitro* and *in vivo* using human and bacterial cell delivery systems.

Characterisation of the physical, chemical and oncolytic potential of our magnetised viruses (MAG-OV) was performed in combination with magnetic guidance strategies in preclinical mouse models of mammary cancer.

Result and discussion

Stable MAG-OV complexes of ~90nm diameter successfully infected human and murine breast cancer cells in a dose-dependant manner, and induced tumour oncolysis. Following MAG-OV infection, a significant increase in viral replication (ICP0, gB, ICP8), ICD (HMGB1, CALR, ATP) and apoptotic (CASP 3, CASP8, FASL) signals were detected. Intravenous delivery of MAG-OV resulted in reduced tumour burden in the presence of magnetic guidance and an increase in tumour-infiltrating T-cells, NK cells and neutrophils. Furthermore, MAG-OV complexes were protective in the presence of neutralising viral antibodies.

Conclusion

This study indicates that magnetising oncolytic viruses results in viral protection from neutralising antibodies and in combination with magnetic guidance reduces tumour burden and induces antitumour immunity.

EACR25-0524

In vitro strategy to discover therapeutic targets in PDAC

J. Le Naour¹, R. Via y Rada², F. Guérin², M. Collet³, Y. Luo¹, H. Darville², N. Provost², D. Piwnica¹, J. Stephan¹, N. Molinié¹

¹*Institut de recherche Servier, Research Pharmacology, Gif-sur-Yvette, France*

²*Institut de recherche Servier, Integrative Molecular Pharmacology, Gif-sur-Yvette, France*

³*Institut de recherche Servier, Translational Medicine Department, Gif-sur-Yvette, France*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer death worldwide with increasing incidence over the years. Due to late onset of symptoms in early stages, early metastasis, limited therapeutic options and high rate of therapy resistance, overall prognosis remains dramatically poor (10% 5-year survival rate). One of the primary reasons for the low success rate is the complex tumor microenvironment of PDAC, characterized by a highly fibrotic and dense stroma surrounding the tumor cells which not only supports tumor progression but also increases resistance to treatment. Thus, developing innovative ex vivo culture modalities that accurately reflect the complexity and heterogeneity of PDAC represents a significant challenge for the precise evaluation of potential therapies.

Material and method

Our experimental approach lies on the set-up and characterization of various models derived from patient samples including tumoral biopsies or resections from

primary tumors or liver metastases, blood and ascites. Comprehensive characterization of patient avatars involves pharmacotyping with standard-of-care (SoC) and advanced multi-omics investigations, such as single-cell transcriptomics, proteomic, and genomics. In recent years, culture of patient-derived explants have emerged as a promising approach for preclinical studies. This model maintains the full tumor microenvironment with its intact architecture. Taking advantage of this highly relevant model, we investigate drug response in tissue slices along with paired control samples (basal state) through histological analyses to evaluate quality and tumoral content. Samples of interest are then evaluated through multiplex and/or multi-omics investigations in the context of associated clinical data. Matched blood samples will allow us to investigate circulating mediators as potential biomarkers of treatment response.

Result and discussion

We have completed the set up of our slicing method and culture conditions. We are currently in the process of sample collection and selection for the different readouts. These investigations are expected to significantly impact our understanding of PDAC complexity and response to treatment

Conclusion

This research project represents a crucial step towards enhancing our understanding of PDAC heterogeneity and refining experimental models for translational studies. The ultimate objective is to employ these avatars as an asset for bench-to-bedside translation for 1) identifying SoC vulnerabilities to uncover new therapeutic targets 2) guiding the selection of optimal therapeutic strategies and 3) identifying or positioning Servier's assets in this indication based on a more nuanced comprehension of the disease. This approach will also facilitate the identification of biomarkers and monitoring of therapeutic responses, further contributing to personalized medicine in pancreatic cancer care.

EACR25-0526

Protein Tyrosine Phosphatase Receptor type Psi (PTPRU) in clinical breast cancer

Z. Xu¹, A. Li¹, T. Martin², W. Jiang², J. Du³, E. Davies⁴

¹CCMRC, Cardiff University School of Medicine, Cardiff, China

²CCMRC, Cardiff University School of Medicine, Cardiff, United Kingdom

³CCMRC, Cardiff University School of Medicine, Changchun, China

⁴Wales Breast Centre, University Llandough Hospital, Cardiff, Cardiff, United Kingdom

Introduction

Receptor-type Protein tyrosine phosphatase Receptor Type U (PTPRU) is a member of the protein tyrosine phosphatase (PTP) family, a family known to have roles in regulating cell growth, cell adhesion and differentiation. PTPRU has been shown to have a possible impact on focal adhesion complex and may interact with the cell adhesion regulator CTNNB1 (b-catenin). It has been shown to influence the development of bone and central nerve system (CNS). However, little is known for the role of PTPRU in cancer and particularly in clinical

cancers. The present study investigated the expression pattern of PTPRU and its clinical significance in clinical breast cancer.

Material and method

Expression levels of PTPRU in a cohort breast cancer tissues including normal and tumour tissues were tested by way of transcript analysis. Patient's clinical, pathological, hormone receptor status, molecular subtypes and clinical outcomes (with a 10 year followup) were analysed against PTPRU expression.

Result and discussion

Breast cancer tissues had a marginally increased expression of the PTPRU transcript ($p = 0.081$) compared with normal mammary tissues. There was a marked reduction of PTPRU transcripts in breast tumours which developed local recurrence ($p = 0.022$, compared with those who remained disease free). ER positive (ER+) tumours had a significantly higher PTPRU than ER negative (ER-) tumours ($p = 0.0049$). PGR negative tumours also had raised levels compared with PGR negative tumours ($p = 0.0106$). Patients who had high levels of PTPRU had a significantly longer disease-free survival (DFS) than those with low levels ($p = 0.046$) and also have a longer overall survival (OS) although this was yet to be statistically significant ($p = 0.056$). The connection between PTPRU and DFS was more prominent in Her3 positive tumours ($p = 0.039$). In the Her2(+)ER(-) molecular subtype, high levels of PTPRU were associated with both longer DFS and OS. Interestingly, PTPRU does not show a correlation with CTNNB1 (a-catenin) in cancer tissues ($r = 0.111$, $p = 0.291$), but significantly correlated with E-cadherin ($r = 0.289$, $p = 0.005$) and a-catenin ($r = 0.208$, $p = 0.046$).

Conclusion

The expression of Protein tyrosine phosphatase receptor type U (PTPRU) has a significant correlation with favourable clinical outcome of patients with breast cancer, a relationship with a strong connection with the ER status of cancer cells. PTPRU thus has a hallmark of being a tumour suppressor in breast cancer and warrant further investigation for its prognostic values in breast cancer.

⁴The Queen Elizabeth Hospital, Department of Surgery, Woodville South, Australia

⁵Royal Adelaide Hospital, Upper Gastrointestinal Surgical Unit, Adelaide, Australia

⁶The Queen Elizabeth Hospital, Upper Gastrointestinal Surgical Unit, Woodville South, Australia

Introduction

Gastric cancer (GC) is a challenging disease with a 5-year survival rate of <6% for advanced disease with current, standard care treatment. Patient-derived organoids (PDOs) are an emerging technology that has shown promise in guiding personalised treatment for cancer patients. A limited number of studies have evaluated PDO for GC, and existing studies test only a very few chemotherapeutic options with low culture success rates. We thus aimed to culture GC PDOs and perform drug testing using standard care and alternative chemotherapeutics to evaluate the efficacy of PDOs in treatment prediction and alternate chemotherapy choices.

Material and method

Tumour tissue samples were obtained from locally or systemically advanced GC patients who underwent tumour resection, and these were cultured as PDOs and expanded. In vitro, drug testing was performed using standard care chemotherapeutics FLOT (Fluorouracil, leucovorin, oxaliplatin, docetaxel), FOLFIRI (Fluorouracil, leucovorin, irinotecan), FOLFOX (fluorouracil, leucovorin, oxaliplatin) and alternate treatments. Cell viability was determined by whole-well ATP quantification using CellTiter-Glo 2.0 and normalized to vehicle-only controls. PDO response to FLOT was correlated with the patient responses using CT/PET imaging.

Result and discussion

GC patients were recruited, and PDOs with varying morphologies and growth characteristics were established. PDOs were treated with three combination chemotherapy regimens with an average treatment duration of five weeks from sample processing. Varying half maximal inhibitory concentrations (IC₅₀) with FLOT were observed, and the viability of PDOs from responders was lower compared to non-responders to FLOT in the clinic.

Conclusion

To date, the establishment of GC PDOs has shown a slightly higher culture success rate at our site than published previously. The heterogeneity of GC has been apparent through varied GC PDO morphologies, growth characteristics, and IC₅₀ drug viability values. PDOs have successfully recapitulated clinical responses, indicating their potential as a reliable model for guiding precision medicine within a clinically relevant timeframe.

Targeting PI3K-Akt Signalling Pathway in the Search for Novel Therapeutic Strategies for Treatment Resistant High-Grade Serous Ovarian Cancer

A. Røssberg Lauridsen¹, A. Skorda², A. Lahtinen³, M. Lund Bay², B. Sophie Rasmussen², E. Valkonen⁴, J. Oikkonen³, J. Hynninen⁵, S. Hautaniemi³, T. Kallunki²

¹Danish Cancer Institute, Cancer Invasion and Resistance, Copenhagen, Denmark

²Danish Cancer Institute, Cancer Invasion and Resistance, Copenhagen, Denmark

³University of Helsinki, Research Program in Systems

Oncology, Helsinki, Finland

⁴Institute of Biomedicine and FICAN West Cancer Centre, Cancer Research Unit, Turku, Finland

⁵Turku University Hospital, Department of Obstetrics and Gynecology, Turku, Finland

Introduction

Ovarian cancer is the most lethal gynecological cancer, and high-grade serous ovarian cancer (HGSOC) is the most aggressive and common form of it. HGSOC is associated with high disease heterogeneity and distinct enriched pathways that mediate progression and resistance towards the current standard-of-care. The standard treatment is primary debulking surgery combined with platinum and taxane-based chemotherapy to which 80% of patients gain resistance towards within a few years. After this there is no additional serious treatment options, giving an urgent need for developing new treatment strategies. Since PI3K-Akt pathway is one of the main survival pathways in chemo resistant HGSOC, research on its inhibition could assist development of novel therapies for chemo resistant HGSOC.

Material and method

Our recent collaborative work is a tumor evolution study based on whole-genome and RNA sequencing data of longitudinal, prospective and multiregional collected tumor samples. This study suggests targets for drug intervention for the relapsed cases, such as inhibition of PI3K (Lahtinen et al. *Cancer Cell* 2023). In this study we have chosen to use a cohort of 2 control patient derived tumor organoids (PDTOS) with baseline PI3K expression and 4 case PDTOS with amplified PI3K expression. We have chosen PDTOS as our model system to gain insight closely resembling the reality of the patient tumor. We evaluated the response to PI3K inhibition through cell viability, proliferation and phosphorylation of Akt1 under a 3D setup with ImageXpress Confocal HT.ai. Image-based quantification was done with MetaXpress analysis software.

Result and discussion

PDTOS that resist chemotherapy become dependent on specific proliferative pathways that are drivers for relapses. We have found a PI3K inhibitor, alpelisib, to successfully kill 50% of the cells in the PDOs from the case group, while having only minor effect on the control group. Quantification of phosphorylation of Akt1 after treatment with alpelisib shows a significant decrease of Akt1 phosphorylation at each of its distinct phosphorylation sites T308 and S473 in the case group. For the control group there is only a significant decrease of phosphorylation of S473, but not for T308. This difference in phosphorylation might be an indicator of how the alpelisib specifically targets the PI3K-amplification in the case group of PDTOS. Future experiments will focus on exploring the synergistic effects of combining alpelisib with other targeted therapies with the focus on exploring the phosphorylation status of Akt1.

Conclusion

The PI3K-Akt pathway pose a great potential target for future treatments, but the need for highly effective treatments killing preferably all tumor cells is crucial when working with a heterogeneous and fast relapsing cancer such as HGSC. Our ultimate goal is to translate

these findings into clinical applications, providing new therapeutic options for patients with refractory cancers.

POSTER IN THE SPOTLIGHT

Ovarian cancer Zebrafish Avatars for personalized multiple drug testing

M. F Estrada¹, F. Amorim¹, F. Silva², C. Rebelo de Almeida¹, J. Casanova², R. Canas-Marques³, M. Castillo Martin³, S. Ferreira², H. Nabais², R. Fior⁴

¹Champalimaud Foundation, Cancer Development and Innate Immune Evasion Lab, Lisbon, Portugal

²Champalimaud Foundation, Gynecology Unit, Lisbon, Portugal

³Champalimaud Foundation, Anatomical Pathology Service, Lisbon, Portugal

⁴Champalimaud Foundation, Cancer Development and Innate Immune Evasion, Lisbon, Portugal

Introduction

Ovarian Cancer is the 1st cause of death amongst gynecological cancers. Treatments are chosen with no evidence of the tumor's response to therapy, exposing patients to unnecessary toxicities. Until now, there is no test to assess the best option for each patient. To solve this unmet need we developed the Ovarian cancer zebrafish Avatar-test (zAvatars).

Material and method

Cells were isolated from ovarian cancer patients, after obtaining their informed consent. zAvatars from 27 patients were generated by injecting cells in the perivitelline space of 2 days post fertilization zebrafish embryos. zAvatars were challenged with the same therapy as their donor patient as well as second line therapeutic options, to evaluate drug sensitivity, in a non-interventional retrospective clinical study.

Result and discussion

Our data shows that, patients that were sensitive to treatment, their matching zAvatars were also sensitive; whereas patients that were resistant their zAvatars also showed resistance to treatment. By plotting the results in a confusion matrix we obtained a positive predictive value of 88% and a negative predictive value of 91%, which corresponds to an overall correlation of 89%. Moreover, through Kaplan-Meier survival curves we demonstrate that patients with a sensitive zAvatar-test have significantly longer PFS and OS ($p<0.0001$) than patients with a resistant zAvatar test. Analysis of the metastatic capacity showed that tumor cells from patients with accumulation of malignant ascitic or pleural effusion fluid, had a higher metastatic potential, regardless of isolating cells from the peritoneal wall or the fluid. These results are in line with the literature that considers that patients with fluids have poorer prognosis despite having the same follow up and treatment as patients without fluid accumulation.

Conclusion

With this clinical study we were able to demonstrate that zAvatars predict the patient response to therapy and thus can be used as a screening method to guide patient therapy. As a next step, we are performing a Multicentric Randomized Clinical Trial (EU CT 2023-509598-22), to demonstrate the clinical benefit of using the zAvatar test

as a screening tool to guide patient therapy and thus improve patient survival and wellbeing.

This research received support from Champalimaud Foundation and FCT (FCT-PTDC/MEC-ONC/31627/2017).

⁴Group of Biomedical Research in Gynaecology, Vall Hebron Institute of Research, Gynaecological Department, Vall Hebron University Hospital, University Autonomous of Barcelona, Center for Biomedical Network Research on Cancer, Barcelona, Spain

Introduction

Ovarian cancer (OC) is a leading gynaecological cause of death, with high-grade serous ovarian carcinoma (HGSOC) as the most common and aggressive subtype, often diagnosed at an advanced stage. Despite optimal surgery and initial response to platinum-based chemotherapy, most patients develop resistant disease, leading to recurrence with peritoneal carcinomatosis and malignant ascites. These ascites contain metastasis-initiating cell aggregates that drive dissemination and therapy resistance. In order to overcome the limited number of clinically-relevant HGSOC cancer models, we are developing 3D in vitro models of organoids from malignant ascites for the study of intrinsic and acquired therapy resistance mechanisms.

Material and method

Malignant ascites from advanced HGSOC patients is collected during surgery to generate patient derived organoids (PDOs). The protocol consists in separating the cells, followed by erythrocytes depletion and cells seeding as 3D in drops embedded in basement membrane extract (BME) with an optimized PDO culture media. Successfully generated organoids are serially passaged and are established after four passages. PDOs are characterized by immunohistochemistry (IHC) and immunofluorescence (IF) using E-Cadherin, EpCAM, Vimentin, F-actin, Ki67 and PAX8 for understanding the 3D complexity and origin. High throughput drug screenings through specialized machinery of Multidrop Dispenser and D300 Digital Dispenser are performed to assess platinum resistance, generating robust data that is correlated with patients' clinical information.

Result and discussion

We successfully generated PDO models from 9 ascites samples, with a 50% of generation success rate. PDO generation from malignant ascites is more challenging than from tumour tissue due to the low presence of epithelial tumour cells (~1-2%) and the predominance of immune cells together with other cell types. IF of established organoids confirmed the epithelial origin and the 3D structure composed of different cell types of our models, while IHC showed strong pathological and molecular correlation with patient tumours. Three PDO models were tested for Carboplatin, Olaparib, and Niraparib response and were able to successfully mimic the platinum-treatment response.

Conclusion

In this study, we demonstrated that PDOs derived from malignant ascites of HGSOC patients can recapitulate the histologic and molecular features of the patients' tumours, and can predict treatment response. These viable and relevant preclinical models are valuable tools to deep on the understanding of therapy resistance and to advance in precision medicine approaches for resistant HGSOC patients.

BQ323636.1 Overexpression Drives mTOR Signaling and Lipid Metabolism via ACSL4 in ER-positive Breast Cancer

T. Ho¹, C. Ho Lam¹, M. Pui Sum¹, K. Ui Soon²

¹The University of Hong Kong, Pathology, Hong Kong, Hong Kong, China

Introduction

BQ323636.1 (BQ), a splice variant of NCOR2, its overexpression in estrogen receptor (ER)-positive breast cancer shown to be predictive of disease recurrence and/or metastases. Previous studies revealed that BQ overexpression enhances polyunsaturated fatty acid (PUFA) levels and represses oxidative stress via NRF2 modulation. As mTOR signaling is critical in tumorigenesis, we investigated how BQ sustains energy production and mTOR activation through lipid metabolism reprogramming.

Material and method

RNA-sequencing assessed BQ overexpression effects. Targeted metabolomics quantified fatty acids, while Western blot and qPCR analyzed protein and gene expression. Lipid, acetyl-CoA, and ATP levels were measured alongside oxygen consumption rates. ACSL4 was inhibited using siRNA, rosiglitazone, and PRGL493. Tumor growth was evaluated in nude mice.

Result and discussion

ACSL4 emerged as a central regulator of BQ-mediated lipid metabolism reprogramming. BQ overexpression increased PUFA levels, confirmed by metabolomics, while ACSL4 knockdown reduced PUFA, acetyl-CoA, and ATP in BQ-overexpressing cells. PUFA susceptibility to peroxidation was repressed by NRF2-induced antioxidant gene expression, lowering ROS and lipid peroxidation. NRF2 knockdown triggered ferroptosis – a lipid peroxide- and iron-dependent cell death – in BQ-overexpressing cells, which ACSL4 inhibition prevented. BQ enhanced mitochondrial oxygen consumption, elevating ATP and GTP via the TCA cycle,

activating mTOR through Rheb. ACSL4 suppression abolished these effects. In vivo, ACSL4 inhibition reduced tumor growth in mice, validating its role.

Conclusion

BQ exploits ACSL4 to elevate PUFA levels, fueling acetyl-CoA and GTP synthesis via the TCA cycle for mTOR activation. NRF2 prevents ferroptosis by limiting lipid peroxidation. Targeting ACSL4 emerges as a promising therapeutic strategy to avert disease progression in BQ overexpressing ER-positive breast cancer.

¹⁰Center for Personalized Cancer Treatment, Netherlands

Introduction

NRAS mutations occur in about 3.1% of all patients (pts) with cancer. To date, no FDA or EMA-approved targeted therapies exist for the treatment of NRAS-mutated (NRASmut) cancer. Trametinib, currently registered for BRAF V600-mutated melanoma and NSCLC in combination with dabrafenib, blocks the RAF/RAS pathway through inhibition of MEK1/2. Therefore, it is hypothesized that this small molecule inhibitor could elicit clinical benefit (CB) in pts with NRASmut tumors. Here, we present the efficacy and safety of trametinib in NRASmut tumors.

Material and method

Pts were treated as part of Drug Rediscovery Protocol (DRUP, NCT02925234), a single-arm, nonrandomized clinical trial treating pts with cancer with anti-cancer therapy based on their tumor molecular profile, outside of their registered indication. Eligible adult pts with progressive advanced or metastatic treatment-refractory tumors harboring a pathogenic, activating NRAS mutation received trametinib 2 mg QD in 28-day cycles until disease progression or unmanageable toxicity. Primary endpoints included CB, defined as confirmed objective response (OR) (partial or complete response

(PR; CR)) or stable disease (SD) ≥ 16 weeks, and safety. Pts were enrolled using a Simon-like two-stage design.

Result and discussion

Twenty-four pts were evaluable for response, two of whom were still on treatment at time of analysis. Nine different tumor types were treated, of which 13/24 were NSCLC (54.1%). The majority of pts (19/24; 79.2%) harbored a p.Q61 NRASmut, the remaining (5/24; 20.8%) a p.G12/G13 NRASmut. With 1 PR (4.2%) and 7 SD at ≥ 16 weeks (29.2%), the resulting CB-rate was 33.3% (95% CI: 15.6–55.3%), and the OR-rate was 4.2% (95% CI: 0.1–21.1%). The median progression-free survival and overall survival amounted to 3.7 months (95% CI: 3.3–5.3 months) and 9 months (95% CI: 5.6–13.5 months), respectively. The pt who achieved PR had an NRAS p.Q61R mutated NSCLC with concomitant BRAF (p.N581S) and TP53 (p.R110C) mutations. No statistically significant survival difference was observed between NSCLC-pts and other tumor types, nor between NSCLC pts harboring a p.Q61 or a p.G12/G13 NRASmut. Notably, 8/24 pts (33.3%) had unconfirmed SD (7/24; 29.2%) or unconfirmed PR (1/24; 4.2%) at the 8-week interim evaluation, that they were unable to sustain at the 16-week primary endpoint assessment. In 10/24 (42%) pts, 15 treatment-related adverse events (trAE) grade ≥ 3 were observed, mainly related to skin (5/15 trAE; 33.3%) and left ventricular function (3/15 trAE; 20%). Together, the trAE grade ≥ 3 led to treatment discontinuation in 3 pts (12.5%) after 27, 97 and 101 days of treatment.

Conclusion

Trametinib showed CB in a subset of NRASmut pts, reaching the primary study endpoint. However, the observed effect was moderate given rapid progression and a short progression-free survival. The high percentage of unconfirmed responses could imply a fast resistance mechanism following treatment with trametinib.

EACR25-0798

Investigating the Therapeutic and Prognostic Utility of Long Non-Coding RNA Targets and their Association with Tumour Microenvironment in KRAS-Mutant NSCLC

C. Murphy¹, A. Rahman², C. Burke¹, C. Jahangir¹, S. Vasyluk¹, L. Fanneran¹, A. Fabre³, M. Coan⁴, R. Johnson⁴, W. Gallagher¹

¹*University College Dublin, School of Biomolecular and Biomedical Sciences, Dublin, Ireland*

²*University College Dublin, School of Medicine, Dublin, Ireland*

³*St. Vincent's University Hospital, Histopathology Department, Dublin, Ireland*

⁴*University College Dublin, School of Biology and Environmental Science, Dublin, Ireland*

Introduction

Lung cancer is the leading cause of cancer incidence and mortality. 85% of cases are classed as non-small cell lung cancer (NSCLC). Of these, 40% bear an oncogenic KRAS mutation (KRASmt) which is associated with

poor prognosis. Some KRAS-targeting therapies are approved but exhibit isoform specificity and resistance. Further, immunotherapy efficacy is limited due to immune contexture heterogeneity between KRAS isoforms. Novel strategies to target other key oncological drivers in KRASmt tumours must be explored. Long non-coding RNAs regulate gene expression at epigenetic, transcriptional, and translational levels, are implicated in several tumourigenic pathways and associated with distinct immune phenotypes. Despite this, >98% remain uncharacterised. UCD researchers have identified 80 candidate lnc-RNA targets for KRASmt NSCLC. This project will examine the clinical expression and immune contexture associated with a subset of these candidates.

Material and method

11 lncRNA candidates were selected for further analysis based on predicted toxicity and efficacy. Antisense oligonucleotides (ASOs) were designed to knockdown (KD) target lncRNA expression, as well as ASOs targeting MALAT1, a lncRNA routinely implicated in NSCLC, and non-targeting ASOs. Per candidate, 5 ASOs were transfected into A549 cells and KD efficacy assessed via qRT-PCR. The anti-proliferative effect of the two most efficient ASOs was analysed in a live cell imaging system. In order to investigate target expression and prognostic utility in archival formalin-fixed paraffin-embedded (FFPE) patient tissue, the BaseScope in situ hybridisation (ISH) protocol was optimised for each target and applied to clinical cohorts. To investigate the immune microenvironment associated with the targets in KRASmt tumours, a multiplex immunofluorescence (mIF)-based macrophage panel, designed by UCD researchers is being adapted to lung cancer tissue. Following this, a co-detection technique combining mIF and ISH will be implemented.

Result and discussion

Of the 11 candidate lncRNAs brought forward, 7 displayed anti-proliferative effects in live-cell analysis. BaseScope ISH protocols have been optimised for both MALAT1 and one of the 7 candidates, GCAWKR in FFPE tissue. These protocols are now being applied to a wide cohort of patient tissue. Regarding immune contexture analysis, preliminary optimisation has been completed in lung tissue.

Conclusion

Several lncRNAs have demonstrated potential therapeutic effect on a cell line level. However, critical to their success as therapeutic targets, and potential prognostic utility, is their expression profile in patients and the correlation to patient outcome. Further, by establishing the relationship between target expression and the immune contexture we can better predict patient response to current and future immune targeting strategies, and offer novel strategies in cases where immunotherapy targets are absent.

EACR25-0890

Canine Melanoma as a Translational Model for Novel Immuno-Nanotherapy and Focal Adhesion Kinase-targeted Strategies in Human Oncology

M. A. L. Silva¹, B. Carreira², R. Acúrcio², M. B. Afonso², C. M. P. Rodrigues², N. Leal¹, L. Mestrinho¹, H. Florindo²

¹*Centre for Interdisciplinary Research in Animal Health (CIISA), Faculty of Veterinary Medicine, University of Lisbon, Lisbon, Portugal*

²*Research Institute for Medicines (iMed. ULisboa), Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal*

Introduction

Melanoma in dogs serves as a well-recognized model for human melanoma due to shared biological and molecular features. Canine melanoma (CM) exhibits aggressive biological behavior and affected dogs have a post-surgical survival time of less than one year. Given the conserved molecular pathways between canine and human melanoma, insights gained from this study may support the development of novel nanoparticle-based immunotherapies and focal adhesion kinase inhibitors (FAKi) for human melanoma patients. On one hand, nanoparticles demonstrate great potential as delivery systems for cancer vaccines, enhancing the co-delivery of tumor antigens and toll-like receptor (TLR) agonists to dendritic cells (DC), resulting in more effective immune system activation. On the other hand, FAK is a protein critical for several cellular processes, including cell survival, invasion, and migration. FAK is associated with advanced stages of cancer development, the presence of metastatic cells, and their increased mobility. Currently, there are no studies in veterinary research that investigated FAK expression in CM, neither the benefits of co-delivery of CM antigens and TLR using a nanoplatform or of FAKi for these patients.

Material and method

This project aims to test the potential of a canine glycoprotein 100 mannosylated-nanoparticle (Gp100-NP) and FAKi using *in vitro* and *ex vivo* models of CM. The polymeric Gp100-NP was formulated using the double emulsion technique. Its physicochemical characteristics were described, and *ex vivo* assays with canine erythrocytes and bone marrow-derived DC evaluated its biocompatibility. FAK expression in CM was assessed using molecular and fluorescent methods. Gp100-NP uptake by primary canine DC was evaluated through flow cytometry and confocal microscopy. The impact of three different FAKi on CM was assessed through cell metabolic activity and migration assays using the TLM-1 cell line.

Result and discussion

Gp100-NP exhibited the targeted characteristics necessary to promote DC uptake ($-5 < \text{Zeta Potential} < +5$; Polydispersity index < 0.2 ; and Size $< 200 \text{ nm}$). Moreover, canine DC successfully and selectively internalized the Gp100-NP. It was found that FAK expression is higher in CM compared to healthy tissue. Mirroring findings in human melanoma, it reinforces FAK's role as a potential therapeutic target. The tested FAKi were able to reduce TLM-1 cell function and viability and appeared to delay cell migration capacity. The observed impact of FAKi on cell viability and migration suggests a conserved mechanism that may be exploited in future translational studies.

Conclusion

Further studies involving canine DC and primary T-cell cultures, alongside co-cultures with CM spheroids, will contribute to examining the benefits of this dual approach for treatment, enhancing its relevance and facilitating comparisons with human cases in support of a One Health strategy for broader benefit.

EACR25-0916

Detection of low frequency variants from low input FFPE samples with comprehensive tumor/normal exome sequencing

A. Babayan¹, A. Mai², S. Deshmukh², K. Swink², S. Kelly², R. Adams², M. Cuadras²

¹*Illumina, Berlin, Germany*

²*Illumina, San Diego, United States*

Introduction

Molecular profiling of solid tumors through comprehensive tumor/normal exome sequencing represents a new paradigm in oncology research. As sequencing capabilities expand and costs decline, Whole Exome Sequencing enables comprehensive screening of tumor samples to identify novel biomarkers and actionable drug targets. Formalin-fixed, Paraffin-embedded (FFPE) tissues are used for retrospective and prospective studies in oncology labs. However, the fixation and processing of the tissues can damage and/or modify DNA making tumor genetic analysis challenging, especially for detecting low abundant somatic mutations.

Material and method

Illumina FFPE DNA Prep with Exome 2.5 Enrichment was tested on FFPE DNA. Libraries were prepared from 40 ng input from 12 tumor–normal pairs using this kit and the Twist Bioscience for Illumina Exome 2.5 Panel. Sequencing was performed on the NovaSeqTM 6000 System using the S1 flow cell.

Result and discussion

Libraries from High-mid quality tumor and matched normal DNA achieved $>100\text{M}$ and $\sim 28\text{M}$ single-end reads respectively. Tumor libraries from mid- to high-quality FFPE samples showed mean target coverage depth above $130\times$ and $\geq 90\%$ targets with $\geq 50\times$ coverage. All libraries achieved $>95\%$ aligned reads and above 70% read enrichment. SNVs and Indels at $\sim 5\%$ VAF, and low abundance CNV were detected at $\geq 90\%$ sensitivity. The performance of the kit detecting key oncology Biomarkers; TMB, MSI and HRD was also assessed.

Conclusion

Illumina FFPE DNA prep with Exome 2.5 enrichment is a novel enrichment library preparation method that uses Unique Molecular Identifiers (UMI) for error correction and demonstrates exceptional performance. For Research Use Only. Not for use in diagnostic procedures.

⁴Chang Bing Show Chwan Memorial Hospital, Department of Radiation Oncology, Changhua, Taiwan

⁵National Central University, Department of Life Science, Taoyuan City, Taiwan

Introduction

Glioblastoma (GBM) is an aggressive CNS tumor with a median survival of less than 15 months. A major challenge in nanoparticle (NP)-based GBM therapy is limited drug delivery due to the blood-brain barrier (BBB) and the immunosuppressive tumor micro-environment. To address this, we developed a novel sugar (CG) coated and photosensitizer methylene blue (MB) conjugated iron oxide (IONP) based NP, IONP@CG@MB. We investigated whether IONP@CG@MB, in combination with laser exposure, can suppress GBM progression by (i) inducing ferroptosis and apoptosis through reactive oxygen species (ROS) accumulation (ii) remodeling the immunosuppressive tumor micro-environment and (iii) enhancing nanoparticle delivery to GBM cells, ultimately leading to tumor suppression.

Material and method

IONP@CG@MB nanoparticles were synthesized via a hydrothermal reaction by loading iron oxide (Fe_3O_4 , IONP) with ortho-nitrophenyl- β -galactoside (CG) and subsequently functionalizing the surface with photosensitizer MB to generate photodynamic therapy (PDT). In vitro, GBM cell proliferation and apoptosis were assessed using cell viability assays, flow cytometry, and immunofluorescence staining, while ferroptosis was confirmed via Western blotting. A PBMC/U87-MG co-culture system was utilized to evaluate T-cell activation through flow cytometry. Statistical significance was determined using Student's t-test and ANOVA ($p < 0.05$).

Result and discussion

IONP@CG@MB combined with PDT significantly reduced GBM cell viability, and Ki67 staining indicated an attenuation in cell proliferation ability. Flow cytometry and immunofluorescence analyses confirmed an increase in both intrinsic and extrinsic apoptosis, along with elevated ROS accumulation. Western blotting further revealed the downregulation of GPX4 and Nrf2, consistent with ferroptosis induction. In a PBMC/U87-MG co-culture model, treatment with IONP@CG@MB enhanced CD3+ T-cell proliferation and activated cytotoxic T lymphocytes (CD8+Granzyme B+), indicating a pronounced immunostimulatory effect.

Conclusion

This study demonstrates that IONP@CG@MB, in combination with PDT, effectively suppresses GBM progression by inducing ferroptosis and apoptosis, enhancing ROS production, and remodeling the immunosuppressive tumor microenvironment. The treatment directly eliminates tumor cells and stimulates anti-tumor immunity, offering a promising strategy for GBM therapy. Future research will optimize nanoparticle design, elucidate the interplay between ferroptosis and

immune activation, and evaluate clinical translation potential.

EACR25-0968

M2 macrophages promote survival and proliferation of patient-derived gastric cancer organoids in a tumor biology-dependent manner

M. Cabeza-Segura¹, A. Aguilar-Cifre¹, A. González-Vilanova², A. Marín-Alonso¹, B. Palomar³, R. Villagrasa⁴, C. Martínez-Ciarpaglini^{3,5}, A. Cervantes^{1,5}, T. Fleitas^{1,5}, J. Castillo^{6,1,5}

⁴Hospital Clínico Universitario de Valencia, Gastroenterology and Hepatology Department, Valencia, Spain

⁵Carlos III Health Institute, CIBERONC, Madrid, Spain

⁶University of Valencia, Biochemistry and Molecular Biology Department, Valencia, Spain

Introduction

Gastric cancer (GC) is one of the leading causes of cancer-related mortality worldwide, with high incidence rates and poor prognosis due to its molecular heterogeneity and therapeutic resistance. In this regard, the use of functional models such as patient-derived tumor organoids can shed light on and allow these issues to be addressed on a patient-specific basis. In addition, tumor microenvironment plays a critical role in GC progression by modulating the immune response and facilitating tumor evasion. In particular, tumor-associated macrophages can adopt pro-inflammatory (M1) or anti-inflammatory (M2) phenotypes, with the latter promoting tumor aggressiveness.

Material and method

A prospective biobank of gastric tumor organoids (GTOs) derived from advanced GC patients was generated according to an in-house protocol from January 2019. The human monocytic THP1 cell line was used and differentiated into macrophages, which were subsequently polarized into M1 macrophages using IFN γ + LPS, and M2 macrophages using IL4. Macrophage polarization was assessed measuring M1 (TNF; CXCL10) and M2 (CD206; MS4A4A) markers by real-time quantitative PCR (RT-qPCR). The conditioned media from M1 (M1CM) and M2 (M2CM) macrophages were used to culture the organoids. To assess the effect of each conditioned medium on organoid viability and proliferation, flow cytometry apoptosis/necrosis and cell cycle assays were performed, respectively. M2 macrophages were repolarized into M1 phenotype by treatment with IFN γ and LPS.

Result and discussion

A biobank of more than 40 GTO lines has been generated covering all gastric cancer subtypes. For this study, 7 GTOs were used: 3 intestinal, 2 diffuse, 1 mixed and 1 undifferentiated, according to Lauren's classification;

with 2 of them being HER2-positive and 2 others presenting microsatellite instability. THP1 cells were differentiated into macrophages and properly polarized into M1 and M2 macrophages. A differential effect of M1CM and M2CM on GTOs viability and proliferation were observed. Concerning GTOs viability, M1CM promoted organoid cell death, significantly increasing the number of cells undergoing apoptosis and necrosis. With regard to proliferation, distinct effects were observed. While most GTOs exhibited an increase in the number of cells in the G2+S cell cycle phases in M2CM compared to M1CM, others experienced no difference, suggesting that the influence of M2 macrophages on tumor cell proliferation depends on tumor-specific biology. Treatment of M2 macrophages with IFN γ and LPS repolarized them toward M1 phenotype. Conditioned medium from these repolarized macrophages reversed the observed effects of M2CM on GTOs.

Conclusion

M2 macrophages promote survival and proliferation in most GTOs but showing an interesting heterogeneous effect possibly due to tumor-specific biology. Therapeutic strategies focused on repolarizing M2 macrophages into an M1 phenotype may improve GC management.

Single-cell spatial atlas of high-grade serous ovarian cancer unveils MHC class II as a key driver of spatial tumor ecosystems and clinical outcomes

F. Perez¹, A. Shabanova¹, L. Wagensveld², A. Junquera¹, V. Cerullo¹, A. Virtanen³, A. Vähärautio¹, P. Sorger⁴, H. Horlings², A. Färkkilä⁵

¹University of Helsinki, Helsinki, Finland

²NKI, Amsterdam, Netherlands

³Helsinki University Hospital, Helsinki, Finland

⁴Harvard Medical School, Boston, United States

⁵University of Helsinki, Espoo, Finland

Introduction

The tumor microenvironment (TME) is a complex network of interactions between malignant and host cells, yet its orchestration in advanced high-grade serous ovarian carcinoma (HGSC) remains poorly understood.

Material and method

To investigate the relationship between the TME ecosystem topography, clinical prognosis, and molecular profiles in HGSC, we applied a multi-omics analysis combined with high-plex imaging at subcellular resolution across 280 advanced HGSC samples. By integrating DNA methylation, gene copy number, and mutational profiling, we established clinico-molecular profiles underpinning critical dynamics within the tumor ecosystem. We then used our image analysis pipelines to resolve the spatial TME at the single-cell level, identifying orchestrated multicellular domains that influence patient outcomes. To integrate single-cell spatial, molecular, and survival data, we developed CEFIIRA (Cell Feature Importance Identification by Random Forest), a custom machine learning tool that uncovers survival-associated features. We further exploited advanced single-cell and spatial transcriptomic

data and immunopeptidomic analyses to uncover the mechanisms underpinning immune activation.

Result and discussion

We present a comprehensive single-cell spatial atlas of metastatic HGSCs, integrating high-dimensional imaging, genomics, and transcriptomics. Utilizing 929 single-cell maps, we identified distinct spatial domains characterized by phenotypically heterogeneous cellular compositions. We demonstrated that immune cell co-infiltration at the tumor-stroma interface significantly influences clinical outcomes. Through spatial profiling of approximately 15.1 million cells across two independent cohorts, we observed that MHCII+ cancer cells within the immunogenic tumor and tumor-stroma interface (TSI) neighborhoods generate immune hotspots. These hotspots showed evidence of coordinated immune activity, particularly with T cells and antigen-presenting myeloid cells, emphasizing the pivotal role of cancer cell-intrinsic MHC class II (MHCII) expression at the TSI in driving immune landscapes. Our findings highlight that MHCII-positive cancer cells contribute to the formation of immune hotspots marked by increased activation of immune cells, impacting prognosis independently of clinicomolecular profiles. Validation with external datasets confirmed that MHCII-expressing cancer cells associate with immune infiltration and shape spatial tumor-immune interactions, further supporting the significance of MHCII in structuring the spatial TME and influencing patient outcomes.

Conclusion

Our comprehensive multi-omics atlas decodes the interplay between tumor and immune cells, shedding light on mechanisms of immune evasion thus paving the way for targeted interventions in HGSC.

EACR25-1014

Exosomes from urine: A multi-purpose system for urine liquid biopsy

S. Bonin¹, M. Mezzatesta¹, E. Azzalini¹, P. Posocco², L. Casalis³, C. Medeot⁴, P. Parisse⁵

¹University of Trieste, Department of Medical Sciences, Trieste, Italy

²University of Trieste, Department of Architecture and Engineering, Trieste, Italy

³Elettra-Sincrotrone Trieste S.C.p.A., Trieste, Italy

⁴University of Trieste, Department of Medical Sciences, Trieste, Italy

⁵IOM-CNR, Trieste, Italy

Introduction

Liquid biopsy is a method of collecting blood or other body fluids for the analysis of molecular alterations, tumor cells, and metabolites. Recently, urine liquid biopsy has gained in importance because of its less invasive sampling. Urine samples, in comparison to blood, allow more real-time monitoring, especially for cancer patients. Nevertheless, urine can rapidly hydrolyzed in a short time, which can result in the production of a large amount of ammonia and degradation of urine components requiring fast processing or stabilization.

Material and method

Urines were collected from 5 healthy volunteers. Each participant provided 10 mL aliquots of urine, that were stabilized in PAXgene Urine Liquid Biopsy Tubes at

room temperature or maintained non-stabilized at 4°C up to preliminary centrifugation procedures. Exosomes were isolated from stabilized and non-stabilized urines by ultracentrifugation. Biophysical characterization by AFM and DLS, protein analysis by Western-Blot, and RNA isolation were carried out in exosomes from stabilized and non-stabilized urines at the time of collection and after 7 days of storage.

Result and discussion

Protein detection showed a higher amount of proteins at the time of collection in non-stabilized samples in comparison to stabilized ones, but after 7 days, the profile reversed which indicates a degradation of proteins in unstabilized samples. AFM analysis confirmed the presence of exosomes both in stabilized and non-stabilized samples at t=0 and after 7 days. After 7 days an increase in aggregates (particles larger than 200 nm in diameter) was observed both in stabilized and non-stabilized urine. In stabilized samples, a higher number of particles/ vesicles than in the non-stabilized samples was detected as a possible sign of decay in the latter ones.

Conclusion

PAXgene Urine Liquid Biopsy Tubes showed to be a multi-purpose collection device for urine liquid biopsy allowing the sampling of urine at room temperature for exosome isolation even after 7 days of storage at room temperature.

EACR25-1055

Chemotherapy during pregnancy – a prospective study of short- and long-term cardiac effects

O. Abramovich¹, I. Kehat¹, I. Ben Aharon¹

¹Technion, medicine, Haifa, Israel

Introduction

Pregnancy-associated cancer poses a unique clinical challenge, requiring a delicate balance between risks and benefits to ensure the safety of both the mother and the fetus. The most commonly used chemotherapy classes during pregnancy are Anthracyclines, predominantly Doxorubicin (DXR), being the primary treatment used during the second and third trimester. However, clinical evidence regarding the short and late term effects of in utero exposure to chemotherapy is limited. The underlying mechanism of DXR-induced cardiotoxicity had been widely studied in cancer patients, there is paucity of data regarding cardiac effects of in utero exposure to chemotherapy. We had formerly demonstrated that DXR induces placental vascular toxicity. In the current study we aimed to characterize the short and long-term cardiac effects of in-utero exposure to chemotherapy.

Material and method

Pregnant ICR mice were injected with DXR (10 mg/kg) or saline on day E14.5 of pregnancy, which is equivalent to the second trimester in human. The in utero exposed mice were followed up from birth until full puberty at three time-points: day 0 (birth), 10 weeks and 6 months. Cardiac performance was evaluated at 10 weeks and 6 months mice via Transthoracic Echocardiography followed by euthanasia and cardiac tissue harvesting at all three-time points. Conventional echocardiographic measurements were obtained, as well as fractional

shortening (FS) calculation and 2D speckle tracking echocardiography. Tissue fibrosis and cardiac hypertrophy were evaluated by histological biomarkers by immunohistochemistry (IHC); Masson's trichrome (TRI) and wheat germ agglutinin (WGA) staining were utilized to evaluate cardiac collagen percentage and calculated cell area, respectively. Ethical approval of animal experimentation was received from the ethical committee of the Rapaport Faculty of Medicine, Thechnion.

Result and discussion

Echocardiogram imaging revealed at 10-week-old and 6-month-old mice reduced FS and thinning of the left ventricular (LV) wall compared with controls. 10-week-old male mice showed decreased ejection fraction (EF) and global longitudinal strain (GLS), accompanied by enhanced fibrotic markers reflected by TRI in IHC section. 10-week-old DXR exposed females displayed LV hypertrophy as evidenced by increased cell area calculated by WGA staining. At 6 months, both male and females presented lengthening of the left ventricular internal dimension (LVID), indicating LV dilation.

Conclusion

In utero exposure to DXR may result in a latent cardiac effect, manifested by reduced cardiac contractility and hypertrophy, in a sex-specific manner, as studied in a pre-clinical model. Future studies should focus on late-term surveillance in in utero exposed children to reveal the potential cardiac outcomes.

Introduction

Guidelines suggest ovarian function suppression (OFS) can be used in combination with endocrine therapies in the treatment of premenopausal ER+ breast cancer. OFS can be achieved through the use of GnRH agonists/ antagonists (GnRHa). Estradiol (E2) measurements are frequently used to define incomplete OFS, however there

is a lack of consensus regarding appropriate cut-off levels or assays. Incomplete OFS has important potential implications on the efficacy of treatment in the premenopausal setting. We are therefore conducting a systematic review to assess the risk of incomplete OFS in premenopausal women with ER+ breast cancer receiving OFS. A case report [1] was identified which described a possible interaction between abemaciclib, a CDK4/6 inhibitor, and a chemiluminescent microparticle immunoassay, which may have resulted in falsely elevated E2 readings. We present analysis of rates of incomplete OFS, as well as assay details, of a subset of studies identified within our systematic review where patients received GnRHa and CDK4/6 inhibitors.

Material and method

The full systematic review protocol has been registered with PROSPERO [2]. A search of MEDLINE and EMBASE was carried out to identify studies which included premenopausal women with ER+ breast cancer receiving treatment with GnRHa. The outcome of interest was measurement of incomplete OFS based on any definition. Titles and abstracts were screened by two authors, with no restriction on study type. Full text screening was completed by two of the authors, any disagreements were discussed with a third author.

Result and discussion

We have identified 125 papers in total for inclusion. Of these, several trials have been identified which included patients receiving both GnRHa and CDK4/6 inhibitors. These include the PENELOPE-B trial, the MONALEESA-7 trial and the PALOMA-3 trial. We will present analysis of rates of OFS, definitions of OFS, and E2 measurement techniques in the subset of included papers including patients treated with both GnRHa and CDK4/6 inhibitors.

Conclusion:

At least a subset of patients receiving GnRHa have incomplete OFS. There has been at least one documented case in the literature of elevated E2 levels which may have been due to an interaction between the assay and concurrent abemaciclib treatment. We summarise the available literature identified in the process of a systematic review in order to further understand current assays in use and rates of incomplete OFS in patients receiving CDK4/6 inhibitors and GnRHa.

BR55: Clinical Development of the First Ultrasound Molecular Imaging Agent for angiogenesis

V. Jeannot¹, S. Cherkaoui¹, A. Filippone², I. Tardy¹, T. Bettinger¹

¹Bracco Suisse SA, Switzerland

²Bracco Imaging, Italy

Introduction

Microbubbles (MB) have revolutionized ultrasound imaging by enhancing contrast for better visualization of

blood flow and tissues. They enable real-time imaging, are safe, cost-effective, making them an invaluable tool in modern medical imaging. MB can be engineered to target specific tissues expressing molecular markers, enhancing the ability to diagnose and monitor diseases at a molecular level, an approach known as molecular imaging. Bracco has been actively involved in this field, with its advanced UltraSound Molecular Imaging agent BR55, a propirety molecular imaging contrast agent of angiogenesis targeting the Vascular Endothelial Growth Factor Receptor 2 (VEGFR2). This lecture will summarize BR55's key achievements, updates on the Phase 2b clinical trial completed in 2024, and outline the next steps towards potential commercialization.

Material and method

The affinity of the VEGFR2 binding peptide was evaluated on immobilized recombinant human and mouse receptors, while the binding efficiency of BR55 was tested on cells expressing VEGFR2 and in vivo tumor models. In vivo imaging performance of BR55 was compared to non targeted clinically approved ultrasound contrast agent. In animals receiving anti-angiogenic treatment, the tumor response was monitored using BR55. Finally, Bracco sponsored the clinical evaluation of the molecular imaging performance of BR55 in ovarian, breast, prostate and thyroid cancer.

Result and discussion

BR55 is a targeted lipid-shelled microbubble specifically developed for molecular imaging of angiogenesis thanks to the use of a high affinity targeting peptide. The binding specificity was demonstrated on recombinant proteins as well as on human and mouse endothelial cells. BR55 demonstrated potential in detecting various cancers in animal models by highlighting areas of angiogenic vessels expressing VEGFR2. Additionally, preclinical models indicated that BR55 could provide early indications of tumor response to antiangiogenic therapies. The clinical exploratory phases across different disease conditions, demonstrated BR55 safety and ability to localize malignant lesions in prostate, breast, and ovarian cancers. Recently, BR55 completed a Phase 2b clinical trial, involving five different diseases (breast, ovarian, and thyroid cancers, rheumatoid arthritis, and Crohn's disease). This trial further validated its efficacy and safety in a larger patient cohort ($n = 250$). The study showed an excellent concordance between BR55 enhancement in ultrasound molecular imaging and VEGFR2 expression in immunohistochemistry.

Conclusion

BR55's ability to provide detailed molecular imaging supports the move towards personalized medicine, where treatments can be tailored based on patient's tumor specific characteristics. The results from the clinical trial are expected to pave the way for potential clinical approval and ultimately commercialization.

EACR25-1130

PET imaging of PD1-positive MOLT-4T-cell lymphoblastic leukemia tumours in NRG mice using 89Zr-labeled pembrolizumab

S. Borlase¹, Z. Cai¹, C. Chan¹, R. Reilly^{1,2}

¹University of Toronto, Department of Pharmaceutical Sciences, Toronto, Canada

²University Health Network, Joint Department of Medical Imaging and Princess Margaret Cancer Centre, Toronto, Canada

Introduction

Pembrolizumab binds to programmed cell-death protein-1 (PD1) on T-cells and inhibits its interaction with PDL-1 on tumour cells which enables a cytotoxic T-cell response. Pembrolizumab labeled with zirconium-89 (89Zr) could be used for PET imaging of pembrolizumab delivery to tumours which may help predict tumour response. The aim of this study was to evaluate and image the PD1-mediated delivery of 89Zr-labeled pembrolizumab to a human T-cell lymphoblastic leukemia tumour in NRG mice.

Material and method

Pembrolizumab was conjugated to deferoxamine (DFO) to complex 89Zr. PD1-positive MOLT-4 tumours were established s.c. in NRG mice. B-cell deficiency in NRG mice results in the mice having very low levels of IgG which leads to high spleen uptake of i.v. injected radioimmunoconjugates. The spleen uptake may be blocked by injecting an excess of non-specific IgG prior to the radioimmunoconjugate. Additionally, PD1 specific tumour uptake can be assessed by injecting an excess of unlabeled pembrolizumab to block PD1 on tumour cells. NRG mice with MOLT-4 tumours were injected i.v. with 2.0–2.5 MBq of 89Zr-DFO-pembrolizumab (20 µg) with or without a 40x excess of IgG to block spleen uptake or excess pembrolizumab to block PD1. PET imaging was performed 72 hours post-injection and the tumour, blood and normal tissues were collected and the percent injected dose per gram (%ID/g) was calculated.

Result and discussion

Pembrolizumab was conjugated to 5.4 ± 0.8 DFO and labeled with 89Zr to a specific activity of 0.15 MBq/ug. The labeling efficiency was $96.2 \pm 0.2\%$. Spleen uptake was very high in mice that did not receive excess IgG (50.3 ± 13.3 %ID/g). Spleen uptake decreased with the administration of excess IgG and excess pembrolizumab (4.0 ± 0.1 %ID/g; $p = 0.0008$ and 3.7 ± 1.2 %ID/g; $p = 0.0008$, respectively). Tumour uptake was modest without excess IgG (6.0 ± 1.0 %ID/g). However, tumour uptake significantly increased to 26.0 ± 4.4 %ID/g ($p = 0.0002$) when spleen uptake was blocked by IgG. This high tumour uptake significantly decreased with the administration of excess pembrolizumab (3.0 ± 1.0 %ID/g; $p < 0.0001$) demonstrating PD1-specific binding of 89Zr-DFO-pembrolizumab to MOLT-4 cells in vivo. PET images corroborated the biodistribution data as there was high spleen uptake that was greatly reduced by the excess IgG and excess pembrolizumab. Additionally, tumours were well-visualized by PET in mice that received excess IgG and the intensity of tumour uptake on the images decreased with the administration of excess pembrolizumab.

Conclusion

PD1-positive MOLT-4 T-cell lymphoblastic leukemia tumours were imaged by PET in NRG mice using 89Zr-labeled pembrolizumab. Achieving high tumour uptake required blocking of spleen sequestration by administering excess non-specific IgG while PD1-

specific uptake was demonstrated by administering excess pembrolizumab. These results are promising for PET imaging of T-cell malignancies using 89Zr-DFO-pembrolizumab.

Melting the Iceberg: Nanomedicines Overcoming Stromal Barriers and Recruiting Effector T Cells in Pancreatic Cancer

R. Acúrcio¹, M. Vives², M. Gonzalez², R. Satchi-Fainaro³, M. Vicent², H. Florindo¹

¹Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal

²Polymer Therapeutics Laboratory, Prince Felipe Research Center (CIPF), Valencia, Spain

³Sackler Faculty of Medicine, Department of Physiology and Pharmacology, Tel Aviv, Israel

Introduction

While immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, pancreatic cancer (PDAC) remains one of the most ICI-resistant tumors [1]. Its unique dense stroma and highly immunosuppressive tumor microenvironment (TME) limit immune cell infiltration and therapeutic efficacy. Here, we demonstrate how nanotechnology-based platforms overcome these barriers to drive an effective anti-tumor response against PDAC. We developed a crosslinked nanoconjugate carrying a focal adhesion kinase inhibitor (FAKi) to remodel PDAC stroma and a nanovaccine to recruit effective immune cells into the TME.

Material and method

We engineered a star-shaped, crosslinked polyglutamate FAKi (St-FAKi) conjugate to enhance FAKi solubility and promote higher accumulation in the TME. Using mannose-grafted PLA/PLGA polymers, we prepared a dendritic cell-targeted nanovaccine (NV) co-entrapping PDAC-associated antigens and immune regulators. NV physicochemical properties, including size, charge, and antigen loading, were extensively characterized. The anti-tumor effect of the nanomedicines was evaluated in vivo using the PDAC KPC-bearing mouse model. Antigen-specific responses and TME immune profiling were thoroughly analyzed.

Result and discussion

Stable and safe nanotechnology-based platforms were achieved. The combination of St-FAKi and nanovaccine led to significant tumor growth suppression, marked by the recruitment of effective CD8+ T cells and CD103+ DC, and modulation of the cancer-associated fibroblast phenotype. In the PDAC in vivo model, our nanomedicines achieved 100% survival at 80 days post-inoculation.

Conclusion

By unlocking the dense, immunosuppressive TME, these nanotechnology-based platforms significantly enhanced anti-tumor immune responses, resulting in tumor regression and improved survival rates in PDAC.

EACR25-1147**Tiny Warriors Against Tumors: A Nanovaccine Approach for Melanoma Brain Metastases**

B. Carreira¹, R. Acúrcio¹, S. Pozzi², A. Matos¹, S. Xapelli³, A. Fernandes¹, R. Satchi-Fainaro², H. Florindo¹

³*Gulbenkian Institute for Molecular Medicine (GIMM), Faculty of Medicine, University of Lisbon, Lisbon, Portugal*

Introduction

Despite advancements with immune checkpoint inhibitors for metastatic melanoma, their benefits are limited to a small percentage of patients, with many experiencing immune-mediated side effects or disease relapse. These challenges stem from tumor-driven immunosuppression and poor T cell infiltration. To overcome these barriers, we developed a precision nanovaccine (NV) targeting dendritic cells (DC). This strategy aims to enhance melanoma-immune cell interactions and broaden the range of targeted immune cells in a site-specific manner, offering a novel approach to improve outcomes.

Material and method

We synthesized and characterized poly(lactic acid) and poly(lactic-co-glycol) (PLA/PLGA)-based NV using mannose-grafted polymers to deliver combinations of melanoma neoantigen and immunoregulators. NV physicochemical properties were fully characterized, including size, surface charge and morphology. The amount of melanoma antigens entrapped within NV was determined by HPLC. Immature DC were used to evaluate the impact of NV on cell viability. NV ability to target and trigger the activation of DC, was assessed in the lymph nodes of immunized mice. The NV anti-tumor effect was evaluated *in vivo* in two primary melanoma-bearing mouse models, and in a melanoma brain metastasis (MBM) mouse model, which included the immune profiling within tumor site by flow cytometry, before and after treatment.

Result and discussion

Polymeric NV were shown to have spherical shape with an average diameter of 180 nm, narrow polydispersity index, near-neutral surface charge, and high loadings of the immune regulators. Both subcutaneous and intranasal immunization induced the activation and maturation of DC within draining lymph nodes and triggered the systemic activation of neoantigen-specific cytotoxic T cells. Treatment with the combination of NV with PD-L1 modulators *in vivo* led to increased tumor inhibition in primary melanoma-bearing mice, with minimal systemic toxicity. Combination of the NV with the anti-PD-L1 antibody was the most effective, with maximal tumor growth inhibition, translated into high infiltration of cytotoxic CD8+ T cells into tumor microenvironment (TME) and reduced expression of immunosuppressor cells. At the metastatic disease, intranasal immunization of the NV combined with anti-PD-L1 led to the prevention of melanoma brain metastases. The

combination strategy led to 100% surviving at 52 days followed intracranial tumor inoculation, and recapitulation into a T-cell inflamed brain TME.

Conclusion

Altogether, the synergy between the nanovaccine and the anti-PD-L1 antibody provides essential insights to devise alternative combinations regimens to improve the efficacy of immune checkpoint inhibitors in metastatic melanoma, thus opening a new line for polymeric nanovaccines as potential tools to advance clinical response to advanced melanoma.

EACR25-1180**Beating Breast Cancer Brain Metastases: Leverage Nano-Immunotherapy to Re-educate Host Immunity**

A. Matos¹, R. Acúrcio¹, B. Carreira¹, M. Ferreira Silva¹,

C. Ferro¹, L. Graça², R. Satchi-Fainaro³, H. Florindo¹

¹*University of Lisbon / Research Institute for Medicines (iMed.ULisboa), Lisboa, Portugal*

Introduction

Breast cancer remains the most common cancer worldwide and is the second leading cause of brain metastases after lung cancer. Breast cancer brain metastases (BrM) can emerge up to a decade after the successful treatment of the primary tumor, representing a significant clinical challenge. In addition, BrM patients face poor prognoses due to the difficulty of crossing the blood-brain barrier with current systemic therapies [1]. Cancer vaccines aim to re-educate the patient's immune system by stimulating T-cell responses to eliminate tumor cells while generating long-term immune memory to prevent metastasis and disease progression [2]. However, most cancer vaccines have not demonstrated clinical benefits as monotherapy for patients with advanced-stage cancers since their anti-tumor efficacy is blocked by compensatory immune escape mechanisms within the tumor microenvironment (TME). Although immune checkpoint blockades are approved for triple-negative breast cancer and other solid tumors, brain malignancies frequently exhibit resistance to anti-PD-1/L1 therapy, making disease management difficult [3]. Here, we hypothesized that the activation of host immunity using a dendritic cell-targeted nanovaccine, while modulating the focal adhesion kinase (FAK) function together with immune checkpoint blockade, can contribute to re-shape the "cold" suppressive BrM-immune-stroma network to a "hot" BrM-permissive landscape, allowing the extensive infiltration of effector T cells to reactivate the anti-tumor immunity.

Material and method

The synergistic immunotherapeutic potential of our nanovaccine, isolated and in combination with the FAK inhibitor (FAKI) and the immune checkpoint inhibitor αPD-L1 monoclonal antibody, was assessed in both primary and BrM immunocompetent EO771 mouse models.

Result and discussion

Mannose nanovaccine combined with FAKi strongly restricted EO771 primary tumor growth, and synergized with PD-L1 blockade, leading to long-term survival when compared with nanovaccine alone. This data was further validated in BrM immunocompetent-bearing mice.

Conclusion

This innovative approach discloses the synergy among the targeted cancer nanovaccine and immune modulatory and checkpoint therapies within the cold and immune-suppressive TME, which overall outcome may constitute a promising nano-immunotherapy for BrM patients.

⁵Clinica de Occidente, Pain medicine and palliative care unit, Cali, Colombia

⁶Universidad Santiago de Cali, Internal Medicine, Cali, Colombia

⁷Clinica de Occidente, Oncology, Cali, Colombia

Introduction

Pain is an unpleasant sensory and emotional experience that may or may not be associated with tissue damage. It is the second most frequent symptom during cancer treatment due to toxicity, surgery, radiotherapy, and other factors. Given its multidimensional nature, pain involves cognitive mechanisms that require additional intervention strategies. Advances in pain neuroscience have led to a better understanding of this phenomenon, contributing to improved management of various painful conditions. The objective of this study was to determine the effectiveness of a neuroscience education program on pain compared to conventional management in individuals with cancer pain.

Material and method

An experimental study was conducted through a randomized controlled clinical trial with parallel groups and evaluator blinding, following CONSORT guidelines and registered in ClinicalTrials.gov [1]. An educational protocol based on the principles of pain neuroscience was developed, consisting of nine sessions covering topics such as the pain system, the alarm system, pain

modulators, fatigue, anxiety and stress, current treatment models, as well as goal setting and achievements (Ordoñez-Mora et al., 2024). Patients in both the control and intervention groups were evaluated at 10 weeks (Ordoñez-Mora et al., 2023).

Result and discussion

A total of 66 patients with cancer pain were included, with breast cancer being the most prevalent type. Regarding cancer staging, 63% of patients were in stage III, 31.8% in stage IV, and 4.5% in stage V. Pain intensity was assessed using the Visual Analogue Scale (VAS). In the intervention group, the mean pain score at T1 (Time 1) 5.41 (± 2.13), which decreased to 4.0 (± 2.06) at T2 (Time 2), representing a reduction of 1.40 points in pain intensity ($p = 0.00$), a statistically significant and clinically relevant result. In the control group, T1 was 5.47 (± 2.30) and T2 a result of 5.39 (± 2.15), resulting in a difference of 0.078 without statistical significance ($p = 0.79$).

Conclusion:

This study demonstrated that an intervention based on pain neuroscience education leads to significant reductions in pain intensity, with a decrease of one point on the VAS, a change considered clinically relevant.

[1] Identifier: NCT05581784

EACR25-1190

PET-based and glycolytic biomarkers reveal 18F-FDG uptake/heterogeneity phenotypes and predict metabolically active disease in aggressive B-cell lymphomas

F. Neto¹, G. Garcia², M. Bonatelli¹, P. Vital¹, M. Alves³, W. Alves⁴, C. Pinheiro¹

¹Barretos Cancer Hospital, Molecular Oncology Research Center, Barretos, Brazil

²Barretos School of Health Sciences Dr. Paulo Prata, Barretos, Brazil

³Aeronautical Technology Institute, São José dos Campos, Brazil

⁴Barretos Cancer Hospital, Department of Nuclear Medicine, Barretos, Brazil

Introduction

Radiomic features derived from 18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET) non-invasively quantify 18F-FDG uptake and intratumoral heterogeneity in intact tumor regions. Despite evidence supporting the prognostic relevance of radiomic features, their biological underpinnings and potential to identify poor responders remain underexplored in aggressive B-cell lymphomas (ABCL). This study investigates associations between baseline radiomic features and glycolysis-related proteins, and their role in predicting metabolically active disease (MAD) on end-of-treatment (EoT) 18F-FDG PET.

Material and method

The immunohistochemical expression of glucose transporters (GLUTs) 1, 3, and 4, hexokinase 2 (HK2), lactate dehydrogenase A (LDHA), carbonic anhydrase 9 (CA9), and cluster of differentiation 147 (CD147) was assessed in 90 ABCL samples, including tumor tissue

and benign cells in the tumor microenvironment (BCTME). Sixteen textural and five semantic radiomic features were extracted from baseline 18F-FDG PET. Patients with Deauville scores 1–3 on EoT 18F-FDG PET were classified as having complete metabolic response, while scores 4–5 indicated metabolically active disease (MAD). Associations between radiomic features and glycolysis-related proteins were evaluated, while similarity network fusion integrated semantic and textural features to reveal distinct uptake and heterogeneity phenotypes. Key predictors of MAD were identified through univariate logistic regression, followed by relevance-based redundancy filtering and random forest (RF) feature importance ranking. Machine learning models, including RF and support vector machine (SVM), were trained with the top-ranked predictors, using 10-fold cross-validation.

Result and discussion

GLUT3 and LDHA expression in BCTME was associated with a low-image-heterogeneity pattern. GLUT3 was associated with increased angular second moment and decreased entropy values, while LDHA was predominantly expressed in instances with low sum variance and sum average values. A higher proportion of CA9-positive and CA9/CD147-positive BCTME was observed in cases with low metabolic tumor volume (MTV) and high image heterogeneity (low-uptake/high-heterogeneity phenotype). The top-ranked predictors of MAD included the textural feature inverse difference moment (IDM), MTV, staging, and HK2 expression in both tumor and BCTME. The SVM model combining these five features to predict MAD achieved an AUROC of 0.850 (95% confidence interval: 0.811–0.889) in cross-validation folds.

Conclusion

GLUT3, LDHA, CA9, and CD147 expression is associated with semantic and textural features of baseline 18F-FDG PET. Moreover, HK2 and IDM act as potential molecular and imaging biomarkers for MAD prediction in ABCL.

EACR25-1192

Engineered v5 PE6A-VLPs Enable In Vivo PCSK9 Gene Editing to Suppress Hepatocellular Carcinoma Progression and Modulate Cholesterol Metabolism

L. Deng¹, Z. Wang¹, S. Zeng¹, W. Zhan¹, A. Chan¹, K. Man¹

¹*The University of Hong Kong, Department of Surgery, Hong Kong, Hong Kong, China*

Introduction:

The sixth-generation prime editor A (PE6A) is a precise and compact genome-editing tool capable of introducing targeted mutations, deletions, or insertions in living cells. Proprotein convertase subtilisin/kexin type 9 (PCSK9), a critical regulator of low-density lipoprotein receptor (LDLR) degradation and serum cholesterol levels, is also associated with hepatocellular carcinoma (HCC) progression. While targeting PCSK9 to manage hyperlipidemia is currently effective, a long-term gene editing therapy that offers patients the possibility to discontinue lifelong medication is still lacking. The naturally

occurring PCSK9 Q152H mutation, which reduces PCSK9 secretion and lowers serum cholesterol, presents therapeutic potential in modulating HCC growth that remains unexplored.

Material and method

We engineered PE6A for packaging into virus-like particles (VLPs) to achieve in vivo delivery. The expression levels of PCSK9 in tumor and adjacent tissues of HCC patients were analyzed by immunoblotting, qPCR, and immunohistochemistry in our clinical cohort. In vitro, PCSK9 knockout, overexpression, and mutation cell lines were constructed to explore the mechanism of PCSK9's effect on HCC cell growth. In vivo efficacy was assessed in mouse models via tail vein injection, evaluating serum cholesterol reduction.

Result and discussion

Technologically, we integrated the sixth-generation prime editing system with the fifth-generation VLP packaging system, showcasing improved production yield and robust editing efficiency in human and mouse cell lines. From a clinical perspective, elevated PCSK9 expression in HCC tissues was found to be associated with poorer overall patient survival. In vitro experiments revealed that PCSK9 knockout or Q152H mutagenesis led to increased LDLR protein levels and inhibited HCC cell proliferation. Moreover, in vivo studies demonstrated that PE6A-VLP administration resulted in decreased mouse serum PCSK9 levels and LDL-cholesterol.

Conclusion

PE6A-VLPs enable efficient PCSK9 editing in vivo, simultaneously lowering LDL-cholesterol. These findings position PCSK9 as a potential dual therapeutic target for metabolic and oncologic interventions.

EACR25-1207

Establishment and Characterization of a Diabetic Sarcopenia Model in Aged Mice: Insights into Metabolic and Muscular Dysfunction

J. Choi¹, J. Kwon¹

¹*Jeonbuk National University, College of Veterinary Medicine, Iksan-si, Korea (Republic of)*

Introduction

Diabetic sarcopenia, a multifactorial condition characterized by concurrent muscle atrophy and metabolic dysregulation, is increasingly prevalent in the aging population. However, appropriate animal models to study the interaction between aging, diabetes, and sarcopenia remain limited. This study aimed to develop and validate a diabetic sarcopenia model in aged mice to assess the combined effects of glucocorticoid-induced muscle atrophy and diet-induced diabetes on muscle function, metabolism, and organ pathology.

Material and method

C57BL/6 mice aged over 12 months and young controls (6 weeks old) were allocated into eight experimental groups, including control, diabetes, sarcopenia, and diabetic sarcopenia models. Diabetes was induced via a high-fat diet (60% kcal from fat) for eight weeks, while sarcopenia was triggered through dexamethasone administration. Body weight, food intake, fasting blood glucose levels, and oral glucose tolerance were

monitored. Muscle strength was evaluated by grip strength and limb hang tests. Following euthanasia, organ weights were recorded, and muscle tissues were collected for gene expression analysis of muscle atrophy-related markers via RT-PCR and Western blot.

Result and discussion

In the aged diabetic sarcopenia (ODS) group, body weight gain was limited compared to the diabetes-only group but higher than the sarcopenia-only group, indicating metabolic disruption alongside muscle loss. Grip strength and limb endurance were significantly reduced in sarcopenia and diabetic sarcopenia groups, with the ODS group showing the most severe decline, suggesting compounded impairment in muscle function due to aging, diabetes, and dexamethasone-induced stress. Muscle loss rate analysis revealed the highest reduction in the ODS group, while organ index analysis indicated increased liver and fat mass in diabetic conditions, highlighting systemic metabolic alterations. Blood glucose analysis confirmed exacerbated hyperglycemia and impaired glucose tolerance in diabetic sarcopenia models, supporting the hypothesis that sarcopenia aggravates metabolic dysfunction. These findings demonstrate that the combination of aging, diabetes, and sarcopenia accelerates muscle atrophy and metabolic deterioration, providing a robust platform for therapeutic evaluation.

Conclusion

We successfully established a diabetic sarcopenia model in aged mice that mimics the complex interplay between muscle degeneration and metabolic abnormalities. This model offers a valuable tool for investigating pathophysiological mechanisms and evaluating potential therapeutic strategies targeting muscle preservation and metabolic regulation in aging populations with diabetes.

Engineering M13 Bacteriophages for Targeted Sonodynamic Therapy of Cancer

M. Nigro¹, P. Costantini², L. Ulfo², R. Saporetti¹, M. Di Giosia¹, E. Turrini³, A. Danielli², M. Calvaresi¹
¹*University of Bologna, Department of Chemistry Giacomo Ciamician, Bologna, Italy*

²*University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy*

³*University of Bologna, Department for Life Quality Studies, Bologna, Italy*

Introduction

Sonodynamic therapy (SDT) is an emerging non-invasive approach for cancer treatment based on molecules, known as sensitizers, that once activated by ultrasound generates reactive oxygen species (ROS), leading to tumor ablation. However, low accumulation of sensitizer in tumoral mass have significantly reduce SDT therapeutic potential. This study explores the potential use of M13 bacteriophages as targeted nanovectors for selective sonodynamic eradication of cancer cells.

Material and method

M13 phages were genetically engineered to display the 7D12 nanobody, which specifically binds the Epidermal Growth Factor Receptor (EGFR), frequently over-expressed in various cancers. The modified phage,

M13D12, was further functionalized with fluorophores, enabling selective recognition of EGFR-overexpressing A431 cells while minimizing interactions with EGFR-negative controls. To enhance its therapeutic potential, M13D12 was chemically conjugated with Rose Bengal (RB), a well-characterized sonosensitizer, via the pVIII major coat proteins. The resulting nanovector, M13D12-RB, was designed to deliver hundreds of RB molecules per phage particle. Upon ultrasound activation, RB generates reactive oxygen species (ROS), leading to oxidative stress and subsequent cancer cell death. The therapeutic efficacy of M13D12-RB was evaluated in both 2D and 3D tumor models, focusing on cell viability and tumor spheroid integrity.

Result and discussion

M13D12-RB demonstrated strong specificity for EGFR-overexpressing cancer cells, leading to selective accumulation of RB within tumor-like structures. Upon ultrasound activation, significant sonodynamic cytotoxicity was observed, resulting in extensive cell death in 2D cultures and substantial disruption of tumor spheroids in 3D models. Notably, ex vivo imaging revealed deep tumor penetration and complete spheroid disaggregation following treatment. These findings highlight the advantages of M13 phage-based nanovectors, including their ability to efficiently target tumor cells and deliver a high payload of therapeutic agents. The combination of targeted phage display and ultrasound-triggered ROS generation provides a highly selective and minimally invasive approach, potentially overcoming limitations of conventional sonodynamic therapy.

Conclusion

The engineered M13D12-RB nanovector represents a promising platform for targeted sonodynamic therapy. Its high specificity, deep tumor penetration, and effective ultrasound-activated cytotoxicity suggest a novel and versatile strategy for treating hard-to-reach malignancies, including glioblastoma. Additionally, M13 phages are cost-effective and highly modular, allowing for easy functionalization with different targeting ligands or therapeutic agents. These advantages position phage-based nanovectors as a scalable and adaptable approach for precision oncology applications.

The Impact of Nanoparticle Size on the Enhanced Permeability-Retention Effect in Breast Cancer

B. Svalbe^{1,2}, J. Bulatova^{1,3}, A. Sizovs^{1,4,3}

¹*Latvian Institute of Organic Synthesis, Laboratory of Pharmaceutical Pharmacology, Riga, Latvia*

²*Baltic Biomaterials Centre of Excellence, Rīga, Latvia*

³*Riga Stradiņš University, Faculty of Pharmacy, Riga, Latvia*

⁴*Baltic Biomaterials Centre of Excellence, Riga, Latvia*

Introduction

Breast cancer remains the most commonly diagnosed malignancy and a major cause of cancer-related deaths among women. Nanoparticles (NPs) offer promising strategies for improving cancer diagnostics and enabling tumour-targeted drug delivery, often relying on the enhanced permeability and retention (EPR) effect.

However, the full potential of EPR and the optimal NP size for efficient tumour accumulation remains uncertain due to rapid opsonization in plasma, which alters NP size and surface properties. To address this challenge, we developed non-opsonizing brush polymers as NP surrogates and systematically investigated how NP size influences pharmacokinetics, biodistribution, and tumour accumulation in a triple-negative breast cancer (TNBC) mouse model.

Material and method

We synthesized heavily PEGylated, fluorescently labelled polymers with three distinct hydrodynamic diameters within the 15–60 nm range. A TNBC model was established by inoculating female Balb/c mice with 100,000 4T1 cells in the fourth mammary fat pad. All procedures were approved by the Latvian Animal Protection Ethical Committee of the Food and Veterinary Service (Riga, Latvia). Once palpable tumours formed, mice were intraperitoneally injected with equivalent doses of different-sized NPs ($n = 6$ per group) for assessment of pharmacokinetics (PK) and biodistribution (BD). Blood samples were collected at multiple time points over a 14-day period. After two weeks mice were euthanized and tissues (heart, kidney, liver, spleen, lung, tumour, and brain) were harvested and homogenized. Fluorometric analysis was performed to quantify NP concentrations in blood and tissues.

Result and discussion

The plasma clearance half-lives of NPs in tumour-bearing mice were indistinguishable from those in healthy controls, with the smallest NP exhibiting the longest circulation time (clearance $t_{1/2} = 3.0$ days). The tumour was the primary site of NP accumulation across all tested materials. Tumour-to-liver selectivity showed an inverse relationship with NP size, with the smallest NP achieving the highest tumour/liver concentration ratio of 4:1. Notably, tumour size did not significantly influence NP accumulation. Interestingly, NP concentrations in the spleens of tumour-bearing mice were significantly lower (2- to 4-fold) compared to healthy controls. Biodistribution to other organs remained largely unaffected by tumour presence.

Conclusion

The non-opsonizing nature of the investigated polymers facilitated prolonged circulation times, enabling an effective assessment of the EPR effect as a function of NP size. Tumour tissue consistently served as the primary site of NP accumulation, independent of tumour size, and did not significantly alter plasma clearance rates. These findings highlight the potential of non-opsonizing materials as valuable tools for studying tumour permeability and optimizing nanomedicine design for targeted chemotherapeutic delivery.

EACR25-1305

Positioning of MS-AP-030 as a clinical candidate in an adjuvant setting to delay metastasis in colorectal cancer

D. Roy Chowdhury¹, C. Amarakanth¹, S. Kannan¹, S. Wahid², S. Kushary³, N. Babu AS¹, T.S. Krishnaparbh¹,

V. Narayanan⁴, A. Roy Chowdhury¹

¹*Mestastop Solutions, Core R&D, Bengaluru, India*

²*Mestastop Solutions, Animal Pharmacology, Bengaluru, India*

³*Mestastop Solutions, Core R&D, Bangalore, India*

⁴*Pepris Technologies, Bengaluru, India*

Introduction

Given that 90% of cancer-related deaths worldwide are due to metastasis and that current anti-cancer drugs do not target metastasis, we were driven to explore the underlying biology of this process. The failure of clinical candidates aimed at metastasis in clinical trials has raised valid concerns regarding the effectiveness of target-based therapies and our understanding of metastasis biology. To address this issue, we took a different approach. Our research focuses on a phenotypic and translational strategy, backed by prospective clinical samples, retrospective clinical trials and animal models. We identified critical steps in metastasis and selected a few potential targets. Using AI-based *in silico* modelling, we identified several FDA-approved drugs for non-oncology indications that bind to at least two of our identified targets. One such drug, MS-AP-030, approved for chronic hyperlipidaemia, was shown to delay metastasis onset.

Material and method

We utilized our proprietary AI-ML platform, METSCAN®, to identify critical targets involved in metastasis. Next, we used AI-based protein-small molecule binding platforms to identify FDA-approved drugs, commonly applied for non-oncology purposes, that bind to at least two of these identified targets. These selected drugs were evaluated using our METAssay® platform to assess their anti-metastatic properties in colorectal cancer cell lines and primary colorectal cancer patient samples. Finally, the efficacy of MS-AP-030 was tested in animal models using the METVivo® platform.

Result and discussion

In vitro studies were performed at non-cytotoxic concentrations. MS-AP-030, the most effective anti-metastatic compound, promoted epithelial-to-mesenchymal transition (EMT) and invasion – key steps in metastasis. Additionally, we observed increased reactive oxygen species (ROS) levels and elevated HIF-1 α expression. Despite these effects, MS-AP-030 inhibited extravasation and blocked mesenchymal-to-epithelial transition and colony formation. In the Drosophila model, the compound significantly reduced metastasis with some impact on the primary tumour volume. Similar results were observed in the mice xenograft model, where MS-AP-030 treatment led to a notable reduction in lung and liver lesions.

Conclusion

Our findings suggest that MS-AP-030 promotes a mesenchymal phenotype to such an extent that the cells lose the ability to revert to an epithelial phenotype, ultimately preventing secondary site growth. We propose repositioning MS-AP-030 as a clinical candidate to delay metastasis in an adjuvant setting.

Whole exome sequencing of non-small cell lung cancers in a cohort of patients enriched for genetic tumor risk

J. Wiggeshoff¹, V. Welter¹, J. Rehker¹, R. Priellip²,

J. Siemanowski-Hrach¹, A. Jahn², S. Merkelbach-Bruse¹,
A. Hillmer¹, E. Schröck², R. Büttner¹

¹University of Cologne, Faculty of Medicine and
University Hospital Cologne, Institute of Pathology,
Cologne, Germany

²University Hospital Carl Gustav Carus at TUD Dresden
University of Technology, Institute for Clinical Genetics,
Dresden, Germany

Introduction

The influence of inherited genetic risk on non-small cell lung cancer (NSCLC) and its impact on somatic mutation profiles remains unclear. As part of the National Network Genomic Medicine Lung Cancer, the Task Force 5 (TF5) "Genetic Tumor Risk" evaluates the molecular landscape of NSCLC in Germany to improve molecular diagnostics and personalized treatment strategies. With a cohort enriched for patients with multiple tumor diseases (45%), family history of cancer (71%) and 28% never smokers, our goals include investigating germline mutations, rare somatic oncogenic drivers and complex molecular alterations that are not yet well characterized in NSCLC, where the predominance of smoking-related risk often masks hereditary factors. Therefore, TF5 integrates whole genome sequencing (WGS) of blood-derived DNA and whole exome sequencing (WES) of formalin-fixed paraffin-embedded (FFPE) tumor samples, a promising yet technically challenging avenue for refining molecular profiling in clinical oncology.

Material and method

A new workflow was developed, integrating Sarek v3.2.2 from nf-core with TheSarekSnake, a containerized pipeline. It integrates multiple small variant callers with an ensemble approach for variant detection in samples with a tumor cell content (TCC) as low as 20%. An adaptive filtering strategy enhances sensitivity while prioritizing calls in known lung cancer hotspots. The analysis focused on 966 cancer-associated genes. In the exome, tumor mutational burden (TMB) and microsatellite instability (MSI) were assessed in samples with at least 40% TCC. Components evaluating somatic loss of heterozygosity, copy number variations, and mutational signatures are being developed for further therapeutic stratification.

Result and discussion

To date, 330 patients have been enrolled in TF5, of which 91 have already been analyzed for somatic alterations and had sufficient coverage. The most frequently mutated genes are TP53 (48.4%), EGFR (25.3%), CSMD3 (24.2%), KRAS (19.8%), LRP1B (18.7%), FAM135B (15.4%), and SPTA1 (14.3%). A total of 75 samples could be assessed for complex genomic alterations; 26.6% were TMB-H (≥ 10 mutations/Mb) and all but one of those patients had smoking history. Among the TMB-H, two had high MSI scores; one was confirmed as mismatch repair deficient by immunohistochemistry.

Conclusion

This ongoing prospective study provides insights into the molecular landscape of selected patients with NSCLC and suspected genetic tumor risk using a comprehensive sequencing approach of tumor and normal tissue. Thus far, our findings support the feasibility of using blood WGS as a reference for FFPE tumor WES in somatic variant detection in a clinical context, although tailored

filtering is needed to accommodate coverage differences while preserving sensitivity for actionable mutations. Our preliminary analysis suggests comparable mutation frequencies between our germline risk-enriched cohort and general NSCLCs.

EACR25-1501

Challenges in the Collection of Biological Samples from the Operating Room - The Champalimaud Foundation Biobank Experience

H. Calá¹, M. Castillo-Martin¹, J. Martin-Fernandez¹

¹Champalimaud Foundation, Champalimaud Foundation Biobank, Lisbon, Portugal

Introduction

Biobanks in the health sector are fundamental to the advancement of biomedical research. However, the effectiveness of a Biobank depends on the quality, quantity and accessibility of these samples, as well as compliance with ethical and legal requirements, such as informed consent. The Champalimaud Clinical Centre (CCC) is an oncological Institution with associated research laboratories; thus, the Champalimaud Foundation Biobank (CFB) is a key infrastructure, mainly focused on cancer. The aim of this study is to perform a retrospective analysis of the logistic challenges encountered when collecting biological material from the operating room (OR) and elucidate actions to increase samples' accrual which could be effectively implemented.

Material and method

The CFB generates a list of "possible collections (PC)" every week after receiving the OR schedule, which are used for internal organizational purposes. For this study, all PC lists were reviewed as well as the procurement forms from 2023 and compared the number of samples collected (tissue and blood) with the PC. Then all the causes for not collecting were annotated.

Result and discussion

We have identified a total of 517 surgeries of interest, mostly in the digestive unit, for 2023, of which 82 were canceled for various reasons, resulting in 435 surgeries of interest performed. A total of 613 samples were collected: 217 tissue samples and 396 blood samples; thus, collection rates resulted in 49,89% and 91,03%, respectively. The most frequent reason for the lack of tissue collection was that the resected specimens were placed in formalin in the OR 90,09% (200/222), followed by 6,31% (14/222) due to the small tumor size, 2,25% (5/222) due to modification of surgery approach, 0,90% (2/222) due to the absence of macroscopic tumor and 0,45% due to the lack of identifiable consent at the moment of surgery. This analysis revealed practices in the OR that could be easily avoided by having a closer communication with the Biobank, such as adding formaldehyde for sample fixation and not sending fresh specimens for biobanking. The inability to identify the informed consent at the moment of surgery, although minimal in our case, prevents the ethical use of the samples and could be guaranteed with a better control of

the consenting workflow. Collection was not possible due to external Biobank factors in almost 10% of the cases.

Conclusion:

This analysis reinforces the need for improvement in collection practices, most of which are feasible with better organization.

Deciphering intestinal zonation and its role in tumour initiation, evolution and progression in mouse models of colorectal cancer

R. Amirkhah¹, M. L Mills², N. C Fisher¹, K. Gilroy², S. B Malla¹, R. Byrne¹, A. D Campbell², R. A Ridgway², O. J Sansom², P. D Dunne¹

¹*QUB, PGJCCR, Belfast, United Kingdom*

²*CRUK Scotland Institute, Glasgow, United Kingdom*

Introduction

The spatial regulation of Wnt signalling and stem cell dynamics across intestinal regions remains incompletely understood, in particular the transition away from normal tissue homeostasis during tumour development. Previous studies, primarily using single markers to define overall pathway activation, have suggested that Wnt activity and canonical stemness are elevated in the small intestine (SI) compared to the colon.

Material and method

In this current study, we integrate bulk and single-cell RNA-seq, with spatial transcriptomics to assess phenotypic changes along the full intestine during normal-precancer-cancer transitional stages. To investigate how genetic alterations shape intestinal biology and tumour evolution, we analysed a novel mouse tissue cohort spanning normal, pre-cancer, and cancer states across 24 genetically engineered mouse models (GEMMs).

Result and discussion

The transcriptomics analysis of normal intestine indicated that, Wnt activity is lower in the SI compared to the colon. Furthermore, while bulk RNA-seq indicates higher Wnt activity in the left-sided colon, epithelial-enriched spatial transcriptomics reveals a more uniform distribution across colonic regions, resolving inconsistencies caused by stromal contamination in bulk analyses. Phenotypic interrogation of the tumour transcriptomic data reveals that the primary driver of biological variation is tumour location (SI vs. colon) rather than genotype, with further class discovery identifying three biologically distinct tumour subtypes within each location. By comparing the phenotypic signalling landscapes of these tumour subtypes to their corresponding normal intestinal regions, we can segregate tumours and genotypes into those that either enhance their native microenvironment or override it entirely, leading to divergent molecular profiles. To maximize impact, we developed a Shiny-based data portal under FAIR principles, bridging mouse models with human colorectal cancer to enhance translational research and precision oncology.

Conclusion

By integrating multi-omics data, we propose an updated model of Wnt signaling and stemness zonation, capturing longitudinal (SI to colon) gradients. Our analysis of

normal and precancerous stages suggests that tumours from SI and colon develop through distinct regulatory mechanisms. By tracking tumour evolution from normal and precancerous states, we uncover key regulatory pathways missed in endpoint analyses, offering insights for targeted therapies.

³*University of California, Los Angeles, Department of Surgery, Los Angeles, United States*

Introduction

Curative-intent oncological lung surgery aims to enhance patient outcomes by achieving histologically negative resection margins. In clinical practice, tumor margins are determined by a histopathological assessment using frozen sections. However, in lung cancer this approach is challenging due to the use of surgical staples for tissue resection, prohibiting sectioning of the stapled margin. MSPen technology is a promising alternative for surgical margin evaluation due to its ability to characterize rich molecular profiles from tissue rapidly and non-destructively. Here, we describe the use of MSPen for intraoperative analysis of the stapled margin of resected lung cancer tissues to enhance the accuracy of margin evaluation during surgery.

Material and method

The MSPen employs a droplet of water to directly analyze a tissue site upon contact. Here, we used a handheld MSPen to analyze freshly resected human wedges and lobes. Multiple MSPen analyses, above and below the stapled margin, were performed. Mass spectrometry analyses were performed in negative ion mode using a QExactive Exploris Orbitrap mass spectrometer at mass-to-charge ratio (m/z) range of 100-1000. Sampled areas were marked, sectioned, and histologically stained, followed by pathological evaluation. Mass spectra were subjected to statistical classification using the least absolute shrinkage and selector operator (LASSO).

Result and discussion

Mass spectra obtained from lung tissue analyses were rich in metabolite and lipid species, particularly in the parenchymal aspect. For example, analysis taken from a tissue region below the stapled margin, close to the tumor, showed high relative abundance of lipids in the m/z 600-1000 range. In the stapled line, a putative negative margin, lipids such as phosphatidylglycerol (PG) (34:1) and PG (36:2) were seen at high relative abundance. Analysis of the tumor tissue showed high relative abundance of (PE) (38:4) and phosphati-dylinositol (PI) (38:4). However, analysis along the stapled margin on the visceral pleura had lower relative abundances of lipids commonly detected between m/z 600-1000. In the m/z 100-400 region, metabolites

including glutamine, glutamic acid, and fatty acids (FA) such as FA (18:1) and FA (18:0) were also detected. A predictive model of the MSPen data was generated using LASSO and trained on datasets acquired from fresh frozen lung specimens. Results showed agreement with histopathology, with a prediction sensitivity of 91%, specificity of 95%, and overall accuracy of 93%. We are currently evaluating classification performance on MSPen data from lung surgeries.

Conclusion

Our results demonstrate the feasibility of the MSPen for rapid and accurate intraoperative assessment of lung cancer margin, highlighting its potential in guiding surgical decision making.

⁸Oslo University, Oslo, Norway

⁹Leids Universitair Medisch Centrum, Leyden, Netherlands

¹⁰Hôpital Universitaire de Genève, Geneva, Switzerland

¹¹Hôpital Jules Bordet, Bruxelles, Belgium

Introduction

Less than 8% of adult patients affected by cancer globally participate in oncology clinical trials, and up to 15–25% in hospitals conducting the trials. Participation in clinical trials improves patients' outcome, healthcare organizations in general, country readiness for clinical trials, therapeutic innovations and economy. Inequalities in access to trials stem from patient identification, screening, and participation procedures. Moreover, 30% of the European population live close to borders that persists to be a major barrier for the access to clinical trials.

Material and method

We propose a vision where existing European consortia create a favorable environment to improve patients' access to clinical trials, supported by optimised organisations and technologies that respects individuals.

Result and discussion

We will present how the use of various data types can enable concrete advances in AI in the health sector, with various impact on patients, specifically:

- CGI-clinics, Trial Match 2, Klineo and DigitalECMT that focus on language and molecular models. They are deploying a suite of AI-powered devices in the hospitals and online to inform patients and caregivers about relevant clinical trials, and bring patients to trials.
- Spiderweb, PCM4EU and PRIME-ROSE that open and expand academic or industry promoted personalized

medicine clinical trials in up to 25 countries in Europe, to bring trials to patients.

We will present the AI and medical devices developed in these projects. We will discuss how it can be organised as a suite of solutions to improve molecular testing coverage in Europe, data interpretation and communication between Hospitals, and ultimately patients' inclusion in clinical trials.

Conclusion

These projects promote AI and medical devices to improve the information, access and experience of patients in personalized oncology clinical trials in Europe. They have the potential to increase country readiness to Oncology clinical trial and therapeutic innovations and can benefit from a community awareness.

²iOnctura SA, Geneva, Switzerland

³iOnctura BV, Amsterdam, Netherlands

⁴University of Bern, Institute of Tissue Medicine and Pathology, Bern, Switzerland

⁵University of Geneva, Department of Cell Physiology and Metabolism, Geneva, Switzerland

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy characterized by a dense desmoplastic stroma and an immunosuppressive tumor microenvironment (TME), both of which limit therapeutic efficacy. Immune evasion and fibrosis within the TME create substantial barriers to effective treatment. Key immunosuppressive cell populations, such as regulatory T cells and Arginase-1 (Arg1)-expressing M2 macrophages, suppress anti-tumor immunity primarily by inhibiting cytotoxic T cell activity. A critical enzyme regulating the immunosuppressive TME is phosphatidylinositol 3-kinase δ (PI3Kδ), which enhances regulatory T cell activation and migration while driving cytotoxic T cell exhaustion. Additionally, lysophosphatidic acid (LPA) signaling, driven by the enzyme autotaxin (ATX), impairs CD8+ T cell activation and proliferation. Elevated ATX levels in PDAC patients not only reinforce immune suppression but also promote fibroblast and immune cell migration, further exacerbating tumor fibrosis.

Material and method

Here, we used two clinically relevant ATX and PI3Kδ inhibitors to simultaneously enhance anti-tumor immunity and remodel the tumor microenvironment (TME). To investigate the role of PI3Kδ and ATX in patient prognosis, we first analyzed human PDAC tissue microarrays. Additionally, we utilized a genetically defined KrasG12D-driven pancreatic cancer mouse

model (KPC mouse model) and an orthotopic mouse model, followed by histological examination and immunohistochemistry stainings of dissected tissues.

Result and discussion

The combination of ATX/PI3K δ treatment improved immune response, diminished fibrosis, and increased activated cytotoxic T cells, ultimately leading to decreased tumor progression and prolonged survival in PDAC. Moreover, combination of ATX/PI3K δ inhibitors with chemo- and immunotherapy further extended survival.

Conclusion

Our findings highlight the potential of this multitargeted approach to enhance anti-tumor immunity and improve therapeutic outcomes.

Loss of the tumor suppressor NUMB drives aggressive bladder cancer via hyperactivation of the RHOA-ROCK-YAP pathway: implications for personalized prognosis and targeted therapy

F. Tucci¹, M. Filippone¹, E. Guerrera¹, L. Acerbi¹, G. Curigliano^{2,3}, G. Renne⁴, G. Musti^{5,3}, G. Vago³, D. Tosoni^{1,3}, S. Pece^{1,3}

¹European Institute of Oncology IRCCS, Department of Experimental Oncology, Milan, Italy

²European Institute of Oncology IRCCS, Early Drug Development for Innovative Therapy Division, Milan, Italy

³University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy

⁴European Institute of Oncology IRCCS, Department of Anatomopathology, Milan, Italy

⁵European Institute of Oncology IRCCS, Division of Urology, Milan, Italy

Introduction

Advances in the personalized management of bladder cancer (BCa) have been hampered by the lack of predictive biomarkers and targeted therapies. This study highlights a previously uncharacterized role for the loss of the tumor suppressor NUMB as a hallmark of biologically and clinically aggressive BCa disease.

Material and method

The relevance of NUMB expression variations to naturally occurring BCa was investigated in longitudinal retrospective patient cohorts of non-muscle invasive BCa (NMIBC) and muscle-invasive BCa (MIBC). In a mouse transgenic NUMB knock-out (KO) model, we explored the contribution of NUMB loss, both as a primary factor and in cooperation with carcinogenic insults, to the neoplastic transformation of the normal urothelium. Comparative transcriptomic and functional analyses in NUMB-proficient versus NUMB-deficient models, including the use of primary mouse and established human BCa cell lines in *in vitro* 3D-Matrigel organoid and *in vivo* xenograft studies, were used to reveal the molecular mechanisms underlying NUMB loss-driven bladder tumorigenesis and identify actionable vulnerabilities to reverse the aggressive phenotypes of NUMB-deficient BCa cells.

Result and discussion

Our clinical studies show that low NUMB expression in primary tumors correlates with increased risk of muscle invasion progression in NMIBC patients and poor survival in MIBC patients. In the NUMB-KO model, NUMB loss induces spontaneous malignant transformation of the normal urothelium, accelerating tumor onset and progression in response to carcinogenic insults. Mechanistically, NUMB loss disrupts the Hippo pathway, activating the YAP oncogene via a RHOA/ROCK-dependent axis, triggering an EMT program and aggressive proliferative and invasive phenotypes. Pharmacological and genetic inhibition of the RHOA/ROCK/YAP-TEAD axis selectively blocks proliferation, invasion, and tumorigenic potential of NUMB-deficient BCa cells, positioning the RHOA/ROCK/YAP axis as a promising vulnerable target for therapeutic intervention in highly aggressive NUMB-deficient human BCa. We also identify a 27-gene NUMB-less signature, characteristic of the NUMB-defective condition, which independently predicts risk of NMIBC-to-MIBC progression and associates with improved BCG (Bacillus Calmette–Guérin) treatment response in a cohort of 535 NMIBC patients enrolled in the UROMOL trial. These findings establish NUMB loss as a prognostic biomarker of aggressive BCa and a predictor of response to targeted RHOA/ROCK/YAP-TEAD therapy.

Conclusion

By identifying NUMB as a tumor suppressor in BCa and exploring the underlying biology of NUMB-deficient BCa aggressiveness, our findings pave the way to the development of new prognostic tools and targeted treatments, including the repositioning of already clinically available anti-ROCK/YAP drugs, thus advancing precision oncology for high-risk NMIBC and MIBC patients.

Enhanced Spatial Proteomics: High-Precision Analysis of the Tumor Microenvironment

J. Rauer¹, M. Ingalls², J. Schwarz², C. Jackson², J. Boog¹, A. Christians¹, K. Cashion², A. Northcutt², A. Brix¹, O. Braubach²

¹Bruker Spatial Biology, Hanover, Germany

²Bruker Spatial Biology, St. Louis, United States

Introduction

Spatial biology is essential for understanding cancer progression and treatment by transforming complex cellular interactions into actionable spatial signatures. Protein biomarkers are key targets for spatial analysis, yet achieving high-plex spatial proteomics has been challenging. To address this, we developed VistaPlex™ Panels using EpicIF™ technology, offering a streamlined and scalable solution for spatial proteomic analysis. EpicIF™ technology enables efficient signal removal and iterative multiplexing without compromising sample integrity.

Material and method

VistaPlex Panels are used for multiplex immuno-fluorescence (mIF) analyses to precisely characterize the tumor immune microenvironment (TiME). These modular panels target key biomarkers for immune and tumor cell segmentation, tissue structures, and functional

markers. The panels are validated for sensitivity, specificity, and reproducibility using the CellScape™ Precise Spatial Proteomics platform across various carcinoma tissues. The workflow includes the EpicIF™ technology allowing rapid and complete photobleaching of fluorophores, ensuring high-fidelity signal removal between staining cycles.

Result and discussion

The VistaPlex™ panels enabled robust segmentation of immune, tumor, and stromal cell populations, supporting comprehensive spatial analysis of the TiME. We identified distinct spatial neighborhoods with immune infiltrates, including B-cells and T-cells, showing heterogeneous expression of developmental and activation markers. The assays mapped cellular interactions within the TiME, revealing immune infiltration patterns and tumor-immune dynamics. EpicIF™ technology ensured consistent signal removal, allowing iterative multiplexing without fluorescence carryover, thereby improving assay reliability and reproducibility.

Conclusion

By integrating VistaPlex™ Assays with advanced spatial proteomics and leveraging EpicIF™ technology for optimized signal removal, we provide a scalable solution for high-plex tissue analysis. This approach streamlines spatial biology workflows, enabling researchers to generate detailed spatial insights with minimal technical barriers. These assays set a new standard for tumor microenvironment characterization, accelerating discoveries in oncology and immunotherapy research.

EACR25-1934

Innovative Multiomic Spatial Biology Assay for Comprehensive Immune Profiling of the Tumor Microenvironment

J. Boog¹, A. Christians¹, T. Böttke¹, D. Sanchez¹, A. Acharya², R. Chen², A. Zieba-Wicher³, S. Basu³, O. Braubach¹

¹Bruker Spatial Biology, St. Louis, United States

²Molecular Instruments, Los Angeles, United States

³Navinci Diagnostics, Uppsala, Sweden

Introduction

Spatial biology has significantly advanced our understanding of cancer biology, highlighting the extensive transcriptomic and proteomic heterogeneity within the tumor-immune microenvironment (TiME). Traditionally, most analytical and diagnostic methods provide only a single type of biological readout per tissue section, making the generation of true multi-omic data challenging. To overcome these assay-based limitations and streamline the integration of multiplex experiments, we developed Enhanced Photobleaching in Cyclic Immunofluorescence (EpicIF™) technology. EpicIF™ technology allows for the quick, gentle, and complete removal of common photostable fluorophores *in situ*, enabling the rapid development and customization of novel spatial omics assays on the CellScape™ spatial biology platform. This technology facilitates the integration of multi-omic analyte detection within the same tissue sections. We successfully combined multiplex immunofluorescence (mIF) with the detection of RNA targets via HCR™ Gold RNA-FISH and the

detection of protein-protein interactions via *in situ* proximity ligation assay (isPLA), creating a tri-omic same-section experiment.

Material and method

This workflow centers around the new signal removal strategy, EpicIF™ technology, which effectively and rapidly removes fluorophores while leaving tissue and probe chemistries unaffected. Using this workflow on the CellScape™ platform, we iteratively performed spatial proteomic, transcriptomic, and interactomic assays on the same tissue sections. Formalin-fixed, paraffin-embedded tissue sections were subjected to standard histological processing and incubated with primary antibodies against PD1 and PD-L1. These were then treated with oligo-nucleotide-modified secondary probes designed for an *in-situ* Proximity Ligation Assay (isPLA) to detect PD1 and PD-L1 interactions. Next, RNA targets were detected using 12 HCR™ HiFi Probes, visualized by adding target-specific fluorescently labeled HCR™ Gold Amplifiers (RNA-FISH). Finally, spatial proteomic labeling was conducted with VistaPlex™ multiplex immunofluorescence (mIF) panels targeting over 30 biomarkers.

Result and discussion

The multi-omic assay was developed and tested on breast cancer samples of various subtypes. High-resolution imaging with the CellScape platform allowed for precise detection and quantification of isPLA, RNA-FISH, and mIF signals on the same slide. The combined assay revealed differential biomarker expression and interaction profiles associated with immune-regulatory processes in the tumor samples, showcasing remarkable inter- and intra-tumoral heterogeneity.

Conclusion

This spatial multi-omics approach provides a comprehensive insight into the complex interplay of immune and non-immune cell populations in the TiME.

⁸Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Introduction

Hepatocellular carcinoma (HCC) is the most common form of liver cancer, with a 5-year survival rate of 30%. While surgical resection is an option for 20–25% of patients with early-stage HCC, ~50% experience recurrence within 3 years. This study aims to use artificial intelligence (AI)-driven tools to predict microvascular invasion (mVI) and HCC molecular subclasses from digitalized histology slides.

Material and method

A transformer-based deep-learning (DL) model was developed using digitized H&E slides from 431 surgically resected HCC patients (in-house training cohort). Here, 5-fold cross-validation was applied, and the model was then deployed on two test sets: TCGA-LIHC (TCGA) ($n = 363$) and advanced-stage HCC (aHCC) ($n = 64$). Cell-type fractions were estimated from bulk RNAseq data using BayesPrism algorithm.

Result and discussion

The pathological evaluation of mVI in the in-house training cohort was an independent predictor of overall survival (OS) ($p < 0.05$) in both uni- and multivariable analyses vs. other prognostic factors. For mVI prediction, the DL model achieved a median area under the curve (AUC) of 0.70 ± 0.08 in internal cross-validation and exhibited acceptable generalizability to the TCGA (AUC = 0.62 ± 0.07). Additionally, TCGA patients with predicted mVI had significantly worse median OS (4.9 vs. 7.6 years for mVI absence; $p = 0.003$). Moreover, HCCs with predicted mVI exhibited higher levels of proliferative hepatocyte-tumour cells and pro-tumorigenic immune cells, including SPP1+ macrophages ($p < 0.001$). These results were paralleled in HCCs with pathologically detected mVI, aligning with the known aggressive phenotype and immunosuppressive features of tumours with mVI. Furthermore, a separate DL model trained to predict molecular subclasses of HCC successfully distinguished poor-prognostic proliferative S1/S2 subclasses, from good-prognostic non-proliferative S3 subclass. Internal cross-validation achieved AUCs of 0.75–0.79 for S1, S2 and S3, with performance replicated in two test sets: AUCs of 0.72–0.80 in TCGA and 0.76–0.81 in aHCC. Notably, predicted S3 was linked to better survival in both TCGA (5-year OS: 52% vs. 44% in S1/S2; $p = 0.02$) and aHCC (3-year OS: 89% vs. 42% in S1/S2; $p = 0.02$). Predicted S3 HCCs displayed significantly higher levels of non-proliferative hepatocyte-tumour cells ($p < 0.01$), but less immune cells, including immunosuppressive TREM2+ macrophages and regulatory T cells (Tregs) ($p < 0.001$). Consistently, these results were mirrored in molecular subclasses of transcriptomically profiled HCCs.

Conclusion

Our AI models demonstrated capability to distinguish patient outcome-related biological features such as mVI and molecular profiles in HCC from a single H&E slide. These models have the potential of providing valuable prognostic insights to stratify patients with favourable or poor tumour biology and pave the way for AI-driven precision oncology in HCC.

Patient-derived HER2-positive gastric cancer organoids display differential response to targeted therapies correlating with patients' outcomes and serving as models to unravel treatment resistance mechanisms

¹A. Aguilar-Cifre¹, M. Cabeza-Segura¹, A. Marín-Alonso¹, A. González-Vilanova², R. Villagrassa³, C. Martínez-Ciapaglini^{4,5}, M. M. Sánchez del Pino⁶, A. Cervantes^{1,5}, T. Fleitas^{1,5}, J. Castilla^{1,5,6}

⁵Instituto de Salud Carlos III, CIBERONC, Madrid, Spain

⁶University of Valencia, Biochemistry and Molecular Biology, Valencia, Spain

Introduction

HER2-positive (HER2+) gastric cancer is an aggressive form of gastric cancer (GC) characterized by an amplification of the ERBB2 gene and is found in approximately 10–20% of cases. Its identification is critical because it allows the use of targeted therapies that have improved patient survival. However, intratumoral heterogeneity and treatment resistance remain major challenges. Therefore, it is essential to develop tumor models that reflect the diversity and behavior of tumors in patients. In this context, patient-derived gastric tumor organoids (GTOs) represent an innovative preclinical model that allows the study of tumor biology and novel therapeutic strategies.

Material and method

A biobank of GTOs was established following an in-house laboratory protocol, including two HER2+ organoids (GTO20 and GTO50). To assess whether the GTOs maintained the primary tumor characteristics, an evaluation of HER2 expression was performed by immunohistochemistry (IHC) and copy number variation (CNV) analyses. Drug sensitivity assays to targeted therapy agents were performed through cell viability experiments and compared with patients' clinicopathological data to assess potential correlations in treatment response. To focus on the anti-HER2 therapy sensitivity, mass spectrometry-based proteomics and differential expression analysis was performed between resistant and sensible models.

Result and discussion

ERBB2 amplification was confirmed in both organoid models by CNV analysis. IHC further revealed heterogeneous HER2 overexpression in the organoid culture,

successfully reproducing the intratumoral heterogeneity observed in patient tissue. Drug sensitivity assays showed increased sensitivity to HER2-targeted therapies, trastuzumab and lapatinib, on HER2+ organoids compared to other organoids, but a striking differential response between them, with GTO20 being more resistant than GTO50. Indeed, GTO20 response was consistent with the patient's clinical history, as it was derived from a relapse after the patient became resistant to trastuzumab. Unfortunately, in the case of GTO50 no correlation could be established since the patient passed away before starting trastuzumab treatment. Exploring deeper into the possible molecular mechanisms underlying anti-HER2 drugs response in our models, quantitative proteomic profiling identified 272 differentially expressed proteins between GTO20 and GTO50. A network analysis grouped these proteins into 18 functional clusters, revealing enrichment in several biological processes, including protein folding, signal transduction, and DNA repair, which may play a role in the response to anti-HER2 therapies.

Conclusion

Patient-derived HER2+ GTOs could represent valuable preclinical models, as they accurately recapitulate the pathological characteristics of patients and allow functional studies on therapy resistance.

EACR25-1997

Enhanced photobleaching for fast and highly multiplexed immunofluorescence staining with broad reagent and assay compatibility

T. Böttke¹, A. Christians¹, M. Böttcher¹, J. Boog¹, J. Feldhaus¹, A. Brix¹, D. Sanchez¹, O. Braubach¹
¹Bruker Spatial Biology, St. Louis, United States

Introduction

The demand for high-plex biomarker detection *in situ* has grown significantly in recent years, driving the development of various cyclic immunofluorescence staining techniques to expand biomarker plexity. These methods rely on the removal of fluorescence signals after each detection cycle, typically through chemical stripping of antibodies, photobleaching of fluorophores, or the use of barcoded antibodies. However, each approach presents unique limitations that pose challenges for the development, validation, and customization of multiplex immunofluorescence assays. To address these issues, we developed "Enhanced Photobleaching In Cyclic Immunofluorescence (EpicIF™ technology), an improved signal removal method that enables rapid, gentle, and complete bleaching of common photostable fluorophores *in situ*.

Material and method

In vitro and *in situ* experiments first assessed the effectiveness and specificity of the EpicIF solution. On formalin-fixed paraffin-embedded (FFPE) slides we performed multiplexed immunofluorescence staining using the CellScape™ platform. We then studied EpicIF solution on signal removal efficacy, as well as its effect on sample integrity and target stability by comparing signal intensity and signal-to-noise ratios between non-

bleached control slides and slides treated with EpicIF method.

Result and discussion

We introduce EpicIF™ technology to enhance fluorophore signal elimination by more than 30-fold compared to conventional photobleaching. This method effectively decolorizes a broad range of commercially available photostable dyes (e.g., AlexaFluor™, Atto-Tec™) both *in vitro* and *in situ*, overcoming their resistance to signal removal in iterative multiplexed staining applications. Additionally, we demonstrate its application in iterative multiplexed detection of protein targets using fluorescently labeled antibodies. Our results confirm that this approach preserves sample integrity and tissue antigenicity, even after multiple rounds of signal removal.

Conclusion

EpicIF™ technology enables rapid and virtually unlimited multiplexing in iterative immunofluorescence staining. By effectively eliminating signals from photostable fluorophores, this method expands the range of commercially available fluorescently labeled antibodies suitable for highly multiplexed *in situ* applications. Importantly, its ability to reliably remove fluorescence signals, regardless of the biomarker assay used, opens the door for a wide range of multiomic multiplexing approaches beyond immunofluorescence.

EACR25-2002

Preclinical combination of selenium nanoparticles and a nanovaccine demonstrates immunotherapeutic properties against luminal B breast cancer

C. Ferro¹, A. Matos¹, R. Acúrcio¹, A. Correia², F. Fontana², H. Santos², H. Florindo¹

¹Faculty of Pharmacy, University of Lisbon, Division of Pharmaceutical Chemistry and Technology, Lisbon, Portugal

²Faculty of Pharmacy, University of Helsinki, Division of Pharmaceutical Chemistry and Technology, Helsinki, Finland

Introduction

Selenium (Se) is an element crucial for human health, with anticancer properties. Although bare SeNPs are unstable in aqueous solutions and prone to aggregation, stabilized SeNPs have been demonstrated to induce apoptosis in cancer cells and to have immunostimulatory properties. Therefore, the aim of this work was to access the main immune cell populations responsible for SeNPs immunotherapy against luminal B breast cancer.

Material and method

SeNPs production and stability: SeNPs were produced using sodium selenite, ascorbic acid as reducing agent and bovine serum albumin (BSA) as stabilizing agent. The stability of BSA-SeNPs was performed in human plasma, cell medium, pH 7.4 and 5.5. Therapeutic Intervention Study Design of the Combination Treatment of BSA1-SeNPs and the KRASwt Nanovaccine: An E0771 luminal B breast cancer orthotopic model was established to evaluate the antitumor efficacy of the combinational treatments of the KRASwt nanovaccine

and the BSA-SeNPs. Once the average volume of tumors reached \approx 50–100 mm³, mice were randomly divided into a control group and 4 treatment groups ($n = 6$ animals per group). KRASwt nanovaccine were subcutaneously administered to mice via injection proximal to both left and right sides inguinal lymph, on days 7 and 14 following tumor inoculation. BSA1-SeNPs were both intratumorally (i.t.) or i.v. administered at 1.25 mg kg⁻¹ every 2 days. Tumors and spleens were collected from mice ($n = 6$ animals per group) after euthanasia and homogenized in a single-cell suspension in cold sterile PBS. Cells were seeded in 96-well plates, washed with PBS, and incubated with Ghost Dye Red 780. Afterwards, cells were stained with extracellular and intracellular fluorochrome-labeled anti-mouse antibodies.

Result and discussion

SeNP were spherical, smaller than 50 nm, and with a narrow size distribution and stable in medium, plasma, and at physiological pH, maintaining their size for a prolonged period. Moreover, the combination of BSA-SeNPs with a KRAS-loaded nanovaccine resulted in a strong tumor growth reduction. Indeed, the synergistic effect of KRASwt nanovaccine combined with SeNPs was confirmed by the tumor growth inhibition of 62.2%, compared to 34% and 16.6% for SeNPs (i.t.) and KRASwt nanovaccine, respectively. This synergistic anticancer effect of the combined treatment significantly increased the tumor infiltration of both B, NK, and CD8+ T effector cells. Furthermore, the tumor infiltration of Tregs and PD1-expressing T cells were decreased for the combined treatment with the SeNPs and the nanovaccine.

Conclusion

Stable SeNPs at physiological pH and plasma were produced. Also, SeNPs presented anticancer properties in EO771-bearing mice, presenting synergy with a KRASwt nanovaccine. Therefore, this study offers valuable insights for the development of innovative combinatorial approaches using SeNPs to improve the outcomes of cancer immunotherapy.

EACR25-2012

Hyaluronic Acid-Coated Nanoparticles for Targeted Delivery in Colorectal Cancer: Unlocking the Potential of CD44-Dependent Therapy

R. Amico¹, P. De Cicco¹, L. Viscovo², P. D'Anna¹, C. Conte¹, F. Quaglia¹, F. Borrelli¹

¹*University of Naples "Federico II", Department of Pharmacy, Naples, Italy*

²*University of Naples "Federico II", Department of Veterinary Medicine and Animal Production, Naples, Italy*

Introduction

The development of targeted cancer therapies is crucial to improve treatment outcomes and minimize side effects. CD44, a transmembrane glycoprotein, is overexpressed in many cancers, including colorectal cancer (CRC), where it plays an important role in tumor progression and metastasis. Nanoparticles (NPs) coated with hyaluronic acid (HA) have shown promise as vehicles for selectively targeting CD44-expressing cells and offer a potential approach for cancer therapy.

Material and method

We investigated the behaviour of HA-coated NPs (HA-NPs) in a translational model using peripheral blood mononuclear cells (PBMCs) from healthy donors and CRC patients. The safety and internalization of the HA-NPs were assessed by flow cytometry. The expression of CD44 and the CD44v6 variant, a specific isoform involved in cancer cell migration and invasion, was evaluated in colon biopsies and on PBMCs from CRC patients by immunofluorescence staining. CD44 was activated by pro-inflammatory stimulation and its effects on HA-NPs uptake were investigated. The study on human biopsies was approved by the clinical research ethics committee of the University of Naples Federico II and A.O.R.N. Antonio Cardarelli. All patients enrolled in this study provided written informed consent.

Result and discussion

HA-NPs did not affect the viability of PBMCs from both healthy volunteers and CRC patients, indicating a favourable safety profile. Furthermore, we observed that PBMCs from CRC patients had a significantly higher uptake of HA-NPs compared to those from healthy volunteers. More specifically, 28.81% of PBMCs from CRC patients internalized the NPs, whereas only 7.32% of PBMCs from healthy donors did. To investigate whether the tumor microenvironment (TME) could enhance NP uptake in PBMCs, we stimulated healthy PBMCs with phorbol myristate acetate (10 ng/mL) plus ionomycin (1 μ g/mL) to simulate the TME. Stimulated PBMCs showed a significant increase in HA-NPs uptake, which was correlated with increased expression of CD44 and CD44v6. These results suggest that the TME promotes the expression of CD44 and CD44v6. Indeed, we also found that CD44 and CD44v6 expression was higher in PBMCs from CRC patients, and this expression correlated with their levels in CRC biopsies from the same patients.

Conclusion

In conclusion, our results indicate that HA-NPs have a safety profile in PBMCs from healthy volunteers and CRC patients. In particular, PBMCs from CRC patients showed a significantly higher uptake of HA-NPs compared to those from healthy donors. Moreover, HA-NPs internalization was enhanced in healthy PBMCs when they were stimulated to replicate the TME. These results support the idea that the TME plays a crucial role in modulating HA-NPs uptake and could be exploited for more effective therapeutic strategies.

EACR25-2016

Building precision oncology via real-world data standardization, privacy preserving infrastructures, and collaboration among IT and clinical experts: TheDIGICORE network experience

A. Traverso¹, G. Tonon², P. Mahon², X. Fernandez², G. Pahlavan²

¹*University Vita-Salute San Raffaele, Milano, Italy*

²*DIGICORE, Brussels, Belgium*

Introduction

Precision oncology necessitates personalized treatments maximizing efficacy while minimizing toxicity. Real-

World Data (RWD) presents a powerful, yet underutilized, resource to achieve this, offering insights complementary to clinical trials and facilitating cross-national comparisons of treatment effectiveness and practice variations. However, significant obstacles persist: data sparsity, unstructured formats, and limited digitization; complex and internationally diverse data privacy regulations hindering collaboration; and heterogeneous IT infrastructure and expertise across institutions.

Material and method

The DIGICORE (Digital Institute for Cancer Outcome Research) consortium – a network of European hospitals and companies – directly addresses these challenges. Its initiatives, among the DIGIONE research plan, include:

- (1) the definition of a set of minimum data elements related to electronic health record systems required to setup RWD studies (MEDOC)
- (2) a standardized survey assessing the digitalization of these key cancer-related data elements and their OMOP-standard adherence;
- (3) AI-based tools such as natural language processing to support data digitization;
- (4) a federated learning infrastructure, leveraging the Dutch Personal Health Train initiative, for privacy-preserving clinical research;
- (5) the development of standards for comprehensive cancer center infrastructure,
- (6) the establishment of disease-focused working groups to foster collaboration, and
- (7) dedicated training programs (IDEAL4OMOP) for clinicians to enhance their IT knowledge.

Result and discussion

To date, three projects have been completed, with additional 10 projects underway. The completed projects are:

Pan-cancer Study: This research, which involves 124,682 patients across Belgium, Germany, Italy, Norway, the UK, and the Netherlands, investigated the impact of the COVID-19 lockdowns on the number of new cancer diagnoses and estimates 12-month survival rates.

Lung Cancer Study: Conducted in Germany, Italy, Norway, the UK, and the Netherlands, this study included 1,294 patients. It aims to explore survival rates in patients with metastatic non-small cell lung cancer based on the location of metastases, treatment patterns by therapy line, and to benchmark care quality according to ESMO guidelines.

Breast Cancer Study: This study, involving 5,000 to 10,000 patients across Belgium, Italy, and the UK, focuses on HR+/HER2– metastatic breast cancer (mBC). It seeks to describe the demographic, clinical, molecular, and next-generation sequencing (NGS) characteristics of patients in two cohorts: those with de novo mBC and those with recurrence after locoregional disease.

Additionally, it compares HER2-low and HER2-zero cases within these cohorts.

Conclusion

DIGICORE's multi-faceted approach promises to unlock the transformative potential of RWD in advancing personalized cancer care

EACR25-2048

3D printing in microfluidic device prototyping for cancer research

D. Bereta¹, S. Szotowski², M. Prochota³, A. Staśczak³, S. Studen³

¹*Silesian University of Technology, Department of Systems Biology and Engineering, Faculty of Automatic Control, Electronics and Computer Science, Gliwice, Poland*

³*Silesian University of Technology, Biotechnology Centre, Silesian University of Technology, Gliwice, Poland, Gliwice, Poland*

Introduction

Three-dimensional printing has enabled the fabrication of master molds for casting PDMS-based microfluidic devices used in in vitro cancer microenvironment simulation. This study presents a novel PDMS microfluidic platform, fabricated via a high-resolution 3D printed mold, designed to replicate complex cancer microenvironments using various human cancer cell lines.

Material and method

The master mold was manufactured using a Anycubic Mono 5s resin printer, achieving a printing resolution of approximately 10 µm in the z-axis. Numerous resins were tested during the development phase, with the best results obtained using TR250LV, biomedical resin, and 8k resin; among these, TR250LV proved to be the cost- and time-efficient option. The 3D printed mold features 15 chambers specifically designed to accommodate human cancer cells and includes all peripheral components such as tube adapters, degassers, and other essential features. The printing parameters provided by the resin producer for a 50 µm resolution were adjusted by reducing them by 40% and extending the resin flow time beneath the build platform, thereby achieving the desired 10 µm resolution. PDMS was subsequently cast onto the mold, cured, and peeled off to form the final microfluidic device.

Result and discussion

The PDMS microfluidic device derived from the 3D printed mold demonstrated excellent replication of the mold's intricate features, achieving channel resolutions approaching 10 µm. The combination of high-resolution 3D printed molds with PDMS casting offers a cost-effective and reproducible method for fabricating microfluidic devices that accurately mimic the cancer microenvironment.

Conclusion

This study successfully demonstrates the use of a commercially available 3D printer, the Anycubic Mono 5s, to fabricate a high-resolution master mold for PDMS-based microfluidic devices. The integration of 15 chambers and detailed peripheral components provides a robust platform for in vitro cancer microenvironment simulation.

(especially drugs) on human and animal cells based on microfluidics" project is carried out within the Proof of Concept (PoC FENG) programme of the Foundation for Polish Science co-financed by the European Union under the European Funds for Smart Economy 2021-2027 (FENG) – SS, MP.

EACR25-2094

Characterisation of the Colon Adenocarcinoma microenvironment with a focus on Natural Killer Cells

H. Calá¹, M. Jacob¹, A. Maia², M. Castillo-Martin¹

¹Champalimaud Foundation, Molecular and Experimental Pathology Laboratory, Lisbon, Portugal

²Dana-Farber Cancer Institute, Harvard Medical School, Medical Oncology Department, Boston, United States

Introduction

Colorectal Cancer (CRC) is the 3rd most common cancer worldwide. In patients with advanced CRC, standard treatment strategies have shown low effectiveness; thus, novel therapeutic approaches are needed for such patients to improve outcomes. Recently, Natural Killer (NK) cells have appeared as an alternative to T-cells as adoptive cell therapy due to their lesser secondary effects, strong cytotoxicity, and tumour microenvironment (TME) regulatory capacity. The main aim of this study is to evaluate the immune infiltrates in CRC tissue specimens, with a focus on NK cells, to better understand the role of these immune cells in tumour control.

Material and method

41 patients (18 females, 23 males) with mean diagnosis' age of 69.5 years (37-89 years) underwent surgery for CRC. Tumour location corresponded to cecum (6), ascending colon (14), hepatic flexure (5), transverse colon (1), descending colon (1) and recto-sigmoid transition (12). Formalin-Fixed Paraffin-Embedded specimens were analysed using multispectral microscopy to assess NK cells, their subtypes and functionality, using NCAM1 /CD56 (NK cells), CD16 (cytotoxic NK cells), NKG2D (activated NK cells), CD3 (T cells), and Pan-Cytokeratin (tumour cells) as biomarkers. For each specimen, 10 regions of interest were acquired using a multispectral camera. The images were generated with Nuance software and analysed using Fiji/ImageJ. Three tumour compartments (intraepithelial, intratumoral and periphery) were examined and correlated with clinicopathological patient data. 34 patients are alive without disease, 2 alive with disease, 3 dead of disease, 1 lost to follow-up and 1 dead of other causes after a mean follow-up of 72.1 months (13.4-123.5 months).

Result and discussion

Intraepithelial and periphery compartments displayed significantly less NK cells across all NK cells' subtypes than intratumoral regions. However, greater variation in NK cells number between patients was observed in the intratumoral area. As expected, most of the NK cells identified in the three compartments of the TME corresponded to regulatory NK cells. A significant correlation was found between the number of periphery NK cells ($p = 0.0456$) and periphery regulatory NK cells ($p = 0.0085$) with pathological stage, decreasing NK cells' numbers in higher stages. Notably, low numbers of intraepithelial activated NK cells were statistically associated with shorter survival ($p = 0.0491$). Although

non-significant ($p = 0.10$), low numbers of periphery NK cells correlated with poorer outcomes.

Conclusion

Results obtained in this pilot analysis revealed that a decrease in NK cell infiltration in CRC TME is significantly associated to disease progression and overall survival, highlighting the fact that analysis of NK cells may be an important prognosis biomarker in CRC. Furthermore, increasing the numbers of NK cells in advanced CRC could be an interesting tactic to control tumour progression and improve patient outcomes.

EACR25-2104

Tissue-Engineered Human 3D Tumor Models for Predictive Preclinical Anti-Cancer Therapy Assessment

M. Wußmann¹, J. Matsch², K. Schmidt², J. Nieves², S. Mathew-Schmitt², C. Nesen¹, T. Weigel¹, D. Zdzieblo¹, F. Groeber-Becker¹, G. Dandekar²

¹Fraunhofer Institute for Silicate Research (ISC), Translational Center 'Regenerative Therapies' (TLC-RT), Würzburg, Germany

²Department for Functional Materials in Medicine and Dentistry, University Hospital Würzburg, Würzburg, Germany

Introduction

Preclinical dropout rates in oncology remain alarmingly high (95%), largely due to the limitations of standard in-vitro systems, which fail to account for spatial orientation and essential stromal components. Chimeric animal models, while commonly used, often yield inaccurate results in humans, highlighting the need for better in vitro methods that replicate tumors and their micro-environment. To address this, we developed a biological xenogeneic matrix from decellularized porcine jejunal segments. This matrix has been successfully applied to various cancer types, including lung, colorectal, breast and pancreatic cancer. However, its biological nature presents challenges for platform standardization. Therefore, the development of novel scaffold materials is crucial to enable both efficient scalability and the preservation of the model's predictive capabilities.

Material and method

A conventional electrospinning process was modified, resulting in a highly porous scaffold. Since this approach allows for cell migration, matrix remodeling, and extracellular matrix synthesis, the scaffold provides an ideal platform for the generation of soft tissue equivalents. Within this study we compared the capacity of the novel material platform to generate tumor models to the previous established biological matrix. Through this comparative analysis, we aimed to assess its suitability for replicating key tumor characteristics and its potential for further applications in oncology research.

Result and discussion

With the successful generation of melanoma models on the novel scaffold material, we took an important step towards improving preclinical efficacy assessment of anti-melanoma therapies. These models, spanning different tumor stages and complexities, closely resemble physiological conditions and the *in vivo* situation with melanoma forming naturally at the basal layer of the stratified epidermis. Additionally, the 3D model captures

key aspects of the respective microenvironment, in which the melanomagenesis takes place. Building on this foundation, this approach was successfully extended to other tumor types, including breast, colon and pancreatic cancer. Overall, niche-specific responses and a stronger correlation to clinical outcomes were observed compared to traditional 2D and animal models.

Conclusion

The innovative scaffold serves as an industry-compatible platform for the generation of advanced in vitro tumor models, offering a reliable alternative to biological matrices. This diverse range of tumor models aligns with the 3R principle – Replace, Reduce and Refine – by minimizing animal testing, reducing experimental models, and enhancing preclinical study relevance. By meeting key preclinical testing requirements, this platform holds great potential for improving drug development and personalized medicine approaches in oncology research.

EACR25-2131

Nerve growth factor inducible (VGF) is a secreted mediator for metastatic breast cancer tropism to the brain

R. Carvalho¹, L. Santos², I. Conde¹, H. Ferreira², A. Silva², C. Gomes², F. Schmitt³, C. Jerónimo⁴, J. Paredes¹, A. Ribeiro¹

¹i3S, Cancer Metastasis group, Porto, Portugal

²iCBR - Institute for Clinical and Biomedical Research, Coimbra, Portugal

³CINTESIS@RISE, Porto, Portugal

⁴IPO-P, Porto, Portugal

Introduction

Brain metastases are one of the most serious clinical problems in breast cancer (BC) progression, associated with lower survival rates and a lack of effective therapies. Significant efforts have been made to identify players involved in this process and to understand how cancer cells directly modulate the brain PMN. However, it remains an unexplored and very challenging area of research. Therefore, in this work, we aimed to decipher the soluble factors secreted by BC cells responsible for the remodeling of the brain pre-metastatic niche (PMN), and how these modifications can impact the brain metastatic capacity of cancer cells.

Material and method

As models, brain organotropic BC cells (without or with HER2 overexpression), derived from the parental 231, were used. To control for brain metastatic specificity, the results were always compared with data obtained with 231.Lung and 231.Bone organotropic BC cells. Organotrophic BC cells were maintained in collagen-embedded 3D cultures and their secretome was collected for proteomic analysis. In parallel, the secretomes were used in the modulation of different components of the brain pre-metastatic niche, in vitro and in vivo, through the measurement of the blood-brain barrier (BBB) integrity and microglia activation, using complementary methods such as functional assays, western blot and immunofluorescence. VGF nerve growth factor inducible mRNA and protein expression was analyzed in the TCGA

database and in a series of primary tumors and metastases from patients with BC.

Result and discussion

We found that BC cells with specific tropism to the brain caused significant blood-brain barrier (BBB) disruption, as well as microglial activation, in both in vitro and in vivo models. Further, we searched for a brain-organo-tropic metastatic signature, as a promising source for the discovery of new biomarkers involved in brain metastatic progression. Of relevance, we identified VGF (nerve growth factor inducible) as a key mediator in this process, also impacting the BBB and microglial functions both in vitro and in vivo. In a series of human breast tumors, VGF was found to be expressed in both cancer cells and the adjacent stroma. Importantly, VGF-positive tumors showed a significantly worse prognosis and were associated with HER2 (human epidermal growth factor receptor 2) overexpression and triple-negative molecular signatures. Further clinical validation in primary tumors from metastatic BC cases showed a significant association between VGF and the brain metastatic location, clearly and significantly impacting on the prognosis of BC patients with brain metastasis.

Conclusion

Our study reveals a unique secretome signature for BC with a tropism for the brain, highlighting VGF as a crucial mediator in this process. Furthermore, its specific impact as a poor prognostic predictor for BC patients with brain metastasis opens new avenues to target VGF to control the progression of brain metastatic disease.

⁵Fondazione Policlinico A. Gemelli IRCCS, Dipartimento della Salute della Donna e del Bambino e di Sanità Pubblica - UOC Ginecologia Oncologica, UOC Carcinoma Ovarico, Roma, Italy

Introduction

Resistance to platinum-based therapies in High-Grade Serous Ovarian Cancer (HGSOC) is observed in 20–40% of patients and no predictive biomarkers exist. This represents a critical unmet need. To address this, we developed an ex vivo 3D organotypic slices culture

(OSC) model that preserves tumor architecture, aiming to provide a fast-track predictive tool.

Material and method

Surgical specimens were collected during primary debulking or explorative laparoscopic surgery from patients with advanced HGSOC treated at Fondazione Policlinico Gemelli IRCCS. Samples were embedded in 4% agar and sectioned into 350 µm-thick slices using a tissue chopper. Slices were cultured in an air-liquid interface for up to six days and treated with Carboplatin (Cp) at 100µM, which was the identified IC50 dose-response assay. The treatment was administered either as a single dose or a double dose (T0: day of surgery, T1: 72 hours post-surgery). Cell viability was assessed at the end of treatment using the CellTiter-Glo 3D assay. For histopathological analysis, samples were formalin-fixed and paraffin-embedded (FFPE), then stained with Hematoxylin and Eosin. Key parameters – including sclerosis, necrosis, fibrosis, tumor cell percentages, and immune composition – were evaluated. Patients' clinical outcomes were monitored to validate the model's predictive accuracy.

Result and discussion

OSCs were successfully generated from five patients. Cytotoxicity assays revealed that three patients exhibited high sensitivity to Cp, with cell viability dropping below 20% after the double dose. One patient showed an intermediate response, with viability decreasing from 62% after a single dose to 34% after the double dose. Notably, one patient displayed resistance to Cp, as cell viability unexpectedly increased from 44% with a single dose to 90% with the double dose – consistent with the patient's clinical outcome. Histopathological analysis aligned with these cytotoxic responses. In samples with reduced cell viability, FFPE-embedded organotypic slices showed decreased tumor cellularity and increased necrosis. Conversely, the resistant sample, which retained higher cell viability, exhibited preserved tumor cellularity without significant histopathological changes. Follow-up data from two patients – one sensitive and one resistant – further supported these findings, reinforcing the correlation between histopathological changes, cell viability, and response to Cp.

Conclusion

Organotypic slice cultures represent a promising ex vivo model for HGSOC, with potential for improving drug screening. Our findings highlight the model's ability to capture the heterogeneity of Cp response. However, validation in a larger patient cohort is needed. If confirmed, this model could be integrated into clinical trials to assess its effectiveness in guiding therapy selection.

Introduction

Colorectal cancer is the 3rd most incident and the 2nd deadly cancer worldwide, with surgery being the only potentially curative treatment. Within patients submitted to colorectal cancer surgery, anastomotic dehiscence (AD) is a significant cause of postoperative morbidity and mortality, after gastrointestinal tract reconstruction. Around 24% of patients undergoing distal rectal surgery are affected, with a mortality rate of approximately 7%. The need for intensive care and revision surgeries to treat complications arising from AD significantly prolongs hospitalization time and increases overall treatment costs. Early detection of AD is critical given the need for diagnosis in order to initiate timely treatments minimizing complications and associated costs. Therefore, we propose the development of a new implantable electronic system, not only for early identification of AD, but also for monitoring the anastomosis over time. This innovative biomonitoring system consists of an advanced adhesive in which sensors made of conductive metal alloys with highly elastic properties will be integrated. This study aimed to evaluate the in vitro cytotoxicity of several sensors with different components, as well as the biocompatibility in vivo of the most promising ones.

Material and method

According to ISO-10993, the sensors' cytotoxicity was evaluated in the VERO cell line using two methodologies, the direct contact and the extraction methodologies. The MTT and the SRB assays were used to evaluate the metabolic activity and protein content 24h after the cell's treatment. Furthermore, the two selected most promising sensors were subcutaneously implanted in 8–12 weeks old male Wistar rats, and the short-term local toxicity was evaluated 2 weeks after implantation [1].

Result and discussion

Our sensors composed of different metal alloys showed no considerable cytotoxicity in vitro in the two tested

methodologies. The two most promising sensors tested in vivo demonstrated a safe profile with minimal local toxicity observed.

Conclusion

These results support the suitability of the sensors for use in the proposed implantable biomonitoring system, demonstrating their potential. Nonetheless, further studies, including genotoxicity assessments and in vivo long-term toxicity evaluations, are necessary to fully validate their application. This innovative approach offers significant potential for enhancing early detection and continuous monitoring of AD in colorectal cancer survivors, paving the way for improved patient outcomes and quality of life, as well as reduced healthcare costs.

Intraductal Carcinoma of the Prostate- A Precursor Lesion?

L. Rijstenberg¹, H. Harikumar¹, E. Verhoeft¹, T. van den Bosch¹, R. Choiniere¹, M. van Royen¹, G. van Leenders¹

¹Erasmus MC, Pathology, Rotterdam, Netherlands

Introduction

Intraductal Carcinoma (IDC) of the prostate is in an in-situ lesion that has been well associated with worse prognoses. However, the pathogenesis of IDC is yet to be determined. The conventional retrograde invasion theory proposes that the malignant glands invade back into preexisting glands, forming the in-situ lesions.

Alternatively, we suggest that IDC is a precursor lesion that further invades the stroma. Characterising these transition areas between in situ lesions and invasive prostate cancer (PCa) glands could help confirm which hypothesis is more likely.

Material and method

75 samples from 46 PCa patients were selected from the IDC database at the Erasmus MC with the approval of the Erasmus MC Ethical Committee. The scoring of the samples was conducted using the H&E slides of the samples. Immunohistochemistry staining for basal cells (34BE12) was performed on these samples. Additionally, six tissue punches of regions containing transitions from Prostatic Intraepithelial Neoplasia (PIN), Atypical Intraductal Proliferation (AIP) or IDC to invasive cancer were fluorescently stained for Keratin 5 and Keratin 8/18 and then cleared. The z-stack was then imaged using an upright Leica SP5 confocal microscope.

Result and discussion

PIN occurred adjacent to IDC in 88.9% of the cases. Additionally, the basal cell stainings indicated that the invasive-like glands lying next to the in-situ lesions were also surrounded by basal cells, similar to in-situ lesions. These glands would have typically been classified as invasive, but due to the presence of basal cells, which are absent around invasive glands, we refer to them as invasive-like glands. Using 3D imaging, we captured spatial continuity between these in-situ lesions and invasive-like glands. Basal cells were also observed to be

scattered around these invasive-like glands and progressively disappeared around farther invasive glands. Based on these results, we propose a new precursor lesion model. According to the ‘Repetitive Invasion, Precursor Progression’ (RIPP) model, PIN is the primary precursor lesion. Upon accumulating enough genomic aberrations, PIN possesses the ability to repetitively invade into the stroma to establish invasive-like glands that eventually lose basal cells upon further proliferation and invasion. Simultaneously, PIN can accumulate more genomic alterations and form IDC structures within pre-existing glands. AIP is a transient stage between PIN and IDC. The newly formed in situ lesions can invade the stroma and form invasive PCa.

Conclusion

This study characterises the transition areas between in situ lesions and invasive PCa. We identified spatial continuity between in-situ lesions and invasive-like glands that eventually transitioned to invasive glands. We present the RIPP model based on these 2D and 3D imaging revelations.

Introduction

Aiming to reduce off-target toxicity, recent advances in oncological pharmacology have focused on smart nanocarrier systems that enable controlled drug release at tumor sites, reducing. Carbon dots (CDs) have gained increasing prominence due to their excellent fluorescence properties, biocompatibility, and high cellular internalization. In parallel, biorthogonal catalysis has emerged as a cutting-edge strategy for targeted activation of pro-drugs directly in the tumor microenvironment, enhancing therapeutic precision while minimizing systemic toxicity.

Material and method

Gold-doped CDs (Au@CDs) were synthesized by a microwave-assisted method at 180 °C for 5 minutes. The synthesized CDs were purified and characterized using UV-Vis and fluorescence spectroscopy, FTIR, TEM, AFM, and XPS. The catalytic activity of Au@CDs was evaluated by activating the non-fluorescent pro-dye, pro-Rhodamine 110 (RH 110), using sodium ascorbate (SA) as a reducing agent. Cell viability was assessed on A375 melanoma cells using MTT assays, and confocal microscopy studies were conducted to visualize cellular uptake and provided insights into the intracellular localization of Au@CDs after 24-hour incubation.

Result and discussion

In the catalytic activation of pro-RH 110, fluorescence emission was detected immediately upon adding Au@CDs to the pro-dye solution, pointing to promising biorthogonal catalytic activity. Preliminary in vitro studies revealed that Au@CDs exhibited minimal toxicity to cells at concentrations up to 100 µg/mL. However, upon adding pro-RH 110 and SA, a significant reduction in cell viability occurred. This result can be attributed to the generation of reactive oxygen species (ROS) induced by SA, amplified by the gold nanoclusters present in Au@CDs. Due to high cell death, fluorescence conversion of pro-RH 110 could not be verified. Cells treated with Au@CDs exhibited strong intracellular fluorescence, especially in the nuclear region, suggesting effective cellular uptake and nuclear affinity.

Conclusion

This study explores Au@CDs in biorthogonal catalysis, specifically for activating pro-RH 110, a non-fluorescent derivative of RH 110. Preliminary results showed the catalytic potential of Au@CDs. Future research should optimize SA concentration and alternative synthesis methods for pro-RH 110 without reducing agents. Upon successful activation, subsequent steps will investigate pro-drug activation within cells.

A controllable and integrated pump system for high-precision microfluidics used for drug testing and cell cultures

M. Ochman¹, M. Czyż¹, A. Staśczak^{1,2}, S. Student^{1,2}

¹Silesian University of Technology, Department of Systems Biology and Engineering, Faculty of Automatic Control, Electronics and Computer Science, Gliwice, Poland

²Silesian University of Technology, Biotechnology Centre, Gliwice, Poland

Introduction

Drug testing and cell culturing require precise environmental control, often dependent on specialized microfluidic equipment. A critical component of these systems is a high-precision pump regulating fluid substance movement. However, research is frequently hindered by outdated and unsupported software, limiting the usability of existing equipment. To address this, we

developed custom software compatible with modern systems while expanding functionality.

Material and method

We focused on two key devices: the New Era Pump System Model NE-1000 and the CorSolutions ECO nano Flow Meter. Both connect to a control computer via an RS-232 to USB adapter, enabling bidirectional data exchange. The control software, written in Python using the pyserial package, imports configuration parameters from a TOML file for easy customization. It features a graphical user interface (GUI) for accessibility and a text-only mode for automation. Commands can be sent interactively or as predefined sequences executing research programs with multiple phases. The system operates in a closed-loop configuration, dynamically adjusting flow rates based on real-time feedback. The GUI displays live flow rate data, active program phases, last executed commands, and system logs for streamlined supervision.

Result and discussion

The developed software restores the full functionality of the outdated equipment, integrating it seamlessly into research workflows. The intuitive GUI reduces user errors and enhances real-time decision-making. The software improves workflow efficiency and system scalability by consolidating multiple devices under a single lightweight program. Its modular architecture allows future expansions and easy adaptation to new research requirements.

Conclusion

Funding: "Innovative methods of biomedical data analysis and classification – the future of diagnostics" as part of the project "Supporting students in enhancing their competencies and skills", European Funds for Social Development Program 2021–2027, W131 - MO, AS. The "Innovative system for testing chemical compounds (especially drugs) on human and animal cells based on microfluidics" project is carried out within the Proof of Concept (PoC FENG) programme of the Foundation for Polish Science co-financed by the European Union under the European Funds for Smart Economy 2021–2027 (FENG) – SS.

EACR25-2395

A Multiomic and Highly Multiplex Method of Imaging Metabolites, Targeted Proteins and Targeted Transcripts on the Same Lung Cancer Tissue Microarray Using Novel Mass-Tagged Affinity Probes

L. Dettori¹, G. Yagnik¹, J. Bell¹, Z. Wan¹, P. Carvalho¹, A. Yatsuhashi¹, K. Rothschild¹, M. Lim¹

¹AmberGen Inc., Billerica, United States

Introduction

Lung cancer is the second most common cancer and the leading cause of cancer-related deaths worldwide. Most lung cancer (80–85%) is non-small cell (NSCLC), comprising mostly adenocarcinoma and squamous cell carcinoma, while roughly 10–15% of lung cancer is small cell lung cancer (SCLC). Accurate subtype identification, for example, is critical for determining treatment.

However, conventional analyses such as immunohistochemistry (IHC) are limited to small numbers and classes of biomarkers imaged, thereby providing a narrow view of the tissue biology. More broadly, understanding the full breadth of tumor biology requires a spatial multiomic approach which can image all biomolecular classes, and

on the same sample, for a truly ‘holistic’ view of tumor microenvironments and tumor heterogeneity. Towards this end, mass spectrometry imaging (MSI) is uniquely capable of detecting small molecules in tissues including metabolites (e.g., lipids), glycans and even xenobiotics such as drugs/drug metabolites. However, macro-molecular MSI of proteins and mRNA presents several challenges. These include the need for *in situ* proteolytic digestion which generates highly complex biomolecular mixtures imaged at each “pixel” in the tissue. This results in signal suppression effects, often restricting detection to only the most abundant targets. While cross-platform approaches such as combining MSI with multiplexed immunofluorescence or spatial transcriptomics partially address this problem, image co-registration is difficult, and these approaches can require serial tissue sections comprising different cell populations.

Material and method

We report a unique, fully multiomic and highly multiplexed MSI approach on the same tissue section that encompasses label-free untargeted small molecules and targeted proteins and mRNAs using novel photocleavable mass-tagged antibody and oligo probes (MALDI-IHC/ISH).

Result and discussion

This approach was applied to lung cancer tissue microarrays (TMAs) and provided comprehensive spatial multiomic information from the same tissue sections using the same MSI platform. To better understand these high-dimensional results, we also demonstrate a novel computational workflow to integrate multiomic images of the same tissue section, scalable to an entire cohort of samples, and profile them through statistical and machine-learning analyses. This spatially resolved multiomic correlative analysis software, developed using Python/FIJI, is designed to rapidly profile entire cohorts from which multiomic/multimodal measurements were made. We show the applicability of this approach to understanding lung cancer and demonstrate the complex biological interactions between the various classes of tissue biomolecules.

Conclusion

This more complete view of tumor tissue biology is expected to lead to future mechanistic studies and ultimately, improved biomolecular signatures for precision medicine.

Introduction

Malignant pleural mesothelioma (MPM) is a fatal cancer, and one of the primary risk factors remains asbestos exposure. Developing robust, safe, and efficient therapeutic targets and models that accurately recapitulate the disease is critical for improving MPM therapeutic strategies. This study aims to modulate nucleolin (NCL), a protein ubiquitously expressed in the cell nucleus and specifically present in the cytoplasmic membrane of some cancer malignancies, and develop a robust *in vivo* orthotopic model to explore additional mechanistic insights on tumor drug targeting as was successfully performed by our group previously [1].

Material and method

Murine malignant mesothelioma AB1, AB12, and AB22 cell lines were used to generate NCL-overexpressing models via lentiviral transduction of the pFUGW plasmids encoding NCL tagged to HA and membrane-bound NCL-overexpressing models via plasmid transfection using the pDisplay™ Mammalian Expression Vector. Inducible downregulated NCL models were generated upon DNA transfection of constructs carrying a reporter gene and an shRNA targeting the coding sequence of human NCL gene under a tetracycline-responsive promoter (TRE) and a puromycin resistance cassette under the human CMV promoter. Individual clones were generated via limiting dilution technique and were characterized by FACS, Western Blotting, and q-RT-PCR. Cells were visualized using the Axio Observer Z1 system while controlling temperature (37°C) and humidity. Balb/c mice were implanted intrapleurally with increasing concentrations of luciferase-expressing MPM cells (kindly provided by Dr. Marco Bianchi, San Raffaele Hospital, Milan, Italy), and tumor growth was evaluated by bioluminescence. Tumors and adjacent tissue were collected at the endpoint and included in OCT.

Result and discussion

All MPM cell lines showed positive expression of NCL in the cell membrane in over 50% of the cells. NCL over-expressing MPM cells display stable NCL expression over time, as detected by q-RT-PCR and western blotting. Specific membrane-bound NCL expression is currently being evaluated. Inducible downregulation of NCL was detected in pool transfected cells in the presence of doxycycline over time. Intrapleural administration of 0.5x106 AB1 cells generated tumors that recapitulated the course of disease, up to 13 days. No metastases were observed outside the pleural compartment.

Conclusion

These findings highlight the importance of versatile *in vitro* models that can be effectively manipulated to develop tailored and effective cancer therapies. New treatment strategies can be further evaluated by using this

robust *in vivo* orthotopic immunocompetent mouse model, an invaluable platform in the context of MPM. [1] doi: 10.1016/j.nantod.2021.101095

Introduction

Neutron capture therapy (NCT) is a highly precise form of radiotherapy that currently exploits ¹⁰B isotopes to produce high linear energy transfer particles, leading to cancer cell death. Current drugs have substantial limitations for successful clinical translation, including low chemical stability, selectivity, and intracellular persistence during neutron irradiation, causing severe side effects. Multifunctional carbon nanocapsules (CNCs) represent an innovative approach for designing more efficient nanotherapeutic agents by exploring new active nuclides. For this purpose, we will explore CNCs that can accommodate high concentrations of ¹⁰B or Lithium (⁶Li)-active nuclides in their internal cavities.

Material and method

B or Li-filled CNCs were synthesized via solvent-free thermal treatment. The MTT assay was performed to evaluate the cytotoxicity of CNCs. For this study, phenotypically normal cells, the kidney epithelial cell line VERO (CCL-81), and lung fibroblast MRC-5 (CCL-171) cell lines were used. They were treated with 20, 40, 60, 80, and 100 µg/mL of compounds and then incubated for 24h or 72h at 37 °C.

Result and discussion

In MRC-5, higher concentrations (100 µg/mL) of CNCs loaded with Li and B resulted in drops of 20.0 ± 13.63% and 21.6 ± 13.97% after 24H, while at lower concentrations (20 µg/mL), the drops were only 10.80 ± 10.33% and 14.52 ± 12.86%, respectively. With 72 h of exposure, a more pronounced decrease was observed at 100µg/mL with 39.59 ± 5.14% and 42.79 ± 4.48 % Li and B loaded CNCs, respectively.

Conclusion

A reduction in cell viability of more than 30%, according to ISO 10993-5, is considered a cytotoxic effect. Thus, the tested CNCs did not show significant cytotoxicity when the cells were exposed for 24 hours. However, cytotoxicity was observed in Vero cells at high concentrations in a dose-dependent manner, particularly in the case of Li-filled CNCs. The CNCs showed an interesting cytotoxicity profile and potential for use in NTC by exploring new active nuclides.

EACR25-2404

A systematic review of Cancer spontaneous remission (CSR) and post-radiation abscopal responses (p-rAR)

T. oliver¹, K. Tipplies², E. Ladoukakis³, B. Nedjar³

¹QMUL Barts Cancer Institute, Director's Office, London, United Kingdom

²Barts Health NHS Trust, Clinical Oncology, London, United Kingdom

³QMUL Faculty of Medicine and Dentistry, Wolfson Institute of Population Health, United Kingdom

Introduction:

Part of radiation's curative power is as a form of "cancer vaccine", by releasing antigenic molecules that contribute to rejection of metastases outside the radiation field (p-r AR). Circulating-lymphocytes are sensitive to radiation, explaining why very-high-dose radiation (more effective at killing cancer cells) that needs 30-35 fractions in 6-7 weeks produces more lymphopenia and worse long-term survival than hypofractionation. Palliative radiation is investigating ultra-hypofractionation i.e. 1-3 fractions in one week rather than in more extensive fractionation schedules as pilot studies have shown increased p-r AR. This abstract compares p-rAR reports to those from reports of CSR

Material and method

This abstract updates systematic CSR and p-r AR reviews, comparing report frequency over 45 years and top tumour types. The p-r AR series reports actuarial survival.

Result and discussion

From 1970-2009, 31 confirmed CSR articles in 40 years (ie 0.78 papers per year). From 2010-2024, 50 confirmed CSR articles in 15 years (ie 3.3 papers per year. 32 lung cancer, 13 colorectal, 9 breast cancer, 29 cases of 8 other cancers). Six systematic reviews of CSR were identified, 3 lung, 1 colon, 1 hepatoma, 1 early cervix cancer (n = 1,481 CIN2, SR: 50.9%, CIN2/3 SR: 36.3%) First reported in 1969, p-r AR has increased from 14 literature reports in 29 years prior to 2010 (1 case in every 2 years) to 41 in 9 years up to 2019 (4.6 cases reported annually), and 33 cases reported in 5 years 2020-2024 (6.6 cases a year). The most recent p-r AR systematic review identified 58 cases up to 2019. On average, it takes 2 months to demonstrate response, the most frequently tumours being lung, renal, lymphoma and melanoma. Actuarial disease controls at 5 years was 39% in this series. There were 2 prospective studies of palliative

radiation, one in non-small cell lung cancer (3/9 PRs) and 2nd in Gastric cancer (4/14 PR)

Conclusion

There is an urgent need to undertake a randomised trial in patients requiring palliative radiation comparing standard of care currently 20 Gy in 5 fractions versus 8Gy in 1 fractions with and without Checkpoint inhibitors

EACR25-2411

3D Tumor Spheroids for Assessing Carbon Nanocapsule-Based Neutron Capture Therapy

⁴Centre for Mechanical Technology and Automation (TEMA), Mechanical Engineering Department, University of Aveiro, Aveiro, Portugal

Introduction

Carbon nanocapsules (CNCs) offer a groundbreaking approach to improve the efficacy of multifunctional nanotherapeutic agents in neutron capture therapy (NCT). This study explored the potential of CNCs to encapsulate high concentrations of active nuclides within their cores to maximize therapeutic efficiency. To assess the interactions between CNC-based therapies and the complex tumour microenvironment, 3D tumour models of head and neck cancer were explored, enabling more realistic evaluations and *in situ* monitoring of this novel therapeutic approach.

Material and method

Spheroids of MRC-5 and FaDu cells were generated using an optimized protocol for three-dimensional cultures. Cells were cultured in their respective media and spheroid formation was promoted using the hanging drop technique. Following spheroid formation, CNCs were added at different concentrations (60 µg/mL and 100 µg/mL). The integrity of the spheroids was assessed using fluorescence microscopy, allowing the visualization of the cellular response to treatment and maintenance of the 3D structure.

Result and discussion

Head and neck cancer spheroids had well-defined, compact, and spherical structures with dense cellular packing, providing a favourable study model for new

CNCs. Spheroids with a size of approximately 1–1.5 mm were produced after 5 days of cell plating. Fluorescence microscopy images indicated that the integrity of the spheroids was maintained even in the presence of the test compounds at concentrations of 60 and 100 µg/mL. Minimal surface irregularities were observed compared with the untreated controls, with overall preservation of the 3D architecture.

Conclusion

Head and neck cancer spheroids provide a robust and physiologically relevant model for evaluating CNC-based therapies. The maintenance of spheroid integrity and 3D architecture, even at higher CNC concentrations, suggested good biocompatibility and minimal structural disruption. These results support the potential of CNCs as a promising platform for NCT, warranting further studies to explore their therapeutic efficacy and mechanistic interactions within the tumour microenvironment.

EACR25-2567

Imaging Mass Cytometry Detects the True Dynamic Range of Low-Abundance Biomarker Expression in Human Tumors

M. Klug¹, S. Kala², Q. Raza², J. Chwee², T. Pfister², L. Lim², D. King², C. Loh²

¹Standard BioTools, Berlin, Germany

²Standard BioTools, Markham, Canada

Introduction

Detecting clinically relevant biomarkers in cancer tissues provides key insights into the unique tumor characteristics of patients, allowing for more personalized and effective therapies. Immunohisto-chemistry (IHC) is the gold-standard technique for biomarker detection and is widely used by pathologists to score low-abundance biomarkers (LABs) in tissues. Limitations related to complexity, quantitation and false signal detection are frequently observed using IHC and day-to-day variability due to multiple steps of signal amplification and pigment mistaken for true signal can misinform pathologists about LAB expression. Imaging Mass Cytometry™ (IMC™) technology is a multiplexed imaging technique that incorporates quantitative assessment of 40-plus biomarkers simultaneously on the same slide. The Hyperion™ XTi Imaging System, in association with an automated slide loader, permits 24/7 data acquisition and provides biological insights critical for assessment of the tumor microenvironment. We strove to determine whether IMC can be used for pathological evaluation of LABs and provides additional key biological insights for clinical evaluation offered through multiplexed analysis.

Material and method

We performed a comparison of IHC and IMC technology to detect clinically relevant LABs (PD-1, PD-L1, CTLA-4 and LAG-3) on human tumor tissue microarray and whole tissue samples. For IMC technology, we detected single cells using the Human Immuno-Oncology IMC Panel, which offers cell phenotyping of tumor and immune cell subtypes and their functional states. We

stained serial sections of tissues using the same antibody clone and generated IHC and IMC data, which was assessed by a board-certified pathologist. We conducted quantitative image analysis to detect LAB expression on single cells.

Result and discussion

Our results demonstrate that while IMC and IHC are similar in detecting LABs, IMC technology can accomplish this without signal amplification, offering an opportunity to evaluate LABs in their true dynamic signal ranges. Quantitative analysis of IHC and IMC data further demonstrated the equivalent performance of both platforms. Multiplexed single-cell analysis using IMC data provided insights about LAB expression on specific immune and tumor cells. While IHC is semi-quantitative and cannot reliably determine the high abundance of a target, IMC technology offers the opportunity of signal quantitation as it displays the complete dynamic range of signal.

Conclusion

Clinical assessment of tissues using IMC technology offers an advantage over traditional IHC methods by providing true biological context due to multiplexing capabilities. The ability of IMC to provide high-dimensional spatially resolved data makes it a powerful tool for clinical and translational applications and shows that it is poised to significantly contribute to biomarker discovery and drug development.

EACR25-2570

A deep-learning approach for tissue mapping and cell phenotyping in imaging mass cytometry data analysis

M. Klug¹, S. Kala², H. Suzuki³, F. Schneider⁴, J. Mansfield², C. Hupple², R. Baird²

¹*Standard BioTools, Berlin, Germany*

²*Standard BioTools, Markham, Canada*

³*Fukushima Medical University, Fukushima, Japan*

⁴*Visiopharm A/S, Hørsholm, Canada*

Introduction

Imaging Mass Cytometry™ (IMC™) technology is a multiplexed imaging technique that generates high-dimensional spatial data at subcellular resolution without the complications of autofluorescence and cyclic imaging. IMC technology has two distinct whole slide imaging (WSI) modes: Preview Mode (PM) and Tissue Mode (TM). PM rapidly scans stained tissue to provide a comprehensive overview within minutes, while TM provides fast acquisition of the entire tissue at 5-micron resolution, mapping out the distribution of over 40 markers and revealing tissue heterogeneity. Both WSI modes enable researchers to make informed decisions about selecting tissue areas that warrant closer examination at single-cell resolution. Following PM, regions of interest (ROIs) are selected on the same slide for high-resolution imaging using Cell Mode (CM). This facilitates single-cell analysis of the ROIs identified during PM. These imaging modes together with an automated slide loader function support non-stop acquisition of tissue samples all week.

Material and method

Tissue sections of lung cancer were stained with a 40-marker IMC panel by combining the Human Immuno-

Oncology IMC Panel with the Human Immune Cell Expansion IMC Panel to study spatial organization and cellular interactions in the tissue. Images were acquired on the Hyperion™ XTi Imaging System (Standard BioTools), first in PM and then in CM with automatic selection of ROIs using Phenoplex™ software (Visiopharm®). ROIs were automatically selected based on three criteria: 1) tertiary lymphoid structures (TLS) expressing CD20 and CD3; 2) Granzyme B-rich areas and 3) areas with high number of CD68 and Vimentin double-positive cell clusters. An adjacent serial section was acquired in TM for a whole slide morphologic segmentation comparison.

Result and discussion

Tissue segmentation for all modes was performed using Phenoplex by training a deep-learning algorithm to recognize morphological features of the images, including the TLS. Single-cell analysis of the images generated in CM was performed using Phenoplex; cell segmentation was based on iridium DNA channels, and phenotyping was performed using the guided workflow. This data was used to compare the immune contexture through a series of t-SNE plots partitioned by spatial region and clinical variables.

Conclusion

Many mature TLS with proliferating germinal centers were present in the tissue. A high number of granzyme B-expressing neutrophils were found. Vimentin-positive macrophage-like cells were associated with the TLS. This work demonstrates that the Hyperion XTi Imaging System with its three acquisition modes (PM, TM and CM) can greatly advance the ability of IMC users to obtain answers from complex samples. The interactive capabilities of Phenoplex allow the user to quickly identify pertinent cell types, find them within a tissue map, define their spatial relationship and analyze their neighbors, leading to valuable biological insights.

Heterogenous tumor immune microenvironment in mismatch repair deficient colorectal cancer patients receiving immune checkpoint inhibitor

W. Lee¹, S. Choi¹

¹*Gachon Univ. Gil Medical Center, Surgery, Incheon, Korea (Republic of)*

Introduction

Mismatch repair deficient (dMMR) colorectal cancers (CRCs) are known to respond well to immune checkpoint inhibitors (ICIs). However, their heterogeneous drug responses and molecular characteristics remain undefined. Here, we conducted a functional transcriptome or spatial proteome analysis to define a heterogeneous immune context reflecting the response to ICIs.

Material and method

Functional transcriptome or spatial proteome analyses of 34 patients with dMMR CRC were conducted to characterize immune subtypes. 11 patients and validation

cohorts ($N = 9$) who received ICIs were further analyzed based on proteomic phenotypes.

Result and discussion

The cohort was dichotomized into “immune-low” group, and “immune-high” group based on transcriptomic data. The percentage of CD8+ TILs was significantly higher in the immune-high group than that in the immune-low group ($p = 0.0256$). The Nearest Neighbor (NN) distances from the CK+PD-L1+ tumor cells to the CD8+ TILs were significantly shorter in the immune-high group when compared to the immune-low group (immune-low vs immune-high, $p = 0.0076$). The NN distances from the CK+PD-L1+ tumor cells to the CD8+ TILs were significantly associated with the response to pembrolizumab in both internal ($p = 0.0114$) and validation cohorts ($p = 0.04762$). CD163+ cells were significantly enriched in the patients with resistance to pembrolizumab.

Conclusion

dMMR CRCs are immunologically heterogeneous, leading to a heterogeneous response rate to ICIs. CD8+ T cells determine the immune subgroups of dMMR CRCs and their response to ICIs. CD163+ macrophages can be considered as potential therapeutic targets. Here, our comprehensive data provide practical insights into predicting ICIs response for heterogeneous dMMR CRC subtypes.

EACR25-0020

The Effects of Palmitic Acid and Insulin as Diabetic Stress Markers in Breast Cancer Associated Fibroblast Model in vitro

W. Al-Iedani¹

¹*Qatar University, Biomedical Sciences, Doha, Qatar*
Introduction

Breast cancer progression is strongly influenced by the tumor microenvironment, particularly cancer-associated fibroblasts (CAFs), which play a pivotal role in tumor growth, invasion, and metastasis. Diabetes, a known comorbid condition, is characterized by metabolic stress markers such as palmitic acid and insulin, which may influence CAF activation and tumor progression. This study investigates the effects of palmitic acid and insulin as diabetic stress markers on the induction of the CAF phenotype in fibroblasts *in vitro*.

Material and method

MDA-MB231 and MCF-7 breast cancer cells were treated with palmitic acid in complete media for 48 hours, and the resulting conditioned media was used to treat human dermal fibroblasts at three increasing doses. Simultaneously, the same doses of palmitic acid were directly applied to fibroblasts without cancer-conditioned media. Negative control (vehicle-treated) and positive control (LPS-treated) groups were included for comparison. Fibroblasts were analyzed for gene and protein expression of CAF markers, tumor progression factors (e.g., angiogenic factors, MMPs, TIMPs, drug resistance), signaling pathways, and oxidative stress markers. Cell motility was assessed using a wound-healing assay.

Result and discussion

Results demonstrated a significant increase in the myoepithelial subtype of CAF phenotype in fibroblasts treated with cancer-conditioned media, accompanied by elevated expression of MMP8, GLUT4, and oxidative stress markers. Increased activation of the PI3K/AKT signaling pathway was also observed.

Conclusion

These findings suggest that palmitic acid-induced diabetic stress promotes CAF activation and enhances tumor-supportive functions, highlighting a potential link between diabetes and breast cancer progression. This study provides insights into the molecular mechanisms underlying the interplay between metabolic stress and the tumor microenvironment, offering potential targets for therapeutic intervention.

⁴*University of Chieti, Medicine and Aging Sciences, Chieti, Italy*

⁵*University of Bari, Precision and Regenerative Medicine, Bari, Italy*

⁶*National Cancer Institute, IRCCS “Giovanni Paolo II, Bari, Italy*

⁷*University of Salento, Experimental Medicine, Lecce, Italy*

Introduction

Trop-2 is a driver of metastatic diffusion of colorectal cancer (CRC) cells upon activation by proteolytic cleavage by ADAM10. Trop-2 activation leads to proteolytic inactivation of E-cadherin, with derangement of β -catenin signaling and disruption of cell-cell junctions. This suggested a direct role of Trop-2 on the acquisition of invasive capacity of CRC, as driven by the loss of E-cadherin and of cell-cell adhesion. Tumor budding was shown to play a role in CRC invasion at the tumor/stroma interface and to impact on disease outcome. We thus investigated whether Trop-2 is expressed by CRC budding cells and drives matrix invasion.

Material and method

We collected 80 primary cases of CRC in a test case series. Outcomes were assessed in a validation case series, that included 73 CRC patients. Histopathology was conducted in all CRC samples. Trop-2 immunohistochemistry (IHC) was performed using anti-framework and anti-activated antibodies. The prognostic impact of the expression of the Trop-2 protein within the tumor, in tumor budding cells (TB) and in poorly differentiated cell clusters (PDC) was determined utilizing Kaplan-Meier curves and Cox regression models. Multiplex Western blotting were performed on cleared cell homogenates, Immunofluorescence confocal

microscopy analysis was conducted in KM12SM cells cultured on glass coverslips. Wound healing assays were performed on transfected MTE4-14 cell monolayers. In vitro invasion assays were conducted on Matrigel matrix. Experimental tumors and metastases were analyzed in CRC xenotransplants in nude mice. Transcriptome profiling was used to reveal Trop-2-driven pro-invasive/pro-metastatic genes. Network analysis of Trop-2-driven pro-invasive/pro-metastatic genes led to the identification of malignant progression models.

Result and discussion

Our findings show that essentially all CRC TB and PDC cells express Trop-2. This associated with tumor stage and disease outcome. In particular, Trop-2-positive tumor TB and PDC associated with metastatic relapse in CRC patients in two independent CRC case series. Trop-2 was then shown to drive cell migration and matrix invasion upon induction of β -catenin signaling and inactivation of E-cadherin. Invasive processes were driven by Trop-2-induced expression of CDC42, phosphorylation/activation of PKC α at Ser657 and of Akt at Thr308. The highest impact on CRC patient prognosis was jointly shown by Trop-2, CDC42 and phosphorylated PKC α , supporting a model of Trop-2-driven CRC progression through a coordinated induction of migration and invasion determinants in tumor TB and PDC cells.

Conclusion

CRC TB and PDC cells were shown to extensively express Trop-2. This associated with tumor stage and disease outcome in independent CRC case series. Our findings candidate Trop-2 as a key determinant of CRC invasion and malignant progression and as a novel diagnostic and prognostic marker in CRC cases.

EACR25-0058

Perinuclear assembly of vimentin intermediate filaments induces cancer cell nuclear dysmorphism

K. Pan¹, H. Chen¹

¹*National Yang Ming Chiao Tung University, Biochemistry and Molecular Biology, Taipei, Taiwan*

Introduction

Nuclear dysmorphism, characterized by crumpled or lobulated polymorphic nuclear shapes, has been used as an index for the malignant grades of certain cancers. The expression of vimentin, a type-III intermediate filament protein, is a hallmark of the epithelial-to-mesenchymal transition. However, it remains unclear whether vimentin is involved in cancer cell nuclear dysmorphism.

Material and method

To examine the role of vimentin in nuclear dysmorphism, vimentin gene was knocked out in breast cancer MDA-MB-231 cells and lung cancer A549 cells by the CRISPR/Cas9 system. The nuclear shape was visualized by immunofluorescence staining for the nuclear lamina. RNA-sequencing analysis was carried out to examine whether the transcription of certain DNA repair genes are affected by vimentin gene knockout in MDA-MB-231 cells.

Result and discussion

We found that vimentin intermediate filaments (VIFs) frequently accumulated at the concave of dysmorphic nucleus in breast cancer MDA-MB-231 cells. Depletion

of vimentin apparently restored the nuclear shape of the cells, which was devastated by re-expression of vimentin, but not its assembly-defective Y117D mutant. Depletion of plectin, a cytoskeletal linker, partially prevented the perinuclear accumulation of VIFs and concomitantly restored the nuclear shape of the cells. In addition, depletion of vimentin in lung cancer A549 cells largely prevented nuclear dysmorphism during the epithelial-to-mesenchymal transition induced by TGF β . Moreover, we found that VIF-mediated nuclear dysmorphism led to defects in DNA repair.

Conclusion

Our results unveil a novel role of VIFs in cancer cell nuclear dysmorphism, which is associated with genome instability.

EACR25-0061

Analysis of Perigallbladder Lymphatic Flow as a Pathway of Gallbladder Cancer Progression

A. Yamamoto¹, H. Okamoto¹, K. Kawashima¹

¹*Tsuru Municipal General Hospital, Surgery, Tsuru, Japan*

Introduction

Gallbladder cancer remains a disease with a poor prognosis and is often detected as an advanced cancer without specific symptoms in the early stages. In addition to direct invasion, lymphatic progression and hematogenous progression through the gallbladder vein into the portal branches P4 and P5 have been reported. However, there are cases in which peritoneal dissemination is confirmed even in cases without extra-serosal invasion, i.e., metastasis occurs even in sites not in contact with or directly exposed to the tumor. Therefore, in this study, we intraoperatively identified lymphatic flow pathways in cases of gallbladder cancer and cholecystitis/gallbladder stones, and considered the possibility that the pathway of gallbladder cancer progression is closely related to lymphatic flow.

Material and method

Laparoscopic cholecystectomy was performed in 57 cases of cholecystitis and cholezystolithiasis and 3 cases of gallbladder cancer at our hospital. Intraoperatively, indocyanine green (ICG) was injected into the serosa of the gallbladder base and neck, and the lymphatic flow pathways were compared by observing fluorescent staining. Based on the characteristics of the observed lymphatic flow pathways, we then aimed to gain new insights related to cancer progression.

Result and discussion

In cholecystitis and cholezystolithiasis cases, ICG coloration was observed in various lymphatic flow pathways depending on the degree of gallbladder inflammation. In addition, with the passage of time after the injection of ICG, fluorescent staining was also observed under the right diaphragm, suggesting the existence of a pathway for lymphatic flow from the gallbladder to reach the right diaphragm. In a case of gallbladder cancer, peritoneal dissemination was observed. In spite of the absence of extra-serosal invasion of the cancer, and the lymphatic flow in the neck of the gallbladder did not show fluorescent staining in that case, suggesting that lymphatic obstruction in the direction of

the gallbladder neck may promote peritoneal dissemination of cancer to the diaphragmatic side. Lymphatic obstruction in the direction of the gallbladder neck in gallbladder cancer can induce not only the development of lymph node metastases but also an abnormal pathway of tumor progression. The results of this study indicate that cancer progression may obstruct lymphatic flow in the gallbladder neck, resulting in greater allocation to lymph flow in the direction of the right diaphragm and the formation of metastatic pathways such as peritoneal dissemination.

Conclusion

We have shown that lymphatic obstruction in the neck of the gallbladder may alter lymphatic flow distribution, which may contribute to the formation of an abnormal pathway of cancer progression. Further case analyses are needed, and it is hoped that these findings will contribute to treatment strategies for gallbladder cancer.

The prostate specific SOCS1-deficient mouse model to study the gut-prostate axis in the pathogenesis of prostate cancer

M. Namvarpour¹, A. Ullah Ihsan¹, A. Armas Cayarga¹, E. Ng Kwan Lim², É. Massé², A. Menendez³, S. Ilangumaran¹, S. Ramanathan¹

¹University of Sherbrooke, Immunology and Cell Biology, Sherbrooke, Canada

²University of Sherbrooke, Biochemistry and Functional Genomics, Sherbrooke, Canada

³University of Sherbrooke, Microbiology and Infectious Diseases, Sherbrooke, Canada

Introduction

Recent epidemiological data suggest that chronic inflammatory bowel disease (IBD) is a potential risk factor for prostate cancer by promoting systemic inflammation and microbial translocation. In IBD, dysbiosis promotes the growth of Enterobacteriaceae, which act as “inflammatory allies.” Pathogenic strains such as enteropathogenic *E. coli* (EPEC) contribute to this process by disrupting epithelial integrity and producing genotoxins such as colibactin, leading to DNA damage and oxidative stress in host cells. These inflammatory processes, however, are regulated multiple mechanisms. Suppressor of Cytokine Signaling 1 (SOCS1) is a key regulator of inflammation and is a tumor suppressor. Our preliminary data show that mice lacking SOCS1 in prostate epithelial cells (*Socs1fl/flPbCre* mice) develop hyperplasia and inflammation after puberty. In this study, we investigate the impact of experimental colitis and associated dysbiosis and systemic inflammation on the prostate glands of *Socs1fl/flPbCre* mice.

Material and method

Chronic colitis was induced in 8–12-week-old *Socs1fl/flPbCre* mice using dextran sulfate sodium (DSS). Disease severity was evaluated through disease activity indices. Prostate tissues were studied by histology and immunohistochemistry for oxidative stress, DNA damage, and inflammatory responses. Prostate organoids

were derived from SOCS1-deficient and control mice and exposed to colibactin-producing EPEC and its colibactin-deficient mutant. Oxidative stress, DNA damage, and inflammatory responses were evaluated in prostate organoids. Proteomes of prostate organoids from DSS-treated mice are being evaluated by mass spectrometry.

Result and discussion

DSS-treated *Socs1fl/flPbCre* and control mice exhibited comparable symptoms of chronic colitis, including intestinal epithelial layer erosion, crypt and goblet cell depletion, and inflammatory cell infiltration. However, the prostate glands of DSS-treated *Socs1fl/flPbCre* mice showed significant luminal epithelial shedding, dysplasia, peri-glandular inflammation, and diffuse hyperplasia, accompanied by markedly increased oxidative stress and DNA damage. Furthermore, organoids exposed to colibactin-producing EPEC displayed significantly higher levels of DNA damage and oxidative stress compared to those treated with the colibactin-deficient EPEC strain.

Conclusion

This study shows that DSS-induced colitis and microbial dysbiosis, particularly EPEC and its genotoxins, induce pathological changes in susceptible prostate epithelial cells that could lead to the development and progression of prostate cancer. The prostate-specific SOCS1-deficient mouse is a suitable model to study the gut-prostate axis and gene-environment interactions in prostate cancer pathogenesis, as well as to evaluate dietary interventions such as probiotics and nutraceuticals.

EACR25-0140

LncRNA PRKCQ-AS1 promotes cancer cell proliferation and inhibits etoposide-induced apoptosis via modulation of HOXA5

T. Nizri-Megnaji¹, D. Ginsberg¹

¹Bar Ilan University, Life Science, Ramat Gan, Israel

Introduction

Long noncoding RNAs (lncRNAs) are major regulators of many cellular processes including cell proliferation, tumorigenesis and chemo-induced cell death.

Material and method

In this study, we report that the expression of lncRNA PRKCQ-AS1 is regulated by transcription factor E2F1 and it plays a role in S phase entry.

Result and discussion

Expression of PRKCQ-AS1 is cell cycle regulated and peaks near the G1/S transition. Inhibition of PRKCQ-AS1 expression in human cancer cells leads to a decrease in the number of cells in S phase and a concomitant increase in the number of cells in G1, suggesting that PRKCQ-AS1 plays a role in S phase entry. In agreement with this notion, prolonged silencing of PRKCQ-AS1 inhibits cells proliferation and, conversely, over-expression of PRKCQ-AS1 induces cell proliferation. Furthermore, PRKCQ-AS1 silencing enhances chemotherapy-induced apoptosis of cancer cells. PRKCQ-AS1 is a nuclear lncRNA and its silencing leads to an increase in the levels of HOXA5 mRNA. Importantly, knockdown of HOXA5 rescues the effect of PRKCQ-AS1 silencing on cell proliferation and etoposide-induced apoptosis.

Conclusion

In conclusions, our data identify PRKCQ-AS1 as a novel E2F-regulated lncRNA that regulates cell-cycle progression, cell proliferation and viability, at least in part via repression of HOXA5.

⁵University Hospital of Jaen, Department of Pathology, Jaen, Spain

⁶KU Leuven and Leuven Cancer Institute (LKI), Laboratory of Cellular Metabolism and Metabolic Regulation, Leuven, Belgium

Introduction

Metastatic cancer cells undergo unique metabolic adaptations that support survival in distant organs, differing from those in the primary tumor. Metabolic rewiring, including exogenous lipid uptake and utilization, activates pro-metastatic signaling through mechanisms like protein acetylation, chromatin remodeling, and fatty acid oxidation in metastatic cells. However, the precise metabolic shifts that sustain dormant disseminated tumor cells remain largely unexplored.

Material and method

To investigate metabolic adaptations related to tumor dormancy, we applied state-of-the-art metabolomic technologies to both in vitro and in vivo models of breast cancer metastasis. Stable isotope tracing assessed glucose and fatty acid (FA) metabolism, while gas chromatography-mass spectrometry (GC-MS) analyzed lipid composition. Genetic and pharmacological inhibition of de novo lipogenesis and acyl-coenzyme-A synthetase long-chain family member 3 (ACSL3) was performed to examine their impact on tumor dormancy, ferroptosis resistance, and metastasis. ACSL3 expression in breast cancer patient samples was evaluated for clinical relevance.

Result and discussion

Unlike proliferative disseminated breast cancer cells (DBCs), dormant DBCs are unaffected by FA uptake inhibition. Instead, they upregulate de novo lipogenesis, redirecting glucose-derived carbons toward FA synthesis. This shift enhances the activation and incorporation of

monounsaturated fatty acids (MUFA) into DBCs membranes through ACSL3, protecting them against lipid peroxidation and ferroptosis. Inhibiting lipogenesis or ACSL3 disrupted MUFA incorporation, shifting lipid composition toward polyunsaturated fatty acids (PUFAs), increasing lipid peroxidation, and triggering cell death. In vivo, ACSL3 or lipogenesis inhibition reduced dormant DBC survival and micrometastasis formation. Clinically, ACSL3 was overexpressed in quiescent DBCs in lymph nodes of breast cancer patients and significantly correlated with shorter disease-free and overall survival, validating the pro-survival role of ACSL3 in dormant DBCs.

Conclusion

Our findings highlight a crucial metabolic adaptation in dormant DBCs, where ACSL3-driven MUFA incorporation prevents ferroptosis and enhances survival. This underscores the viability of targeting de novo lipogenesis or ACSL3 as a therapeutic approach to eliminate dormant breast cancer cells and emphasizes the therapeutic potential of targeting the diverse functions of FAs in the metastatic process.

EACR25-0162

Erythrocyte-derived sphingosine-1-phosphate promotes tumor cell survival in the circulation

A. Vucetic¹, K. Roquid¹, E. Akyildiz², S. Grünter³, L. Hahnenfeld⁴, R. Gurke⁴, B. Strilic¹, S. Offermanns¹

¹Max Planck Institute for Heart and Lung Research, Department of Pharmacology, Bad Nauheim, Germany

²Akyildiz, Department of Pharmacology, Bad Nauheim, Germany

³Max Planck Institute for Heart and Lung Research, Deep Sequencing Platform, Bad Nauheim, Germany

⁴Faculty of Medicine, Goethe University Frankfurt, Institute of Clinical Pharmacology, Frankfurt/Main, Germany

Introduction

The majority of tumor cells metastasize through the blood stream. While circulating in the blood, most tumor cells do not survive because of attacks by the immune system or due to mechanical stress exerted by hemodynamic forces. Tumor cell survival during hematogenous dissemination requires particular cell autonomous functions or interactions with other corpuscular components of the blood. Here we explored the possibility that erythrocytes, the most abundant cell type in the blood stream, can promote tumor cell survival. Erythrocytes have various functions besides the exchange and transport of respiratory gases, and e.g. contain G-protein-coupled receptors (GPCRs) or ion channels, which regulate downstream signaling pathways, which can result in the release of different mediators.

Material and method

To study the potential role of erythrocyte GPCR signaling in tumor cell metastasis, mice with erythrocyte-specific deficiency of the G-protein α -subunits $\text{G}\alpha_s$, $\text{G}\alpha_q$ and $\text{G}\alpha_{13}$ were generated, and tumor metastasis was analyzed using B16F10, E0771 and LLC1 syngeneic murine metastasis models. By taking advantage of in vivo bioluminescence imaging, histological techniques, fluorescent microscopy, flow cytometry, mass

spectrometry, and RNA sequencing, we assessed both in vivo phenotypes and molecular mechanism.

Result and discussion

When studying mice with erythrocyte-specific loss of Gs, Gq or G13 in murine metastasis models, we found that mice lacking Gq, but not Gs or G13, in erythrocytes showed reduced metastasis due to increased tumor cell death during hematogenous spreading. Activation of Gq-coupled receptors on erythrocytes led to increased formation and release of various lipids including sphingosine-1-phosphate (S1P). In mice with erythrocyte-specific loss of sphingosine kinase 1, which catalyzes the formation of S1P, tumor cell survival in the circulation and metastasis formation were reduced. Moreover, under in vitro conditions, S1P induced anti-apoptotic effects in tumor cells through activation of the S1P receptor 2 (S1PR2), and tumor cell-specific loss of S1PR2 led to reduced survival and metastasis in vivo. In addition, we confirmed that tumor cells exposed to mechanical stress require the release of ATP through the pannexin 1 channel to promote their survival. Finally, we found that the stimulation of erythrocytes with ATP led to S1P release.

Conclusion

We show that circulating tumor cells utilize erythrocytes to improve their survival in the pro-apoptotic environment of the blood. We propose a model in which circulating tumor cells, that release ATP under the influence of mechanical stress, activate erythrocytes in their immediate vicinity through Gq-coupled purinergic receptors. This leads to the release of S1P, which by activation of the S1PR2 receptor has anti-apoptotic effects on tumor cells and thereby improves their intravascular survival and increases the potential for tumor cell metastasis.

EACR25-0166

Deciphering the Role of TCF21 in Regulating the Cancer-Associated Fibroblast (CAF) State in High Grade Serous Ovarian Cancer

N. Bui¹, S. Hui¹, C. Karamboulas¹, A. Ng¹, K. Nixon¹, F. Yeung¹, J. St-Germain¹, B. Draught¹, L. Ailles¹

¹*University Health Network, Princess Margaret Cancer Centre, Toronto, Canada*

Introduction

High-grade serous ovarian cancer (HGSOC) is not only the predominant, but the most lethal subtype of ovarian cancer. The roles of CAFs are particularly important in HGSOC as the tumors and metastases have highly complex tumor microenvironments. Our previous study identified CD49e as a novel pan-fibroblast marker in HGSOC. We demonstrated the existence of two distinct CAF states distinguished based on the expression of fibroblast-activation protein (FAP) within the CD49e+ population: FAP-high (FH) and FAP-low (FL) CAFs. Further characterization of the transcriptional profiles of the two CAF subtypes using RNAseq identified transcription factor TCF21 as a master regulator of the CAF state.

Material and method

Here, to elucidate mechanistic insights into how TCF21 transforms FH CAFs to a more FL-like phenotype, we overexpressed TCF21 in FH CAF lines and performed RNAseq and CUT&RUN to characterize the TCF21-regulated transcriptional networks. In addition, BioID proximity ligation assays were carried out in CAFs to identify novel TCF21 binding partners that work together with TCF21 to modulate its target genes.

Result and discussion

Integrated analyses of the RNAseq and CUT&RUN data demonstrated that TCF21 binds to promoters and down-regulates most of its target genes, indicating that TCF21 is a transcriptional repressor. Overlapping targets between TCF21-putative down-regulated genes and the FH gene signature included genes involved in collagen and extracellular matrix organization, and cell adhesion, suggesting that TCF21 inhibits pro-tumorigenic functions of FH CAFs through the down-regulation of highly expressed FH CAF genes. Motif analysis of CUT&RUN data identified TCF21 motifs, as well as motifs for the TEAD family. BioID results indicated that YAP1 (but not TEADs) is a potential TCF21 interactor. Co-IP experiments showed binding of TCF21 to YAP1 when overexpressed in 293T cells. Duolink proximity ligation assay confirmed the competitive binding of TCF21 over TEADs to YAP1 in CAFs. Moreover, YAP1 knockdown in FH CAFs conferred a less aggressive phenotype, and revealed common target genes of YAP1 and TCF21 in regulating the CAF states.

Conclusion

Together, our data suggest that the expression of TCF21 in CAFs may compete with TEADs in binding to YAP1 at the promoters/enhancers of genes related to CAF activation. This would lead to down-regulation of their target genes, and could drive FH CAFs toward a more FL-like phenotype. Further characterizations are being carried out to determine the underlying mechanisms of how TCF21 and YAP1 interaction could potentially reprogram FH CAFs to a more FL-like state. Therefore, targeting TCF21-YAP1 axis in CAFs may represent a potential therapeutic approach to treat HSGOC.

Hypoxia tolerance mechanisms in Head and Neck Squamous Cell Carcinoma

C. Gonzalez Maroto¹, A. Biddle², M. Tavassoli³

¹*Queen Mary University of London, Centre for Cell Biology and Cutaneous Research, Faculty of Medicine and Dentistry, London, United Kingdom*

²*Queen Mary University of London, Centre for Cell Biology and Cutaneous Research, Faculty of Dentistry, Oral and Craniofacial Sciences, London, United Kingdom*

³*Kings College London, Centre for Host Microbiome Interactions, London, United Kingdom*

Introduction

Metastasis is a major contributor to poor outcomes in Head and Neck Squamous Cell Carcinoma (HNSCC). This process largely driven by cancer cell plasticity that enables phenotype switching via epithelial mesenchymal transition (EMT). This facilitates migration, alongside drug and radiotherapy resistance. Tumour micro-

environment (TME) stimuli play a pivotal role in regulating cancer stem cell (CSC) plasticity, and the resulting metastasis and therapy resistance. Among these, hypoxia and cancer associated fibroblasts (CAFs) are key prognostic factors for poor patient outcome and radiotherapy resistance in HNSCC. Although the importance of the TME in tumorigenesis is evident, our understanding of CSC-CAF crosstalk under hypoxic conditions remains limited.

Material and method

Herein, we employ two complementary 3D HNSCC models to study the impact of hypoxia and CAFs on CSC dynamics: co-culture spheroids to recapitulate the complexity of tumour biology and microfluidic technologies that enable high-resolution immunofluorescent imaging of individual cells in a 3D environment. Changes in HNSCC CSC phenotype were monitored with flow cytometry and immunofluorescent imaging using established markers CD44 and EPCAM, as well as the novel plasticity marker podoplanin. The oxygen gradients within the 3D models were investigated to mimic physiological conditions and understand cellular responses.

Result and discussion

2D experiments demonstrated that long-term chronic hypoxia promoted EMT in HNSCC cell lines. Similarly, oxygen levels were tailored to influence cellular behaviour in the 3D models. Hypoxic probe immunofluorescent imaging was used to identify hypoxic regions and accordingly 3D models were optimised to ensure control over oxygen levels. 3D spheroid co-culture with CAFs induced EMT and plasticity changes in HNSCC cells. As microfluidic models allow for high-content imaging phenotypic switches and underlying CSC-CAF interactions and hypoxia are being characterised at a single-cell level.

Conclusion

This study highlights the importance of modelling of oxygen gradients and CAFs in 3D models for understanding cellular responses and developing therapeutic strategies. The data suggests long-term hypoxia and CAFs promote a mesenchymal phenotype by modulating CSC plasticity in HNSCC, emphasizing the importance of the TME on tumorigenesis.

Defining the metastatic niche for colorectal cancer dissemination

M. Mohammadi¹, S. Herrick¹, P. Caswell¹, B. Chakrabarty², P. Sutton³

¹*University of Manchester, Division of Cell Matrix Biology and Regenerative Medicine, Manchester, United Kingdom*

²*The Christie NHS Foundation Trust, The Colorectal and Peritoneal Oncology Centre, Manchester, United Kingdom*

³*The Christie NHS Foundation Trust, The Colorectal and Peritoneal Oncology Centre, Manchester, United Kingdom*

Introduction

Colorectal cancer (CRC) is one of the most prevalent cancers and is frequently associated with peritoneal metastasis (CRPM), where cancer cells spread from the

primary tumor, enter the peritoneal cavity, and form metastatic nodules at distant sites. However, the factors determining why some CRC patients develop peritoneal metastases while others do not remain unclear.

Mesothelial cells form a protective barrier lining the peritoneum, preventing metastatic invasion. Upon interaction with cancer cells, mesothelial cells undergo mesothelial-to-mesenchymal transition (MMT), losing epithelial characteristics and acquiring a fibroblastic morphology. This transition weakens the protective barrier and contributes to the formation of mesothelial-derived cancer-associated fibroblasts (mesoCAFs), which support tumor progression. We hypothesize that mesothelial cells in patients with peritoneal metastases are more susceptible to MMT, thereby creating a premetastatic niche. The aims of the project are: To elucidate the appearance mesoCAFs in samples from CRC patients with and without metastasis using immunocytochemistry; To define the MMT molecular signature in peritoneal tissue of CRC patients with peritoneal metastasis using multi-omics approaches; To develop a 3D co-culture invasion assay of peritoneal metastasis incorporating primary cells from CRC patients to investigate the spatiotemporal dynamics of colorectal cancer-mesothelial cell crosstalk and induction of MMT.

Material and method

Mesothelial and CAF markers were immunolocalised in peritoneal samples from affected and non-affected sites. A publicly available dataset (ArrayExpress E-MTAB-5998) of purified mesothelial cells was analyzed using enrichment analysis and regulatory networks to identify genes regulating MMT. Induction of MMT by conditioned media from CRC cells (HT-29) was assessed using confocal/phase-contrast imaging, and gene expression of mesothelial and CAF mesenchymal markers was analysed by qRT-PCR, in comparison with Transforming Growth Factor-β1 (TGFβ1) induced MMT.

Result and discussion

MesoCAFs were localised in affected peritoneal samples. TGFβ1-treated mesothelial cells exhibited increased fibroblastic morphology, proliferation, and migration, alongside upregulation of gene expression for Collagen Type I (Col1a1) and downregulation of Cingulin (CGN). Similarly, HT-29 conditioned media-treated mesothelial cells demonstrated enhanced fibroblastic morphology and proliferation. Notably, several MMT-related genes, were upregulated in both treatments or exclusively in CRC-conditioned media.

Conclusion

Soluble factors produced by CRC cells act in a similar fashion to TGFβ1 in the induction of MMT. The long-term goal is to identify mechanisms mediating the generation of mesoCAFs and metastatic niche, as well as possible new targets for therapeutical manipulation to retain a protective peritoneal barrier.

EACR25-0201

Modelling the extracellular matrix to elucidate collagen-mediated alterations in colorectal cancer using 3D patient-derived organoids

Introduction

Colorectal cancer (CRC) remains a leading cause of cancer-related mortality, with tumour progression heavily influenced by the tumour microenvironment (TME), which consists of fibroblasts, immune cells, and the extracellular matrix (ECM). During cancer progression, the ECM – composed of fibrillar collagens, fibronectin, elastin, and laminins – undergoes aberrant deposition, particularly of collagen I. This disrupts homeostatic control, exposing tumour cells to a collagen-rich stroma that promotes proliferation, invasion, metastasis, and tumour growth.

Material and method

We developed 3D patient-derived CRC organoids (PDCO) cultured in Matrigel® enriched with collagen I to investigate how ECM composition influences cancer behaviour. Microrheology was employed to assess the viscoelastic properties of the model matrix. We integrated transcriptomic and proteomic analyses to identify key molecular pathways modulated by the ECM. Additionally, we utilized atmospheric pressure matrix-assisted laser desorption/ionization mass spectrometry (AP-MALDI-MS) to perform single-cell lipidomic profiling of PDCOs cultured in collagen I-enriched and control matrices. This pioneering study introduces AP-MALDI-MS for single-cell lipidomic profiling in PDCO models, providing a novel approach to studying tumour metabolism in a physiologically relevant microenvironment.

Result and discussion

We successfully optimized a 3D model of a collagen-enriched matrix to better understand CRC progression using PDCOs. Characterizing the viscoelastic properties of the model matrix provided insights into how collagen influences cancer cell behaviour. We found that increased collagen I deposition over time upregulated the cholesterol biosynthesis pathway and activated the Sterol Regulatory Element Binding Protein (SREBP) pathway, a key regulator of cholesterol biosynthesis. This metabolic reprogramming supports cancer cell proliferation. Our multiomics approach offers a comprehensive understanding of how a collagen I-rich TME drives cancer metabolism and progression.

Conclusion

Our findings underscore the critical role of the ECM, particularly collagen I, in driving CRC progression within a 3D *in vitro* model. This research identifies new metabolic vulnerabilities in CRC, potentially leading to novel therapeutic targets and improved precision medicine strategies.

Genome-Wide Analysis of Intrinsic Sequence RNAs associated with Invasive Lobular Breast Cancer

E. Doğan¹, Z. Orhan¹, D. Gürer¹, Ş. E. Ceren¹,

İ. Erdoğan Vatansever¹, B. Akgül¹

¹*Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey*

Introduction

Breast cancer is the most prevalent malignancy among women globally, with a lifetime risk of 1 in 8.

Histological examinations of breast cancer can be categorized as ductal or lobular, depending on the location of tumor cells. Invasive lobular breast cancer is the second most prevalent kind, exhibiting a 15% incidence rate. Numerous proteins play a role in the development of breast cancer, as evidenced by extensive research over the years. Research indicates that certain non-coding RNAs may contribute to the development of breast cancer. One of the most fascinating advancements regarding the roles of non-coding RNAs in breast cancer pathology is intronic RNAs, which reside within the introns of protein-coding genes and are synthesized from their own distinct promoters, separate from the promoters of the associated protein-coding genes. This study aims to identify intronic RNAs with differential expression in healthy breast epithelium and invasive lobular breast cancer cell lines.

Material and method

RNA was extracted from the healthy breast epithelial cell line (MCF10A) and the invasive lobular breast cancer cell line (MDA-MB-134), followed by DNase treatment. The purity and integrity of RNAs were assessed using gel electrophoresis and a Nanodrop spectrophotometer. rRNA depletion was conducted on the extracted RNAs, and total RNA, polyA+, and polyA- RNAs were subjected to deep sequencing in accordance with our intronic RNA selection criteria. The nextflow pipeline developed in our laboratory revealed intronic sequences that exhibited differential expression in both cell lines. Potential candidates were visually assessed using Integrated Genome Viewer (IGV). RNAs were transcribed into cDNA, and 3' and 5' RACE was conducted to establish the boundaries of intronic transcripts. Transcripts were inserted into a TA vector and sequenced via the Sanger technique.

Result and discussion

The nextflow pipeline developed in our laboratory identified 367 possible intronic sequence RNAs in the MDA-MB-134 cell line and 276 in the MCF10A cell line. The criteria for selecting intronic RNA were: 1. Presence of a polyA signal, 2. Location within the gene's intron, 3. Absence of any corresponding exon for the candidate transcript, 4. Lack of splicing with adjacent exons. According to these criteria, 16 candidates were identified in MDA-MB-134 cells and 12 candidates in MCF10A cells using visual analysis in IGV. The experiments undertaken thus far have identified the boundaries of one candidate that is highly expressed in MDA-MB-134 and one candidate that is highly expressed in MCF10A.

Conclusion

Intronic RNAs exhibit variable expression in invasive lobular breast cancer. The stability investigations performed in this study will demonstrate the stability of intronic RNAs, followed by their functional characterisation. These investigations may elucidate the regulatory role of intronic RNAs in invasive lobular breast cancer.

²Istituto Italiano Tecnologia, Center for Life Nano-& Neuro-Science, Rome, Italy

³National Research Council, Institute of Molecular Biology and Pathologies, Rome, Italy

⁴Sapienza University, Department of Biology and Biotechnologies Charles Darwin, Rome, Italy

Introduction

Group 3 (G3) is one of the most common, aggressive and fatal subtypes of the paediatric cerebellar tumour Medulloblastoma (MB), primarily driven by the MYC oncogene. Targeting MYC has long been challenging and this, combined with our incomplete understanding of G3 MB molecular bases, has hindered the development of effective targeted therapies. Long noncoding RNAs (lncRNAs), with their extensive oncogenic roles, cancer-specific expression, and connection to MYC biology, offer opportunities for unravelling this complexity and providing new insights and therapeutic targets.

Material and method

Using genome-wide, molecular and cellular assays, we characterised the activity of the MYC-dependent, anti-apoptotic lncRNA lncMB3 in G3 MB cells. Through transcriptomic and interactomic analyses, we clarified lncMB3 function and mode-of-action and we targeted it with a novel delivery system.

Result and discussion

LncMB3 controls the TGF- β pathway, critically altered in G3 medulloblastomagenesis. This regulation occurs via the direct coding-noncoding RNA interaction between lncMB3 and the mRNA for the epigenetic factor HMGN5, with both sharing targets in the TGF- β cascade. This axis converges on apoptosis through OTX2, another G3 MB driver gene, and photoreceptor lineage genes. Synergistic effects between lncMB3 targeting and cisplatin treatment underscores the relevance of this regulatory network in vitro. Finally, we propose novel ferritin-based nanocarriers as efficient delivery tools for antisense oligonucleotides targeting lncMB3.

Conclusion

LncMB3 emerges as a central node linking MYC amplification to apoptosis inhibition through a circuit involving RNA-based mechanisms, G3 MB key drivers and underexplored factors. This integrated framework deepens our understanding of G3 MB molecular underpinnings and lay the foundation for translating lncRNA research into potential applications.

EACR25-0213

Characterization Of m6A Regulatory Proteins and Identification Of Target Genes In Invasive Lobular Breast Cancer

Y. Gazaloglu¹, A. Akçaöz-Alasar¹, İ. Erdogan-Vatansever¹, B. Akgül¹

¹Izmir Institute of Technology, Department of Molecular Biology and Genetics, Izmir, Turkey

Introduction

Invasive Lobular Breast Cancer (ILBC) is the second most common histological subtype of breast cancer and constitutes 15% of breast cancers. It arises in the milk producing lobules and metastasizes to different parts of the body. Although p53 gene mutation and E-cadherin deficiency are known, the regulatory mechanisms of this cancer are not fully understood. Epitranscriptomic mechanisms, such as N6-methyladenosine (m6A) RNA modification, play a role in the regulation of gene expression. m6A is regulated by writer, eraser and reader proteins and affect the fate of RNAs. m6A is known to regulate biological processes such as proliferation, metastasis and cell death in cancer cells. This study aimed to investigate the phenotypic effects and potential target of m6A regulatory proteins on ILBC.

Material and method

Expression levels of m6A regulatory genes were investigated in MCF10A healthy epithelial breast cells and MDA-MB-134 ILBC cells by RT-PCR and western blot analyses. Molecular cloning of FTO eraser protein and overexpression in MDA-MB-134 cells were performed. FTO gene was knocked down in MCF10A cells by siRNA transfection. Then, phenotypic changes such as apoptosis, cell cycle and viability of cells were examined by flow cytometry and WST-8 assay. Based on the phenotypic changes observed in cells, the expression of potential FTO target genes was examined by RT-PCR upon knockdown and overexpression experiments.

Result and discussion

While the expression levels of RBM15 and WTAP genes were similar in MDA-MB-134 and MCF10A cells, the expression levels of FTO and METTL14 genes were decreased in MDA-MB-134 cells compared to MCF10A cells. Overexpression of the FTO gene resulted in increased viability of MDA-MB-134 cells. Additionally, silencing the FTO gene in MCF10A cells reduced cell viability and caused cell cycle arrest.

Conclusion

In this study, m6A regulatory proteins were screened for the first time in ILBC. The difference in the expression levels of FTO and METTL14 m6A regulatory proteins in MDA-MB-134 cells compared to healthy breast cells was revealed. Furthermore, the effect of FTO protein-mediated regulation of m6A modification on the viability of ILBC cells was observed, which could be a potential biomarker for ILBC diagnosis or treatment.

EACR25-0217

Investigation of m1A and m6A Methylation in Metastatic and Non-Metastatic Triple-Negative Breast Cancer Cells

B. Sağlam¹, A. Akçaöz Alasar¹, B. Akgül¹

¹Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey

Introduction

The study of epitranscriptomics covers over 170 RNA modifications including N6-methyladenosine (m6A) and N1-methyladenosine (m1A), which are crucial in a range of diseases such as cancer. The most common type of methylation, m6A, has received significant attention for its potential roles in cancer diagnosis and treatment. On the contrary, although m1A also contains crucial functions, it has not attracted as much attention as m6A until recent studies. Nevertheless, the impact(s) of m6A and m1A RNA methylations remain still unclear in triple-negative breast cancer cells, such as non-metastatic HCC1143 and metastatic MDA-MB-231. This study aims to evaluate the phenotypic effects of m6A and m1A RNA methylation in triple-negative breast cancer cells by considering metastatic feature after knock-down of METTL3 and TRMT61A that has the catalytic activity to add m6A and m1A on mRNA, respectively.

Material and method

The knockdown of METTL3 and TRMT61A was performed by using siRNAs and transfection reagent (DharmaFECT®). Subsequently, cellular phenotypes, such as proliferation, apoptosis and cell cycle were examined to assess the impact of these writers. The viability assay was performed by WST8 colorimetric assay (NutriCulture®). Afterwards, apoptosis rate of cells was measured by staining with annexin V-FITC and 7AAD (Biolegend®) while cell cycle analysis was carried out by propidium iodide (PI) (Biolegend®) staining in flow cytometry. Lastly, RNA sequencing was performed to probe into the molecular pathways affected by knockdown of the writers. The cancer cell lines were also compared with a healthy breast cell line, MCF10A.

Result and discussion

The maximum reduction of METTL3 and TRMT61A was attained at 72h after transfection in MCF10A and HCC1143 cells. The cell viability decreased 40.1 and 27.4% upon METTL3 and TRMT61A knockdown, respectively. To identify the cause of the reduced viability, analyses of apoptosis and the cell cycle were conducted. Although there was no change in the apoptotic rate, 34.27% G2/M phase arrest was noted in HCC1143 cells following the silencing of METTL3 while G1/S phase arrest was obtained in MCF10A cells after TRMT61A silencing. RNA sequencing analysis identified 585 and 687 differentially expressed genes (DEGs) in METTL3- and TRMT61A-silenced cells. Gene Ontology Enrichment Analysis conducted on DEGs with a 1.5-fold change showed that METTL3 silencing significantly impacted pathways related to cell migration, whereas TRMT61A silencing notably affected immune-related pathways.

Conclusion

Our results show that each chemical modification has a different impact on triple-negative cancer cell biology. Further investigation will be performed for the metastatic cell line, MDA-MB-231.

Genome-wide profiling of intronic RNAs in triple-negative ductal breast carcinoma

S. E. Ceren¹, D. Güller¹, N. Akkas¹, İ. Erdogan

Vatansever¹, U. Karaca¹, Z. Orhan¹, B. Akgül¹

¹Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey

Introduction

Triple-negative breast cancer (TNBC) comprises 10–20% of all invasive breast cancer cases, with histopathological analyses indicating that most TNBC cases originate from ductal tissue. The heterogeneous nature of TNBC and its limited treatment options, compared to other breast cancer subtypes, underscore the urgent need for targeted therapies. Recent studies have highlighted the critical roles of non-coding RNAs (ncRNAs) in regulating cancer hallmarks and contributing to therapy resistance, underscoring their significance in cancer progression. Long non-coding RNAs (lncRNAs) are among the most extensively studied classes of ncRNAs. However, lncRNAs transcribed from intronic regions of annotated genes remain largely unexplored due to their low expression levels and the historical perception that these regions merely represent transcriptional noise or degradation byproducts. Advances in RNA sequencing technologies have begun to reveal their potential roles in cellular processes and disease. This study investigates novel intronic RNAs in triple-negative ductal breast carcinoma using HCC1143 (triple-negative ductal breast carcinoma) and MCF10A (non-tumorigenic) cell lines.

Material and method

Strand-specific RNA sequencing was performed on ribodepleted total RNA, poly(A)+ RNA, and poly(A)- RNA isolated from HCC1143 and MCF10A cell lines.

Bioinformatic analysis using our custom-developed Nextflow-based pipeline identified intronic RNAs with poly(A) tails. Differentially expressed intronic RNAs were further examined through visual inspection using Cap Analysis of Gene Expression (CAGE) data to map their 5' ends, along with the presence of a polyadenylation signal (PAS) at the hypothesized 3' end. The transcript boundaries of candidate intronic RNAs identified through this process were further validated using rapid amplification of cDNA ends (RACE).

Result and discussion

Bioinformatic analysis identified 270 poly(A)+ intronic RNAs in HCC1143 and 293 poly(A)+ intronic RNAs in MCF10A cells. Interestingly, some of these transcripts exhibited differential expression between HCC1143 and MCF10A cells. The successful identification of transcript boundaries for several selected candidates validates the existence of these differentially expressed intronic RNAs in TNBC; however, further validation by northern blotting is required.

Conclusion

Our findings reveal previously uncharacterized intronic RNAs with distinct expression patterns in TNBC. These results underscore the emerging recognition of intronic RNAs as a novel class of ncRNAs and highlight the need for further investigation into their structural characterization and biological roles in TNBC.

EACR25-0226

Transcriptomics analysis identifies intronic RNAs in ER+/PR+ and HER2-enriched ductal breast carcinoma

S. E. Ceren¹, D. Gürer¹, N. Akkas¹, İ. Erdoğan Vatansever¹, U. Karaca¹, B. Akgül¹

¹Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey

Introduction

Breast cancer is the most prevalent malignancy among women and one of the primary contributors to cancer-related mortality globally, featuring various subtypes. Among these, invasive ductal carcinoma (IDC) represents approximately 80% of breast cancer cases, making it the most diagnosed form. IDC exhibits significant molecular heterogeneity and aggressive behavior. HER2-enriched IDC is characterized by increased tumor proliferation and resistance to targeted therapies, highlighting the urgent need for novel molecular insights. Despite the growing recognition of non-coding RNAs (ncRNAs) in breast cancer development, intronic RNAs have been largely overlooked and remain poorly studied. However, recent advancements in RNA sequencing have uncovered their potential to be functional in various biological processes. In this study, we examine intronic RNAs in ER+/PR+ and HER2-enriched IDC using BT474 cells, with MCF10A serving as a healthy breast cell line.

Material and method

Ribo-depleted total RNA, poly(A)+ RNA, and poly(A)-RNA were extracted from BT474 and MCF10A cell lines and subjected to strand-specific RNA sequencing, followed by the identification of poly(A)+ intronic RNAs using our in-house-developed Nextflow-based pipeline. The Integrative Genomics Viewer (IGV) was used for visual analysis to map the 5' and 3' ends of selected differentially expressed intronic RNA candidates by identifying Cap Analysis of Gene Expression (CAGE) peaks and polyadenylation signals (PAS), respectively. Rapid amplification of cDNA ends (RACE) was performed to validate the 5' and 3' ends of the transcripts.

Result and discussion

A total of 293 poly(A)+ intronic RNAs were identified in MCF10A, and 389 poly(A)+ intronic RNAs were identified in BT474, with some showing differential expression. The identification of boundaries for some of these differentially expressed intronic RNAs suggests their presence and potential role in cancer regulation. However, further studies are needed to validate their presence and confirm their involvement in cancer regulation.

Conclusion

Our findings highlight differentially expressed novel intronic RNAs in ER+/PR+ and HER2-enriched ductal breast carcinoma and underscore the need for functional studies to explore their role in cancer progression.

EACR25-0227

GTF2A1-AS lncRNA orchestrates cisplatin-induced cell death transitions as a stress response regulator

Y. Ciftci¹, I. Erdogan-Vatansever¹, D. Gürer¹, B. Akgül¹

¹Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey

Introduction

Historically, programmed cell death has been primarily linked to caspase-dependent apoptosis. However, recent findings indicate that caspase-independent cell death (CICD) mechanisms can be activated by genotoxic and oxidative stressors to modulate cell fate. Parthanatos is a type of CICD mediated by PARP1 activation through DNA damage leading to PAR accumulation, and cell collapse. Although several protein-coding genes have been associated with parthanatos, the contribution of long non-coding RNAs (lncRNAs) is not elucidated well. The aim of this study was to uncover the potential role of general transcription factor 2A1 antisense (GTF2A1-AS) lncRNA in modulating cisplatin-mediated parthanatos in HeLa cells.

Material and method

HeLa cells were treated with cisplatin (CP) of 80 µM for 16 h; and DMSO of 0.1% (v/v) as the control group, followed by total RNA isolation and RNA-seq analysis. After selecting GTF2A1-AS as a CP-inducible lncRNA candidate, phenotypic analyses were performed by gain-and loss-of function studies. GapmeR-assisted silenced cells were also subjected to RNA-seq analysis to reveal the possible role of GTF2A1-AS in modulating cell fate-related biological processes. Additionally, higher concentrations of cisplatin were also combined with the overexpression and knockdown experiments to examine the regulatory effect of GTF2A1-AS on drug metabolism.

Result and discussion

GTF2A1-AS lncRNA was a CP-inducible candidate based on the differential expression pattern upon drug treatment. Time-course experiments indicated that GTF2A1-AS silencing elicited apoptosis by 10% whereas overexpression did not induce cell death significantly. RNA-seq analyses of GTF2A1-AS-silenced cells revealed that DNA damage response genes were affected. When GTF2A1-AS silencing and overexpression were combined with 80 and 540 µM cisplatin concentrations, cells showed increased chemosensitivity, as depicted in flow cytometry analysis by shifting to late apoptosis. Notably, 540 µM CP treatment in GTF2A1-AS-silenced cells resulted in a significant increase in PARP-1 and PAR polymer accumulation, as detected in western blot.

Conclusion

This study identifies GTF2A1-AS as a CP-inducible lncRNA, emphasizing its significance in cancer research. Silencing of GTF2A1-AS promoted apoptosis, while its overexpression did not significantly impact cell viability. Additionally, at higher CP concentrations, GTF2A1-AS silencing influenced parthanatos. Given the importance of lncRNAs in cancer progression and drug resistance, it suggests that GTF2A1-AS may serve as a therapeutic target for modulating different cell death modes, enhancing chemotherapy efficacy.

Identification of Intronic RNAs Involved in Apoptosis

Z. Orhan¹, M. Kara², D. Gürer¹, S. E. Ceren¹, İ. Erdoğan Vatansever¹, B. Akgül¹

¹Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey

²Max Planck Institute for Biology of Ageing, Mitochondrial Proteostasis, Cologne, Germany

Introduction

Apoptosis, a form of programmed cell death, is a cellular process that is crucial for the maintenance of cellular homeostasis. As apoptosis plays a vital role in controlling the balance between cell death and cell proliferation, inappropriate apoptosis can result in various conditions, including cancer. The process of apoptosis is regulated by various proteins and genes within the cell. Also, apoptotic pathways can be induced by certain chemicals, such as the chemotherapeutic drug cisplatin, which activates the intrinsic pathway of the apoptosis. Besides, even if non-coding parts of the genome were referred to as junk regions in the early days, advanced transcriptomics studies have revealed many regulatory non-coding RNAs involved in not only apoptosis but also many other essential cellular processes. Interestingly, recent studies uncovered the presence of intronic RNAs, the long non-coding RNAs that are derived from the introns of other genes. The aim of this study is to characterize intronic RNAs involved in the regulation of apoptosis under cisplatin-mediated apoptotic conditions.

Material and method

Firstly, RNA was isolated from the cisplatin- and DMSO-treated HeLa cells, the cervical carcinoma cell line. After ribosomal RNA depletion, total RNA, polyA⁺ and polyA-eliminated fractions were subjected to deep sequencing. The bioinformatic analysis was performed by using an in-house pipeline to identify intronic transcripts differentially expressed between cisplatin-treated conditions and DMSO-treated control. In order to map the borders of the transcriptional unit of intronic RNAs, 5' and 3' RACE PCRs followed by molecular cloning and Sanger sequencing were performed. The differential expression of candidates was confirmed by quantitative PCR analysis.

Result and discussion

The bioinformatic analysis revealed 598 upregulated and 161 downregulated candidate intronic transcripts upon cisplatin treatment. The deep sequencing profiles of candidate regions were visually examined with Integrated Genome Viewer (IGV). During the candidate intronic RNA selection, the presence of polyadenylation signal near 3' end and the absence of any annotated exon in the candidate region were taken into consideration. This study uncovered candidate intronic RNAs differentially expressed under cisplatin-mediated apoptotic conditions. The transcriptional unit of a candidate intronic RNA was determined. The differential expression of the candidate under cisplatin-treated conditions was confirmed, pointing out its potential to be involved in the regulation of apoptosis.

Conclusion

Intronic RNAs produced from intronic regions of other genes may modulate many cellular processes, including apoptosis which is crucial for cancer development and progression. Understanding the characteristics and functions of these regulatory elements would be valuable to unveil the new insights of the mechanism of cancer.

Dose-Dependent Regulatory Effects of Melatonin on miRNA Expression in PANC-1 Pancreatic Cancer Cells

D. Sari Ak¹, B. Akyol², B. Sarikamis Johnson², K. Gunduz², N. Ercin², N. Besli², Ü. Kılıç³

¹University of Health Sciences, Hamidiye International School of Medicine Department of Medical Biology, Istanbul, Turkey

²University of Health Sciences, Hamidiye Institute of Health Sciences Department of Medical Biology, Istanbul, Turkey

³University of Health Sciences, Hamidiye School of Medicine Department of Medical Biology, Istanbul, Turkey

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and lethal malignancies, largely due to its late diagnosis and resistance to conventional therapies. Recent studies suggest that microRNAs (miRNAs) play a crucial role in cancer progression by regulating gene expression at the post-transcriptional level. Melatonin, a widely conserved neurohormone with antioxidant and anti-tumor properties, has been shown to modulate several oncogenic pathways, including those mediated by miRNAs. This study investigates the dose-dependent effects of melatonin on the expression of miR-27a, miR-148a, miR-203, and miR-196a in PANC-1 pancreatic cancer cells, aiming to identify potential therapeutic implications.

Material and method

PANC-1 pancreatic cancer cells were cultured and treated with 2 mM and 2.5 mM melatonin to determine its inhibitory effects. The cytotoxic effect was assessed using the MTT assay to establish the IC₅₀ value. Total RNA was extracted from untreated and melatonin-treated cells, followed by cDNA synthesis. The expression levels of miR-27a, miR-148a, miR-203, and miR-196a were analyzed using quantitative real-time PCR (qRT-PCR). Statistical analyses determined the significance of expression changes in response to melatonin treatment.

Result and discussion

qRT-PCR analysis revealed significant dose-dependent alterations in miRNA expression following melatonin treatment. At 2 mM melatonin, miR-148a and miR-196a were significantly upregulated, suggesting a tumor-suppressive role, while miR-27a and miR-203 were downregulated, indicating inhibition of proliferation and metastasis-associated pathways. At 2.5 mM melatonin, miR-148a remained upregulated, reinforcing its tumor-suppressive function, while miR-27a, miR-203, and miR-196a showed significant downregulation, suggesting a broader inhibitory effect on oncogenic miRNA signaling. These findings support the hypothesis that melatonin modulates miRNA expression, potentially influencing PDAC progression by targeting key regulatory networks involved in proliferation, apoptosis, and metastasis. The observed miRNA changes align with previous studies highlighting melatonin's anti-proliferative and anti-metastatic effects in various cancer models.

Conclusion

This study provides evidence that melatonin regulates the expression of key miRNAs involved in PDAC progression in a dose-dependent manner. The upregulation of miR-148a and miR-196a, along with the downregulation of miR-27a and miR-203, suggests that melatonin influences miRNA-mediated signaling pathways that control tumor growth and metastasis. These findings highlight the potential of melatonin as a therapeutic agent for pancreatic cancer by modulating miRNA expression. Further studies are needed to validate these results in *in vivo* models and clinical settings, as well as to explore the broader implications of melatonin in miRNA-targeted cancer therapy.

⁵Faculty of Medicine, Biochemistry, Microbiology and Immunology, Ottawa, Canada, University of Ottawa

⁶Department of Medicine, Ottawa, Canada,

Introduction

The bone marrow microenvironment is highly saturated with bone marrow adipocytes (BMA), which differentiate from their precursor, mesenchymal stem cells (MSC). Evidence in the literature suggests BMA confer chemotherapeutic resistance to tumour cells, thereby ascribing a tumour-supportive role to BMA. Evidence from patient trials suggests that bone marrow adiposity is increased in patients following some forms of chemotherapy, however it has been suggested this is due to hypertrophy. We hypothesize that chemotherapy actively promotes adipogenesis by altering expression of genes associated with adipocyte differentiation, resulting in increased levels of mature BMA with altered phenotypes that promote tumour growth in bone.

Material and method

Human MSC were treated with adipogenic differentiation media in the presence or absence of doxorubicin.

Differentiation into BMA was confirmed by expression of adipocyte marker genes by RT-qPCR and percentage of lipid-droplet containing cells by BODIPY staining. RNA-seq analyses were performed to identify gene alterations associated with doxorubicin treatment in differentiating MSC. Alterations in the fibroblast growth factor (FGF) pathway were identified and target changes validated by RT-qPCR, ELISA and Western blot.

Contribution of the identified target FGF2 (fibroblast growth factor 2) to adipogenesis was confirmed using siRNA depletion strategies. The effects of conditioned media from doxorubicin or vehicle control treated BMA on PC3 prostate tumour cell growth was also assessed.

Result and discussion

Doxorubicin treatment of differentiating MSC led to increased numbers of BODIPY+ mature adipocytes, which was confirmed by elevated levels of adipocyte markers. RNA-seq analysis identified significant increases in FGF pathway genes, which were validated by RT-qPCR. We confirmed increased mRNA and secreted protein levels of FGF2 with doxorubicin treatment, which may be due to increased levels of the transcription factor EGR1 (early growth response 1), known to bind to the promoter region of FGF2, which was also significantly increased in doxorubicin-treated cells. Furthermore, siRNA targeting FGF2 impeded the doxorubicin enhanced formation of lipid-containing BMA returning it to levels similar to vehicle-treated BMA. As FGF2 is a secreted protein we tested and confirmed that transfer of conditioned media from doxorubicin-treated BMA enhanced proliferation of PC3 prostate tumour cells *in vitro*.

Conclusion

Our findings suggest that doxorubicin treatment of differentiating MSC leads to increased numbers of BMA, which have alterations in the FGF pathway that not only enhance adipogenesis, but also alter prostate tumour cell growth as a result.

³University of Texas, Southwestern Medical Centre, Ophthalmology, Dallas, United States

⁴All India Institute of Medical Sciences, Ophthalmology, Dr. R. P. Centre, New Delhi, India

Introduction

Uveal melanoma (UM) is an aggressive intraocular malignancy with limited therapeutic options and high metastatic potential. Mutations in GNAQ or GNA11 are early occurring driver events in UM and induce cellular senescence. These mutations also contribute to the constitutive activation of central mediators YAP/TAZ in the Hippo signaling pathway, thereby promoting tumor proliferation and metastasis. Although, GNAQ and GNA11 mutations are mutually exclusive in UM, studies suggest that GNA11-driven tumors exhibit more aggressive behavior than GNAQ-driven tumors. This study investigates the differential impact of GNAQ and GNA11 mutations on Hippo pathway components to predict tumor dormancy in UM.

Material and method

Whole-exome sequencing was performed on 41 prospective UM cases to determine the mutational status, then cases were segregated into group 1 (GNAQ mutant) and group 2 (GNA11 mutant). Quantitative real-time PCR (qRT-PCR) was performed to assess the mRNA expression level of Hippo pathway components and cell cycle inhibitor in these groups. Western blot was performed to validate the protein expression levels. The

expression profiles were correlated with clinicopathological parameters and patient outcomes.

Result and discussion

Group 1 (GNAQ mutant) and group 2 (GNA11 mutant) includes 25 (60.98%) and 16 (39.02%) cases, respectively. Scleral invasion and optic nerve invasion were found in group 1 (36% & 16%) and group 2 (56% & 6%) cases, respectively. In both groups, the central mediator YAP was upregulated in 16% and 12% cases, respectively. The 14-3-3 retention protein, which stabilizes cytoplasmic YAP, was upregulated in nearly 40% of cases with a mean-fold change of 2.73 (group 1) and 3.30 (group 2). LATS1, a key Hippo kinase, was downregulated in more than 90% of cases in both the groups. However, other kinases were more frequently upregulated in group 2 than in group 1. SAV1, a Hippo pathway scaffold protein, was upregulated in 40% of group 1 cases and downregulated in over 90% of group 2 cases. Protein expression levels corroborated these findings. The cell cycle inhibitor p16 was upregulated in 36% (group 1) and 50% (group 2) cases. Eight patients with mutant GNAQ/11 developed distant metastasis with upregulated p16, and 5 patients died due to the disease. This suggests that p16 upregulation in the presence of oncogenic signals may initially induce dormancy but could later contribute to tumor reactivation and metastasis.

Conclusion

This is the first study to comprehensively analyze the differential impact of GNAQ and GNA11 mutations on Hippo signaling pathway regulation in UM. The upregulation of p16 in the presence of oncogenic signals may support tumor dormancy, potentially delaying metastasis. The observed mutation-specific expression patterns of Hippo pathway regulators could provide insights into novel therapeutic strategies targeting YAP/TAZ and LATS kinases, thereby improving patient outcomes.

EACR25-0272

Reprogramming the immunosuppressive tumor microenvironment to overcome resistance to CAR-T-cell immunotherapy in pancreatic cancer

S. Tondi¹, R. Wu², M. Roberto¹, K. Jiang², A. Aicher³, C. Heeschen¹

¹Candiolo Cancer Institute - FPO - IRCCS, Pancreatic Cancer Heterogeneity, Candiolo, Italy

²Shanghai Jiao Tong University School of Medicine, Center for Single-Cell Omics, School of Public Health, Shanghai, China

³China Medical University, Precision Immunotherapy, Graduate Institute of Biomedical Sciences, Taichung, Taiwan

Introduction

Pancreatic cancer is rare but highly lethal, with poor survival rates and limited treatment options due to late-stage diagnosis. The most common form, pancreatic ductal adenocarcinoma (PDAC), is highly heterogeneous and resistant to treatment, primarily due to cancer stem cells that drive tumor growth, metastasis, and drug

resistance. Current therapies fail to eradicate these resistant stem cells, leading to disease relapse. While CAR-T cell therapy has shown success in blood cancers, its effectiveness in solid tumors is at least in part hindered by the unique tumor immune microenvironment (TIME), characterized by a distinctive immune composition and complex cellular interactions. Therefore, enhancing the efficacy of CAR-T cell therapy requires transforming TIME from an immunosuppressive to an immunopermissive state.

Material and method

Murine PDAC cells (5,000 cells in 30 µL Matrigel) were injected orthotopically into the pancreas of 6-8-week-old C57BL/6 immunocompetent mice. Tumor growth was monitored by IVIS acquisition, and once tumors were fully established, mice were treated intraperitoneally or intravenously with different TIME modulators. All animal procedures were conducted in accordance with the 3Rs and the regulations for animals in science.

Result and discussion

In vivo studies showed that most of the tested immune modulators at least partially reprogrammed the TIME, e.g. by increasing the presence of T cells and NK cells, or by reducing the presence of myeloid derived suppressor cells (MDSCs). Notably, directly targeting the activity of regulatory T cells showed promising results, inducing a more pronounced remodelling of TIME by increasing the frequency of T cells, NK cells and M1 macrophages, and simultaneously reducing the presence of immunosuppressive populations such as MDSCs and M2 macrophages, which may aid in increasing the efficacy of our CAR-T cells based immunotherapy.

Conclusion

Reprogramming the pancreatic TIME before delivering highly specific CAR-T cell immunotherapy has the potential to slow or even reverse pancreatic cancer progression. Our research identified a key immune population - regulatory T cells - that plays a central role in remodelling the TIME, thereby potentially enhancing the effectiveness of CAR-T cell-based immunotherapy for PDAC.

The role of the neuronal-cancer crosstalk in melanoma brain metastases using hPSC-derived Assembloids

A. Verrillo¹, R. Luongo¹, J. Van Lent¹, A. Nepote¹, L. Pavinato¹, P. Spina², M. Levesque³, F. Bertoni⁴, L. Cascione⁴, A. Baggolini¹

¹Institute of Oncology Research, Stem cells and cancer, Bellinzona, Switzerland

²Ente Ospedaliero Cantonale, Lugano, Switzerland

³Universität Zürich, Faculty of Medicine, Zurich, Switzerland

⁴Institute of Oncology Research, Lymphoma Genomics, Bellinzona, Switzerland

Introduction

Cutaneous melanoma is one of the most aggressive skin cancers due to its high metastatic potential. Over 60% of advanced-stage melanoma patients develop brain metastases, with a 1-year survival rate of only 10-20%. While genetically engineered mouse models have been

useful for studying brain metastasis, much remains unknown about the cellular interactions in the human brain microenvironment. Species-specific differences highlight the need for a human model to study melanoma brain metastasis.

Material and method

In this study, we generated a complex hPSC-derived brain assembloid that recapitulate specific aspects of the human brain microenvironment, including neural progenitor cells, cortical neurons, interneurons, glial populations (astrocytes and microglia), and pericytes. This cerebral environment allows the modelling of the adaptive process of melanoma cells metastasizing to the brain.

Result and discussion

Transcriptional data suggest that melanoma cells exhibit neuronal-like features upon exposure to the human brain assembloid. Specifically, melanoma brain metastases exhibit upregulation of genes associated with calcium signaling, synapse formation, and neuronal plasticity, enabling these cancer cells to adapt and proliferate in the brain environment. Electron microscopy images suggest that melanoma cells may establish synaptic-like connections with surrounding cortical neurons. These aberrant connections appear to alter the brain's electrical network, potentially contributing to the metastatic cells' survival and growth.

Conclusion

With this preliminary data, we aim to investigate the neuron-melanoma crosstalk and its role in the adaptation of melanoma metastatic colonies in the brain. Additionally, we will explore how melanoma metastases influence the brain environment and impact its physiological functions.

Immunomodulation of Glioblastoma Tumor Microenvironment by NF1-LRD-Loaded Extracellular Vesicles

Y. Vijayanathan¹, J. Yeo¹, J. Tan¹, F. Mohamad¹, N. Abdul Halim¹, R. Ho¹, F. Ginhoux², L. Zeng¹, I. Ho¹
¹*National Neuroscience Institute, Research, Singapore, Singapore*

²*Singapore Immunology Network, Research, Singapore, Singapore*

Introduction

Extracellular vesicles (EVs) are potential carriers for cancer therapeutics. In prior studies, we showed that re-expression of the leucine-rich domain (LRD) of neurofibromin (NF1) inhibited glioblastoma (GBM) invasion and inhibited microglia/macrophage recruitment into the tumor microenvironment (TME). Since tumor-associated microglia/macrophages (TAMs) play a critical role in GBM progression, we investigated whether EVs containing NF1-LRD (NF1-LRD-EVs) could modulate the TME and attenuate GBM progression.

Material and method

NF1-LRD-EVs were isolated from glioma cells stably expressing the NF1-LRD domain using ultracentrifugation. Characterization of these EVs followed MISEV2023 guidelines, employing western blotting, Nanosight tracking analysis, and transmission electron microscopy. To assess the immunomodulatory effects of

NF1-LRD-EVs, primary mouse microglia and iPSC-derived macrophages (iMacs) were exposed to EVs for 24h. Morphological and molecular changes were analyzed through immunofluorescence, phagocytosis assays, tumor infiltration assays, and immunoblotting.

Result and discussion

NF1-LRD-EVs significantly reduced TAM recruitment and infiltration by 60-80% in both transwell migration assays, compared to control EVs. These results suggest that NF1-LRD-EVs effectively modulate the TME by inhibiting pro-tumor TAMs infiltration. Furthermore, iMacs and microglia treated with NF1-LRD-EVs exhibited enhanced phagocytic activity, similar to that observed in LPS-stimulated cells, indicating that NF1-LRD-EVs-primed immune cells for a more potent anti-tumor response. Exposure to NF1-LRD-EVs also led to upregulation of pro-inflammatory cytokines, including TNF- α and IL1 β , which are associated with anti-tumor immunity. In contrast, the expression of anti-inflammatory cytokines such as Arginase and TGF β 1 was downregulated, further supporting a shift toward a pro-inflammatory phenotype. These findings, confirmed by qPCR, Luminex assays, and immunofluorescence, suggest that NF1-LRD-EVs reprogram TAMs to promote immune activation while suppressing immunosuppressive pathways within the TME.

Conclusion

Our results demonstrate that NF1-LRD-EVs reprogram TAMs within the GBM TME, enhancing pro-inflammatory immune responses and limiting immunosuppressive pathways. This modulation of the immune environment positions EVs as a promising platform for neuro-immunomodulation, offering a novel therapeutic approach for targeting the TME in GBM. Further studies are needed to evaluate the clinical potential of EV-based therapies to improve outcomes in GBM and other cancers with immune evasion.

Combined K8 and Apc loss-derived mouse model for colon-specific tumorigenesis

M. Tayyab¹, M. Minkkinen¹, C. Stenvall¹, L. Polari¹, Y. Shah², D. Toivola¹
¹*Åbo Akademi University, Department of Biosciences, Cell Biology, Turku, Finland*

²*University of Michigan, Ann Arbor, Department of Molecular & Integrative Physiology and Department of Internal Medicine, Ann Arbor, Michigan, United States*

Introduction

Loss of the epithelial intermediate filament protein keratin 8 (K8) has been shown to increase susceptibility towards colonocyte hyperproliferation and tumorigenesis. However, most colorectal cancer (CRC) mouse models require carcinogen, develop small intestinal tumors or have long latency period. The aim was to establish a genetic, colon-specific and more human like CRC model driven by loss of K8 and Apc.

Material and method

Colon epithelium specific targeting using CDX2P-CreERT2 mice was used to generate K8flox/flox; CDX2P-CreERT2 and K8flox/flox; CDX2P-CreERT2; Apcflox/+ mice. Body weight and stool consistency were

monitored, and colon was analyzed for tumor burden and histopathology. Keratin expression, inflammation, and proliferation were assessed using immunoblotting and immunofluorescence analysis. This data was compared to K8 expression analysis in patients with CRC using UALCAN database.

Result and discussion

K8 downregulation in adult K8^{flox/flox}; CDX2P-CreERT2 mice triggers mild diarrhea and leads to loss of K8 and reduced partner keratin levels in a mosaic pattern in the colonic epithelium, while ileal K8 protein levels are unchanged. K8-negative colon areas display increased crypt loss and more MPO+ cells predominantly in the proximal colon. Increased colonocyte proliferation is observed as increased percentage of Ki67+ cells and lower IL-22BP protein levels throughout the colon. These results highlight the protective colonocyte-autonomous roles of K8 in maintaining a balance proliferation in the colon, and in protection from inflammation. Mice with combined K8 and monoallelic Apc inactivation show dramatically increased colon tumor formation. The combined loss of the cytoskeletal protein K8 and a tumor suppressor protein Apc in right amount accelerates the process of colon tumorigenesis. Furthermore, this model offers an advantage over Apc mutant models, as tumors are located in the distal colon. This feature makes it a better model for CRC, as patients more frequently develop tumors in the colon and not in the small intestine. The model also recapitulates the here identified downregulated K8 expression in CRC patients, independent of disease type and stage, age or gender, supporting the tumor suppressive contribution of K8 in the colon. Pro-tumorigenic epithelial changes in K8-negative areas of our model adjacent to K8-positive areas also resemble diseased colon epithelium next to the normal epithelium in human CRC.

Conclusion

New genetic and colon-specific mouse model with loss of K8 and Apc adequately resembles human CRC. This study also highlights a role of colonocyte K8 in maintaining colon epithelial integrity and protecting against colon tumorigenesis.

⁴*Cancer Research Center (CRC), Québec, Canada, Laval University*

⁵*Centre Nutrition, Santé et Société (NUTRISS) et Institut sur la nutrition et les aliments fonctionnels (INAF), Québec, Canada,*

Introduction

Current treatment options for prostate cancer are often highly invasive and associated with significant adverse effects, which severely compromise patients' quality of life. Chronic tissue inflammation is frequently observed in prostate cancer and contributes to disease progression. Given this, our research team conducted a clinical trial evaluating the effect of a daily supplementation with a long-chain omega-3 fatty acid with known anti-inflammatory properties, called monoacylglyceride-coupled eicosapentaenoic acid (MAG-EPA). Clinical outcomes from this trial demonstrated a significant reduction in cancer aggressiveness (downgrading) between biopsy and surgery, as well as a reduced risk of biochemical recurrence in patients supplemented with MAG-EPA compared to placebo. The present study aims to explore the impact of MAG-EPA supplementation on the tumor immune microenvironment and its potential influence on clinical outcomes.

Material and method

We enrolled 130 patients diagnosed with intermediate- to high-grade prostate cancer, all scheduled for a radical prostatectomy. They were randomized to receive either MAG-EPA or placebo for 6 to 8 weeks prior to surgery and continued for one-year post-surgery. Tissue microarrays were constructed using prostate samples collected at surgery, comprising six cores of 1mm diameter per patient (four from tumoral and two from normal tissue). The main immune cell phenotypes were profiled through immunohistochemistry and multiplex immuno-fluorescence, allowing precise spatial analyses of their density and location.

Result and discussion

Cluster analyses revealed a higher number and larger size of lymphoid aggregates in the microenvironment of MAG-EPA-treated patients who experienced downgrading compared to the placebo group ($p = 0.03$), suggesting a well-organized and functionally engaged immune infiltration. Furthermore, lymphoid aggregates from MAG-EPA-treated patients exhibited a higher density of CD8+FOXP3+ cells ($p < 0.001$). This phenotype may reflect increased immune cell activity or plasticity in the tumor microenvironment of MAG-EPA-treated patients who experienced downgrading. It has been previously observed in prostate cancer, but further analyses are necessary to fully characterize its functional role within the tumor immune microenvironment in this context.

Conclusion

These findings suggest that MAG-EPA induces a reorganization of the immune compartment which is associated with reduced cancer aggressiveness. This underlines the potential of MAG-EPA as a complementary therapeutic approach in prostate cancer management. Further analyses of the immune cell interactions will highlight the anti-tumoral mechanisms implicated.

²University of Palermo, Tumor Immunology Unit, Department of Health Sciences, Palermo, Italy

³ASST Valle Olona, ASST Valle Olona, Busto Arsizio, Italy

Introduction

Castration resistant prostate cancer (CRPC) is a fatal disease. Androgen receptor pathway inhibitors, like enzalutamide, are initially effective but resistance eventually occurs, often associated to the emergence of aggressive neuroendocrine variants (NEPC). Even immunotherapy induced limited results in prostate cancer, governed by an immunosuppressive microenvironment.

Material and method

We propose that new approaches to revert castration resistance and to turn the immune milieu from “cold” to “hot” would be synergic against CRPC. To this aim, we investigated in preclinical models the effects of a combination between enzalutamide and the drug GSK-126, which inhibits the epigenetic modulator EZH2.

Result and discussion

We show that enzalutamide and GSK-126 can synergize to restrain the growth of CRPC in vitro and in vivo. Moreover, this therapeutic combination efficiently reduced NEPC differentiation, in both subcutaneous and autochthonous in vivo models, increasing the rate of cured mice with regressed lesions. The antitumor efficacy of the enzalutamide and GSK-126 combination observed in immunocompetent mice bearing subcutaneous syngeneic CRPC tumors was lost in immunodeficient mice. Furthermore, in the TRAMP spontaneous model this combination treatment restored cytotoxic activity and IFNγ production of tumor-specific CD8+ T cells, otherwise tolerant, and increased IL-17 production in CD4+ T cells. The two drugs did not modulate T cell activity in vitro, suggesting the importance of micro-environment accomplices in triggering these effects.

Conclusion

These results promote the combined use of enzalutamide and GSK-126 to restrain CRPC growth and NEPC differentiation, and, simultaneously, to awake antitumor T cell response, opening new possibilities for immunotherapy in prostate cancer.

EACR25-0333

A multitarget drug as potential candidate for antimetastatic adjuvant therapy

J. Motta¹, C. Roberto-Fernandes¹, K. Micheli¹, P. Araújo¹, L. Martins¹, A. Lima¹, V. Morandi², P. Mourão¹, M. Pereira¹

¹Federal University of Rio de Janeiro, Medical Biochemistry Institute, Rio de Janeiro, Brazil

²State University of Rio de Janeiro, Biology Institute, Rio de Janeiro, Brazil

Introduction

Cancer is the second leading cause of death worldwide,

and preventing metastatic dissemination remains a significant challenge. During metastasis, tumor cells migrate and remodel the extracellular matrix. Once in the bloodstream, circulating tumor cells must survive in the circulatory environment, with their interaction with platelets – particularly through the P-selectin/ligand pathway – playing a crucial role. Subsequently, they need to interact with endothelial cells to extravasate from the vessel, a process primarily mediated by the VCAM-1/VLA-4 interaction. Studies have shown that heparin (porcine UFH), a glycosaminoglycan composed of repetitive disaccharide units of uronic acid and glucosamine, can interfere with both P-selectin and VCAM-1 interactions. Our group purified by ion exchange chromatography a fraction from bovine heparin that presents low anticoagulant potential, named LA-hep (~15% porcine UFH) whose major benefit is its reduced risk of bleeding side effects. Our aim with this work was to investigate the LA-hep potential as an antimetastatic agent in vivo and evaluate in vitro its ability to interfere with tumor cell-platelets and tumor cell-endothelium interactions.

Material and method

For this, we challenged 8–12 weeks wild-type and P-selectin KO C57BL/6 mice with 4 mg/kg of porcine UFH or LA-hep followed by intravenous injection of B16F10 cells (murine melanoma). In another assay, we injected 4T1 cells (breast triple negative murine carcinoma) orthotopically in female Balb/c mice and treated them daily from the 7th day to 28th day with 4 mg/kg of porcine UFH or LA-hep. After 21 days (melanoma) or 28 days (breast cancer), lungs were collected, and metastatic foci were counted and analyzed. In vitro, we evaluated the interaction of MV3 cells (human melanoma) with platelets and HUVEC cells in the presence of LA-hep. Moreover, the ability of MV3 cells treated with LA-hep to migrate and invade the matrix was analyzed.

Result and discussion

The number of metastatic foci was strongly reduced when animals were treated with heparins (~70% of reduction in melanoma and ~50% in breast cancer). Even in P-selectin KO mice, which present lower rates of metastases, LA-hep was still able to reduce metastasis burden. In vitro both heparins inhibited platelet adhesion to MV3 cells and MV3 cell adhesion to HUVEC in a dose-response manner. The direct binding of tumor cells to immobilized P-selectin and VCAM-1 was also reduced in the presence of LA-hep. Additionally, LA-hep, but not porcine UFH, seems to reduce MV3 invasion in transwell plates.

Conclusion

In summary, LA-hep, a heparin derivative with low anticoagulant activity, has shown promising multitarget potential in suppressing metastasis across various carcinoma models. Therefore, it could be considered as a potential adjuvant therapy for cancer patients.

A whole-genome RNAi screen to identify genes required in Flower-mediated cell competition in *Drosophila melanogaster*

C. Marçal-Costa¹, C. Brás-Pereira^{1,2}, D. Coelho¹, M. Curado Avelar¹, J. Couceiro¹, C. Rhiner¹, E. Moreno¹

¹Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal

²Gulbenkian Institute for Molecular Medicine (GIMM), Lisbon, Portugal

Introduction

In the initial stages of tumorigenesis, mutated cells escape tissue surveillance mechanisms. The expansion of these pre-malignant cells occurs at the expense of wild-type cells via conserved cell competition mechanisms discovered in fruit flies. These competitive cell-cell interactions rely on the comparison of relative cell fitness. Enhanced metabolic capacity (dMyc over-expression) or resistance to mechanical compression turns mutated cells into supercompetitors. Cells express different isoforms of the transmembrane protein Flower (Fwe), labelling them according to their fitness status. For instance, human tumours display FWE Win fingerprints, while stroma expresses FWE Lose. Despite its significance, this cell selection mechanism remains poorly understood.

Material and method

To overcome the lack of mechanistic understanding of this pathway, we developed the innovative Easy Win Assay in *Drosophila*. It allows to identify genes functionally required in cell competition triggered by the expression of the conserved loser isoform, humanFWE1. We then performed a whole-genome RNAi screen based on phenotypic analysis of results in the eye of the adult fly to identify modifiers of the elimination of hFWE1 loser cells.

Result and discussion

In this blind screen, we categorized candidate genes according to the rescue or enhanced elimination of loser cells. After validating these results, we identified at least 30 genes as being required in this competition scenario. We are going to explore some of the working hypotheses related to the stronger candidate genes and test them in cell competition assays in developing epithelia. Next, through epistasis analysis, we will place these candidates in the pathway, and finally, we will shed light on their requirement in various Fwe-dependent contexts, including development and cancer (dMyc supercompetition).

Conclusion

A better understanding of cell-cell communication between cells with differential fitness will be essential to developing new approaches to optimize tissue fitness and increase healthspan.

EACR25-0358

Local and systemic interactions drive prostatic intraductal carcinoma dissemination

D. Yanushko¹, A. Pichot², C. Keime², D. Metzger¹, G. Laverny¹

¹IGBMC, FGC, Illkirch, France

²IGBMC, Genomics platform, Illkirch, France

Introduction

Prostate cancer is a heterogeneous disease with a slow progression and a highly variable clinical outcome. Prostatic intraductal carcinoma (IDC) is a subset of prostate cancer strongly associated with metastatic

spreading and a poor outcome [1]. Thus, unraveling the mechanisms underlying its aggressiveness might lead to the development of personalized therapies. PTEN and TP53 loss are common genetic alterations in IDC [2]. Moreover, recent studies reported that extensive hypoxia is associated with high-risk disease [3], but its contribution to tumor progression is incompletely understood.

Material and method

We characterized tumor progression in genetically engineered mice, in which Pten and Trp53 are inactivated in prostatic epithelial cells (PECs) at adulthood (Pten/Trp53(i)pe/- mice) using single-cell and spatial transcriptomic profiling, as well as by flow cytometry. Hypoxia-inducible factor 1 (HIF1) inhibition was achieved by treatment with PX-478 or by genetic inactivation of Hif1a in PECs.

Result and discussion

Pten/Trp53(i)pe/- mice develop intraductal carcinomas (IDC) that disseminate to liver. We uncovered that the cell plasticity and metastatic potential is driven by a crosstalk between PECs and cancer-associated fibroblasts [4]. Importantly, IDCs of Pten/Trp53(i)pe/- mice are characterized by an hypoxic core and Visium Spatial transcriptomic profiling revealed that the hypoxic regions are enriched in immune system-related pathways. Deeper analyses, including cell type inference and flow cytometry, unraveled that the immune infiltrate is mainly composed of immunosuppressive macrophages and neutrophils. Both genetic inactivation and pharmacological inhibition of HIF1 signaling decrease neutrophil infiltrates in prostatic tumors and resensitize them to androgen deprivation. However, only pharmacological HIF1 targeting impairs circulating neutrophil levels and eradicates hepatic micrometastases, indicating a key role of these immune cells in tumor spreading.

Conclusion

Taken together, our study highlights local and systemic interactions of prostatic epithelial cells that contribute to their metastatic dissemination, and opens novel therapeutic avenues for treatment-resistant and metastatic prostate cancer.

Algeria, Blida, Algeria

³Laboratory of Pharmaco-toxicology, National Agency of Pharmaceutical Products, University of Algiers 1, Algiers, Algeria

Introduction

Squamous cell carcinomas of the tongue are among the most common tumors of the upper aerodigestive tract. Despite advances in surgery and radiotherapy, treatment often fails for many high-risk patients, and a 5-year survival rate is achieved in only 30–50% of cases. In an experimental model of oral squamous cell carcinoma (OSCC) generated by 4-nitroquinoline-1-oxide (4NQO) in BALB/c mice, we investigated the ability of arsenite (NaAsO₂), chloroquine (CQ), and dichloroacetate (DCA) to interfere with tumor cell immunometabolism (TNF- α and nitric oxide).

Material and method

Eight-week-old female BALB/c mice were exposed to chemical induction with the carcinogen (100 µg/ml) or treated with placebo (water control) for 16 weeks, then observed for up to 16 additional weeks. At 32 weeks post-treatment, mice were sacrificed, and their tongues were removed. The oral tumor tissues were then cultured for 24 hours in the presence of NaAsO₂, CQ, and DCA. The tissues were analyzed for histology, and culture supernatants were collected to measure nitric oxide (NO) using a modified Griess method and TNF- α by ELISA.

Result and discussion

The histopathological examination of the tongues of 4NQO-treated mice verified the existence of malignancies. Our findings show that inflammatory mediators in the combination-treated invasive tissues were dramatically reduced when combined with DCA compared to untreated OSCC tissues for NO levels (30.28% of reduction) and TNF- α (52.32% of reduction).

Conclusion

Our findings indicate that BALB/c mice are susceptible to developing OSCC after exposure to 4NQO due to the activation of pro-tumoral TNF- α that necessitates nitrosative stress. Our research suggests that DCA in combination with NaAsO₂ and CQ interferes with the inflammatory status of TNF- α /NO in 4NQO tumors. These findings bolster the attractiveness of DCA as an optimal strategy for therapeutic advantage in OSCC.

Colorectal cancer hepatic metastasis modelling by advanced 3D bioprinting and demonstration of oncolytic viral chemotherapeutic delivery

C. Milet¹, N. Forraz¹, M. Lacroix¹, Y. Sbirkov², V. Sarafian², C. Ebel³, A. Spindler³, V. Koerper³, P. Erbs³, C. McGuckin¹

¹CTIBIOTECH, CTIPharma, Meyzieu, France

²Medical University-Plovdiv, Department of Medical Biology, Plovdiv, Bulgaria

³Transgene S.A, Oncolytic Virus Laboratory, Illkirch-Graffenstaden, France

Introduction

Animal replacement in pharmaceutical and advanced chemotherapeutic development requires better in vitro and ex vivo modelling, not just tests that seem useful but

rather models that give results that researchers really need. We advanced our static and bioreactor-created colorectal cancer models with 3D bioprinting modalities creating reproducible screening for solid tumors.

Although organoid / spheroid testing is very useful in the early stages of screening it is not expansive enough to model longer growing tumors, nor for penetration testing. Here, using bioprinting, we tested colorectal cancer cell lines with hepatic donor cells to understand longer term tumor kinetics and demonstrate how oncolytic viral-delivered therapy can penetrate in 3D and evaluate effects over time.

Material and method

JVE-103 and JVE-253 colorectal cancer cell lines were amplified, and primary human hepatocytes freshly prepared and frozen following ethical consent. A 3D computer generated metastatic model was constructed with a central core of colorectal and outer significant covering of hepatocytes and the g-code transferred to a bioprinter. Cells were bioprinted with an alginate-nanofibrillar cellulose loaded bioink into 24 well plates creating multiple reproducible models, growing at 37°C, 5% CO₂, 15–80 days. Evaluation was made for metabolism, Caspase-3 cleavage, Masson-Trichrome histology, Ki67, EPCAM, Pancytokeratin and structural integrity of the resulting tumor formation. Response to infused 5-FU treatment and oncolytic viral-delivered 5-FU was evaluated.

Result and discussion

3D tumor formation, demonstrated with histological evaluation was achieved by 15 days with significant in-situ organoids and cultivation could continue for 80 days allowing for long-term evaluation, formation of necrotic cores and re-metastatic events. 5-FU infusion was dose responsive. Oncolytic virus loaded with the non-toxic chemotherapeutic did not target the hepatocytes, but did penetrate into the area of colorectal tumors. Intracellular enzyme-conversion there into local 5-FU was achieved and had the same effect as a higher 5-FU dose directly infused.

Conclusion

This level of modelling which advances on short-term organoid testing proved not only appropriate for investigation of speed and quantity of tumor formation over time, but also demonstrated defined and effective targeting of the oncolytic viral system as a novel chemotherapeutic delivery system.

EACR25-0381

Complement protein C3 from breast cancer-associated fibroblasts as a regulator of the tumor microenvironment

E. Mourati¹, K. Papadakos¹, B. King¹, A. Blom¹

¹Lund University, Translational Medicine, Malmö, Sweden

Introduction

Cancer-associated fibroblasts (CAFs) are a major component of the breast tumour microenvironment, shaping the behaviour of breast cancer and affecting its progression. Complement protein C3 is a central component of the complement system, essential element of innate immune response. The aim of the current study

was to evaluate the role of C3 in the initiation and progression of breast cancer.

Material and method

Expression data from patients with breast cancer pooled in Kaplan-Meier plotter were analyzed to determine the prognostic role of C3. Single-cell RNA-sequencing data from Single Cell Portal were also used to explore the expression levels of C3 in distinct cell populations within the tumour. The CRISPR/Cas9 system was employed to knock-out C3 in CAF2 cells by deletion of four exons. RNA-sequencing analysis of the obtained CAF2 clones was performed. The Bio-Plex® Pro Human Cytokine Assay was used for simultaneous screening of multiple cytokines, chemokines and growth factors secreted by CAF2 clones. The results were validated by DuoSet® ELISA kits. Finally, a xenograft mouse model was established by co-injecting human MDA-MB-231-Luc cells and control or C3 knock-out CAF2 cells, mixed in a ratio of one to three, orthotopically into NXG immune-deficient mice. Tumour volume was measured twice per week using the digital caliper and metastasis was evaluated using the IVIS® Spectrum 2 in vivo imaging system.

Result and discussion

Database analysis revealed that low C3 expression in breast cancer was associated with decreased overall survival ($p = 3.2e-5$), relapse-free survival ($p = 2.1e-9$) and distant metastasis-free survival ($p = 1.0e-5$) of patients. As C3 is highly expressed in CAFs cells, C3 knock-out in CAF2 cells was achieved by CRISPR/Cas9, as shown by C3-specific ELISA assay and Western blotting. Three control and three C3 knock-out clones were used for the subsequent experiments. The RNA-sequencing data highlighted the role of C3 in cytokine and chemokine activity and binding, cell cycle regulation, angiogenesis, and neutrophil activation. Lack of C3 expression resulted in altered cytokine secretion, IL-8 and MCP-1 in particular, validating the RNA-sequencing analysis data. Finally, the xenograft mouse model revealed that C3 deriving from breast CAFs slows down tumour growth ($p = 0.0096$) and drastically delays metastasis ($p = 0.0052$), as shown by the 2-fold increase of luminance.

Conclusion

Our study indicates that C3 secreted from breast CAFs has a protective effect in tumor progression and metastasis. Nevertheless, the exact mechanism of action of C3 for the regulation of the tumor microenvironment remains to be elucidated.

Three-dimensional Microtissues: An In-Vitro Platform to Recapitulate the Heterogeneity and Complexity of Head and Neck Squamous Cell Carcinoma

A. Chopra¹, E. Reszczynska¹, A. Anameric¹, M. Nees¹

Introduction

Head and neck squamous cell carcinoma (HNSCC) is a malignancy with a complex tumour microenvironment

(TME). Conventional in-vitro models, such as two-dimensional (2D) monolayer cultures, fail to capture the intricate cellular and molecular interactions within tumours, limiting their translational and physiological relevance. We have developed an advanced in-vitro model that recapitulates the tumour heterogeneity and the dynamic interplay between cancer cells and the TME as a straightforward and technically simple platform for studying HNSCC biology.

Material and method

Our 3D microtissues integrate three-dimensional (3D) culture techniques based on cells isolated from fresh tumour biopsies, cultured on a collagen type I/hyaluronic acid/ Matrigel® matrix. This allows us to directly culture cell crude suspensions from biopsies, containing patient-derived squamous epithelial cells along with all stromal components (cancer-associated fibroblasts (CAFs), immune cells, and endothelial cells). This system promotes tumour-stroma interactions, resulting in the spontaneous formation of tissue-like structures and matrix remodelling. Various 3D culture conditions differentially stimulate the capacity of the cellular components to mimic the organization of the original tumour. Furthermore, immunofluorescence (IF) staining was performed to validate distinct cell populations in the microtissues, and single-cell RNA sequencing (scRNA-seq) to confirm the preservation of tumour heterogeneity and specific differentiation patterns.

Result and discussion

Our microtissues spontaneously recapitulate key phenotypic and genotypic traits of cancer tissues, with a characteristic cellular heterogeneity that closely mimics the spatial organization of the original tumour. The use of different culture conditions (cell density, media, growth factors, serum etc) significantly modulated the growth, survival, and differentiation of both stromal and epithelial cell types, highlighting the role of the TME in shaping tumour architecture and ECM remodelling. scRNA-seq analysis confirmed that various components of the original tumour heterogeneity were maintained, depending on the conditions used. Strong tumour cell plasticity was also observed, which contributed to rapid phenotypic adaptations to conditions, and differential formation of tissue-like structures. This indicates the model's ability to replicate the architecture of squamous tumours.

Conclusion

By bridging the gap between conventional and in-vivo models, our microtissues provide a robust and translationally relevant platform for investigating HNSCC biology. Its ability to preserve tumour heterogeneity, mimic TME interactions, and model therapeutic responses makes it a valuable tool for preclinical research, personalized medicine, and drug discovery, contributing to improved therapeutic outcomes in HNSCC.

Exploring the role of innervation in thyroid cancer and modulation by therapy-induced senescence

E. Muraro¹, M. Mazzoni¹, T. Di Marco¹, A. Greco¹

Introduction

Nerves in the tumor microenvironment (TME) actively drive cancer progression, playing a key role in cancer initiation, metastasis, and recurrence across multiple solid tumors. A dynamic crosstalk between cancer cells and nerves creates a feedback loop that accelerates tumor growth, by recruiting neuronal precursors or exploiting locoregional nerves to promote neurogenesis and axogenesis. Despite growing evidence in other malignancies, the impact of innervation in thyroid cancer (TC) remains largely unexplored. Emerging evidence suggests that innervation within the TME may be linked to TC progression, with higher nerve density in TC being associated with extra-thyroidal invasion compared to benign tissue. Cellular senescence, a growth arrest triggered by stressors including anti-cancer treatments (therapy-induced senescence, TIS), can drive cancer aggressiveness via the senescence-associated secretory phenotype (SASP). Notably, senescent cells secrete brain-derived neurotrophic factor (BDNF), a SASP component required for their survival, and axon-guidance molecule Netrin-1. Therefore, our aim is to investigate the role of innervation in TC and examine whether senescent cells, particularly those induced by anti-cancer therapies, contribute to this process through the paracrine effects of the SASP.
