Introduction

Currently, there are not efficient therapies with curative intent for advanced breast cancer (BC). Chronic inflammation is a well-established hallmark of cancer and a major driver for metastasis, which is the leading cause of death in BC patients. Understanding how inflammatory signals orchestrate pro-malignant effects in the tumour microenvironment (TME) is key to designing new therapeutic strategies to target tumour-promoting inflammation.

Material and method

Cytokines are the main regulators of inflammation. We recently characterized the cytokine Oncostatin M (OSM), as a central node for multicellular interactions within the breast TME¹. In the current unpublished work, we examine the effect of OSM on tumour immune remodelling and metabolism within the TME, by combining molecular biology techniques, flow cytometry, seahorse analyses and multiomics (including single cell RNA sequencing, proteomics and metabolomics) on patients' data, murine models and cell lines.

Result and discussion

Our findings identified myeloid cells as the primary source of OSM in human breast cancer and healthy breast. In vivo studies showed that activation of the OSM receptor OSMR remodels the breast tumour immune landscape by increasing macrophage and neutrophil recruitment, in addition to decreasing the number of CD8+ T cells. The opposite effect is observed when the OSM/OSMR pathway is blocked in OSMR KO mice. In addition, OSM increases the expression of key chemokines and inhibitory immune checkpoint regulators, and the phagocytosis-inhibiting signals, indicating a relevant role for OSM/OSMR signalling in immune regulation. Furthermore, OSM stimulation enhances metabolic reprogramming of cancer cells, CAFs and tumours, increasing glycolysis and hypoxia-related gene expression. Finally, our findings reveal a common mechanism via hypoxia inducible factors for both OSM-induced metabolic reprogramming and immune evasion.

Conclusion

This work unravels the mechanisms by which OSM influences the immune landscape and metabolic configuration of the TME and lays the groundwork for further development of targeted interventions to disrupt this pro-tumoral signalling.

³Pathology Department, CHUC, Coimbra, Portugal

Introduction

Breast cancer (BC) is the most prevalent malignancy in women, with HER2 amplification detected in 25–30% of metastatic cases. While HER2-targeted therapies such as trastuzumab have significantly improved patient survival, their efficacy in HER2+ brain metastases (BrM) is often compromised by acquired resistance and limited blood-brain barrier (BBB) permeability. This study investigates the potential of trastuzumab radiolabeled with the β^- -emitting radionuclide $[^{177}\text{Lu}]$ [Lu-DOTA-Trastuzumab] as a strategy to overcome resistance in HER2+ BrM.

Material and method

HER2+ BC cell lines and their brain-tropic derivatives were evaluated for HER2 expression and sensitivity to trastuzumab and $[^{177}\text{Lu}]$ [Lu-DOTA-Trastuzumab]. In vivo models were established via orthotopic implantation of HER2+ BC cells for primary tumor development and intracardiac injection to generate BrM. Tumor progression was monitored using magnetic resonance imaging (MRI), while HER2 expression was assessed through $[^{89}\text{Zr}]$ Zr-DFO-Trastuzumab positron emission tomography (PET) imaging. BBB permeability across metastatic lesions was evaluated using dynamic contrast-enhanced MRI (DCE-MRI).

Result and discussion

Brain-tropic HER2+ cells maintained HER2 expression but exhibited resistance to trastuzumab. In contrast, $[^{177}\text{Lu}]$ [Lu-DOTA-Trastuzumab induced significant DNA damage and cytotoxicity in vitro. PET imaging confirmed specific radiotracer uptake in HER2+ primary tumors and BrM. A single dose of $[^{177}\text{Lu}]$ [Lu-DOTA-Trastuzumab effectively suppressed primary tumor growth and led to complete BrM remission in 40% of treated animals. BBB permeability varied across metastatic lesions, potentially influencing radiotracer uptake and therapeutic response.

Conclusion

These findings highlight $[^{177}\text{Lu}]$ [Lu-DOTA-Trastuzumab as a promising therapeutic strategy to overcome trastuzumab resistance in HER2+ BrM. Its potent anti-tumor effects and ability to target brain metastases underscore its potential to improve outcomes in patients with metastatic HER2+ BC.

EACR25-1517**IL-1R8 acts as an immune checkpoint in CD8+ T cells, limiting cytokine-induced anti-tumor immune responses**

R. Garuti¹, D. Supino², A. Mariancini¹, E. Magrini², L. Minutte², J. Zeleznjak³, E. Bonavita², S. Jaillon², A. Mantovani², C. Garlanda²

¹*Humanitas University, Pieve Emanuele, Milan, Italy*

²*IRCCS Humanitas Research Hospital, Pieve Emanuele, Milan, Italy*

³*University of Rijeka, Center for Proteomics, Rijeka, Croatia*

Introduction

IL-1R8 is an atypical Interleukin-1 receptor (ILR) family member that controls inflammation by dampening ILR and Toll-like receptor (TLR) downstream pathways. Studies conducted on IL-1R8-deficient NK cells highlighted its pivotal role as immune checkpoint and negative regulator of IL-18-dependent activation. In particular, IL-1R8-deficiency has been shown to trigger NK cell-mediated immune surveillance against hematogenous metastasis, liver cancer and viral dissemination. Currently, genetic and pharmacological targeting of ILR and IL-18 are under investigation to improve CD8+ T cell-based immunotherapy. The relevance of IL-1R8 in mitigating IL-18-driven activation and, conversely, the pathways induced by IL-1R8 loss-of-function in T lymphocytes are still elusive.

Material and method

Combining transcriptomic analysis, high dimension flow cytometry, genetic silencing/inhibition, and *in vivo* models, we investigated IL-1R8 expression by CD8+ T cells and its function in Tumor Infiltrating Lymphocytes (TILs) and T-cell based immunotherapies.

Result and discussion

IL-1R8-deficiency led to anti-tumor immune resistance against colon carcinoma and fibrosarcoma by enhancing CD8+ TIL fitness, synergizing with the immune checkpoint inhibitor anti-PD-1. TILs exhibited accelerated maturation/proliferation kinetic, induction of IL-2R complex and increased tumoricidal potential independently of antigen presenting cells (APCs). Mechanistically, we found that IL-1R8 controlled both IL-2/EOMES/IL-2R signaling axis and IL-18-mediated Type-1 polarization thus affecting the production of antitumor molecules Interferon-γ (IFNγ) and Granzyme B (GZMB) in antigen-specific and polyclonal T cell responses. Relevant to T cell therapy, we reported increased antigen-induced proliferation for IL-1R8-deficient OT-I cells *in vitro* and superior tumoricidal potential of IL-1R8-deficient OT-I T cells *in vivo*. In human, we demonstrated that IL-1R8 is rapidly induced in early-mature precursors and the central memory stage of CD8+ T cells in healthy donors and cancer patients. Finally, an original anti-human IL-1R8 inhibitor and CRISPR-Cas9 mediated IL-1R8 ablation potentiated both primary human T lymphocytes and CAR-T cells against B-cell lymphoma.

Conclusion

Overall, the study revealed a profound impact of IL-1R8 deficiency or blockade on CD8+ T lymphocyte immunobiology, which promoted cytokine-induced responses and

conferred superior anti-tumor potential. Thus, IL-1R8 is a promising and targetable immune checkpoint of both NK and CD8+ T cells to be exploited for implementing cancer immunotherapy.

EACR25-1932**Genome-Wide CRISPR Screening Identifies Lipid-Sensing Chemosensor Receptors as Regulators of Tumor-Associated Macrophage Function in Cancer**

G. Marelli¹, S. Puccio¹, P. Colombo¹, M. Lazzeri¹, L. Morosi¹, E. Bonavita¹, F. Bertoni², L. Walsh³, E. Lugli¹, D. Di Mitri¹

¹*Humanitas clinical and research hospital, Pieve Emanuele, Italy*

²*Institute of Oncology Research, Bellinzona, Switzerland*

³*McGill University, Montreal, Canada*

Introduction

The infiltration of macrophages is considered a hallmark of cancer progression, and re-education of tumor-associated macrophages (TAMs) toward an anti-tumor phenotype is a promising strategy in cancer immunotherapy. However, the mechanisms governing macrophage education by cancer cells remain largely elusive, posing challenges for therapeutic exploitation. Understanding the molecular pathways involved in TAM plasticity could lead to novel therapeutic approaches to enhance anti-tumor immunity.

Material and method

To gain deeper insights into TAM plasticity, we conducted an unbiased genome-wide CRISPR screening on primary macrophages, allowing us to identify key regulators involved in macrophage polarization within the tumor microenvironment. The functional impact of selected candidate genes was assessed *in vitro* and *in vivo* using murine cancer models, while human prostate cancer tissues were analyzed using innovative spatial strategies, such as spatial lipidomics and imaging mass cytometry, to confirm translational relevance.

Result and discussion

Our investigation confirmed the role of known regulators, in orchestrating TAMs responses and unveiled novel insights into TAMs behavior. Notably, we identified olfactory and vomeronasal receptors, commonly referred to as chemosensors, as major drivers of macrophage tumor-supportive functions. Both the genetic deletion and the pharmacological inhibition of selected chemosensors in TAMs *in vivo* led to cancer regression and an increased infiltration of tumor-reactive CD8+ lymphocytes, suggesting a role in shaping the immune landscape of the tumor microenvironment. In human prostate cancer tissues, we found that palmitic acid binds to Olfactory Receptor 51E2 (OR51E2) expressed by TAMs, thereby enhancing their pro-tumoral phenotype. To further validate these findings, we conducted spatial analysis, which confirmed the presence of palmitic acid in close proximity to TAMs within prostate cancer patient samples. This supports the notion that lipid mediators contribute to macrophage-driven immune suppression in tumors.

Conclusion

Collectively, our findings highlight the role of chemo-sensors in macrophage sensing of the lipid-enriched tumor microenvironment. By demonstrating their impact on macrophage function and tumor progression, this study identifies chemosensor receptors as potential therapeutic targets for enhancing anti-tumor immunity. Targeting these receptors could provide a novel strategy to reprogram TAMs and improve cancer immunotherapy outcomes.

EACR25-2439

A novel spatial DNA sequencing method for the detection of somatic mutations from hundreds of regions in archival tissue sections

C. Soitu¹, W. Bonnaffé², M. Bilici¹, A. Magnusson¹, J. Rittscher¹, I. Mills¹, D. Woodcock¹, F. Hamdy¹, C. Verrill¹, S. Rao¹

¹*University of Oxford, Nuffield Dept. of Surgical Sciences, Oxford, United Kingdom*

²*University of Oxford, Department of Biology, Oxford, United Kingdom*

Introduction

Somatic mutations are typically identified in cancer using bulk sequencing which results in loss of histological context. Spatial transcriptomics has been used to profile copy number alterations, but it is limited by low genomic resolution and high noise. We hypothesised that a low cost high-throughput spatial DNA sequencing method would enable more accurate characterisation of genomic changes in tissue sections.

Material and method

We developed a novel method called Adaptive Resolution Multiscale Spatial (ARMS) DNA sequencing to characterise the genome at sub-millimetre resolution, while preserving the histopathological context in formalin fixed paraffin embedded (FFPE) tissue sections. FFPE sections (4 µm) from prostate cancer patient samples were laser captured as 0.09–0.25 mm² tiles. Uniquely barcoded whole genome libraries from the tiles were sequenced on the Illumina platform. Copy number calling was performed using CopyKit. The Segment Anything Model 2 (SAM2) was fine-tuned to segment prostate epithelium, from which tissue (nuclear and gland) features were extracted.

Result and discussion

We successfully derived whole genome copy number profiles at 50 kb resolution in more than 1000 tiles from 3 patient samples. Copy number calls were confirmed by bulk whole genome sequencing data from adjacent tissue. Furthermore, principal component analysis showed distinct grouping of the tiles suggesting spatially distinct genomic profiles. Tiles with similar copy number profiles were clustered to identify subclones, which in turn were used to build phylogenetic trees. Mapping the subclones to spatial transcriptomics from adjacent sections revealed significantly altered gene expression between the subclones. We identified 2 previously undiscovered (by bulk WGS) subclones through spatial DNA sequencing. Prostate gland clustering independent of genomic status identified morphologically distinct regions (> 3 in each

patient), which were also genetically distinct. Nuclei in different prostate cancer regions (high grade vs. low grade) were also more intensely stained (1.5-fold, $p < 0.0001$).

Conclusion

We have developed a novel spatial DNA sequencing method, which facilitates cost-effective profiling of somatic mutations from whole slides. When it is integrated with histopathological data and spatial transcriptomics, it reveals a more complete picture of cancer evolution and enables the identification of ‘early’ and ‘late’ morphologies. Integration of spatial genomics with digital pathology has the potential to reveal hidden relationships between genotype and phenotype.

Symposium: Next-generation Immunotherapy Modalities

EACR25-0734

Synergistic effect of thiopurine 6TG and immunocheckpoint blockade to inhibit melanoma growth

L. Nazerai¹, C. Tsivouli¹, L. Vardouli¹, K. Schmiegelow², D. De Zio^{1,3}

¹*Danish Cancer Institute, Melanoma Research Team, Copenhagen, Denmark*

²*Rigshospitalet University Hospital & Institute of Clinical Medicine, Department of Pediatrics and Adolescent Medicine, Copenhagen, Denmark*

³*University of Southern Denmark, Institute of Molecular Medicine, Odense, Denmark*

Introduction

Significant developments in cancer immunotherapy, such as immune checkpoint inhibitors (ICI), have revolutionized the treatment of metastatic patients. Despite these breakthroughs, a group of patients does not respond favorably to ICI, partly due to a lack of cancer neoepitopes. Mutations acquired during tumorigenesis can increase the number of neoepitopes on tumor cells, eliciting a cytotoxic T-cell response that is then boosted by ICI therapy. We use a compound called thiopurine 6-thioguanine (6TG) to trigger random mutations in the tumor in order to enhance the number of neoepitopes produced by tumor cells. In preclinical models of low-mutational burden melanoma, we demonstrated that 6TG-induced mutations enhanced T cell-mediated tumor suppression and significantly improved responsiveness to anti-PD-1 therapy. However, while this strategy augmented immune activation, it remained insufficient to achieve complete tumor regression (Nazerai et al. 2023).

Material and method

YUMM1.1 (Yale University Murine Melanoma) cells have been co-cultured with mouse splenocytes; cell viability and flow cytometry analyses have been performed to evaluate T-cell mediated cell death of tumor cells treated or not by 6TG. YUMM1.1-based syngeneic mouse model has been used to test the effect of 6TG with anti-CTLA-4 monotherapy or combined with anti-PD-1. Tumor growth kinetics and immune memory have been assessed.

Result and discussion

We explored additional ICI combinations to optimize treatment outcomes, specifically evaluating anti-CTLA-4 alone or in combination with anti-PD-1 in 6TG-treated tumors. Our findings revealed that anti-CTLA-4 – particularly when combined with anti-PD-1 – achieved complete tumor remission, but only when treatment was initiated at smaller tumor volumes. In contrast, efficacy declined when therapy began at later stages, emphasizing the critical importance of early intervention.

Additionally, we found that mice experiencing complete tumor regression after 6TG + ICI treatment developed long-term immune memory. When re-exposed to tumor cells, these mice effectively suppressed tumor growth, suggesting durable protection against recurrence.

Conclusion

These findings (Nazerai et al. 2025) have significant clinical implications, highlighting the potential of 6TG-based combinatorial strategies to extend the benefits of immunotherapy to low-TMB patients and overcome current resistance.

EACR25-2222

Systematic identification of recurrent immunogenic neoantigens in treatment-resistant tumors

N. Gumpert¹, S. Sagie-Groher¹, C. Arnedo², T. Babu³, A. Gonzalez², J. Mateo⁴, F. Martinez Jiménez⁴, N. Lopez², Y. Samuels¹

¹*The Weizmann Institute of Science, Rehovot, Israel*

²*Institute for Research in Biomedicine, Barcelona, Spain*

³*The Weizmann Institute of Science, Israel*

⁴*Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Introduction

Cancer immunotherapy revolutionized cancer treatment paradigms. Yet, only around 20% of the patients respond to immunotherapy. Neoantigens have emerged as promising targets in cancer immunotherapy since they are tumor-unique and can mediate an effective tumor-directed T-cell response. Recurrent neoantigens, derived from hotspot mutations, are becoming increasingly attractive targets for immunotherapy as they are shared among large groups of patients and may pave the way toward “off-the-shelf” cancer therapies. However, identifying immunogenic ‘HLA-peptide’ pairs represents a significant challenge. HLA genes are the most polymorphic region in the human genome and are highly variable. Our study aimed to uncover recurrent neoantigens presented by HLA class I molecules, focusing on genes linked to treatment resistance. This research is crucial because new approaches that generate long-lasting therapeutic responses are critically needed, especially for cancer patients with tumors that have evolved resistance to existing therapies.

Material and method

We have developed a novel analysis pipeline, SpotNeoMet, emphasizing the identification of recurrent, clonal, driver mutation-derived neoantigens specifically presented on metastatic tumors resistant to specific targeted therapies. Analysis of large patient cohorts from the Hartwig Medical Foundation dataset and the Cancer

Genome Atlas followed by systematic HLA immuno-peptidomics.

Result and discussion

In this study, using SpotNeoMet, we discovered three recurrently presented novel neo-peptides derived from the Androgen Receptor (AR) H875Y mutation, the most common castration-resistant prostate cancer mutation. We validated these neoantigens as highly immunogenic and isolated their cognate T-cell receptors (TCRs) from healthy donor PBMCs. Further characterization revealed that these TCRs are highly sensitive and specific to their targets, demonstrating remarkable efficiency in recognizing and eliminating prostate cancer cells presenting these neo-peptides.

Conclusion

The emergence of resistance to targeted treatments in metastatic cancer patients underscores the urgent need for innovative therapeutic approaches. Our study introduces SpotNeoMet and using AR H875Y mutations as a proof of concept, we demonstrate the robustness of our pipeline in developing a T cell-based immunotherapy.

SpotNeoMet promises a systematic method to uncover ‘HLA-peptide’ pairs and their cognate TCRs across treatment-resistant cancers. Importantly, our data suggest that resistance drivers can be transformed into therapeutic opportunities through various immunotherapy modalities.

⁴*Wellcome Sanger Institute, Cancer, Ageing and Somatic Mutation, Cambridge, United Kingdom*

⁵*Wellcome Sanger Institute, Cambridge, United Kingdom*

Introduction

Colorectal cancer incidence rates vary geographically and have changed over time. Notably, in the past two decades, the incidence of early-onset colorectal cancer, affecting individuals under the age of 50 years, has doubled in many countries. The reasons for this increase are unknown.

Material and method

We investigated whether mutational processes contributed to geographic and age-related differences by whole-genome sequencing 981 colorectal cancer genomes from 11 countries, and examining their

mutational signature dynamics and driver mutations in cancer driver genes.

Result and discussion

No major differences were found in microsatellite unstable cancers, but variations in mutation burden and signatures were observed in the 802 microsatellite-stable cases. Multiple signatures, most with unknown etiologies, exhibited varying prevalence in Argentina, Brazil, Colombia, Russia, and Thailand, indicating geographically diverse levels of mutagenic exposure. Signatures SBS88 and ID18, caused by the bacteria-produced mutagen colibactin, had higher mutation loads in countries with higher colorectal cancer incidence rates. SBS88 and ID18 were also enriched in early-onset colorectal cancers, being 3.3 times more common in individuals diagnosed before age 40 than in those over 70, and were imprinted early during colorectal cancer development. Colibactin exposure was further linked to APC driver mutations, with ID18 responsible for about 25% of APC driver indels in colibactin-positive cases.

Conclusion

This study reveals geographic and age-related variations in colorectal cancer mutational processes, and suggests that early-life mutagenic exposure to colibactin-producing bacteria may contribute to the rising incidence of early-onset colorectal cancer.

EACR25-1472

Fibroblast specific endoglin deletion increases colorectal cancer tumorigenesis in a subset-specific manner

S. Abdukelimu¹, M. J. A. Schoonderwoerd¹, M. Paauwe¹, E. S. M. de Jonge-Muller¹, S. G. T. Janson¹, N. van Montfoort¹, L. J.A.C. Hawinkels¹

¹Leiden University Medical Center, Gastroenterology & Hepatology, Leiden, Netherlands

Introduction

Growing evidence highlights the heterogeneity of fibroblast subsets, with distinct populations playing different roles in the initiation, progression, and metastasis of colorectal cancer (CRC). While we previously reported that endoglin expression on cancer-associated fibroblasts promotes metastatic spread in CRC, its role in early-stage tumor development is unknown. Here, we investigated whether and how the fibroblast subset-specific deletion of endoglin influences tumorigenesis in a chemically induced colitis-associated CRC model.

Material and method

We generated two inducible fibroblast-specific endoglin (ENG) knockout mice Collagen1α1 CreERT2.ENGfl/fl (ENGCol1α1^{-/-}) and Collagen1α2-CreERT.ENGfl/fl (ENGCol1α2^{-/-}). Cre-mediated recombination in mice was induced by oral administration of tamoxifen for three consecutive days. Polyp formation was induced by a single injection of azoxymethane (AOM), followed by three cycles of dextran sodium sulphate (DSS). Immunohistochemistry (IHC) staining was performed to evaluate the stromal compartment and immune infiltration in polyps. Flow cytometry was used to analyze immune cell composition in colons.

Result and discussion

ENGCol1α1^{-/-} mice developed significantly more colonic polyps than non-induced controls (average 20

vs. 6, respectively, $P < 0.0001$), whereas ENGCol1α2^{-/-} showed no significant difference in polyp count (average 16 vs. 13, respectively, $P = 0.1557$). Immunohistochemical analysis revealed an increase in total stroma content (vimentin-positive) and a higher number of activated α-smooth muscle actin-positive fibroblasts in ENGCol1α1^{-/-} mice, whereas no significant changes were observed in ENGCol1α2^{-/-} mice. Moreover, ENGCol1α1^{-/-} mice showed increased infiltration of F4/80⁺ macrophages and Ly6G⁺ neutrophils, compared to controls. These findings suggest that Collagen1α1 subset-specific endoglin deletion enhances polyp formation, stroma expansion, and myeloid infiltration in AOM/DSS-induced polyps. To investigate early immune changes, which might be instrumental in polyp initiation, mice were sacrificed after the first DSS cycle. Flow cytometry analysis showed an increase in F4/80⁺ Ly6C⁺ macrophages in ENGCol1α1^{-/-} colons, whereas their number decreased in ENGCol1α2^{-/-} colons, despite no change in the overall CD45⁺ immune cell population. Furthermore, the number of F4/80⁺ CD206⁺ M2-like macrophages was also increased in ENGCol1α1^{-/-} colons, suggesting their potential role in shaping a protumorigenic microenvironment.

Conclusion

Collagen1α1-specific endoglin deletion promotes polyp formation by enhancing stromal expansion and myeloid infiltration, whereas Collagen1α2-specific deletion does not impact tumor development. These findings highlight the intriguing and opposite roles that different fibroblast subsets can play in tumorigenesis.

Reshaping Tumor-Vascular-Immune Crosstalk by VEGFR-3 Modulation in Breast Cancer Brain Metastases

C. Macela¹, R. Acúrcio¹, H. Florindo¹

¹Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal

Introduction

Brain metastases affect 10–30% of metastatic breast cancer patients. Limited treatment options and poor clinical outcomes highlight the unmet need for effective therapies. The lymphatic vasculature plays a critical role in cancer progression, serving as the primary route for metastasis and promoting an immunosuppressive microenvironment by inhibiting cytotoxic T cells and dendritic cell maturation. However, its role in brain metastases remains unclear. Here, we investigate whether modulating VEGFR-3, a key receptor in endothelial lymphatic cells, can normalize lymphatic vasculature, influence immune cell infiltration in the tumor microenvironment (TME), and reduce tumor growth and metastases.

Material and method

VEGFR-3 expression was assessed in EO771 and 4T1 breast cancer (BC) and 2H-11 lymphatic endothelial cell

lines. Cell tolerance to VEGFR-3 inhibitor (VEGFR-3i), SAR131675, was evaluated in vitro using increasing compound concentrations. VEGFR-3i was tested ex vivo in 2D and 3D cultures of BC TME-derived cells. BC and breast brain metastases (BBM) in vivo models were generated via orthotopic inoculation of murine EO771 and 4T1 cell lines. For BBM, the primary tumor was surgically removed, mimicking clinical conditions, followed by intracranial inoculation. VEGFR-3i was administered orally, intravenously, or intraperitoneally. Lymph nodes (draining and non-draining), primary tumors, and BBM were collected at various time points to assess VEGFR-3 expression and perform immune profiling via spectral flow cytometry.

Result and discussion

In vitro studies showed minimal VEGFR-3 expression among cell lines, as expected, with a dose-dependent reduction in metabolic activity following SAR131675 treatment. Cytotoxic effects occurred only at higher concentrations, with triple-negative 4T1 being the most sensitive. In 2D primary cultures, VEGFR-3 expression was higher in BBM than primary BC, underscoring its critical role in metastases. In 3D-spheroid models, BBM displayed increased aggressiveness compared to BC, as evidenced by greater growth and sprouting. However, VEGFR-3 modulation effectively controlled BC spheroid growth and sprouting, with a moderate effect on BBM. In vivo, VEGFR3i reduced tumor volume and reprogrammed the TME.

Conclusion

These findings suggest that normalizing lymphatic vasculature through VEGFR3 modulation can reshape the tumor-immuno-lymphatic landscape, fostering a more effective anti-tumor immune response and potentially enhancing immunotherapy efficacy.

Loss of Kmt2c or Kmt2d drives brain metastasis via KDM6A-dependent upregulation of MMP3

M. Seehawer¹, Z. Li¹, J. Nishida¹, P. Foidart¹, A. Reiter¹, E. Rojas-Jimenez¹, M. Goyette¹, P. Yan¹, M. Papanastasiou², K. Polyak¹

¹Dana-Farber Cancer Institute, Boston, United States

²The Eli and Edythe L. Broad Institute, Cambridge, United States

Introduction

Breast cancer is the most common cancer type worldwide accounting for more than 2 million newly diagnosed cases in 2020. Despite recent development of new therapies, disease-free survival rates of triple-negative breast cancer (TNBC) patients are still relatively low. The histone modifier KMT2C and KMT2D are among the most commonly mutated genes across all cancer types including TNBC. However, their direct role in promoting metastases which could be exploited for a targeted therapy approach is still unknown.

Material and method

To unravel functional implications in metastases we generated CRISPR/Cas9-mediated Kmt2c and Kmt2d KO derivatives of murine TNBC cells and used them in immunocompetent mouse models. We performed

scRNA-seq to characterize the specific immuno-microenvironment of KO tumors and combined histone mass spectrometry, RNA-seq and ChIP-seq to identify metastasis-driving events. Functional studies using genetic or pharmacologic inhibition of metastases driver were combined with experimental mouse models to validate our findings.

Result and discussion

Loss of Kmt2c or Kmt2d did not impact tumor growth in vivo, however, KO tumors were highly metastatic to multiple organs. Despite profound changes in immune cell populations in primary tumors, metastatic phenotypes were independent of a functional immune system. Tumor cell intrinsic analysis showed direct target of Kmt2c/d, H3K4me1 levels were not altered, however, H3K27me3 was reduced and H3K27ac was increased in KO cells. In accordance, ChIP-seq for these histone modifications revealed KO-specific changes and ChIP-seq peaks for KDM6A, another histone modifier, were highly enriched. By integrating our multi-omics data we identified the matrix metalloproteinase Mmp3 as a main target upregulated upon Kmt2c/d KO which we also validated in KMT2C KO patient samples. Functional data showed that MMP3 expression is independent of H3K4me1 levels but depends on H3K27 demethylase KDM6A or acetyltransferase p300 activity. Finally, genetic or pharmacologic perturbation of KDM6A decreases MMP3 expression eventually preventing Kmt2c/d KO cells from metastasizing to the brain.

Conclusion

This study revealed that mutations in Kmt2c and Kmt2d are sufficient to induce brain metastases through MMP3 upregulation and that KDM6A inhibition might be a novel strategy to treat or prevent metastasis.

Epigenetic regulation shapes the tumor microenvironment in NSCLC and impacts the outcome of immune checkpoint blockade therapy

M. Gallardo-Gómez¹, M. Lázaro¹, I. Alonso-Álvarez¹, A. Francisco-Fernández^{1,2}, C. García-Benito¹, A. Rodríguez-Casanova³, A. Díaz-Lagares³, L. Juaneda-Magdalena¹, M. Martínez-Fernández¹

²Medical Oncology Department, Pontevedra, Spain,

³ONCOMET, IDIS, CHUS, CIBERONC, Epigenomics Unit, Cancer Epigenomics, Santiago de Compostela, Spain

Introduction

Immune Checkpoint Inhibitors (ICI) have revolutionized advanced Non-Small Cell Lung Cancer (NSCLC) treatment, but low response rates highlight the need to understand response mechanisms. This work explored the

impact of epigenetics and viral mimicry in the immunogenicity of the tumor microenvironment (TME) and ICI outcome in NSCLC.

Material and method

We collected primary tumors from 30 advanced NSCLC patients before first-line anti-PD1, and evaluated the epigenetic (MethylationEPIC array), transcriptomic (RNAseq) and somatic mutation profiles (WES). We evaluated differential methylation and expression between patients with disease control at 6 months (DC, 12) and non-responder patients (NR, 18). Epigenetic silencing was assessed by integrating methylation and transcriptomics, defining genes as silenced if >30% promoter methylation correlated with lower expression (Wilcoxon $p < 0.05$).

Result and discussion

A random forest classifier integrating 156 differentially methylated CpGs, 49 differentially methylated regions and 123 differentially expressed genes discriminated DC patients (AUC 0.972). RNAseq confirmed the functional consequences of DNA methylation, revealing signaling pathways enriched in both differentially methylated and expressed genes. Pro-proliferative signaling such as Ras, NF-kB or Wnt were downregulated in DC, while CD8+ T cell differentiation and activation was upregulated. NR patients showed a global upregulation of the PI3K-Akt pathway. Despite the mutational profile of our cohort did not explain the expression differences, we found aberrant methylation of the PI3K-Akt pathway, with some of its dependent genes epigenetically silenced. Collins et al (JITC 2022) reported that PI3K-Akt activation enables ICI resistance and immune evasion. Concordantly, we found that PIK3CA and AKT3 expression correlated with the expression of immunosuppressive cytokines. Isoyama et al (JITC 2021) showed that combining PI3K inhibitors with ICI can enhance antitumor immunity by turning a ‘cold’ into a ‘hot’ TME. In line with our findings, the baseline activation of PI3K-Akt pathway predicts a poor ICI response in NSCLC. We also report that the tumor load of transposable elements (TE) derived from RNAseq positively correlated with the expression of antiviral responses, IFN I and III, and JAK/STAT pathway activation. DC patients with longer progression free survival (PFS) had the highest TE load, while those with low TE load and weak antiviral response show shorter PFS, suggesting the presence of viral mimicry which was proposed to enhance tumor immunogenicity, favoring ICI response (Ng et al, Nature 2023).

Conclusion

DNA methylation shape the TME and serve as predictive baseline biomarkers for ICI response in NSCLC.

Precisely, PI3K-Akt pathway is affected by epigenetic silencing and its activation may indicate a poor response to anti-PD1, while a viral mimicry state may enhance tumor immunogenicity and ICI response.

Monitoring genetic and epigenetic evolution of metastatic colorectal cancer through longitudinal ctDNA profiling

F. Chemi¹, M. Dale¹, D. Rambaldi¹, C. James¹, M. Prisciandaro², F. Palermo², A. Raimondi², F. Morano², F. Pietrantonio², A. Sottoriva¹

¹Human Technopole, Computational Biology Research Centre, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Medical Oncology, Milan, Italy

Introduction

Circulating tumour DNA (ctDNA) is a valuable resource for monitoring the evolving molecular landscape of cancers under the selective pressure of therapy. Here, we are evaluating ctDNA molecular dynamics in metastatic colorectal cancer (CRC) patients enrolled into the MAYA trial, whereby patients with microsatellite-stable and O6-methylguanine-DNA methyltransferase silenced tumours receive temozolamide (TMZ) as immune sensitizing strategy followed by immunotherapy.

Material and method

ctDNA was isolated from serially collected plasma samples at baseline, post-TMZ induction, during immunotherapy and, when available, at disease progression. Whole genome ctDNA and germline DNA libraries were generated by using NEBNext® Ultra™ II kit and indexed with Unique Dual Index (UDI) UMI Adaptors. Pools with up to 9 ctDNA and germline DNA libraries were subjected to targeted exome capture by using Twist® Human Comprehensive Exome kit. Additionally, NEBNext® Enzymatic Methyl-seq ctDNA libraries were pooled and enriched for cancer-specific methylated regions using a targeted panel.

Result and discussion

A total of 95 plasma samples from 28 patients were initially profiled through deep whole exome sequencing. To reconstruct the subclonal architecture of longitudinal ctDNA samples, we developed LOBSTER, a computational tool, adapted from the previously established method MOBSTER (Caravagna et al., 2020). By using this approach, we were able to successfully discern subclonal versus clonal mutations and most importantly we identified, in every patient, clones which were expanding under treatment. In 40% of patients, these expanding clones were driven by mutations in mismatch repair genes, in particular MSH6. Notably, we observed the emergence of the SBS11 signature, characteristic of temozolamide exposure, along with an increased tumor mutational burden exclusively in MSH6-mutant patients. This suggests that the acquisition of MSH6 mutations serves as a biomarker of temozolamide-induced genetic alterations. Next, we investigated transcription factor binding site accessibility (TFBS), inferred from low-pass whole genome sequencing data, and identified an epigenetic rewiring, particularly in patients who initially responded to immunotherapy. Furthermore, distinct methylation patterns were also observed throughout immunotherapy and at disease progression, suggesting that epigenetic changes, in addition to the expansion of clones driven by genetic events, might contribute to tumour evolution and disease progression.

Conclusion

Taken together, these results underscore the potential clinical utility of longitudinal ctDNA analysis for studying real-time colorectal cancer genetic and epigenetic evolution.

Circulating tumor cells shed a new class of "shearosome" large extracellular vesicles in capillary bifurcations that drive metastatic processes

A. Vrynas¹, S. Bazban-Shotorbani¹, F. Blackhall², K. Simpson³, C. Dive³, P. Huang⁴, S. Au¹

¹Imperial College London, Bioengineering, London, United Kingdom

²Christie Hospital, NHS Trust, Manchester, United Kingdom

³CRUK Manchester Institute, CRUK National Biomarker Centre, Manchester, United Kingdom

⁴Institute of Cancer Research, ICR, London, United Kingdom

Introduction

Circulating tumor cells (CTCs) and their clusters are the drivers of metastasis, but we have an incomplete understanding of how they interact with capillary beds. One open question is why are CTCs isolated downstream of capillary beds smaller than those isolated upstream of capillary beds? Is it possible that forces within capillaries may reduce the size of CTCs in the microvasculature?

Material and method

We designed 13 variants of microfluidic microchannel models that mimic the geometric variations present in human capillary bifurcations. These devices were then used to explore how small cell lung cancer patient CTCs, CTC-derived explant (CDX) cells and cancer cell lines of breast, pancreatic and ovarian cancer origins behaved within these constrictions under physiological conditions. We then used a fluorescent microscopy, scanning electron microscopy, transmission electron microscopy, proteomics, RNAseq, flow cytometry and microfluidic models of endothelial microvascular networks to characterise CTC transit and their products.

Result and discussion

We observed the shedding of 1-11 micron diameter nuclei-free fragments by all tested cells within microfluidic bifurcations. Shedding of these fragments dependent on the size of CTCs, diameter constrictions and presence of bifurcations. Importantly, shedding reduced cell sizes up to 61%, which facilitated the transit of CTCs through bifurcations. We then used published MISEV guidelines to demonstrate that shed fragments are a novel subclass of large extracellular vesicles (LEVs), "shearosomes", that require shear stress for their biogenesis and whose proteome was enriched for proteins associated with immune-related pathways. Shearosomes exhibited functions characteristic of previously identified EVs including a) cell-directed internalization by endothelial and immune cells, and b) intercellular communication abilities relevant to pre-metastatic niche formation and metastasis such as disruption of endothelial barrier integrity in 2D and microfluidic models of microvasculature, polarization of monocytes towards M2 tumor-promoting macrophages lineages.

Conclusion

These findings suggest that CTCs may routinely shed a new class of highly reactive large extracellular vesicle that drive key processes involved in the formation of pre-metastatic niches and cancer metastasis.

Cockle transmissible cancers characterized by horizontal transfers and instability of mitogenomes

A. Bruzos¹, S. Díaz², C. Détré³, J. Tubio⁴

¹Université de Caen Normandie, UFR des sciences, Caen, France

²Universidade de Aveiro, CESAM/DBIO, Aveiro, Portugal

³Office Français de la Biodiversité, UFR des sciences, Brest, France

⁴Universidade de Santiago de Compostela, Genetics Department, Santiago de Compostela, Spain

Introduction

Transmissible cancers, or contagious cancers, are a disease in which cancer cells are transmitted from one individual to another, establishing new tumors in the recipient host. Initially identified in dogs and Tasmanian devils, these cancers have also been found in at least ten bivalve species, including cockles (*Cerastoderma edule*). In bivalves, the disease affects their hemocytes and manifests as hemic neoplasia (HN), a leukemia-like condition where cancer cells spread through the host and the marine environment until they colonize new hosts.

Material and method

This study provides an evolutionary perspective of transmissible cancers in cockles through the genomic and transcriptomic analysis of 7,800 individuals.

Result and discussion

Our findings emphasize the role of mitochondrial genome evolution in these cancers, revealing multiple horizontal mitochondrial DNA (mtDNA) transfers and recurrent amplifications in the control region. Unlike nuclear genomes, mtDNA is compact, encoding essential genes for oxidative metabolism so it is highly conserved. In cockles, mtDNA is maternally inherited, as supported by our analysis of 481 healthy individuals. Phylogenetic analysis of mtDNA revealed nine distinct monophyletic cancer lineages, demonstrating no overlap with their matched-normal haplotypes or evidence of non-transmissible cancer. While these nine mitochondrial lineages were identified, only two lineages were observed in nuclear DNA consistently corresponding to two histological phenotypes that were observed. This suggests that mitochondrial diversity does not directly correlate with nuclear genomes and phenotypic variation. To resolve this complexity, we developed a mtDNA deconvolution method based on tumor purity and allele frequency. This approach confirmed the presence of nine mtDNA cancer lineages, indicating that mitochondria from transient hosts have been repeatedly captured, likely avoiding the extinction of these transmissible cancer cells. Further investigation of mtDNA sequencing revealed three independent amplifications spanning the control region of the D-loop in three independent lineages, absent in healthy cockles. These amplifications share a

conserved start motif and overlapping microhomology at their boundaries, indicative of errors in DNA break repair. While their evolutionary significance remains uncertain, they may reflect selfish mitochondrial selection or confer a selective advantage to cancer cells. Interestingly, similar D-loop amplifications have been observed in other transmissible cancers, such as those in soft-shell clams, and even in human cancers.

Conclusion

Our findings provide compelling evidence for the dynamic evolution of mtDNA in bivalve transmissible cancers, offering new insights into their survival strategies and the potential mechanisms by which they survive in natural populations.

Unveiling the role of migratory dendritic cells in liver cancer

C. Volponi^{1,2}, A. Gazzillo^{1,3}, C. Simini^{1,3}, A. Romanzi^{1,3}, E. Bonavita^{1,3}

¹*IRCCS Humanitas Clinical and Research Center, Cellular and Molecular Oncoimmunology Lab, Rozzano (MI), Italy*

²*Humanitas University, Biomedical Sciences, Pieve Emanuele (MI), Italy*

³*Biomedical Sciences, Pieve Emanuele (MI), Italy*

Introduction

The liver immune milieu balances immune activation against pathogens with tolerance toward microbiota and food-derived antigens. However, this inherent tolerogenicity can impair effective anti-tumor immunity. Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, with most patients ineligible for surgery and resistant to immunotherapy. A prerequisite for efficient anti-tumor immunity is antigen presentation to T cells. Conventional dendritic cells (cDCs), particularly mature/activated cDCs (mDCs), can migrate to lymph nodes, cross-present tumor antigens, and secrete immuno-stimulatory signals that orchestrate cytotoxic responses. However, the role of mDCs in HCC immunity remains poorly understood.

Material and method

To evaluate the proficiency of mDCs in antigen cross-presentation, we performed *in vitro* assays using bone marrow-derived dendritic cells loaded with tumor-derived material from OVA-expressing cells. We compared mDCs with other cDC subsets by assessing their ability to process and present tumor antigens to OT-I T cells. *In vivo*, we utilized a murine HCC line (Hep53.4) implanted subcutaneously (s.c.) to study mDC function in tumor growth and antigen trafficking to the draining lymph node. To further investigate the role of mDCs in HCC, we employed two gene-targeted mouse models: one enabling mDC tracking (mDC-RED) and another allowing their inducible depletion (mDC-DTR). Two-photon microscopy was used to examine mDC localization in liver tumors. Additionally, we established autochthonous HCC models induced either by carcinogen

exposure or genetic manipulation. The impact of different oncogenic drivers on the tumor immune landscape was analyzed using flow cytometry and scRNAseq.

Result and discussion

We observed that mDCs exhibit superior CD8⁺ T cell activation capacity compared to other cDC subsets *in vitro*. In the Hep53.4 s.c model, we demonstrated that migratory DCs are the only subset capable of trafficking tumor-derived material to the tumor-draining lymph node. In an orthotopic Hep53.4 model, we observed that while mDCs accumulate near the tumor, they are actively excluded from the tumor mass. Similarly, in chemically induced HCC, mDC abundance is reduced, yet they remain the primary source of immuno-stimulatory cytokines within the tumor microenvironment. In β-catenin-driven HCC, we observed a profound reduction in mDC interactions with other immune cells, along with their complete exclusion from the tumor mass.

Conclusion

Our findings highlight a potential role for mDCs in orchestrating effective anti-tumor immune responses. However, their abundance and function appear to be shaped by the tumor microenvironment. Ongoing studies are aimed at further dissecting the mechanisms that regulate cDC activation, migration, and antigen presentation in HCC.

EACR25-2072

Bulk and spatial B cell receptor repertoire analysis to characterize antibody maturation in relation to tertiary lymphoid structures and response to immunotherapy

G. Pupier¹, A. Bougoüin¹, C. Sun¹, Y. Vano¹, S. Sibérial¹, C. Sautès-Fridman¹, W. Fridman¹

¹*Inserm, Centre de Recherche des Cordeliers, Paris, France*

Introduction

Recent studies have described B cells and tertiary lymphoid structures (TLS) as biomarkers of response to immune checkpoint inhibitors (ICI), notably in clear cell renal cell carcinoma (ccRCC). B cells are activated into TLS leading to the generation of IgG- and IgA-producing plasma cells (PCs). An elevated IgG tumor cell coverage predicts response of ccRCC patients treated with ICI (Meylan et al, *Immunity*, 2022). We are now dissecting that intra-tumoral antibody response focusing on class-switch recombination (CSR) and the identification of antibodies associated with response to ICI.

Material and method

From the BioniKK cohort which includes 199 patients with metastatic ccRCC treated in majority with ICI (159), we profiled BCR repertoire for both heavy (IGH) and light chains from 95 pre-treatment frozen tumors as well as pre- and post-ICI blood samples from 30 patients. TLS in tumors were assessed by immunohistochemistry and TLS transcriptomic signatures. Spatial BCR repertoires were also analyzed from previously generated Visium spatial transcriptomics on 12 frozen ccRCC sections, and with the SpatialVDJ method (Engblom et al, *Science*, 2024) for 4 ccRCC tumors. This approach enabled the targeted and more comprehensive spatial profiling of

full-length BCR repertoires with an increasing resolution, notably for IGH.

Result and discussion

BCR reconstructed from bulk RNAseq allowed to identify hundreds of unique IGH present in multiple isotypes per tumor suggesting that CSR can occur in tumors. The main CSR events are from IgG isotypes to other IgG, suggesting switch from memory B cells but some CSR from IgM were also identified suggesting that naïve B cells could also switch within the tumors. The highest numbers of IGH with multiple isotypes were found in TLS containing tumors, especially within tumors with the highest TLS signature scores, strongly suggesting that CSR occurs in TLS. Untargeted spatial transcriptomics indicated that the same IGH is found on different isotypes inside and outside TLS areas. Using targeted BCR capture with SpatialVDJ, we profiled hundreds of unique IGH which are distributed over more than a thousand spots consistent with B cells or PC gene expression. Grouping closely related IGH in clones, we were able to find amplified clones with more than hundreds individual cells distributed over the tissue within and outside TLS areas in different isotypes supporting the role of TLS in CSR. Analysis of tumors revealed that certain IGH clonotypes are shared between several responding patients and that same IGH clonotypes can be found in the tumor and the blood of the same patient blood before and after ICI treatment.

Conclusion

Overall, our results strongly suggest the involvement of TLS in antibody selection, amplification and CSR described through fine BCR repertoire analysis with potential response to ICI. Identification of BCR repertoire in responding patients may help uncover novel therapeutic antibodies.

Cambridge, United Kingdom

⁸Faculty of Medicine, University of Helsinki, Helsinki, Finland

Introduction

Tumor-initiating mutations can occur years before cancer is diagnosed, offering an opportunity for early detection and prevention. In clear cell renal cell carcinoma (ccRCC), VHL is inactivated in 90% of cases, and PBRM1 mutations are found in 50%. Despite their role in carcinogenesis, the progression from VHL inactivation to cancer can take decades. This study uses a genetic mouse model with VHL/PBRM1 inactivation and single-cell sequencing to explore early ccRCC progression and identify potential intervention targets.

Material and method

We used a mouse model in which tamoxifen induces inactivation of Vhl and Pbrm1 in renal epithelial cells. This inactivation led to a spectrum of renal lesions, including tumours, appearing around 20 months post-treatment. Single-cell RNA-sequencing (scRNA-seq) and chromatin accessibility (scATAC-seq) were performed at multiple time points to explore transcriptional and chromatin changes.

Result and discussion

Using scRNA-seq, we identified a set of cells with VHL inactivation, primarily in Proximal Tubule (PT) S1 cells, possible origin of ccRCC. The transition to transitional states involved a wave of transcriptomic changes driven by transcription factors (TFs). scATAC-seq confirmed these TFs as key regulators of KO1-specific gene programs. Analysis of scRNA-seq data from an acute kidney injury (AKI) mouse model revealed similarities between early progression of Vhl/Pbrm1 null renal epithelial cells and AKI, with the same TFs activated. The key difference was that, unlike AKI, the TF expression in the mutant renal epithelium remained unresolved and continuously active. Further analysis of a large population-based dataset showed a strong association between AKI, CKD, and renal cancer, including ccRCC. Interestingly, some of these TFs are activated in normal mouse and human PT cells with age.

Conclusion

VHL and PBRM1 are the most commonly mutated tumor suppressors in ccRCC, and unlike other ccRCC driver genes, they are often clonally inactivated in human ccRCC. However, the majority of Vhl/Pbrm1 null cells in the mouse renal epithelium remain transcriptionally stable for months, with most mutant cells never progressing to tumor formation. The similarities and differences between the pre-tumor ccRCC and renal injury signatures suggest that ccRCC may arise from an improper response to kidney injury. This offers a perspective on cancer progression, possibly helping to explain the long latency between the genetic event and tumor formation, where intrinsic cellular responses to environmental insults, accumulating over time with aging, together with preceding genetic mutations, drive tumor development.

¹*Hebrew University of Jerusalem, Immunology, Jerusalem, Israel*

²*Hadassah Medical Center, Sharett Institute of Oncology, Jerusalem, Israel*

Introduction

RNA splicing generates isoform diversity that plays a critical role in T cell biology. However, the functional roles of many alternative splice isoforms remain unexplored. To bridge this gap, we constructed a splicing atlas for CD8 T-cells, uncovering a rich landscape of isoforms across distinct subsets. Building on these insights, we developed SpliceSeek, a CRISPR-based platform, to investigate the functional relevance of isoforms identified in the atlas. This study aims to uncover the relationship between splicing diversity and T-cell functionality and identify isoforms with therapeutic potential.

Material and method

CD8 T cells from healthy donors were activated in vitro and sequenced using single-cell short-read (Illumina) and long-read (PacBio) platforms to create a comprehensive expression and splicing atlas. Functional analysis was performed using SpliceSeek, a new developed CRISPR screen targeting splice sites of 150 immune receptor. Transduced T cells expressing the NY-ESO-1 TCR and SpliceSeek constructs were sorted based on IFNg production after co-culture with tumor cells, and functional isoforms were identified through sequencing.

Result and discussion

The splicing atlas revealed that isoform-based clustering mirrored expression-based clusters, demonstrating their complementary roles in defining T cell subsets. For example, in effector T cells (Teff), both clustering approaches enriched similar pathways, though splicing analysis identified distinct genes driving these pathways. Using SpliceSeek, we explored the functional impact of isoforms of immune receptors. LRRN3 emerged as a top candidate, significantly enhancing IFNg secretion, GZMb production, and tumor-killing capacity in-vitro and in-vivo. This isoform-specific effect highlights the ability of SpliceSeek to validate atlas-derived hypotheses and uncover therapeutic targets.

Conclusion

This study establishes a powerful pipeline connecting splicing atlas discovery with functional validation. The integration of splicing and expression data provides a comprehensive view of CD8 T-cell biology, and SpliceSeek successfully identifies isoforms like LRRN3 with significant therapeutic potential, paving the way for splicing-based cancer immunotherapies.

Introduction

T cells are essential in the anti-tumor immune response, with T cell-based therapies emerging as key strategies in cancer immunotherapy. While most studies focused on conventional CD4+ and CD8+ T cells, unconventional T cells (UTCs), such as invariant natural killer T cells (iNKT) and mucosal-associated invariant T cells (MAIT), are gaining recognition for their pivotal role in tumor immunity. Recently, our group identified a subset of UTCs, double-negative CD4⁻CD8⁻ TCRαβ⁺ T cells (DNTαβ), as key players of immune resistance in murine sarcoma (Ponzetta A, Cell. 2019). These cells express a TCRαβ, lack CD4 and CD8 expression and are not recognized by antigen-loaded CD1d and MR1 tetramers, distinguishing them from iNKT and MAIT. However, the biology and functional role of DNTαβ in steady-state and cancer remain poorly understood.

Material and method

Transcriptomic analyses and multiparametric flow cytometry were used to characterize DNTαβ in tissues. We assessed the capacity to proliferate, produce cytokines, exert cytotoxic activity against tumor cells and modulate immune response in vitro.

Result and discussion

DNTαβ were present across multiple tissues of healthy mice at different ages, with the spleen serving as their main reservoir. Unlike most UTCs, DNTαβ express a polyclonal TCRαβ repertoire. Remarkably, their development is independent of both classical and non-classical MHC molecules, as evidenced by their persistence in Cd1d, Mr1, β2m, and MhcII deficient mice. Transcriptomic analysis further revealed that DNTαβ possess a unique gene signature associated with T cell activation. Additionally, they express innate-like molecules and show elevated levels of IL-1 family

receptors (IL1R1, IL18R1). Consistently, DNT $\alpha\beta$ exhibit enhanced ability to proliferate and produce effector molecules (IFN- γ , GRZB) upon cytokine stimulation only compared to conventional T cells. In particular, IL-18 is required for the effective activation of DNT $\alpha\beta$ to produce IFN- γ , and their polarization is altered in IL-18-/- mice. DNT $\alpha\beta$ were found in the immune infiltrates of different murine cancer models. Interestingly, conditioned medium from cytokine-stimulated DNT $\alpha\beta$ induced macrophages polarization towards an anti-tumor M1-like phenotype. Additionally, DNT $\alpha\beta$ showed cytotoxic activity against cancer cells in vitro. Finally, a population of DNT $\alpha\beta$ with similar phenotypic and functional characteristics to their murine counterparts was found in the peripheral blood of healthy donors and in human tumors. Notably, analysis of The Cancer Genome Atlas (TCGA) database revealed that, in sarcoma patients, a DNT $\alpha\beta$ -associated gene signature correlated with a type 1 immune response and favorable prognosis.

Conclusion

We uncovered the biology and functional properties of a previously understudied population of UTC, paving the way for their use as therapeutic targets.

Introduction

Ovarian cancer (OC) remains a major clinical challenge due to its high recurrence rates and resistance to standard therapies. High-grade serous ovarian cancer (HGSOC), the most common and aggressive OC subtype, often presents with tumor-infiltrating lymphocytes (TILs), yet immune checkpoint blockade (ICB) therapies have shown limited efficacy. Our studies aims to dissect the spatiotemporal evolution of the OC tumor micro-environment (TME), reprogram T cell networks, and develop next-generation immunotherapies to restore anti-tumor immunity. Our research has uncovered critical T cell networks that regulate immune responses in OC, revealing that tumor evolution and chemotherapy-induced microenvironmental shifts contribute to TIL dysfunction and immune evasion.

Material and method

We integrate high-resolution spatial proteomics, single-cell transcriptomics, and computational modeling to map TIL dynamics across primary, recurrent, and treatment-

resistant OC. Preclinical models, including syngeneic BRCA1-mutant and wild-type mouse models of OC recurrence, are employed to investigate tumor-intrinsic and TME-driven mechanisms of immune suppression during OC relapse.

Result and discussion

We utilized digital pathology multiplex immunofluorescence (mIF) to classify 697 ovarian cancer (OC) specimens from five independent cohorts, offering the most extensive CD8+ T cell-based immune profiling to date. Our predictive algorithm identified distinct tumor immune phenotypes in OC – i.e. purely inflamed, mixed inflamed, excluded, and desert – based on TIL infiltration and spatial organization, which correlate with HRD status and predict therapeutic outcomes. We observed significant immune and molecular heterogeneity between these tumor immune phenotypes and their dynamics during disease recurrence. Inflamed HRD tumors, maintained T cell-myeloid niches post-chemotherapy. In preclinical models, this was associated with restoration of genomic rearrangements. Recurrent murine HRD tumors upregulated the immunosuppressive PGE2-EP2/4 pathway and targeting of COX-driven PGE2 production during chemotherapy significantly prolonged relapse and survival in preclinical mouse models, identifying a key vulnerability for the recurrence of human HRD OCs. In contrast, homologous recombination repair proficient (HRP) OC tumors evolved into T-cell excluded or desert phenotypes, characterized by malignant cells over-expressing Nduf4L2/Galectins and Trem2/ApoE over-active tumor-associated macrophages. Our data suggest that therapeutically targeting of TREM2 overexpressing TAMs may improve anti-tumor immune responses and delay recurrence after first-line CTX in HRP OC.

Conclusion

Our work highlights novel immune biomarkers and therapeutic targets that can be exploited to retune anti-tumor T cell responses, paving the way for clinically actionable strategies in recurrent OC and other immunoresistant malignancies.

Introduction

Recent studies have highlighted the importance of non-genetic adaptive mechanisms through which tumors acquire resistance by rewiring transcriptional programs. To investigate the emergence of adaptive resistance in breast cancer, we employed a patient-oriented approach, analyzing drug-induced transcriptional changes relative to the dysregulated state of the primary tumor.

Material and method

We collected matched triplets of archived tumor biopsies from breast cancer patients who underwent neo-adjuvant chemotherapy, including pre-treatment, post-treatment and adjacent normal epithelium samples. Whole-transcriptome mRNA sequencing was performed for each sample. A longitudinal pattern analysis algorithm was developed to track dynamic gene expression remodeling at the individual patient level. Enrichment analysis was used to identify rewired resistant pathways. Finally, we constructed personalized chemoresistome maps to illustrate patient-specific resistance dynamics.

Result and discussion

Personalized chemoresistome maps disclosed molecular pathways that adapt to resist chemotherapy while exposing persistent vulnerabilities in each patient. The patient-specific dynamics of gene expression modulations during chemotherapy depicted key principles underlying adaptive resistance:

1. Primed adaptive resistance state: Resistance-associated genes are already dysregulated in the primary tumors.
2. Convergence to confined resistance states: Despite the involvement of multiple resistance-related genes, they converge into distinct dysregulated modules.
3. Drug-specificity: some of these dysregulated modules are directly linked to the drug mechanism of action. Our findings suggest that to withstand the cytotoxic effects of treatment, tumor cells either maintain their "primed" dysregulated state or intensify it, specifically bypassing the drug's mechanism of action.

Conclusion

Understanding the dynamics of phenotypic alterations underlying adaptive resistance may provide crucial insights into critical stages of treatment response. These insights could pave the way for the development of personalized therapeutic strategies aimed at preventing or overcoming resistance.

⁴*CIMA-University of Navarra, Bioinformatics Platform, Spain*

⁵*VHIO, Preclinical and Translational Research Program, Madrid, Spain*

Introduction

The generation of direct KRAS inhibitors (KRASi) represented a milestone in lung cancer therapy offering targeted treatment to vast patient cohorts with KRAS mutations. Nevertheless, escape mechanisms based on tumour compensatory activation, genetic evolution, or phenotypic switch limit their antitumor efficacy and restrict survival benefit. Thus, it is of paramount importance to uncover drug combinations which could maximize the antitumor effect of KRASi.

Material and method

We interrogated bulk and single cell transcriptome of human and mouse mutant KRAS (mtKRAS) lung cancer cell lines exposed to genetic and pharmacological KRAS inhibition, and used a reporter system to assess DNA repair functionality. Combination therapies consisting of KRASi and PARP inhibitors (PARPi) were tested in vitro, as well as in cell line-derived xenograft (CDX), allografts (CDA) or PDX in vivo. Integration of CRISPR screening data of genes sensitizing to PARPi with the Connectivity Map was employed to nominate KRASi-induced transcriptional nodes regulating genome instability which were functionally validated. In vitro and in vivo models of pancreatic and colorectal cancer were deployed to test the efficacy of KRASi + PARPi in additional KRAS-driven cancers.

Result and discussion

We report a commonly downregulated gene signature upon KRAS blockade related to DNA damage integrity, and show compromised homologous recombination (HR) functionality. Single cell analysis shows that tumoral populations able to tolerate pharmacological KRAS inhibition abrogate key elements of HR. This early adaptive response to KRASi is vulnerable to therapeutic attack with PARPi, eliciting a lethality in numerous lung cancer models reflected as delay of the onset of resistance in vitro and potent tumor regressions in vivo. At the cellular level, HR depletion exacerbates DNA damage in the context of PARPi which may underscore the synthetic lethal phenotype. Mechanistically, we unveil that KRASi-mediated loss of genome stability is via the transcription factor FOSL1, a known key effector of KRAS signalling. In vitro, FOSL1 levels correlate to PARPi efficacy, and FOSL1 genetic abrogation depletes vast elements of genomic integrity in addition to BRCA2 levels to sensitize to PARPi. mtKRAS lung cancer patients with high FOSL1 levels display poor prognosis when treated with DNA damaging agents. Lastly, we found that these observations span other mtKRAS cancers such as those of the pancreas and colorectum.

Conclusion

Our data provide nominate a mechanistic driven combination for hard-to-treat mtKRAS cancers consisting of KRASi and PARPi which defines a path for clinical translatability. In addition, we provide molecular and cellular data positioning the transcription factor FOSL1 as a key player in tumoral genome integrity and response to DNA damaging therapies.

Targeting senescent macrophages inhibits metastatic dissemination in adrenocortical cancer

D. Garcia-Garcia¹, A. Voisin¹, J. Wilmouth¹, L. Brugiere¹, R. Guiton¹, A. Martinez¹, P. Val¹

¹Institute GReD, CNRS UMR6293, Clermont-Ferrand, France

Introduction

Cellular senescence plays a dual role in cancer, acting as both a barrier to tumorigenesis and a potential driver of tumor progression. Adrenocortical carcinoma (ACC) is a highly aggressive malignancy originating from steroidogenic cells of the adrenal cortex, with limited treatment options and a median overall survival of less than 15 months. The most frequent genetic alteration in ACC is the inactivation of ZNRF3, a tumor suppressor and inhibitor of WNT signaling. Previously, we demonstrated that male mice with conditional inactivation of Znrf3 in adrenocortical cells are protected from tumor development due to testosterone-dependent induction of senescence, leading to immune-mediated clearance of preneoplastic lesions. Interestingly, the most aggressive ACCs in patients frequently exhibit ZNRF3 inactivation combined with alterations in the P53/RB/CDKN1B pathway, suggesting a potential link between senescence dysregulation and tumor progression. To investigate this hypothesis, we developed a mouse model with conditional genetic ablation of both Znrf3 and Trp53 in the adrenal cortex (Znrf3/Trp53 dKO).

Material and method

Primary tumors and lung metastases from Znrf3/Trp53 dKO mice [1] were analyzed using immunohistochemistry, spectral flow cytometry, bulk RNA sequencing, single-cell sequencing, and spatial transcriptomics.

Result and discussion

Combined Znrf3 and Trp53 inactivation circumvented the initial senescence-mediated tumor clearance, leading to the development of highly aggressive, metastatic, and lethal ACC in both male and female mice within six months. Characterization of the immune micro-environment revealed that tumor progression was associated with a decline in T cell and NK cell-mediated antitumor immunity, alongside an accumulation of immunosuppressive macrophages in the most aggressive primary tumors. Single-cell sequencing of CD45⁺ immune cells showed that immunosuppressive macrophages displayed senescent characteristics, a finding confirmed by SA-βGal and p16 immunostaining. Interestingly, spatial transcriptomic analysis of lungs also revealed the presence of senescent immunosuppressive macrophages associated with glucocorticoid-producing metastases. This suggested that senescent macrophages may be involved in metastatic dissemination and homing in ACC. Supporting this hypothesis, treatment with the senolytic ABT-737 significantly reduced primary tumor growth and strongly inhibited metastatic spread.

Conclusion

These findings indicate that senescent immunosuppressive macrophages play a key role in metastatic dissemination in ACC. Their targeted clearance using senolytic therapy presents a promising therapeutic strategy for combating metastatic progression in this aggressive malignancy.

⁵Charité - Universitätsmedizin, Department of Hematology, Oncology and Tumor Immunology, Berlin, Germany

Introduction

Acute myeloid leukemia (AML) is a heterogeneous blood cancer typically treated with intensive chemotherapy; yet early treatment failure remains a major challenge. Therapy-induced senescence (TIS) is a stress response that can elicit immune-mediated responses. However, its functional role in AML eradication and immune surveillance by the adaptive immune system remains ill-defined. In this study, we investigated how senescent AML blasts interact with the immune system to uncover factors influencing AML responses to chemotherapy and immunotherapy.

Material and method

We exploited ex-vivo cultures of primary AML primary samples or cell lines undergoing senescence upon chemotherapy treatment. Multiparametric flow cytometry analysis integrated with quantitative imaging was used to measure senescent markers and human leukocyte antigen (HLA) expression in a cohort of primary AML samples at diagnosis and upon ex-vivo therapy. The mixed lymphocyte reaction assay was performed to evaluate T cell activation. Additionally, in vivo experiments using patient-derived xenografts (PDX) models were conducted to further validate the immunogenic effects of TIS. Western blot, nuclear proteomics and CUT&Tag analysis were exploited for assessing histone modifications associated with transcriptional activation or repression in senescence high and senescence low patients.

Result and discussion

Our results show that TIS boosts AML blast immunogenicity by upregulating senescence, interferon and HLA

genes, along with presenting senescence-associated self-peptides presentation. This induces an antigen-presenting cell (APC)-like phenotype in senescent leukemic blasts, enhancing the activation of autologous CD4+ and CD8+ T cells and their capacity to recognize AML cells. Of note, these findings were also confirmed in PDX models. Additionally, we found that TIS-driven immunogenicity synergizes with immune checkpoint blockade (ICB) therapies *in vivo*. Importantly, we identified the Polycomb Repressor Complex 2 (PRC2) as a key regulator of this process, with its inhibition restoring HLA expression and T cell activation in non-senescent AML blasts. These findings highlight a potent senescence-driven immune mechanism with potential to reduce AML relapse by augmenting anti-leukemic immune responses.

Conclusion

Our findings uncover a previously unrecognized role of therapy-induced senescence in enhancing the immunogenicity of AML blasts by promoting antigen presentation and T cell activation. By identifying loss of PRC2 activity as a key regulator of this process, we provide new insights into how senescence can be leveraged to boost anti-leukemic immune responses. Targeting the senescence pathway and its regulatory mechanisms could pave the way for novel senescence-based immunotherapies aimed at preventing AML relapse and improving patient outcomes.

Introduction

Immune checkpoint inhibitor-resistant advanced non-small cell lung cancer (NSCLC) is characterised by limited effective treatment options. There is an unmet need to improve outcomes for patients with this condition. Oncolytic viruses represent an attractive treatment approach due to their dual activity in inducing tumour cell lysis directly and augmenting anti-tumour immunity.

Material and method

Here, we present the safety, efficacy and translational findings from a phase I/II single-arm trial utilising CVA21 (CAVATAK®), an oncolytic coxsackie virus, in combination with pembrolizumab in patients with advanced pre-treated NSCLC. We applied whole genome sequencing and spatial proteomics with multiplex-ion beam imaging in pre- and post-treatment samples to comprehensively characterise the response to treatment.

Result and discussion

Ten patients received intravenous CVA21 and pembrolizumab, eight of whom had prior treatment with anti PD-(L)1 immune checkpoint inhibitor (ICI) therapy. Combination CVA21/pembrolizumab therapy was well tolerated with no serious treatment-related adverse events. Striking partial responses were seen in two patients with prior anti-PD-1 resistance. The clinical benefit rate was 80%. High baseline tumour mutational burden and PDL-1 expression was observed in patients with better response to treatment. Interestingly, an increase in antigen presentation and CD8 T cell infiltration was observed on treatment compared with baseline in patients with better progression-free survival, demonstrating the potential of oncolytic virus to modulate the immunogenicity of tumour cells and remodelling the tumour microenvironment.

Conclusion

The combination of CVA21 and pembrolizumab is safe and shows promising efficacy in ICI pre-treated patients with advanced NSCLC. Our translational multi-omic analysis provides insights that may enhance patient selection for future trials investigating novel immunotherapeutic strategies.

Translational control shapes Treg cell fate in the tumor microenvironment

S. Oliveto¹, F. Ivan¹, P. Ritter¹, S. Biffo¹

¹INGM, Milan, Italy

Introduction

Cancer immunotherapy has revolutionized oncology, yet only a fraction of patients respond. Our previous work revealed that T cells rapidly deploy translational machinery during activation within the tumor microenvironment, raising questions about how translational regulation affects T cell trajectories in tumors. Regulatory T cells (Tregs) – the master

orchestrators of immune suppression – represent a critical barrier to effective anti-tumor immunity. Despite their crucial role, the translational landscape shaping Treg function within tumors remains largely unexplored.

Material and method

We performed multifocal analysis of tumor infiltrating lymphocytes (TILs) translatomes in pleural mesothelioma (PM) and lung cancer (NSCLC). We developed CITePuro-seq technology to simultaneously capture, for the first time, single-cell translation and gene expression in human lymphocytes. Single-cell metabolic activity was analyzed using a microfluidic system with pH-sensitive fluorescence.

Result and discussion

Our discovery reveals a striking translational divergence in TILs across tumor types:

1. CD4+ T cells exhibit dramatically higher translation rates in mesothelioma compared to lung cancer, with actively translating Tregs predominating in PM,
 2. translation is not uniformly active in the tumor and
 3. specific genes are controlled at the translational level.
- Transcriptomic analysis revealed significant heterogeneity in Treg populations between PM and NSCLC. Moreover PM-associated Tregs exhibited a distinct signature enriched for translational machinery. Patient-specific Treg profiles revealed two clusters with divergent signatures. Using CITePuro-seq, we associated single-cell RNA sequencing with direct measurement of translational activity. The super-imposition of the the translational activity of CD4+ Tregs with their transcriptional profile leads to cluster highly suppressive cells and to define known and novel subtypes of Tregs by differential translation. Remarkably, our *in vitro* translational signature manifested *in vivo* in PM tumors, with tumor hypoxia emerging as a critical driver of Treg translational reprogramming and metabolic adaptation. Most surprisingly, Tregs with different translation levels exhibited functional versatility beyond immuno-suppression, revealing an unexpected plasticity.

Conclusion

Our findings establish translation as the hidden regulator shaping T cell fate in the tumor microenvironment. The differences in translational potential across TILs reveal how tumor-specific factors reprogram cellular function independently of transcription. This demonstrates why purely transcription-based analyses can be misleading. Our work identifies translational control as a previously unrecognized checkpoint in TIL programming, suggesting a promising avenue for enhancing immunotherapy.

Symposium: New Drugs on the Horizon

EACR25-0376 Inhibition of WEE1 kinase activity to overcome secondary resistance to targeted therapies in colorectal cancer

K. Buzo¹, L. Bizzozero², A. Opattova², B. Hernandez Suarez¹, C. Nisticò¹, G. De Lazzari¹, G. Grasso³, E. Mariella³, A. Bardelli⁴, S. Arena¹

¹*University of Torino and Candiolo Cancer Institute, FPO - IRCCS, Department of Oncology and Laboratory of Translational Cancer Genetics, Candiolo, Italy*

²*Candiolo Cancer Institute, FPO - IRCCS, Laboratory of Translational Cancer Genetics, Candiolo, Italy*

³*University of Torino, Department of Oncology, Torino, Italy*

⁴*University of Torino and IFOM-ETS, Department of Oncology, Torino, Italy*

Introduction

Molecular therapies targeting the EGFR/MAPK signaling pathway have markedly improved treatment outcomes for colorectal cancer (CRC). However, the emergence of secondary resistance – whether through pre-existing factors or adaptive mechanisms – remains a major challenge in achieving long-term therapeutic success. The DNA damage response (DDR) plays a pivotal role in enabling cancer cells to cope with therapy-induced genotoxic stress. In CRC, dysregulation of the DDR pathways contributes to the survival of tumor cells despite DNA damage, suggesting DDR as a potential therapeutic target in the context of secondary resistance.

Material and method

We generated a series of models with acquired resistance to anti-EGFR based targeted therapies, referred to as the ARes platform. To assess the impact of secondary resistance on cancer cells' dependence on DDR pathways for survival, we performed a drug screening, by exposing parental and resistant models to a range of DDR inhibitors (DDRi). *In vivo* validation of these findings was performed using xenograft mouse models.

Mechanistic studies were conducted to evaluate DNA damage levels, repair capacity, cell cycle dynamics, and replication stress in selected cell pairs. These studies employed a range of techniques, including western blotting, comet assay, immunofluorescence for foci analysis, cytofluorimetry, and fiber assay, to provide comprehensive insights into WEE1i efficacy.

Result and discussion

Pharmacological screening of the ARes platform with several DDRi revealed WEE1 as the most promising therapeutic target. *In vivo* experiments using xenograft models demonstrated that CRCs with acquired resistance to anti-EGFR therapies exhibited sustained or even enhanced sensitivity to WEE1i, consistent with *in vitro* observations. Mechanistic investigations showed that resistant cells maintain constitutive activation of the MAPK pathway and present heightened basal levels of DNA damage. In the same models, elevated RAD51 expression mediates tolerance to DNA damage and replication stress. However, we found that WEE1i treatment accelerates G2/M entry and disrupts RAD51 activity, leading to higher DNA damage accumulation and consequent cell death. Remarkably, these effects were observed even at sublethal concentrations of WEE1i, suggesting potential for synergistic strategies when combined with conventional chemotherapeutic agents.

Conclusion

Our results highlight the therapeutic potential of WEE1 inhibition in CRC patients who have developed acquired resistance to EGFR-targeted therapies. These findings provide preclinical evidence for future clinical investigations into the use of WEE1 inhibitors as part of combination therapies to overcome secondary resistance in CRC.

EACR25-0553

Reversing Acidic Immune Suppression in Cancer with PTT-4256, A First-In-Class Small Molecule Inhibitor of GPR65

A. Corbin¹, B. Cipriani¹, D. Miller¹, A. Naylor¹, T. McCarthy¹, S. Hughes¹, P. Higham¹

¹*Pathios Therapeutics Limited, Pathios, Abingdon, UK*

Introduction

Extracellular acidification is a recognised driver of tumour immunosuppression. Pathios identified GPR65 as the primary pH-sensing GPCR in human immune cells. Activation of GPR65 suppresses immune effector homing and function and induces a pro-tumour phenotype in macrophages: downregulating interferon and immunostimulatory genes and upregulating wound repair and remodelling factors. Consequently, acid sensing by GPR65 explains tumour resistance to current immunotherapies. Validating this target in immuno-oncology, cancer patients homozygous for the hypomorphic GPR65 variant (I231L) exhibit profoundly improved survival compared to patients with other genotypes.

Material and method

Pathios have developed PTT-4256, a first-in-class small molecule inhibitor of GPR65. The in vitro efficacy of PTT-4256 under low pH conditions was determined by cAMP screening, gene expression and cytokine release profiling of primary immune populations. Anti-tumour activity was assessed using the MC38 and B16.F10 syngeneic mouse models, whilst immunomodulatory effects in MC38 tumour-infiltrating leukocytes were profiled by targeted RNAseq. Notably, PTT-4256 is markedly more potent at human GPR65 versus the mouse receptor. To determine its full potential in patients and to develop an accurate prediction of efficacious human exposure, we employed a range of approaches including molecular pharmacology, site-directed mutagenesis, PK/PD modelling, and genetically engineered mice.

Result and discussion

PTT-4256 fully counteracts the low GPR65-dependent pH-driven immunosuppressive programme in immune cells. Molecular modelling and site-directed mutagenesis identified three key residues that explained the 1000-fold difference in potency of PTT-4256 between mouse and human GPR65. Incorporating these residues in a transgenic knock-in mouse restored human pharmacology in vitro and provided an important translational platform. PTT-4256 displays an excellent oral PK profile across species and elicits monotherapy efficacy in MC38 and B16.F10 mouse models that exceeds anti-PD1 control alongside rapid upregulation of anti-tumour NK and T cell genes.

Conclusion

GPR65 is a key checkpoint on tumour-infiltrating immune cells that links the chronically acidic tumour microenvironment to tumour-promoting immuno-

suppression. Pathios' oral small molecule GPR65 inhibitor, PTT-4256, targets fundamental biology co-opted by all solid tumours with a mechanism that is orthogonal to established anti-tumour therapies including anti-PD1. An ongoing First in Human Phase 1/2 clinical trial (RAISIC-1) to establish safety and PK started in Q4 '24.

EACR25-0457

Dietary Histidine controls intestinal stem cell activity, providing a potential protective role against colorectal cancer

C. Biehler¹, V. Hietakangas¹

¹*University of Helsinki, Biotechnology institute, Helsinki, Finland*

Introduction

Intestinal stem cells (ISCs) are essential for maintaining tissue homeostasis by regulating the continuous intestinal turnover. They achieve this balance through self-renewal and differentiation into specialized cells in response to environmental cues such as nutrient availability.

Dysregulation of these processes is a hallmark of colorectal cancer (CRC). However, the mechanisms by which nutrient signaling modulates ISC activity during the early stages of CRC remain poorly understood

Material and method

To decipher which and how nutrients affect oncogenic ISC, we took advantage of the *Drosophila* midgut and its fully defined diet to screen for single amino acid vulnerability of wild-type ISCs and those bearing common CRC-associated mutations (Apc-Ras). Based on this screen, we further focused on one amino acid that stood out with a putative role in regulating ISC activity. Combining advanced genetic and bioinformatic tools, we dissected its metabolic pathway and validated our findings in a primary mouse crypt-derived intestinal organoid model.

Result and discussion

Our data from the single amino acid-deficient dietary screen highlighted overgrowth of Apc-Ras ISCs fed on Histidine-deprived diet compared to the normal one, suggesting that dietary Histidine exerts a protective effect against Apc-Ras-driven tumorigenesis. In the wild-type *drosophila* intestine, we demonstrate that dietary Histidine plays a critical role in regulating ISC activity by promoting their differentiation through an unexpected downstream metabolite. Mechanistic analyses indicate that this metabolite operates via two distinct functions: one activating ISC asymmetric division, and the second, mTOR-dependent, promoting enterocyte differentiation. Moreover, we found that dietary supplementation of this metabolite was reducing stemness of Apc KD ISCs and triggering their differentiation, providing a mechanistic basis for Histidine's protective role. Finally, experiments using primary crypt-derived intestinal organoids confirmed that this metabolite is sufficient to enhance

ISC differentiation, demonstrating the conservation of the mechanism in mammals.

Conclusion

These findings indicate that Histidine metabolism is essential for ISC maintaining homeostasis by triggering enterocyte lineage differentiation program. Because enhanced stemness is a hallmark of early colorectal cancer, dietary histidine supplementation could represent a novel strategy to modulate ISC behavior and counteract early tumorigenesis.

EACR25-0647

Pancreatic Cancer Initiation: Wnt Signalling and Cell Dormancy Enable Kras Mutant Cell Survival

B. Salvador-Barbero¹, M. Alatsatianos¹, J. Morton², O. Sansom², C. Hogan¹

¹*Cardiff University, ECSCRI, Cardiff, United Kingdom*

²*CRUK Scotland Institute, Glasgow, United Kingdom*

Introduction

How does cancer start if epithelial tissues possess robust defence mechanisms to eliminate aberrant or genetically mutant cells? The way cancer-causing mutations override tissue defences remain poorly understood. We have shown that the adult pancreas protects against early cancer by actively expelling genetically mutated cells. Cell expulsion requires cell-cell interactions between mutant cells and normal neighbours and dynamic remodelling of E-cadherin dependent cell-cell adhesions. Pancreatic cancer starts with cells carrying oncogenic KRAS mutations. This suggests some KRAS mutant cells must override cell elimination mechanisms to survive in tissues. Here we aim to understand how some Kras mutant cells survive tissue homeostasis mechanisms.

Material and method

We employed a mouse model of sporadic pancreatic cancer to explore the early stages of cancer initiation. Oncogenic mutations in Kras gene were induced in low numbers of adult pancreatic epithelial cells, which were tracked using a fluorescent reporter. Gene signatures of the surviving mutant cell populations were identified through bulk RNA sequencing. Key molecular pathways were validated in the murine pancreas via immuno-fluorescence and functionally tested through in vitro epithelial co-culture systems and in vivo inhibitor studies.

Result and discussion

We showed that when KrasG12D mutations are expressed only in few cells in the adult pancreas, most of them are eliminated. However, a small population of Kras mutant cells are not eliminated and instead remain in the tissue, eventually progressing into pre-malignant lesions. Transcriptomic analysis of retained cells identified Wnt5a signalling, cell dormancy and stemness as key features of surviving KrasG12D cells in vivo. We functionally validated these results in vitro showing that Wnt5a, but not Wnt3a, inhibits cell elimination of RasV12 cells by promoting stable E-cadherin based cell-cell adhesions at RasV12: normal cell-cell boundaries. RasV12 cells arrested in the cell cycle are not eliminated and this is rescued when Wnt signalling is inhibited. In vivo, we confirmed that cell-cell adhesions were stabilised between retained KrasG12D cells and normal

neighbours with an increase in Wnt signalling, E-cadherin and β-catenin at normal-mutant cell-cell contacts. Importantly, inhibition of Wnt signalling in mice increased KrasG12D cell elimination, showing that active Wnt signalling is a general mechanism required to promote mutant cell survival in vivo. Finally, we found expression of Wnt5a increased in human pancreatic tumours and pre-malignant lesions.

Conclusion

RAS mutant cells activate Wnt5a, stemness signatures and a dormant cell state to avoid cell elimination and survive in the adult pancreas. These findings shed light into how cell-cell interactions can activate important signatures for cancer initiation and progression at very early stages.

Symposium: Tumour Innervation

Medullary sinus macrophages limit cancer therapy efficacy by an efferocytosis-induced IL-33/ST2 axis in the tumor-draining lymph node

S. Lamorte¹, R. Quevedo¹, L. Neufeld¹, R. Jin¹, K. Liu¹, D. Brooks¹, T. Mak¹, Z. Saeed², S. Girardin¹, T. McGaha¹

¹*University of Toronto, Immunology, Toronto, Canada*

²*University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada*

Introduction

Cell death is a fundamental aspect of tissue homeostasis that can expose potentially immunogenic cell components that must be removed to prevent inflammatory autoimmunity. We have shown immune suppression in response to apoptotic cell phagocytosis (a process called efferocytosis) is dependent on tissue-resident macrophages. Indeed, if we disrupt macrophage regulatory responses post-efferocytosis, the same apoptotic cells induce inflammation suggesting macrophage responses to dying cells are a key determinant of tolerance. We predict that resident macrophages lining the lymphatic sinus inside the lymph nodes are responsible for tolerance against tumor apoptotic cells.

Material and method

Melanoma tumor-bearing mice were treated with chemotherapy or targeted therapy to induce tumor cell death. Both tumor and the tumor-draining lymph node (TDLN) were analyzed at different time points after treatment. In some experiments, we used a novel mouse model, generated in our laboratory, where IL33 was specifically deleted in a subpopulation of macrophages of TDLN, called medullary sinus macrophage (MSM) (MSM-IL33ko).

Result and discussion

Using our mouse melanoma model, we observed that after either chemotherapy or targeted therapy MSM avidly phagocytosed dying tumor cells and acquired a tolerogenic phenotype. RNA sequencing analysis revealed MSM rapidly and exclusively induced expression of the alarmin IL-33 as opposed to other MF

or dendritic cell populations in the TDLN. Importantly, genetic deletion of IL33 (MSM-IL33ko) or blockade of the IL-33 receptor ST2 with IgG, transformed responses to both chemotherapy or targeted therapy with prolonged, enhanced tumor control and reduced cancer reoccurrence. Functionally, MSM-derived IL-33 triggered accumulation and activation of regulatory T cells expressing ST2 in the TDLN which then migrated to the tumor limiting intratumoral CD8+ T cell function.

Conclusion

Our data revealed a previously undescribed tumor cell death-induced mechanism limiting anti-cancer immunity and therapy efficacy. The findings from this project have resulted in a manuscript that was recently accepted by *Cancer Cell* journal.

Spatially Resolved Analysis of Cancer-Infiltrated Nerves Identifies DRAKIN as a Marker of Injury Response with Tumor-Suppressive Potential

A. Ozga¹, K. Bach¹, D. Eletto¹, M. Repson¹, L. Nechyporenko¹, D. Dominguez¹, D. Lenggenhager², J. Michler¹, A. Moor¹

¹ETH, DBSSE, Basel, Switzerland

²USZ, Zurich, Switzerland

Introduction

Perineural invasion (PNI), the spread of cancer cells along nerves, is a hallmark of pancreatic ductal adenocarcinoma (PDAC) and is associated with poor prognosis, local recurrence, and metastasis. However, the biological processes underlying these outcomes remain unclear.

Material and method

To address this gap, we used spatial transcriptomics (10x Genomics Visium) to profile cancer-invaded and non-invaded nerves from three PDAC patients *in situ*.

Result and discussion

Transcriptomic analysis, combined with multiplexed immunofluorescence, showed that cancer infiltration induces nerve damage, leading to changes in the nerve secretome. Among the upregulated factors, we identified DRAKIN, an axon-guidance protein involved in neural development but with a largely unexplored role in cancer. Functional assays, including *in vitro* proliferation studies and CRISPR-based screens, demonstrated that recombinant DRAKIN induces cancer cell death.

Conclusion

These findings provide new insights into the molecular changes in cancer-infiltrated nerves and highlight DRAKIN as a nerve-derived factor with anti-tumor properties.

⁴The Institute of Cancer Research, Translational Immunotherapy, Breast Cancer Immunology, London, United Kingdom

⁵The Institute of Cancer Research, Integrated Pathology, London, United Kingdom

Introduction

Cancer evolution is driven by selective pressures favouring clones that evade immune surveillance and adapt to their microenvironment. Radiotherapy, a standard treatment for breast cancer, reduces recurrence risk by 10–25%, depending on the stage and molecular subtype. While its success is partly attributed to immune activation, the underlying mechanisms remain unclear. We hypothesise that radiotherapy fuels immune response through DNA damage and neoantigens release, inducing the transition of immune-cold to immune-hot tumours. However, there is a lack of computational tools to identify immunoediting and stratify patients for improved outcomes. Here, we analysed data from 24 breast cancer patients enrolled in two clinical trials testing neoadjuvant radiotherapy. Genomic and transcriptomic data at multiple time points (diagnosis, pre-/post-radiotherapy, and at surgery) were used to quantify immunoediting and correlate it with clinical response. Our computational strategy enables the study of tumour-immune co-evolution across different therapeutic regimens and mutational landscapes.

Material and method

FFPE tissue samples from primary breast tumours and draining lymph nodes were subjected to WES, WTS, TCR-Seq, and multiplex IF. Standard bioinformatic pipelines were used for somatic variant calling (Sarek), transcriptome analysis (rnaseq) and HLA genotyping (hlatyping). Downstream genomics analysis included “dndscv” to measure patterns of selection, “mutSignatures” for mutational signatures, “TcellExTRECT” for T cell infiltration, and “pVACseq” for neoantigen calling. Our in-house tools, SOPRANO and NegSelect, quantified patient-specific immunoediting in samples with low TMB. Given this context, we aim to develop an integrated pipeline for immune multi-omics analysis.

Result and discussion

Preliminary genomic analysis of primary breast tumours revealed that mutations in PIK3CA, ERCC2, SPEN and HLA-C were positively selected in one of the clinical trials. Moreover, radiotherapy-treated patients showed

increased SBS3 (homologous recombination deficiency) and decreased SBS16 (chromosomal instability) compared to controls. By using the ratio of non-synonymous to synonymous mutations (dN/dS) in the immunopeptidome, we identified differences in the proportion of immune-escaped tumours between the two clinical trials. Ongoing computational work is focused on integrating data from all modalities to study genetic and non-genetic mechanisms of immune evasion, the contribution of T cell infiltration, and the potential use of immune dN/dS as a predictive marker for response to treatment.

Conclusion

We have established a bioinformatic pipeline to successfully integrate immune multiomic data from longitudinal samples collected within two neoadjuvant radiotherapy trials in breast cancer, and further research is ongoing to fully characterise the immunogenomic evolution and therapeutic implications.

Introduction

Human cancers are heterogeneous. Their genomes evolve from genetically diverse germlines in complex and dynamic environments, including exposure to potential carcinogens. This heterogeneity of humans, our environmental exposures, and subsequent tumours makes it challenging to understand the extent to which cancer evolution is predictable.

Material and method

Addressing this limitation, we re-ran early tumour evolution hundreds of times in diverse, inbred mouse strains, capturing genetic variation comparable to and beyond that found in human populations. The sex, environment, and carcinogenic exposures were all controlled and tumours comprehensively profiled with whole genome and transcriptome sequencing.

Result and discussion

Within a strain, there was a high degree of consistency in the mutational landscape, a limited range of driver mutations, and all strains converged on the acquisition of a MAPK activating mutation with similar transcriptional disruption of that pathway. Despite these similarities in the phenotypic state of tumours, different strains took markedly divergent paths to reach that state. This included pronounced biases in the precise driver

mutations, the strain specific occurrence of whole genome duplication, and differences in subclonal selection that reflected both cancer susceptibility and tumour growth rate.

Conclusion

These results show that interactions between the germline genome and the environment are highly deterministic for the trajectory of tumour genome evolution, and even modest genetic divergence can substantially alter selection pressures during cancer development, influencing both cancer risk and the biology of the tumour that develops.

⁵*University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom*

⁶*University of Toronto, Medicine, Toronto, Canada*

Introduction

Human breast cancers display significant genomic and phenotypic heterogeneity which are major factors in the development of treatment resistance. Recent advances have made it possible to combine clonal tracking methods with single cell RNA sequencing (scRNAseq) to associate clonal response to treatment with transcriptomic changes at the single cell level. With this approach, we aim to investigate clonal response to chemotherapy in human breast cancer patient-derived xenograft (PDX) models to understand the role of tumour cellular heterogeneity in molecular response and clonal adaptation to chemotherapy.

Material and method

A custom-built expressed lentiviral-based cellular barcoding system was used to label and track the growth of single cell-derived clones in 4 PDX models (2 ER-positive, and 2 triple-negative) serially propagated in primary and secondary tumour xenografts. Secondary xenograft replicates that contained the same barcode clones propagated from the primary were treated with Carboplatin or Paclitaxel, and compared to untreated controls.

Result and discussion

40 barcoded xenografts (treated and untreated) were analysed by DNA amplicon sequencing (DNAseq) and scRNAseq to track clonal response to chemotherapy and associate each clone with its transcriptomic profiles at single cell resolution. DNAseq identified 3260 barcode clones in total; 153/454 (34%) and 537/1102 (49%) were chemo-resistant in the 2 ER-positive models, and 480/633 (76%) and 737/1071 (69%) were chemo-resistant in the 2 triple-negative models. Strikingly while both treatments altered the clonal landscape of the 2 PDX models that showed resistance from bulk tumour growth rates after chemotherapy (1 ER-positive and 1 triple-negative), they had little impact on the clonal landscape of the 2 sensitive models. This implies that treatment selects for pre-existing resistant clones or a rapid adaptation to confer resistance in some clones. From scRNAseq a large dataset comprising ~500,000 high quality single cell RNA profiles was generated where expressed barcodes allowed single cell RNA profiles to be annotated based on response to chemotherapy.

Conclusion

We generated a robust set of clonal tracking data coupled with scRNAseq allowing for clonal response to chemotherapy to be investigated on a single cell level. We found that treatment profoundly alters the clonal landscape of resistant xenografts but has little impact on sensitive xenografts. This analysis will allow us to explore molecular pathways that distinguish chemo-resistant from chemo-sensitive clones and develop novel therapeutic strategies to overcome chemotherapy resistance in human breast cancer.

Unveiling the impact of intratumoral microbiota in the treatment efficacy of soft tissue sarcoma

L. Tiraboschi¹, G. Vella¹, A. Gatti¹, A. Bernardinello¹, A. Ruggieri¹, M. Lizier¹, F. Cananzi¹, S. Renne¹, A. Bertuzzi¹, M. Rescigno¹

¹*Humanitas Research and Clinical Hospital, Milan, Italy*

Introduction

The intratumoral microbiome has been recently recognized as an “Emerging Hallmark of Cancer” due to its presence in the tumor microenvironment. Bacterial DNA has been detected in various cancers, revealing tumor-type-specific microbiome compositions. Tumor-resident bacteria influence cancer biology by promoting progression, enhancing metastatic potential, and modulating antitumor immunity. Additionally, they may impair anticancer therapies by inactivating drugs or reducing cancer cell sensitivity. Despite this, the role of the intratumoral microbiota in soft tissue sarcomas (STSs) remains underexplored. Given STS heterogeneity, with over 100 histological subtypes, personalized treatment is complex. Doxorubicin remains the gold-standard chemotherapy for advanced STSs, though its efficacy is low. Since doxorubicin is a natural anthracycline produced by Streptomycetaceae, some bacteria may have evolved mechanisms to inactivate it. This study investigates STS microbiota and its potential impact on doxorubicin efficacy.

Material and method

Bacterial presence in STSs was assessed using Fluorescence In Situ Hybridization (FISH) targeting the 16S rRNA gene. Microbiome profiling via 16S rRNA sequencing compared tumor-associated microbiota with adjacent healthy tissues. Additionally, we isolated 46 bacterial strains from STSs, identifying facultative and obligate anaerobes adapted to hypoxic tumor conditions. Functional assays exposed these isolates to doxorubicin to evaluate drug inactivation assessed also with mass spectrometry approaches. Proteomic analysis of *Proteus vulgaris* under anaerobic conditions identified upregulated enzymes, and molecular docking simulations investigated their interaction with doxorubicin.

Result and discussion

FISH confirmed the presence of bacteria across different sarcoma histotypes. 16S rRNA sequencing revealed distinct microbiome profiles between STSs and adjacent tissues, correlating more with histological subtype than tumor location. Functional studies showed that certain bacteria, including *Porphyromonas* and *Proteus vulgaris*, inactivated doxorubicin. In a doxorubicin-sensitive fibrosarcoma mouse model, intratumoral *Porphyromonas* infection induced chemoresistance. Proteomic analysis of *P. vulgaris* revealed high expression of nitrite reductases under anaerobic conditions, and molecular docking suggested their role in doxorubicin inactivation. These findings suggest a link between bacterial nitrogen metabolism and chemoresistance.

Conclusion

Our findings highlight the role of the intratumoral microbiome in shaping therapeutic responses, showing that specific bacteria can inactivate doxorubicin and induce chemoresistance. Considering tumor-associated bacteria may be crucial for optimizing cancer treatments and overcoming microbiome-driven drug resistance.

Introduction

Cancer pathogenesis is a cumulative outcome of multiple factors that prime a conducive environment for cells to sustain diverse stress conditions, proliferate and metastasize. Proliferation, though central to growth, is largely undermined as a unidimensional and standalone hallmark. Its mechanistic involvement in heterogeneous tumor organization, intercellular interactions, and metabolite exchanges is largely unexplored. In this study, we uncover a mechanism of tumor growth via collective proliferation, where cells exchange thymidylate (dTMP),

a nucleotide critical for DNA synthesis, rendering its synthesis indispensable in a significant portion of proliferative tumor cells. Collective proliferation rheostats key tumor phenotypes, and thereby, impacts pathophysiology of cancer.

Material and method

dTMP synthesizing de novo enzyme thymidylate synthase (TS) and/or the salvage enzyme thymidine kinase (TK1) were knocked out in cancer cells with nuclear GFP tags. A coculture system was setup between the KO cells and cells expressing TS and TK1, where the KO cells were exclusively recognized by a real-time imager Incucyte S3 based on its GFP expression. Single cell RNA sequencing and spatial transcriptomics were used to analyze the contribution of dTMP deficient cells in patient samples. A Kras-p53 driven genetic mouse model with dual knockout TS and TK1 (KPTT) was used for in vivo validation of collective growth. Molecular dynamics were studied at single cell level by quantitative image-based cytometry (QIBC).

Result and discussion

Our study elucidates a novel proliferative mechanism where cells lacking intrinsic dTMP synthesis (by TS and/or TK1) employ gap junctions to form a cellular syncytium with dTMP-proficient cancerous and several non-cancerous cell types, such as macrophages and endothelial cells. dTMP equilibration in this network allows proliferation of dTMP-deficient cells, dispensing the need of ubiquitous activation of TS and TK1. Analysis of dTMP-sharing at cellular level further hints that this mechanism influences key processes such as senescence, inflammation and genomic instability. The mechanism is also observed in clinical samples and is associated with key pathological features of cancer. Collective proliferation is validated in a genetic mouse model of lung cancer harboring a dual Ts/Tk1 tumor-specific knockout, in which tumors grow despite lacking enzymatic dTMP synthesis and tumor progression is opposed by gap junction inhibition.

Conclusion

These findings revise the current dogma of ubiquitous nucleotide biosynthesis in each proliferating cancer cell in tumors and suggest that a programmed dTMP distribution maintains collective tumor growth. Collective tumor growth allows proliferation to functionally connect with other cancer hallmarks, affecting cancer pathology, thereby not only alters the basic biology of cancer, but also opens new therapeutic options by targeting metabolite sharing.

Deconvolution of heterogeneous 3D mammary spheroid dynamics using Oblique Plane Microscopy (OPM)

N. Moderau¹, L. Rowe-Brown², S. Meyler¹, N. Curry², J. Stebbing¹, C. Dunsby²

¹*Imperial College London, Department of Surgery and Cancer, London, United Kingdom*

²*Imperial College London, Department of Physics, London, United Kingdom*

Introduction

Genetic heterogeneity is increasingly recognised as a critical factor in breast cancer progression. The dynamic process of clonal evolution in breast cancer can be driven by ageing, menstrual cycles, pregnancy, and menopause, leading to a diverse genetic landscape. Malignancy can arise in these clones through secondary mutations, field cancerisation, or competitive behaviour. The heterogeneous composition of each tumour, under selective pressure, can shift the competitive advantage, leading to resistance of certain clones and recurrence of the disease with limited therapeutic options.

Material and method

In this project, we developed a mammary spheroid system that enables longitudinal observation and analysis of clonal competition from the onset of mutational heterogeneity to the progression to the invasive stage, facilitating the study of drug responses in a heterogeneous background. Using oblique plane microscopy (OPM), a light-sheet microscopy technique that illuminates a tilted plane of the specimen and collects fluorescence with the same high numerical aperture objective, we captured high-content, 3D time-lapse imaging of up to 180 spheroids over 8 days at 8-hour intervals. Machine-learning-based nuclear segmentation with Cellpose allowed for precise nuclei counting and categorisation into up to three different oncogenes, each associated with a unique fluorescent protein. This segmentation tool enabled measurements of fluorescence intensity, nuclear size, and nuclear count for each oncogene, quantifying clonal competition over time.

Result and discussion

The ability to track individual clones over time revealed shifts in competitive advantage and clonal composition under selective pressure. Our findings indicate that rare clones, such as BRAF mutant clones, may be shed early and evade detection through classical sequencing approaches, potentially explaining its low frequency in primary breast cancer and increased frequency in circulating tumour cells as well as secondary sites. High-content imaging with OPM provided detailed spatial information on heterogeneous spheroid architecture and clonal localisation, offering insights into clonal competition or resistance mechanisms. In addition, utilising this pipeline, we established a drug screening platform, validated with a proof-of-principle drug combination.

Conclusion

We developed a genetic model of heterogeneity and demonstrated the utility of high-content longitudinal imaging using OPM, combined with machine learning, to analyse clonal dynamics. Our platform offers a valuable tool for studying tumour evolution and competition in heterogeneous background, rare clones behaviour, and resistance mechanisms, supporting the development of more effective drug discovery strategies.

Neuroblastoma metastatic cells adopt an embryonic diapause-like state in the fetal bone marrow driven by mTOR activity

C. Castillo Ferrer¹, S. Bouaud¹, O. Otero Laudouar¹, Q. Fort¹, B. Dumont², M. Pratviel¹, F. Reynaud¹, V. Maguer-Satta¹, S. Lefort¹, C. Delloye-Bourgeois¹

¹*Cancer Research Center of Lyon, Lyon, France*

²*Pediatric Hematology and Oncology Institute, Lyon, France*

Introduction

Neuroblastoma (NB) is a deadly pediatric cancer of the peripheral sympathetic nervous system. NBs arise from an embryonic transitory cell lineage: the sympathoadrenal cells of the neural crest (NC). NB primary tumors typically form in the abdomen along the sympathetic chain and in the adrenal gland. Over 50% of NB patients are diagnosed with extensive metastases, particularly in the bone marrow (BM), precluding early therapeutic intervention and therefore representing a major clinical challenge. Although both tumor initiation and metastatic onset towards the BM have been proposed to occur during fetal life, in a temporal sequence that parallels the fetal development of the NC, why BM-infiltrating NB cells remain undetected up until large metastatic colonization of the BM and diagnosis of the disease is unknown.

Material and method

We combine multiscale analyses of patient samples with functional experiments in innovative and adapted models that reproduce the fetal (FBM) and pediatric (PBM) bone marrow microenvironment, in the context of NB metastasis. We exploit an avian graft model that faithfully recapitulates NB metastatic spread from sympathoadrenal tumors, with NB cells primarily reaching the fetal BM through the dorsal aorta (DA) and peripheral nerves. Complementary to this fetal model of BM metastasis, we use a standardized 3D model of human BM, implemented with primary fetal and pediatric mesenchymal stem cells (MSC) to decipher the complex and dynamic ecosystem provided by the fetal and pediatric BM upon NB seeding.

Result and discussion

Upon reaching the fetal BM, single cell transcriptomic analyses show that NB cells initially enter a reversible diapause-like resting state. Through a series of functional assays, we demonstrate that NB cells exposed to fetal BM-MSCs or to their secretome only are driven into this dormant state, whereas pediatric BM-MSCs have the opposite effect, promoting diapause exit, cell cycling and metabolic activity. Moreover, we describe that fetal BM-MSCs drive this diapause-like state by decreasing the activity of the growth-regulating mTOR signaling pathway, whereas pediatric BM-MSCs reactivate this pathway. Such regulation appears to be mediated by specific MSC secreted factors that impact tyrosine kinase receptors (RTKs) and integrin signaling.

Conclusion

These findings explore for the first time the spatio-temporal dynamics of NB metastasis in the BM,

revealing a feto-pediatric transition from a diapause-like resting state to an awaken pediatric state, and therefore provide a major insight in the understanding of the dynamics of NB metastases and of the role the BM compartment plays in this process.

EACR25-2481

Translational Reprogramming Drives Immune Evasion in Melanoma Persister Cells Through MIF Secretion

L. Soumoy¹, H. Chen¹, S. Faouzi¹, S. Mohammadnezhaddaryani¹, S. K-murali², M. Kazemimanesh¹, S. Agoussi¹, S. Vagner³, S. Shen⁴, C. Robert¹

³*Institut Curie, U3348, Saclay, France*

⁴*West China Hospital, Institute of Thoracic Oncology and National Clinical Research Center for Geriatrics, Chengdu, China*

Introduction

Metastatic melanoma often relapses following targeted therapy (TT) or immune checkpoint inhibitors (ICI), suggesting that melanoma persister cells (MPC) evade immune surveillance. We investigated how translational reprogramming in MPC contributes to tumor persistence and immune evasion.

Material and method

We analyzed supernatants from melanoma cell lines (parental vs. MPC) using chemokine arrays and ELISA, and assessed their impact on lymphocytes and monocytes through metabolic and functional assays. MIF secretion was measured in patient biopsies before and after treatment initiation. CRISPR-Cas9 and siRNA approaches were used to study MIF regulation and its transporter ABCA7. Polysome profiling was performed to assess translational regulation in MPC.

Result and discussion

MPC exhibited globally reduced translation but increased translation of specific mRNAs encoding proteins involved in chromatin remodeling and immune modulation. MIF was identified as a key immunosuppressive factor highly secreted by MPC, leading to reduced immune cell fitness. MIF knockout in MPC abrogated these effects, confirming its role in immune evasion. The transporter ABCA7 was upregulated at the translational level in MPC and identified as a key regulator of MIF secretion. Additionally, low immune infiltration and poor patient outcomes correlated with high expression of MPC markers in biopsies. Targeting eukaryotic initiation factor 4A (eIF4A) in combination with TT delayed resistance and improved survival.

Conclusion

MPC persistence is driven by translational reprogramming, which enhances MIF secretion through ABCA7, fostering an immunosuppressive tumor microenvironment. Targeting translation may represent a promising therapeutic avenue to counteract melanoma persistence and resistance.

EACR25-0439

Spatial and multi-omic profiling of HGSC to identify immune vulnerabilities for precision immunotherapy

A. Shabanova¹, I. Niemiec¹, Z. Liang¹, A. Junquera¹, U. Haltia¹, A. Virtanen², M. Salko¹, A. Färkkilä¹

¹Research Program in Systems Oncology, University of Helsinki, Helsinki, Finland

²Research Program in Systems Oncology, University of Helsinki, Helsinki, Finland

Introduction

Tumorigenesis and cancer progression rely on malignant cells evading immune system. Despite promising immunotherapies, many high-grade serous carcinoma (HGSC) patients do not respond, highlighting the need to explore spatial immune dynamics. We aim to use spatial multi-omic profiling, and machine learning to uncover immune evasion strategies, identifying prognostic markers and therapeutic targets for precision oncology.

Material and method

This project used samples collected during Oncosys-Ova study. We analyzed 42 FFPE tumor samples, including 16 paired chemo-naïve and treated samples, alongside clinical and sequencing data. Spatial single-cell protein analysis was performed using t-CycIF imaging of FFPE samples, targeting ten key markers for tumor, stromal, and immune cells. Additionally, we conducted Nanostring GeoMX spatial transcriptomics on regions of interest (ROIs) from adjacent FFPE slides, guided by t-CycIF imaging.

Result and discussion

We developed a new method to choose ROIs in GeoMX, using t-CycIF to improve the identification of cell hubs through specific immune markers. In this project, we focused on the following immune markers: CD4 (CD4+ T cells), CD8 (CD8+ T cells), CD11c (dendritic cells), Iba1 (macrophages), and NKG2a (natural killer cells). Raw images underwent pre-processing to reduce noise and enhance true cell signal clustering. Overlaps of pre-processed true signals were identified across different marker combinations, and the most informative ROIs were selected through automated selection based on their size, as well as subsequent manual inspection in Napari viewer. We acquired 10 ROIs in 14 samples and a varying quantity in additional 28 samples (median 17 ROIs), prioritizing diversity in selected ROIs. Spatial transcriptomics (GeoMX) analysis was performed adjacent to the t-CycIF slide for selected ROIs to assess gene expression profiles in tumor and stromal compartments. We analyzed 213 compartments in 14 samples and approximately 800 more compartments from the remaining 28 samples. Our multi-omic study integrated gene and protein expression profiles from tumor, immune, and stromal cells in around 1000 compartments across 42 samples. Combining these datasets with patient genomic and clinical data enabled a detailed characterization of the spatial molecular landscape of HGSC tumors. Such protein and

transcriptomic atlas reveal immune hubs and their interactions with cancer and stromal cells, offering insights into immune escape mechanisms. Preliminary data indicate that spatial tumor microenvironment features correlate with clinical outcomes, highlighting potential immune vulnerabilities and therapeutic targets, which could be uncovered with the help of machine learning.

Conclusion

Our study aims to provide insights into the spatial immuno-genomic landscape of HGSC, informing the development of targeted immunotherapeutic strategies for improved patient outcomes.

High-throughput drug screening in breast cancer PTCs enables clinically relevant drug discovery for personalised medicine

R. Masina¹, D. Guerrero Romero¹, E. Esmaeilishirazifard¹, S. Cosulich², C. Crafter², M. Lawson², J. Brenton¹, S. Sammut³, O. Rueda⁴, C. Caldas⁵

¹University of Cambridge, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom

²AstraZeneca, Cambridge, United Kingdom

³Institute of Cancer Research, London, United Kingdom

⁴University of Cambridge, MRC Biostatistics Unit, Cambridge, United Kingdom

⁵University of Cambridge, Clinical Biochemistry, Cambridge, United Kingdom

Introduction

Traditional drug discovery for precision medicine relies on high-throughput drug screening (HTDS) on cancer cell lines (CCLs). However, CCLs have lost their resemblance to primary tumours, which leads to a modest conversion rate of clinically useful discoveries. Patient-derived Xenografts (PDXs) more faithfully recapitulate the original tumour phenotype than CCLs, but their application in drug screens is limited by logistical constraints specific to in vivo drug testing. Here, we performed HTDS in PDX-derived tumour cells (PTCs) and demonstrate their superiority to CCLs and PDXs for clinically relevant drug discovery in precision medicine.

Material and method

We treated PTCs from 34 different breast cancer PDXs with 67 compounds at 7 concentrations in 3 technical replicates, generating a total of 47 838 drug response data points. The compounds were either approved cancer treatments or drugs targeting key cancer pathways. Viability was measured by Cell-Titer-Glo (CTG) after 7 days and area under the dose-response curve (AUC) was calculated to determine therapy effectiveness. Tumours were profiled by shallow whole genome sequencing, whole exome sequencing, single-cell RNA sequencing, methylation-sequencing, protein mass cytometry and reverse phase protein array, yielding an average of >200 000 features per PDX. Machine learning was used to extract integrative multiomic signatures predictive of drug response. These were validated by testing their ability to predict drug response in real-world clinical trials.

Result and discussion

First, we described the landscape of drug response in breast cancer PDTCs. As expected, drugs sharing similar biological targets displayed similar activities. This held true both at the scale of drug class (e.g. DDR vs mitogenic inhibitors), and drug target (e.g. ERK/MEK inhibitors vs PI3K inhibitors). Subsequently, we characterised the multiomic profile of PDXs and linked it with drug response. We found that ER status associated with resistance to DDR agents, but not to mitogenic signalling, while PI3K activation led to resistance to drugs targeting mitogenic signalling, but did not alter sensitivity to cytotoxic chemotherapy. We showed that a multiomic machine learning model trained on PDTCs could predict drug response in clinical trials. Moreover, this PDTC-based model was superior to an equivalent model trained on CCLs – for example, at predicting pathological complete response in a trial of neoadjuvant anthracycline of 168 patients ($p < 0.01$).

Conclusion

We showed that PDTC drug screens result in higher rates of clinically relevant drug discoveries than traditional CCL HTDS, without the logistical impairments linked to screening PDXs *in vivo*. This approach could be used to accelerate the implementation of precision medicine across all cancers.

Symposium: DNA Repair and Immunosurveillance

EACR25-0256

Exploit neutrophil heterogeneity to induce synthetic lethality in breast cancer

C. Garda¹, L. Boffa¹, M. Massara¹, A. Calcinotto¹

¹Institute of Oncology Research, Cancer Immunotherapy, Bellinzona, Switzerland

Introduction

About 80% of breast cancers are hormone-dependent. Although anti-hormonal therapy remains a treatment mainstay, a considerable fraction of these patients does not respond to the therapy and ultimately progress with advanced cancer. Tumor evolution is one of the primary mechanisms responsible for acquiring therapy-resistant and more aggressive cancer clones. Whether the tumor microenvironment through immune-mediated mechanisms might promote the development of more aggressive cancer types is crucial for identifying additional therapeutic opportunities.

Material and method

To achieve these goals, my team has set up innovative state of the art methodologies, used different *in vivo* mouse models of breast cancer and performed validation in the patients.

Result and discussion

Recent results from my lab identified a subset of immature neutrophils named Neutrophil Precursors (PreNeu) that are enriched and can proliferate in the tumors of highly proliferative hormone-dependent breast cancer patients, an aggressive tumor type characterized by poor prognosis. We demonstrated that these cells directly promote cancer genomic instability, favoring the

generation of therapy-resistant cancer clones.

Mechanistically, we found that the oncometabolite succinate, secreted by tumor-associated PreNeu, impairs homologous DNA repair, promoting error-prone DNA repair through non-homologous end-joining regulated by PARP-1. Consequently, breast cancer cells acquire genomic instability, resulting in tumor progression and resistance to endocrine therapies. Selective inhibition of these pathways induces increased tumor cell kill *in vitro* and *in vivo*. Intra-tumour PreNeu score correlates with copy number alterations in highly proliferative hormone-dependent tumors from breast cancer patients. Having found that the PreNeu induce dependence of the tumor cells on alternative DNA repair mechanisms mediated by PARP, we tested and demonstrated that the presence of PreNeu in the tumor sensitizes the tumors to PARP inhibitors. Treatment with PARP inhibitors counteracts the pro-tumorigenic effect of these neutrophils and reverses endocrine resistance.

Conclusion

Our data add novel insights into the neutrophil heterogeneity in breast cancer, describing an unexpected new function for this immune subset as cellular mediator of synthetic lethality in tumors. For a clinical prospective, these data demonstrate that olaparib treatment can be effective not only in tumors that harbor genetic homologous recombination deficiency *per se* but also in tumor contexts in which the homologous recombination is altered by the presence of tumor-associated PreNeu.

EACR25-0468

Intratumoral STING pathway activation enhances anti-tumor immune responses and therapeutic efficacy of ATR inhibition

T. Sen¹

¹Icahn School of Medicine at Mount Sinai, Oncological Sciences, New York, United States

Introduction

Small cell lung cancer (SCLC) is the most aggressive lung cancer subtype. Recent trials of immune checkpoint blockade (ICB) combined with chemotherapy have observed modest benefits. This study explores the therapeutic potential of targeting ATR, the key activator of the replication stress response, in SCLC.

Material and method

In this study, we performed genetic and pharmacological inhibition of ATR in a panel of human and murine SCLC cell lines. Furthermore, we investigated the effect of ATR inhibition either alone or in combination with PD-L1 blockade in multiple immunocompetent mouse models of SCLC. The downstream effects of ATR inhibition were assessed by bulk RNA sequencing, multicolor flow cytometry, western blot analysis, and real-time qRT-PCR. SCLC clinical samples from treatment-naïve patients and patients treated with an ATR inhibitor were analyzed by single-cell and bulk RNA sequencing to ascertain the effect of ATR on immune subsets.

Result and discussion

In multiple immunocompetent SCLC mouse models, ATR inhibition (ATRi) remarkably enhanced the anti-tumor effect of PD-L1 blockade. We next tested ATR inhibition either alone or in combination with PD-L1 in the second-line regimen for SCLC. We observed that

ATR inhibition in combination with PD-L1 blockade significantly reduced tumor volume and prolonged survival of aggressive mouse models compared to PD-L1 alone. Targeting ATR enhanced the expression of PD-L1, activated the cGAS/STING pathway, induced the expression of Type I and II interferon pathways, and caused significant infiltration of cytotoxic and memory/effector T-cells into tumors. Interestingly, ATRi also led to significant induction of MHC class I in SCLC in vitro and in vivo models. Analysis of pre- and post-treatment clinical samples from a proof-of-concept study of a first-in-class ATR inhibitor, M6620 (VX970, berzosertib), and TOP1 inhibitor topotecan, in patients with relapsed SCLCs, validated the induction of MHC class I and interferon pathway genes, for the first time in this disease. Single-cell analysis of patient samples revealed how ATR inhibition modulated antigen presentation and confirmed the immunosuppressed phenotype in SCLC.

Conclusion

Our findings highlight ATRi as a potentially transformative vulnerability of SCLC, paving the way for combination clinical trials with anti-PD-L1. Given the increasing importance of immunotherapy for the management of SCLC and the fact that ATR inhibitors are already in clinical trials, combining an ATR inhibitor with PD-L1 blockade may offer a particularly attractive strategy for treating SCLC and contribute to the rapid translation of this combination into the clinic.

Symposium: Prevention and Early Detection

EACR25-0817

Tumour genotype shapes blood biomarker expression for use in pancreatic cancer detection and diagnosis

A. Serrels¹, D. Lonergan¹, C. Ferguson¹, P. Gautier², A. von Kriegsheim², M. Canell¹

¹*University of Edinburgh, Cancer Research UK Scotland Centre, Edinburgh, United Kingdom*

²*University of Edinburgh, Institute of Genetics and Cancer, Edinburgh, United Kingdom*

Introduction

Typically diagnosed late, when systemic metastasis has already occurred, pancreatic ductal adenocarcinoma (PDAC) has one of the worst 5-year survival rates of any cancer type. For many patients with advanced disease, current chemotherapy regimens offer only modest benefit despite significant toxicity and surgical resection, the only treatment option with curative potential, is not possible. Therefore, while new treatments are much needed, diagnosing patients at an ‘earlier’ disease stage when surgery remains possible and the window of opportunity for treatment response is longer will be critical to improving patient outcomes. In this regard, the identification of biomarkers present in biospecimens that can be easily sampled from patients remains the focus of considerable research, however success has not been forthcoming.

Material and method

Using a suite of novel genetically defined murine isogenic models of early PDAC, engineered using CRISPR-Cas9 gene editing to represent the most common mutational backgrounds found in the human disease, coupled with the multi-omics analysis of blood, we sought to address whether common driver gene mutations in PDAC, and thus the genetic heterogeneity inherent to the disease, may represent an important confounding factor in the identification of a one-size-fits-all biomarker suitable for early detection.

Result and discussion

We show that both loss of Cdkn2a and / or Smad4 on the background of a KrasG12D p53^{-/-} genotype has profound effects on the profile of differentially expressed RNA species including protein coding RNAs, lncRNAs, snoRNAs, scRNAs, snRNAs and miRNAs, and on plasma protein expression, when compared to both healthy controls and chemically induced pancreatitis.

In addition, we find that loss of Smad4, a genomic event that occurs following progression from PanIN to PDAC, substantially limits the availability of blood biomarkers.

Conclusion

These findings identify the need to move towards genotype-specific biomarker signatures and uncover a potential role for SMAD4 loss in limiting opportunities for the early detection of pancreatic cancer.

EACR25-1604

Multi-omic spatial analysis reveals reshaping of tumour-immune dynamics at the transition to invasive colorectal cancer

A. Baker¹, E. Smith¹, C. Sakr¹, K. Bräutigam¹, N. Trahearn¹, H. Egginton², M. Lacle³, M. Rodriguez-Justo⁴, S. Leedham², T. Graham¹

¹*Institute of Cancer Research, Centre for Evolution and Cancer, London, United Kingdom*

²*University of Oxford, Wellcome Centre for Human Genetics, Oxford, United Kingdom*

³*University Medical Center Utrecht, Department of Pathology, Utrecht, Netherlands*

⁴*University College London, UCL Cancer Institute, London, United Kingdom*

Introduction

The introduction of bowel cancer screening has led to an increase in the detection and removal of pre-malignant adenomas, however many of these would never progress to colorectal cancer (CRC) within a patient’s lifetime. This implies a key evolutionary bottleneck at the transition from adenoma to carcinoma, with immune surveillance likely playing a central role in suppressing the outgrowth of invasive cells. Here we analysed a cohort of “ca-in-ads” (adenomas with a small focus of cancer) to provide a unique snapshot of the invasive transition. We combined genomics, spatial transcriptomics, digital pathology and multiplex imaging, concurrently deriving the distribution of tumour clones, their gene expression and their interplay with the immune microenvironment.

Material and method

We performed multi-region low-coverage whole genome sequencing (lcWGS) and T-cell receptor sequencing (TCRseq) on archival ca-in-ads from 40 patients. For a subset of cases we performed spatial transcriptomics using the 10x Genomics Visium platform, including custom probes to detect T-cell clonotypes of interest. We applied a deep learning cell classifier to haematoxylin and eosin (H&E) stained sections to determine the abundance and spatial distribution of eight cell types, with detailed immunophenotyping on selected cases (using a 50-marker panel on Akoya's PhenoCyclerFusion platform).

Result and discussion

We found a significant increase in copy number alterations in carcinoma regions relative to adenomas, and this was accompanied by a large shift in the composition of the local T-cell repertoire. TCR sequencing revealed expanded T-cell clonotypes that were adenoma-specific or carcinoma-specific, and we validated the spatial exclusivity of these using a custom Visium assay. Digital pathology and cyclic immuno-fluorescence revealed significantly increased infiltration of macrophage and neutrophil populations in regions of invasive cancer.

Conclusion

Taken together our analysis suggests a striking reshaping of tumour-immune dynamics at the transition to an invasive phenotype in CRC. Understanding what governs this invasive shift could highlight new avenues for cancer prevention or identify individuals at risk of CRC.

MYCN copy numbers, accelerating intratumor genetic heterogeneity. We hypothesized that ecDNA-driven genetic heterogeneity fosters phenotypic diversity, enabling neuroblastoma cells to adapt to treatment-induced selective pressures. We investigated the impact of ecDNA-driven heterogeneity on phenotypic diversity and therapeutic response across primary tumors, patient-derived xenografts, and cell lines.

Material and method

MYCN copy numbers were quantified from neuroblastoma cell lines, patient-derived xenografts and neuroblastomas -/+ genotoxic therapies using fluorescence in situ hybridization (FISH). These data were integrated with mathematical models of oncogene copy number-dependent fitness, single-cell ecDNA quantification, and phenotypic analyses.

Result and discussion

Pronounced ecDNA-driven intratumor heterogeneity was observed in all 95 MYCN-amplified neuroblastoma samples. FISH-guided spatial proteomics revealed cells with high MYCN copy numbers exhibited protein signatures associated with replication stress and DNA damage, whereas senescence-associated pathways were enhanced in cells with low MYCN copy numbers. Single-cell ImmunoFISH confirmed varying ecDNA copy numbers influenced cell fate under chemotherapy. High-MYCN cells underwent apoptosis, while low-MYCN cells persisted as senescent or resumed proliferation after drug withdrawal. These ecDNA-mediated changes drive tumor phenotype and therapy response, as low-MYCN cells contribute to therapy resistance. Consequently, a senolytic "one-two punch" using doxo-rubicin and navitoclax achieved significant tumor growth control in neuroblastoma PDX models.

Conclusion

This study establishes how ecDNA-driven MYCN variability underpins tumor heterogeneity and therapy resistance. Conventional treatments eliminate high-MYCN cells, but low-MYCN cells survive, persist in senescence, and regain proliferative capacity. Refining therapeutic strategies to target low-MYCN cells may improve outcomes for high-risk MYCN-amplified neuroblastomas.

³Max-Delbrück-Center for Molecular Medicine in the Helmholtz Association (MDC), Laboratory of Spatial Proteomics, Berlin, Germany

⁴Centre for Dynamics Systems, School of Mathematical Sciences, Queen Mary University of London, London, United Kingdom

Introduction

Despite initial responsiveness to neoadjuvant chemotherapy, neuroblastomas with MYCN amplification frequently relapse, implicating dynamic processes in treatment resistance. In neuroblastomas, MYCN amplification predominantly occurs on extra-chromosomal DNA (ecDNA), which, due to the lack of centromeres, segregates unevenly during cell division. This uneven segregation generates cells with variable

EACR25-2262

Investigating the impact of extrachromosomal DNA amplification on cell fate decisions and therapy resistance

R. Schmargon¹, G. Montuori¹, A. Henssen¹, J. Dörr¹

¹Charité - Universitätsmedizin Berlin, Berlin, Germany

Introduction

Despite advances in precision oncology, persisting treatment resistance necessitates a better understanding of therapy response mechanisms. In various tumours, the extrachromosomal amplification of oncogenes accelerates intratumoral heterogeneity development. Due to the lack of a centromere, ecDNA can undergo random segregation during cell division, enabling rapid copy number changes. While gradual selection pressures during tumor evolution are known to shape ecDNA composition, the effect of acute selection pressures on both ecDNA copy number and resulting cell fate

decisions, such as apoptosis, senescence or resistance, remains poorly understood.

Material and method

To investigate the relationship between ecDNA copy number dynamics and cell fate decisions, we utilized neuroblastoma and astrocytoma cell lines and patient-derived xenografts (PDX) harboring MDM2, CDK4 or MYCN amplifications, either in linear or extra-chromosomal form. These models were subjected to different targeted and cytotoxic therapies. To precisely capture rapid ecDNA copy number changes in relation to cell fate outcomes, we employed fluorescence *in situ* hybridization (FISH) for real-time ecDNA assessment. Cell fate responses were characterized using ATP-based viability assays and senescence-associated β -galactosidase (SA- β -Gal) stainings. To functionally link ecDNA copy number dynamics to cell fate on a single cell level, we coupled FISH with immunofluorescence (IF) for selected markers, such as H3K9me3, Cleaved Caspase-3, p21 and TP53.

Result and discussion

We show that both cytotoxic and targeted therapies induce ecDNA copy number changes and that cell fate decisions are tightly linked to ecDNA dynamics primarily by eliminating cells with defined ecDNA copy numbers. Importantly, cytotoxic and targeted therapies can influence ecDNA copy numbers differently as exemplified in neuroblastoma cells with extra-chromosomal MDM2 amplification and its impact on TP53 activation. MDM2 copy numbers, which strongly correlate with MDM2 protein levels, rise upon doxorubicin exposure to suppress TP53-mediated apoptosis to promote cell survival and fuel treatment resistance. Conversely, treatment with the MDM2 inhibitor Nutlin-3a leads to a marked decrease in MDM2 ecDNA due to higher TP53 activation in high MDM2 copy number cells and their subsequent cell death.

Conclusion

Our study demonstrates that ecDNA dynamics are intricately linked to cell fate outcomes as exemplified by a clear association of ecDNA copy number changes and TP53-mediated apoptosis in MDM2-amplified neuroblastoma cells. The results highlight how rapid alterations in ecDNA copy number heterogeneity serve as a reservoir for promoting resistance, emphasizing the need for combined ecDNA and cell fate-oriented therapeutic strategies to prevent relapse and improve treatment outcome in ecDNA-driven cancers.

Deciphering Tumor-Immune Crosstalk Through Multiplexed Imaging-Powered Deep Visual Proteomics (mipDVP)

X. Zheng¹, A. Mund², M. Mann³

¹Aarhus University, Biomedicine, Aarhus, Denmark

²University of Copenhagen, CPR, Copenhagen, Denmark

³Max Planck Institute of Biochemistry, Proteomics and Signal Transduction, Munich, Germany

Introduction

The tumor microenvironment (TME), a dynamic ecosystem of tumor, immune, and stromal cells, dictates cancer progression and therapy response. Understanding its complexity is critical for advancing immunotherapy, yet conventional methods lack the spatial resolution and multiplexing depth to fully resolve cell-specific interactions. We introduce multiplexed imaging-powered Deep Visual Proteomics (mipDVP), an integrative platform combining high-plex immunofluorescence imaging, automated single-cell laser microdissection, and ultrasensitive mass spectrometry. This approach enables spatially resolved, single-cell-type proteomic profiling to investigate how tumor-immune interactions drive immune evasion.

Material and method

Using the MACSima Imaging Platform, we spatially mapped cell populations in formalin-fixed, paraffin-embedded tissues from colorectal and tonsil cancers (14–22 markers). Targeted single-cell-type laser microdissection (Leica LMD7) isolated ~100–200 cells per population (e.g., tumor cells, macrophages, cytotoxic T lymphocytes [CTLs]), followed by data-independent acquisition (DIA) mass spectrometry (timsTOF/Astral platforms).

Result and discussion

This workflow quantified 4,000–6,000 protein groups per population, achieving proteomic depth previously unattainable in spatially resolved studies:

1. Colorectal cancer (A cold tumor case): Macrophages formed spatially compartmentalized immunosuppressive barriers, limiting CTL infiltration. Proteomics revealed M2-like polarization and impaired antigen presentation in macrophages, while tumor-adjacent CTLs showed suppressed cytotoxicity.
2. Tonsil Cancer (A hot tumor case): CTLs localized near tumor cells exhibited hypoxia-driven metabolic adaptation, enhancing their cytotoxic function. Tumor cells proximal to CTLs displayed heterogeneous expression of immune-regulatory proteins, suggesting adaptive resistance.

Conclusion

mipDVP bridges the gap between spatial biology and proteomics, unveiling mechanisms of immune evasion and activation. By identifying metabolic checkpoints and

immunosuppressive drivers, this platform pinpoints therapeutic targets and predictive biomarkers. Its ability to decode TME heterogeneity at single-cell-type resolution positions mipDVP as a tool for precision oncology, guiding therapies tailored to a tumor's unique immune context.

EACR25-0176

HALO Breast IHC AI: Demonstration of its Application as a Training Tool for Students

W. Solass¹, C. Desteffani¹, F. Kalberer¹, B. Scattolo¹, B. Zagrapan¹, D. Mulkern², P. Caie², M. Wartenberg³, I. Zlobec³, M. Lodge²

¹*University Bern, Institute of Tissue Medicine and Pathology, Bern, Switzerland*

²*Indica Labs, Indica Labs, Albuquerque, New Mexico, United States*

³*Universiy Bern, Institute of Tissue Medicine and Pathology, Bern, Switzerland*

Introduction

Introduction: Immunohistochemical assessment of HER2, ER, PR, and Ki67 is essential in diagnosing invasive breast carcinomas and guides treatment, prognosis, and patient management. Here, we show how Indica Lab's clinical software can be utilised to undertake research projects and train medical students at the University of Bern; focussing on a recent study comparing breast cancer IHC scoring by undergraduates to that of trained pathologists, when unassisted or assisted by HALO Breast IHC AI.

Material and method

Fifty cases (250 slides) stained for ER, PR, HER2, and Ki67 were scored twice by three students and two certified pathologists. Initial scores were obtained using manual digital pathology methods (Visual Dx), followed by reassessment with AI assistance by HALO Breast IHC AI after a 4-week washout period (AI-Assisted Dx). Accuracy and agreement of the student scores were compared to those of the pathologists.

Result and discussion

AI-Assisted Dx produced greater agreement at the clinical cutoff for all four biomarkers for both students (ER: 85% to 91%, PR: 19% to 73%, HER2: 47% to 82%, Ki67: 58% to 98% agreement) and pathologists (ER: 98% to 100%, PR: 44% to 90%, HER2: 71% to 100%, Ki67: 75% to 98% agreement). Similarly, Fleiss' Kappa for all biomarkers increased for AI-Assisted Dx by an average of 0.42 for both students and pathologists. When both groups were combined, agreement at the clinical cutoff also showed improvement (ER: 85% to 91%, PR: 20% to 57%, HER2: 35% to 80%, Ki67: 51% to 98% agreement) indicating that student scores more closely aligned with pathologists when assisted by HALO Breast IHC AI.

Conclusion

HALO Breast IHC AI provides support for both students and certified pathologists, improving agreement and consensus scores across groups with different levels of experience. HALO Breast IHC AI can objectively standardise scores and be an effective training tool for students.

EACR25-0192

From Transcriptomic Data to Therapeutic Potential: Drug Repositioning for Papillary Thyroid Carcinoma

Ö. Karabiyik Acar¹

¹*Istanbul Okan University, Genetics and Bioengineering Department, Istanbul, Turkey*

Introduction

Papillary thyroid carcinoma (PTC) is the most prevalent type of thyroid malignancy, with an increasing incidence worldwide. Although conventional treatments are effective for many patients, some individuals encounter resistance or lack appropriate therapeutic options. This highlights the necessity for alternative therapeutic strategies. Drug repositioning has emerged as a promising approach in oncology, providing a faster and cost-effective manner for new treatments. This study aimed to identify potential repositioned drug candidates for PTC treatment and conduct their preliminary in vitro evaluation using a PTC cell line.

Material and method

Four microarray datasets (GSE6339, GSE3467, GSE27155, and GSE138198) were analyzed to identify differentially expressed genes (DEGs) between normal and PTC tissues. Drug repositioning was conducted based on commonly upregulated and downregulated genes using L1000CDS² search engine. The gene expression signatures method was employed to identify potential therapeutic molecules, leading to the identification of 50 repositioned drug candidates. Selected candidates were tested on the MDA-T32 PTC cell line to evaluate IC₅₀ values.

Result and discussion

The IC₅₀ values of the tested drugs varied considerably against MDA-T32 cells. NSC632839 exhibited the highest cytotoxicity, with an IC₅₀ value of 178.9 nM, followed by MP7 (2.166 μM), Iodophenpropit dihydrobromide (7.325 μM), and H89 (10.85 μM), indicating their strong inhibitory effects on MDA-T32 cell viability. Other tested compounds, including Cinnamyl-3, 4-dihydroxy-α-cyanocinnamate (14.59 μM), L741,626 (18.05 μM), and L732,138 (68.56 μM), demonstrated moderate cytotoxicity, whereas Clofibrate acid showed the lowest potency (3.926 mM) against PTC.

Conclusion

These findings indicate that NSC632839 and MP7 may serve as promising candidates for further evaluations. Future studies should focus on elucidating mechanisms of action and validating the therapeutic potential of those repositioned drugs.

EACR25-0205

A clinically interpretable machine learning model using 19 proteins to predict recurrence/metastasis in OSCC patients

K. Sun¹

¹*The University of Hong Kong, Department of Anaesthesiology, Hong Kong, Hong Kong, China*

Introduction

Oral squamous cell carcinoma (OSCC) is a lethal disease with increasing incidence globally and poor prognosis (5-year survival ~50%), due to late diagnosis and high rates of recurrence and metastasis. The aim of this study is to develop a predictive model to identify the risk of recurrence or metastasis in patients who have undergone curative resection surgery for OSCC, in order to assist in personalised treatment planning and the implementation of better post-treatment monitoring.

Material and method

Clinical information from OSCC patients, including 27 clinical, diagnostic and treatment characteristics, and immunohistochemical images showing expression levels and patterns for 19 proteins, were used to develop and implement predictive models. Two machine learning approaches were compared: Decision trees and neural networks. The decision tree model was implemented using Scikit-learn, with hyperparameters tuned to control complexity and prevent overfitting. The neural network used a multimodal architecture combining convolutional layers for image feature extraction and fully connected layers for clinical data fusion to capture complex patterns in multimodal data. The models were trained on a 70-30 split of training and test data.

Result and discussion

A total of 200 patients (mean age = 61.4 ± 14.3 years), 63 patients had cancer recurrence/metastasis within the 3-year follow-up after undergoing curative resective surgery. For outcome prediction, the predictive models were evaluated which showed that decision tree achieved significantly higher accuracy than neural network (75% vs. 63%). The decision tree model also provided higher interpretability, with feature importance analysis revealing eight features contributed significantly to the prediction model. These were the expression levels of six proteins (CA9, E-cadherin, B-catenin, P-cadherin, Slug, and Versican) and two clinical features (invasion depth, age at diagnosis). These proteins promote tumour cell migration and invasion by regulating epithelial-mesenchymal transition, enhancing hypoxia adaptation, and remodelling tumour microenvironment, which the model has identified as potential biomarkers of OSCC progression.

Conclusion

The decision tree model exhibited superior performance and interpretability, and is a robust model for predicting OSCC recurrence and metastasis, though it is limited by the relatively small sample size. Future validation in multicentre cohorts is warranted. The proposed model has the potential to serve as a valuable tool for clinicians to improve post-treatment monitoring for OSCC patients.

EACR25-0282

MetaboDynamics: a Bioconductor package for the probabilistic analysis of longitudinal metabolomics data

K. Danielzik¹, S. Kitanovski¹, J. Matschke², D. Hoffmann¹

¹*University of Duisburg-Essen, Bioinformatics and Computational Biophysics, Essen, Germany*

²*University Hospital Essen, Institute of Cell Biology (Cancer Biology), Metabolism&Radiation Response Group, Essen, Germany*

Introduction

Deregulated metabolism is one of the emerging hallmarks of cancer. While modern experimental methods can measure many metabolites over time and under different conditions, it is still challenging to analyze this kind of complex, noisy data. Current tools often rely on pairwise comparisons between time points or experimental conditions, limiting our understanding of dynamic metabolic changes. Additionally over-representation analysis is often restricted to pathways missing broader changes in the metabolome. To address this gap we developed “MetaboDynamics” [1], an R-package now available on Bioconductor.

Material and method

The MetaboDynamics workflow starts with concentration tables of metabolites over multiple time points and experimental conditions such as radiation doses. We use this data to fit a hierarchical Bayesian model, a model type known to avoid over- and under-fitting. From the fit we obtain estimates of concentration changes between time points and thus dynamics profiles for all included metabolites. These profiles can be used as input for clustering. Once clusters of metabolites with similar dynamics under one experimental condition are identified these clusters can be analyzed in three different ways:

- 1) By quantifying the probability of a pathway or biological function, represented by a KEGG functional module, being over-represented in a dynamics cluster using a hypergeometric probabilistic model
- 2) By comparing the dynamics profiles of clusters or groups of metabolites from different experimental conditions with a Bayesian model
- 3) By comparing the metabolite composition of metabolite clusters from different experimental conditions

Result and discussion

We applied MetaboDynamics to study the longitudinal effects (0-24 h) of different radiation doses (2 Gy & 10 Gy) on the metabolome of cancer cells in vitro. Estimated concentration differences between time points revealed consistent changes in amino acid concentrations over time. Clustering identified metabolite groups with similar dynamics, and functional enrichment analysis highlighted biological functions such as amino acid, nucleotide, and energy metabolism. Combining dynamics and metabolite composition comparisons revealed clusters with similar metabolite compositions but differing dynamics between radiation doses. This suggests radiation dose-dependent changes in cancer cell metabolism in vitro. These results demonstrate the utility of MetaboDynamics in uncovering complex metabolic changes and providing new insights into longitudinal effects of experimental conditions or treatments on metabolism.

Conclusion

MetaboDynamics provides a robust and interpretable framework for analyzing complex metabolomics data, offering insights into dynamics and functional enrichment that traditional methods may overlook.

Identification of Olveremabatinib as a Potential Inhibitor for ROR1+ Triple-negative Breast Cancer

O. Bender¹, I. Celik², R. Ceylan^{3,4}, A. Aciksari⁴, S. Cetinel^{3,4}, A. Atalay¹
¹Ankara University, Biotechnology Institute, Ankara, Turkey
²Erciyes University, Faculty of Pharmacy, Department of Pharmaceutical Chemistry, Kayseri, Turkey
³Sabanci University, Faculty of Engineering and Natural Sciences, Istanbul, Turkey
⁴Sabanci University, Nanotechnology Research and Application Center, SUNUM, Istanbul, Turkey

Introduction

Receptor tyrosine kinase-like orphan receptor 1 (ROR1) is an attractive target in breast cancer research due to its overexpression. This study aims to identify potential ROR1 inhibitors for investigation in triple-negative breast cancers through high-throughput virtual screening, molecular docking, molecular dynamics (MD) simulations, and cell-based in vitro validation. The binding affinity and stability of a potential inhibitor, Olveremabatinib, were compared with Ponatinib, a known ROR1 inhibitor.

Material and method

Virtual screening was performed using the Glide SP docking module in Schrödinger 2022.2, screening over 9,000 compounds from DrugBank against ROR1 (PDB ID: 6TU9). The best-scoring compounds were further analyzed for their binding interactions, including hydrogen bonding, hydrophobic contacts, and π - π stacking. MD simulations were conducted using Gromacs v2023.3, with input files prepared via the CHARMM-GUI server. Protein-ligand complexes were solvated in a TIP3P water box, and the system was equilibrated under NVT and NPT conditions at 303.15 K and 1 bar. A 300 ns MD simulation was performed for Olveremabatinib and Ponatinib, and key analyses such as root mean square deviation (RMSD), root mean square fluctuation (RMSF), and interaction stability were conducted. Additionally, Olveremabatinib and Ponatinib were tested on ROR1+ MDA-MB-231 and ROR1- MCF-7 breast cancer cells using the WST-1 assay in a time- and dose-dependent manner.

Result and discussion

Olveremabatinib demonstrated the best docking score (-14.511 kcal/mol) among all screened compounds, including Ponatinib (-14.023 kcal/mol), indicating its strong binding affinity to ROR1. Olveremabatinib formed dual hydrogen bonds with Ile555, in addition to π - π stacking with Phe552 and a π -cation interaction with His613, which were absent in Ponatinib. Hydrophobic interactions with Leu487, Leu530, and Val536 further contributed to its stability. MD simulations confirmed these findings, with Olveremabatinib maintaining key hydrogen bonds with Ile555 and Asp633. RMSD analysis showed lower fluctuations, while RMSF indicated minimal flexibility in critical binding site residues. Cell viability assays demonstrated that Olveremabatinib had higher selectivity and inhibitory activity in ROR1+ cells than in ROR1- cells. It appeared to be more selective than Ponatinib against ROR1+ cells while demonstrating

comparable effectiveness. The long-lasting effects of Olveremabatinib across decreasing doses were especially remarkable.

Conclusion

This study highlights Olveremabatinib as a promising ROR1 inhibitor with strong and persistent interactions, making it a viable lead compound for further preclinical validation and development of targeted therapies against ROR1-driven triple-negative breast cancers.

EACR25-0320

Evolution of phenotypic plasticity leads to tumor heterogeneity with implications for therapy

S. Syga¹, H. Hatzikirou², A. Deutsch¹
¹TUD Dresden University of Technology, Center for Interdisciplinary Digital Sciences, Dresden, Germany
²Khalifa University, Mathematics Department, Abu Dhabi, United Arab Emirates

Introduction

Intratumor heterogeneity is a major challenge in cancer treatment, arising from both somatic evolution and phenotypic plasticity. While genetic diversity in tumors has been widely studied, the interplay between evolutionary changes and phenotypic plasticity remains poorly understood. In glioblastoma, the most aggressive brain tumor, plasticity between migration and proliferation plays a crucial role in tumor progression. We investigate how somatic evolution shapes phenotypic plasticity, particularly how tumor cells respond to microenvironmental changes.

Material and method

We develop a spatially explicit model that tracks both genetic and phenotypic states of individual tumor cells. In our model, cells switch between migratory and proliferative states, with switching dynamics influenced by inherited genotypes, mutations, and local microenvironmental conditions. We use analytical and computational approaches to predict evolutionary outcomes and quantify resulting heterogeneity patterns.

Result and discussion

Our simulations reveal that tumor cells at the periphery tend to evolve toward a migratory phenotype, whereas cells within the tumor bulk favor proliferation. Strikingly, this pattern emerges from different genetic configurations, highlighting the role of microenvironment-driven selection. We further show that tumors display varying levels of genetic and phenotypic heterogeneity, with phenotypic heterogeneity emerging as a strong predictor of tumor recurrence time after treatment. Unlike genetic heterogeneity, higher phenotypic heterogeneity correlates with worse treatment outcomes.

Conclusion

Our study provides a mechanistic explanation for the heterogeneous recurrence patterns observed in glioblastoma. We show that phenotypic heterogeneity, rather than genetic heterogeneity, is a key determinant of treatment success. This insight may help refine therapeutic strategies by targeting tumor plasticity to improve patient outcomes.

EACR25-0321**Integrated Genomic and Structural Analysis Reveals Novel Insights into Polymerase Proofreading Deficiency Drivers***D. Dayan¹, Y. Maruvka²*¹*Technion - Israel Institute of Technology, Biotechnology and Food Engineering, Haifa, Israel*²*Technion - Israel Institute of Technology, Lori Loka Center for Life Science and Engineering, Haifa, Israel***Introduction**

Polymerase proofreading deficiency (PPD), caused by mutations in POLE and POLD1 genes, leads to extremely high tumor mutation burdens and distinct mutational signatures. While PPD tumors show promising responses to immunotherapy, identifying the specific variants responsible remains challenging. Current variant classification efforts are incomplete, with many variants of unknown significance, including well-known drivers like POLE P286R and V411L.

Material and method

We analyzed 235,161 sequenced tumors from three major databases (GENIE, TCGA, and CPC) using an iterative SVM approach that incorporated both mutation burden and signature analysis. For structural characterization, we leveraged AlphaFold2 to generate 160 models for each variant, developing a novel metric based on pLDDT scores to assess structural impact. We further employed AlphaFold3 to analyze magnesium ion binding in specific variants. Clinical correlations were examined across different driver clusters.

Result and discussion

We identified 567 PPD tumors across 13 cancer types, with 515 harboring driver variants. Our analysis revealed novel POLE drivers outside the exonuclease domain, challenging traditional assumptions about variant pathogenicity. Structural analysis achieved an AUC of 0.85 in distinguishing drivers from passengers, outperforming existing tools like AlphaMissense (AUC = 0.73) and MutPred2 (AUC = 0.63). We identified three distinct structural regions affected by PPD variants and classified drivers into six clusters based on their structural impact. These clusters showed significant associations with MMR status, mutation burden, and signature profiles. Clinical analysis revealed age-related correlations specific to male colorectal cancer patients and endometrial cancer cases. Our integrated approach provides novel insights into PPD variant classification and their functional impacts. The characterization of distinct structural clusters suggest multiple mechanisms through which PPD variants affect polymerase function. The differential associations of clusters with clinical features and molecular characteristics indicate potential prognostic and therapeutic implications. Saturation analysis suggests that while additional drivers may be discovered with larger datasets, the current list captures most clinically relevant variants.

Conclusion

This comprehensive analysis of PPD drivers combines genomic evidence with structural insights to advance our understanding of polymerase proofreading deficiency.

Our findings provide a framework for variant classification and suggest that different PPD drivers may operate through distinct mechanisms, potentially influencing clinical outcomes. The established relationships between structural impacts and molecular features offer new perspectives for personalized therapeutic approaches in PPD tumors.

EACR25-0400**Deep Learning-Based PET Synthesis from CT Scans: Advancing Abdominal Lymph Node Metastasis Assessment***W. Gong¹, Y. Qu², M. Zhou³, F. Li¹, H. Zhang¹, H. Wang⁴, A. Liu¹, P. Sun¹*¹*Yantai Yuhuangding Hospital, Department of Oncology, Yantai, China*²*Yantai Yuhuangding Hospital, Radiology Department, Yantai, China*³*Yantai Yuhuangding Hospital, Nuclear Medicine Department, Yantai, China*⁴*Yantai Yuhuangding Hospital, Information Technology Department, Yantai, China***Introduction**

Abdominal lymph node metastasis (ALNM) plays a critical role in cancer staging, treatment decision-making and defining radiotherapy target boundaries. However, traditional CT imaging lacks functional metabolic data, making it difficult to distinguish benign lymph nodes from malignant ones especially the tiny lesions. PET/CT is commonly used to identify ALNM, offering both metabolic and anatomical data. Despite its benefits, widespread use is limited by high costs, radiation exposure, and limited availability. With advances in deep learning, particularly Generative Adversarial Networks (GANs), generating synthetic PET-like images from CT scans provides a feasible computational strategy for PET imaging, potentially complementing standard imaging workflows. This study explores a deep learning model to generate PET-like images from CT to enhance ALNM assessment and improve clinical decision-making for cancer patients.

Material and method

A deep learning model was derived from Reg-GAN. The model was trained on a training set using paired CT and PET/CT scan images of patients with suspected ALNM. After training, the PET/CT images were synthesized with an estimated average approximately 40 seconds per patient. The diagnostic quality of contrast, sharpness, and lesion visibility was assessed by three independent radiologists using a 5-point Likert scale, ensuring the confidentiality of the image type.

Result and discussion

The synthetic PET images closely resembled real PET scans, with radiologists rating nearly 85% as "good" or "excellent" (Likert score ≥ 4), with a high inter-reader agreement ($\kappa = 0.82$). The generated images improved lesion detection, particularly those with a diameter ≤ 10 mm, which are often missed by conventional CT or MRI. Unlike previous studies on PET synthesis focusing on lung or brain cancer imaging (CT-to-PET, MRI-to-PET), this model is specially designed for ALNM, where metabolic imaging significantly influences clinical

decisions. The results support AI-generated PET synthesis as a practical adjunct to CT, improving diagnostic capabilities, particularly in preoperative planning and follow-up assessments of lymph node involvement.

Conclusion

This study demonstrates the potential of PET synthesis generated from CT images using deep learning, providing a cost-effective and radiation-free option for ALNM assessment without direct PET acquisition. The method may improve surgical strategies and radiotherapy target delineation. To enhance its applicability in diagnosis and cancer management, future research will focus on multi-center validation and integration with multimodal biomarkers.

EACR25-0449

nf-hlamajority: a Nextflow pipeline for consensus MHC class I genotyping and its application to neoantigen identification in breast and lung cancer stromal cells

K. Ryan¹, D. O'Connor², B. Digby¹, L. Barkley², P. Ó Broin¹

¹*Ollscoil na Gaillimhe - University of Galway, Department of Mathematical and Statistical Sciences, Galway, Ireland*

²*Ollscoil na Gaillimhe - University of Galway, School of Medicine Lambe Institute for Translational Research, Galway, Ireland*

Introduction

Cancer-associated fibroblasts (CAFs) are a heterogeneous cell type found in the tumour microenvironment. CAFs can support tumour growth and metastasis and contribute to therapeutic resistance, making them a potential therapeutic target. Here, we aim to identify neoantigens resulting from somatic mutations in CAFs. HLA genotyping, a critical step for neoantigen prediction, can be performed using DNA sequencing data with various tools available. Claeys et al. (PMID:37161318) found that a majority voting approach improved HLA typing performance. No end-to-end pipeline exists to apply this approach, making it difficult for non-informatics to implement. The objectives of this study were to:

- 1) develop a Nextflow pipeline implementing majority voting for MHC class I typing from DNA sequencing, and
- 2) use HLA calls from this pipeline to identify neoantigens in CAFs.

Material and method

CAFs and corresponding tumour-associated normal fibroblasts (TANs) were cultured from the tissue of 11 patients with breast cancer (10 Luminal A, one triple-negative) and 10 patients with lung cancer (six adenocarcinoma, two squamous cell carcinoma, two of unknown subtype). Whole-exome sequencing (WES) and bulk RNA sequencing were carried out on all samples. Using our pipeline, nf-hlamajority, we carried out HLA typing on our patient WES data and WES data from 12 NCI-60 Human Tumor Cell lines using Optitype, Polysolver, HLA-LA, and Kourami. For each HLA gene, the pipeline assigned the HLA genotype called by the

highest number of tools. These HLA genotypes were used as input to Landscape of Effective Neoantigens Software (LENS), along with the WES and RNA-sequencing data, to identify CAF-specific neoantigens (PMID: 37184881).

Result and discussion

Results from the NCI-60 dataset showed 97% accuracy, with 68 out of 70 HLA calls matching PCR-based genotyping. LENS identified potential neoantigens resulting from missense mutations, with more high-confidence expressed mutations observed in lung cancer CAFs compared to breast cancer CAFs (Welch's Two Sample t-test, $p = 0.017$). All missense mutations were private, although two lung cancer CAF samples had a mutation in the COASY gene. Interestingly, this gene and other genes harbouring mutations are implicated in lipid metabolic pathways. CAFs contribute to lipid metabolism within the TME, thus impacting cancer progression and tumour immunogenicity.

Conclusion

In this study, we have developed an automated pipeline for consensus HLA genotyping which we envisage will be useful to the research community. nf-hlamajority has helped us identify candidate neoantigens in breast and lung cancer CAFs. Future work will focus on validation using T-cell immunogenicity assays and investigating the CAF subpopulation distribution of our candidate neoantigens using single-cell RNA sequencing. This will improve our understanding of the potential of targeting CAF neoantigens to enhance the efficacy of anti-cancer therapies.

Integrative analysis of the TBXT-driven transcriptome and proteome in chordoma

C. Erkut^{1,2,3}, S. Umbaugh^{1,2}, M. Groth^{4,2}, S. Dolaner^{1,2}, K. Lee^{4,2}, J. Kapp⁵, B. Dreier⁵, A. Plückthun⁵, S. Fröhling^{4,2,3}, C. Scholl^{1,2,3}

¹*German Cancer Research Center (DKFZ), Applied Functional Genomics, Heidelberg, Germany*

²*National Center for Tumor Diseases (NCT) Heidelberg, Germany*

³*German Cancer Consortium (DKTK), Heidelberg, Germany*

⁴*German Cancer Research Center (DKFZ), Translational Medical Oncology, Heidelberg, Germany*

⁵*University of Zurich, Department of Biochemistry, Zurich, Switzerland*

Introduction

Chordoma is a rare spinal neoplasm driven by over-expression of the embryonic transcription factor (TF) TBXT. Pharmacologic inhibition of TBXT is challenging, and its molecular network in chordoma is not well studied. Using designed ankyrin repeat proteins that specifically bind TBXT and prevent its binding to DNA (T-DARPin), we profiled and integrated the transcriptomes and proteomes of chordoma cells upon TBXT inhibition to identify TBXT-regulated genes and proteins that might represent novel, targetable vulnerabilities.

Material and method

Chordoma cells were transduced with vectors encoding a non-targeting control DARPin or three T-DARPin in

biological triplicates. Total RNA was sequenced using Illumina TruSeq Stranded RNA Kit (paired end, 100 cycles), and raw data were processed with an in-house workflow that uses STAR for alignment and featureCounts to estimate gene expression. Proteomes were analyzed via liquid chromatography-tandem mass spectrometry and raw data were processed with MaxQuant or Spectronaut to estimate relative protein abundance. Gene and protein annotations were imported from GENCODE and UniProt. A custom workflow based on the R packages DESeq2, DEP, and limma was developed to analyze, integrate, and annotate differentially expressed genes (DEGs) and proteins (DEPs). Functional annotation analysis was performed via pre-ranked gene set enrichment analysis (GSEA). Potential drug targets were selected based on The Cancer Druggable Gene Atlas.

Result and discussion

TBXT inhibition induces widespread changes in the transcriptome and proteome. We found 3,271 DEGs common to all three T-DARpins and 960 DEPs common to at least two. In addition to known TBXT targets and chordoma-associated genes, IGFBP3 stood out as the most upregulated protein. 393 DEPs/DEGs are targetable by clinically approved or experimental drugs. GSEA indicated suppression of pathways associated with cell division and DNA replication and repair upon TBXT inhibition, in line with TBXT's oncogenic role in chordoma. We also observed downregulation of embryonic progenitor cell signatures and upregulation of differentiated cell type signatures, suggesting alteration of cell identity, and downregulation of interferon response and JAK-STAT signaling pathways, which we found to be active in tumors of chordoma patients. Proteome profiling of cells with combined TBXT and IGFBP3 inhibition showed that part of the TBXT regulome is modulated by IGFBP3, particularly the interferon response pathway. Accordingly, chordoma cells were sensitive to JAK2 inhibition, suggesting a novel treatment option for chordoma patients using clinically approved JAK2 inhibitors.

Conclusion

DARPin-mediated TF inhibition combined with integrative multi-omics represents a novel strategy to investigate the regulatory networks of cancers driven by aberrant TF activity, which can lead to novel entry points for targeted therapies.

EACR25-0461

Mutational signatures as footprints of tumors' metastatic tropism

A. Yaacov¹, A. Popovtzer¹, S. Rosenberg¹

¹*Hadassah University Medical Center, Sharett Institute of Oncology, Jerusalem, Israel*

Introduction

Tumors vary in their metastatic pattern. Metastases (mets) often exhibit distinct mutational landscapes compared with primary tumors. Mutational signatures – patterns of mutations reflecting underlying sources of cancer mutagenesis – have been extensively studied in primary tumors. However, their role in metastatic disease remains less well understood. In this study, we performed a

comprehensive analysis of mutational signature enrichment in primary tumors and metastases across multiple metastatic sites and cancer types.

Material and method

We analyzed more than 14,000 samples from the MSK-MET and MSK-IMPACT cohorts. Dominant mutational signatures were identified using MESiCA (Yaacov et al., 2024), a machine learning tool we developed for targeted gene panels. Briefly, MESiCA uses a neural embedding model that learns to represent mutation and signatures as vectors. For each new sample, observed mutations are compared to reference signature values. MESiCA detected the presence of APOBEC, SBS1, SBS5, MMR, POLE, and UV signatures. Two-sided Fisher's exact test was used to assess associations between signatures and metastatic samples, as well as with different metastatic sites.

Result and discussion

Mutational signature landscape between mets and primary tumor specimens was compared, stratified by cancer type. Of the total, 7,793 samples were primary and 5,294 were mets. APOBEC, SBS5, and UV signatures were enriched in mets samples, whereas SBS1, MMR, and POLE were enriched in primary tumor. The Tobacco signature showed no enrichment. Notably, APOBEC was enriched in mets originated from head and neck cancer (Odds Ratio [OR] 4.77), non-small cell lung cancer (OR 1.34), and thyroid cancer (OR 1.94). SBS5 was enriched in colorectal cancer mets (OR 1.40) and UV in melanoma mets (OR 2.47). Conversely, SBS1 was enriched in primary cervical (OR 0.17) and colorectal cancer (OR 0.71). MMR and POLE were linked to primary endometrial and colorectal cancer (OR 0.70 and OR 0.20, respectively). In site-specific analyses (comparing each metastatic site against the other 19 sites in a pan-cancer approach), mets harboring APOBEC were significantly associated with bladder, bone, brain, head and neck, mediastinum, and pleura (OR 1.3–1.91), but negatively associated with gastrointestinal sites (biliary tract, bowel, intra-abdominal, and liver; OR 0.58–0.71). UV signatures were highly enriched in skin (OR 4.56) and brain mets (OR 1.33). POLE showed no significant enrichment. All reported associations were significant at an FDR-corrected $p < 0.05$.

Conclusion

This large-scale analysis reveals distinct enrichment patterns of mutational signatures between primary and metastatic specimens and across different metastatic sites. Our findings demonstrate site-specific preferences for certain signatures, suggesting that mutational processes may influence metastatic tropism and could help in guiding clinical strategies.

EACR25-0475

Classification of Small Blue Round Cell Tumors via mass spectrometry imaging of peptide and glycan content

C. Bollwein¹, K. Schwamborn¹, T. Tran², A. Ly², N. Patterson², J. Gonçalves¹

¹*Technical University of Munich, Institute of Pathology, School of Medicine, Munich, Germany*

²*Aspect Analytics NV, Genk, Belgium*

Introduction

Small blue round cell tumors (SBRCT) is an umbrella term referring to tumors of similar histological presentation but may have completely different origins, e.g. Ewing sarcoma or nephroblastoma. Correct diagnosis is therefore essential due to significantly different treatment approaches and prognosis for each tumor entity. Matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) is a technique enabling visualization and analysis of the spatial distribution of different molecular classes, such as peptides, glycans, lipids, and metabolites. We used MALDI-MSI of tryptic peptides and N-glycans from archival SBRCT samples to create classification algorithms that could reliably distinguish the different entities and identify discriminatory features between the tumor types.

Material and method

Six different SBRCT types were assembled into a tissue microarray (TMA; n = 26): acute lymphoblastic leukemia/lymphoma (ALL, n = 5), Ewing sarcoma (EWS, n = 5), neuroendocrine carcinoma (NEC, n = 5), nephroblastoma (NEPB, n = 3), neuroblastoma (NEUB, n = 3), and rhabdomyosarcoma (RMS, n = 5). TMA sections underwent on-tissue enzymatic digestion using either N-glycosidase F or trypsin, followed by matrix application and measurement on a mass spectrometer (rapifleX, Bruker). Following measurement, the sections were H&E stained, digitized and histopathologically annotated (QuPath, v.0.4.3). Data analysis was performed using SCiLS Lab (Bruker, v.2024a), Weave (v.1.0, Aspect Analytics), and Python (v.3.9). Weave was used for image co-registration, combining the peptide and glycan data into a single dataset. This enabled comparison of analytes and histology, and interactive browsing of data analysis results through a web-based report.

Result and discussion

MALDI-MSI data was employed for the training and validation of four classification algorithms (gradient boosting, support vector machine, k-nearest neighbor, and linear discriminant analysis) using 10-fold cross-validation on a pixel level. Multiclass classification was implemented as a one vs. rest (one entity vs. all other entities) and one vs. one (one entity vs. every other entity) approach. For the one vs. rest strategy, the mean accuracy of all classifiers was 90.5% with a mean accuracy of 88.7% for peptide analysis, 92.4% for glycan analysis, and 95% for combined peptides and glycans. For the one vs. one approach, mean accuracy of all classifiers was 92.4% with a mean accuracy of 88.8% for peptide analysis, 96.1% for glycan analysis and 97% for the combined dataset.

Conclusion

In summary, MALDI-MSI of peptides and glycans, particularly in combined form, shows potential in distinguishing between different SBRCT entities. Future work will expand the patient cohort size and explore alternative statistical methods to further improve classification performance.

Weave: a software package for integrated spatial multi-omics visualization and data analysis

W. Zhang¹, T. Tran¹, F. Wee², C. Joseph², L. Chong², Z. Neo², J. Yeong^{2,3}, A. Ly¹, M. Claesen¹, N. Patterson¹

¹Aspect Analytics NV, Genk, Belgium

²Agency for Science, Technology and Research (A*STAR), Institute of Molecular and Cell Biology (IMCB), Singapore, Singapore

³Singapore, Singapore,

Introduction

There has been enormous progress in single-omics spatial technologies, which has revolutionized our understanding of the tumor microenvironment (TME). While the data generated from these methods have helped to unravel cellular intricacies within spatial context at the genomic, transcriptomic, metabolomic and protein levels, users are increasingly combining different omics readouts to obtain a holistic view of TME heterogeneity and complexity. However, spatial multi-omics data analysis presents specific bioinformatics challenges, as the data is typically acquired at different spatial resolutions, using a variety of platforms, and generates large data volumes. We present Weave, a cloud-based software for spatial omics bioinformatics, enabling efficient integration and joint visualization of different spatial-omics assays.

Material and method

Human lung cancer sections were sequentially analyzed with spatial transcriptomics using a cancer panel targeting 289 genes (Xenium, 10X Genomics), followed by multiplexed immunofluorescence using a 40-antibody panel (COMET, Lunaphore), and then H&E staining. The H&E images were digitized (Axioscan 7, Zeiss), and pathology annotation performed in QuPath. Cell segmentation was performed on the Xenium dataset using DAPI-based nuclear expansion (10X Genomics), and on the COMET dataset using CellSAM. All data were co-registered at full resolution using a non-rigid spline-based algorithm, then visualized in a web-based viewer (Weave, Aspect Analytics).

Result and discussion

Weave software was developed to address several spatial omics bioinformatics challenges. This software fully supports joint visualization of different spatial omics assays, and multiple common downstream multimodal analysis pipelines. The cloud-based software allows interactive browsing of datasets at full resolution via web-browsers, enabling communication of results between collaborators, and removes limitations of location or operating system. For the use case presented here, we utilized an advanced integration pipeline to match readouts across the COMET, Xenium and H&E data, accounting for different sized measurement regions and spatial resolutions. Pathology annotations and cell segmentation results were integrated and overlaid as additional visualization layers. We conducted correlation analysis to identify which transcript-protein pairs had similar spatial expression and if this correlation was affected by cell segmentation approach. Some pairs had high correlation regardless of cell segmentation, while proteins from complexes derived from multiple genes (e.g. CD3) yielded variable correlations.

Conclusion

As spatial multi-omics is increasingly used to investigate TME biology, we present software addressing the need for appropriate bioinformatics solutions.

EACR25-0534

Optimizing Chemoradiotherapy for Malignant Gliomas Using a Validated Mathematical Model and In Silico Trials

M. Itália¹, M. Perales Patón¹, M. Castelló Pons², I. Gómez Soria², J. Belmonte Beitia¹, P. Sánchez Gómez², V. Pérez García¹

¹*Universidad de Castilla-La Mancha, Department of Mathematics, Mathematical Oncology Laboratory (MOLAB), Ciudad Real, Spain*

²*Instituto de Salud Carlos III (ISCIII), Neurooncology Unit, Unidad Funcional de Investigación de Enfermedades Crónicas (UFIEC), Madrid, Spain*

Introduction

Malignant gliomas (MGs), including glioblastomas, are among the most aggressive cancers, characterized by rapid progression and resistance to standard therapies such as temozolomide (TMZ) and radiotherapy. Standard treatments, such as the Stupp protocol, offer limited survival benefits and high toxicity. This study aims to optimize chemoradiotherapy (CRT) protocols using a validated mathematical model and in silico trials to optimize patient outcomes. Finally, our model can be adapted to other cancers with similar resistance mechanisms, suggesting broader utility.

Material and method

We developed a mathematical model using ordinary differential equations to simulate MG dynamics and CRT response. The model integrates key biological processes, such as cell proliferation, tumor dormancy, and resistance mechanisms. Key features include Ki-67, the role of persister cells in the development of TMZ resistance and the impact of treatment timing on survival. We calibrated and validated the model using experimental data from a mouse subventricular zone (SVZ) model developed through retroviral expression of EGFR-wt in primary cultures of neural stem cells from mice. For calibration, we administered 3 daily sessions of 3 Gy each, beginning 40 days post-tumor injection, and monitored tumor progression via bioluminescence using the In Vivo Imaging System (IVIS), which tracks tumor cell viability. In addition, survival data from prior TMZ experiments were utilized. To validate the model, we compared *in vivo* and *in silico* survival data from a combined CRT treatment protocol adapted from the Stupp protocol, with 3 consecutive concomitant CRT daily sessions (3 Gy and 3.33 mg/kg of TMZ) followed by a 2-day break and 3 subsequent adjuvant TMZ sessions (6.66 mg/kg daily) separated by 3 days. Finally, we translated the model and the optimal treatment into humans.

Result and discussion

Our *in silico* simulations revealed that concomitant CRT protocols, incorporating treatment breaks, resulted in a 17% improvement in median overall survival (OS) in mice compared to the standard Stupp protocol, with reduced toxicity. Translating these findings to human contexts, extended treatment protocols with concomitant

CRT or concomitant CRT plus adjuvant TMZ separated by treatment breaks resulted in a median OS of up to 48 months, a 280% increase over the standard Stupp protocol. These results underscore the potential of optimized protocols to enhance OS and reduce side effects.

Conclusion

This study highlights the power of mathematical modeling and *in silico* trials in optimizing oncology, providing valuable insights into the design of more effective CRT regimens for MGs. Our findings indicate that extended treatment schedules with treatment breaks could significantly improve OS and quality of life. Clinical trials are required to confirm our findings in real-world settings.

⁶*Sun Yat-sen University Cancer Center, Sun Yat-sen University Cancer Center, Guangzhou, China*

⁷*The Second Hospital of Tianjin Medical University, The Second Hospital of Tianjin Medical University, Tianjin, China*

Introduction

Cancer poses a significant health threat to women in China, with lung, colorectal, gastric, breast, cervical, kidney, and reproductive tract malignancies exhibiting persistently high incidence and mortality rates, covering 61.2% of female cancer-related deaths. Current female-specific screening paradigms are limited to individual cancers (e.g., mammography for breast, Pap tests for cervical) and lack accessibility in underserved populations. Herein, we developed and validated a metabolomics-based machine-learning model for simultaneous multi-cancer screening and tumor localization in women.

Material and method

The 1,360 participants were enrolled in this study, including 1,097 cancer patients spanning eight cancer types (breast, ovarian, endometrial, cervical, lung, gastric, colorectal, and renal cancers) and 263 non-cancer controls (176 healthy controls and 89 benign cases) across seven centers. Plasma samples were analyzed using GC-MS and LC-MS multi-platforms. The cohort was randomly divided into discovery ($N = 1159$) and validation ($N = 201$) sets. A two-stage machine learning pipeline was applied: (1) a multi-cancer screening model (with 96.0% specificity) to differentiate cancer patients

from non-cancer controls, and (2) a tumor localization classifier to predict the origin of cancers. Performance was assessed in the validation cohort using sensitivity/specificity for cancer detection and the accuracy of the top one predicted origin (TPO1) and top two predicted origins (TPO2) for tumor origin classification.

Result and discussion

In the validation set, the model showed consistent performance, with a specificity of 95.2% (95% CI: 83.8% to 99.4%). Sensitivity for detecting early-stage cancers (I-II) was 45.9% (95% CI: 37.3% to 54.7%) across eight cancer types. Sensitivity improved with advancing cancer stages: 41.4% at stage I, 54.2% at stage II, 64.1% at stage III, and 84.2% at stage IV. For tumor localization, the accuracy of TPO1 and TPO2 was 74.1% and 85.5%, respectively. Additionally, the model achieved an accuracy of 89.4% in predicting the top one origin of the three most common cancers in women – lung, colorectal, and breast cancer – in terms of both incidence and mortality. Age and menopause status were unlikely to affect the model's accuracy, making it applicable across diverse populations.

Conclusion

This study highlights the potential of metabolomics-based machine learning models as a non-invasive tool for multi-cancer screening and precise tumor localization in women. With validation across large-scale datasets, our approach offers a simple, cost-effective method for improving early detection and clinical outcomes. Future work will expand the model by incorporating more cancer types and developing gender-neutral screening solutions.

EACR25-0678

Computational identification of pan-cancer multi-omic metabolic signatures as prognostic biomarkers and therapeutic targets

H. Almeida Cordeiro Nogueira¹, E. Rodrigues de Souza¹, A. Garcia¹, E. Medina-Acosta¹

¹*Universidade Estadual do Norte Fluminense, Laboratório de Biotecnologia, Campos dos Goytacazes - RJ, Brazil*

Introduction

Metabolic reprogramming is a key factor in tumor progression and immune evasion, influencing prognosis and therapeutic response. Here, we conducted a multiomic analysis to identify metabolic signatures as potential prognostic biomarkers and therapeutic targets, covering energy, carbohydrate, lipid, amino acid, nucleotide, vitamin, and cofactor metabolism.

Material and method

We developed algorithms to integrate omic data from enzyme-coding genes, mature miRNAs, lncRNAs, and transcript isoforms, correlating them with tumor phenotypic features and clinical outcomes across 33 TCGA tumor types. Only targets with statistically significant associations ($p.\text{adj} < 0.05$) were selected for further analyses. We applied differential expression, Cox regression, log-rank, and Spearman correlations with immune infiltrates to define metabolic signatures. We adopted an innovative strategy: candidates belonging to

the same metabolic pathway with consistent results across all analyses were aggregated, and common molecular interactions among signature elements were identified. We developed the CancerMetabolismGPSShiny, an interactive tool that facilitates the exploration of our database results through visualizations and report outputs, paving the way for new discoveries in precision oncology.

Result and discussion

We identified 251,687 multi-omic signatures associated with 33 tumor types, distributed across carbohydrate (23.87%), lipid (23.32%), amino acid (22.38%), vitamin and cofactor (13.49%), nucleotide (6.17%), energy (4.81%), and other amino acid (5.96%) pathways. After selecting for signature clinical potential (risky, protective, and poorer prognosis) in all survival metrics, we identify 2,949 signatures, including 744 whose elements have known pharmacological interactions, in 20 tumor types. For example, in Liver Hepatocellular Carcinoma (LIHC), we identified the signature (ADH4 + TAT) involved in tyrosine metabolism and interacting with hsa-miR-376c-3p. This signature is downregulated in LIHC ($p = 3.5e-21$), with a negative correlation with stemness ($\rho = -0.3$, $p.\text{adj} = 1.01e-40$) and a protective effect in Cox regression analyses for OS ($p = 0.000008$), DSS ($p = 0.0005$), DFI ($p = 0.008$), and PFI ($p = 0.002$). Log-rank tests confirmed that higher expression is associated with improved prognosis ($p < 0.005$ across all survival metrics). This signature is linked to a cold immune phenotype and dual-profile (pro- and antitumor) immune cells. ADH4 and TAT interact with agonistic drugs (e.g., linolenic acid, griffolic acid) and inhibitors (e.g., nitrefazole, RO-24-7429), highlighting their therapeutic potential.

Conclusion

Our findings underscore the value of metabolic signatures as prognostic biomarkers and therapeutic targets, while the data available in CancerMetabolismGPSShiny can foster new hypotheses, experimental validation, and the development of tumor metabolism-based therapeutic strategies.

EACR25-0721

Describing Molecular Alterations in Breast Cancer Through a Multi-Omics Lens

A. Halama¹, S. Dib¹, S. Kader¹, N. Khattab¹, W. Ibrahim¹, A. Anand², S. Al-Shibani², G. El Mabrok², S. Gehani², K. Junejo²

¹*Weill Cornell Medicine Qatar, Physiology and Biophysics, Doha, Qatar*

²*Hamad Medical Corporation, Surgery, Doha, Qatar*

Introduction

The identification of breast cancer-related genetic mutations and gene expression profiles has contributed to better patient stratification for treatment modalities and improved patient outcomes. However, the molecular landscape of cancer expands beyond genetic components. The alterations in protein and metabolite profiles could be considered as more precise determinants of breast cancer phenotype. Nevertheless, such monitoring is limited as studies focusing on multi-omics profiling of tumor tissue are rather scarce due to limitations in robust

protocols. Moreover, the benefits of implementation of multi-omics profiling for single patients are also not fully understood. Our goal was to establish a robust protocol for multi-omics tissue profiling and to assess the relevance of molecular landscape revealed across different layers of alterations.

Material and method

This is part of Breast Cancer Omics Research Qatar (B.CORQ) project in which specimens from 200 patients (100 benign and 100 malignant) of Arab and Asian ethnicity were collected and processed. Tumor and adjacent tissues were collected during the operation and processed. Different omics including untargeted metabolomics, targeted lipidomics, proteomics, transcriptomics, methylation and genomics were conducted on those samples.

Result and discussion

The genetic and transcriptomic outcomes aligned with histopathological tumor characterization. Altered gene expression profiling, in agreement with proteomic analysis, revealed strong alterations of peroxisome proliferator-activated receptors (PPARs), actin cytoskeleton organization and metabolic process. Among 647 metabolites identified by untargeted metabolomics 289 distinguished tumor tissue from adjacent normal tissue. These differentiating metabolites were distributed across various pathways including metabolism of methionine, carnitine and aspartate as well as purine metabolism. The targeted lipidomic profiling revealed sphingolipids, phosphatidylcholines as well as triacylglycerols as the main lipid classes differentiating tumors from adjacent tissue. These metabolic differences were linked to enzymes showing corresponding alterations in gene expression and protein abundance.

Conclusion

This study advances the integration of multi-omics approaches into the clinical pipeline. It also highlights interactions across various omics layers within the dysregulated tumor molecular network, offering insights that could aid in optimizing treatment strategies.

EACR25-0724

Using the CancerHubs approach and web application to define novel cancer-related protein interaction hubs

*I. Ferrari¹, E. Arsuffi¹, F. De Grossi¹, G. Lai¹, S. Oliveto¹, G. Deroma¹, S. Biffo¹, N. Manfrini¹
¹INGM, Istituto Nazionale Genetica Molecolare Romeo ed Enrica Invernizzi, Milan, Italy*

Introduction

Discovering the players and understanding the molecular mechanisms involved in cancer initiation and progression are fundamental issues for developing effective targeted therapies. Conventional methods for predicting protein involvement in cancer typically focus on isolated analyses of single-gene aberrations or transcript level correlations with patient survival. These methods are usually performed separately and concentrate on a single gene/protein at a time, ignoring nucleotide changes outside coding regions or the simultaneous mutations in genes within the same interaction network.

Material and method

To address these limitations, we have recently developed CancerHubs, a systematic data mining and elaboration approach that integrates unbiased mutational data, clinical outcome predictions and interactomics to define novel cancer-related protein hubs. The approach is based on a newly introduced metric termed the 'network score', which is able to predict the level of involvement of a certain gene in a particular cancer by defining the number of mutated interactors its encoded protein has.

Result and discussion

Here, we will present the web application we have implemented based on the CancerHubs approach. We will describe the application functionalities, including data input processes, network visualization and output interpretation and will demonstrate how the CancerHubs web application enables the users to easily navigate through complex molecular interactions, generate testable hypotheses, and prioritize candidate proteins for further study.

Conclusion

By providing an intuitive and robust tool for cancer research at a systems-level, CancerHubs empowers researchers to uncover hidden biological insights and accelerate the discovery of novel therapeutic targets.

EACR25-0725

Radiomics-based survival prediction in glioblastoma using the RaSPr score

K. Kundal¹, R. Kumar¹

¹Indian Institute of Technology Hyderabad, Department of Biotechnology, Hyderabad, India

Introduction

Glioblastoma (GBM) is an aggressive brain tumor with significant survival variability, necessitating advanced prognostic tools for personalized treatment. Radiomic features extracted from medical imaging offer a non-invasive approach to characterizing tumor heterogeneity and predicting clinical outcomes. This study aimed to use radiomic analysis to assess survival variability in GBM and develop a predictive tool to support clinical decision-making.

Material and method

We analyzed a cohort of GBM patients from the TCGA-GBM dataset, extracting radiomic features from contrast-enhanced T1-weighted MRI (T1ce) scans. A total of 1,213 radiomic features were extracted, and feature selection was performed in two stages, first with univariate analysis ($P < 0.05$) followed by LASSO regression to refine the set. The selected features were weighted using LASSO coefficients to develop the "Radiomics Survival Predictor (RaSPr)" score, stratifying patients into low- and high-risk categories. Kaplan-Meier analysis was performed to evaluate the survival prediction efficiency. Independent datasets, UCSF-GBM and UPENN-GBM, were used for validation. Differential gene expression (DEG) analysis provided biological insights into tumor characteristics, and the RaSPr score was integrated into our self-developed "RadGLO" web platform for personalized survival predictions.

Result and discussion

From the initial 1,213 radiomic features, 8 key features were identified to construct the Radiomics Survival

Predictor (RaSPr) score, stratifying patients into low- and high-risk categories. Kaplan-Meier analysis showed that high RaSPr scores were associated with worse survival ($P < 0.05$), demonstrating its predictive power. We validated RaSPr using the UCSF-GBM and UPENN-GBM datasets, confirming its robustness and generalizability across cohorts. Differential gene expression analysis revealed significant upregulation of MDM2 in high RaSPr patients. MDM2, a negative regulator of the tumor suppressor protein p53 that promotes tumorigenesis, links radiomic risk with molecular markers. To enhance clinical adoption, RaSPr is integrated into "RadGLO" [1], allowing clinicians and researchers to submit MRI images or radiomic features for personalized survival risk predictions.

Conclusion

These findings underscore the potential of RaSPr score in personalizing GBM prognosis and guiding risk-based treatment strategies. By offering a non-invasive, efficient method for survival risk assessment, RaSPr can significantly enhance clinical decision-making and facilitate tailored treatment plans to improve patient outcomes. Integrating RaSPr into the 'RadGLO' web platform further enhances accessibility, providing clinicians and researchers with an easy-to-use tool for submitting MRI images or radiomic features and receiving personalized survival predictions.

Multimodal inference of morphogenomic phenotypes using morphology and expression data optimal clustering (MEDOC)

J. Sankaran¹, I. Joanito¹, J. Lee¹, G. Wijaya¹, Z. Chen¹, V. Krishnan², K. Chen³, S. Ong², T. Hein^{2,4}, S. Prabhakar¹

¹Genome Institute of Singapore, Laboratory of Systems Biology and Data Analytics, Singapore, Singapore

²Duke-NUS, Medical School, Singapore, Singapore

³Genome Institute of Singapore, Laboratory of Imagenomics, Singapore, Singapore

⁴Singapore General Hospital, Department of Haematology, Singapore, Singapore

Introduction

Spatial omics integrates three key types of information: cellular location, gene expression, and morphology. While current algorithms primarily combine gene expression with spatial location, they often neglect morphological features.

Material and method

In this study, we present Morphology and Expression Data Optimal Clustering (MEDOC), a novel algorithm that incorporates morphology into spatial omics analysis. MEDOC transforms contour representations and their derivatives into the Fourier domain, selects optimal shape features, and applies graph clustering for improved cell classification. To benchmark MEDOC, we evaluated its performance on a synthetic dataset containing 18 distinct shapes and a bacterial dataset comprising four different species. MEDOC outperformed several recently published algorithms in both accuracy and computational efficiency.

Result and discussion

To demonstrate its biological and clinical applications, we applied MEDOC to the morphogenomic analysis of bone marrow samples from chronic myelomonocytic leukemia (CMML), a rare hematologic malignancy characterized by sustained peripheral blood moncytosis, bone marrow dysplasia, and overlapping features of myelodysplastic syndromes (MDS) and myeloproliferative neoplasms (MPN). Increased monoblast levels – immature monocytes with round nuclei – are a known risk factor in CMML, yet their underlying molecular drivers remain unclear. Since suspension cells, such as bone marrow mononuclear cells (BMMCs), are not compatible with conventional spatial omics workflows designed for adherent cells, we developed a new immobilization protocol. This enabled MERFISH spatial RNA analysis of 492 genes in ~25,000 cells across a 16 mm² region of interest within 34 hours. We then applied this assay to samples from 12 CMML patients and 8 healthy controls. MEDOC analysis of this dataset identified multiple nuclear shape-associated genes involved in myeloid cell maturation, revealing shared differentiation pathways between cancerous and healthy bone marrow. Additionally, we successfully distinguished a promonocyte population, a monoblast subtype that was previously difficult to classify. These findings suggest that integrating morphological analysis with gene expression using MEDOC could enhance CMML patient stratification and uncover the molecular underpinnings of clinically relevant malignant cell morphologies.

Conclusion

More broadly, MEDOC provides a fast, scalable, size, reflection, and rotation-invariant approach for extracting novel morphogenomic phenotypes from any large-scale, cellular-resolution spatial omics dataset with an imaging component.

EACR25-0737

AI-Powered Nuclei Segmentation in Cervical Cytology: Advances with Deep Learning Models

A. Mosquera-Zamudio¹, S. Cancino², G. Cárdenas-Montoya², J. García³, R. Parra-Medina²

¹Instituto Nacional de Cancerología, Bogotá, Colombia

²Instituto Nacional de Cancerología, Bogota, Colombia

³Universidad Nacional, Bogota, Colombia

Introduction

Cervical cancer remains a significant public health concern worldwide, with early detection playing a crucial role in reducing mortality rates. Whole Slide Imaging (WSI) in cervical cytology enables digital analysis of cellular morphology but presents challenges in nuclei segmentation, essential for accurate diagnoses. This study aims to evaluate and compare deep learning (DL) models for nuclei segmentation in cervical cytology images.

Material and method

We implemented three DL models: U-Net, Vision Transformer (ViT), and Detectron2 (Mask R-CNN architecture). The models were trained on the CNseg dataset and evaluated on the ISBI 2014 dataset and an independent institutional dataset. Preprocessing steps included annotation with QuPath, patch extraction, and

exclusion of regions with less than 60% cytologic material. Performance was assessed using the Dice Similarity Coefficient (DSC), Intersection over Union (IoU), and Panoptic Quality (PQ).

Result and discussion

The models achieved high segmentation accuracy on public datasets, with Detectron2 obtaining a PQ of 0.98 on ISBI 2014, surpassing previously reported methods. On the CNseg dataset, U-Net performed best (DSC: 0.86, PQ: 0.86). Performance decreased on the institutional dataset (U-Net PQ: 0.62), likely due to variations in image acquisition and blurred nuclei. Notably, the models detected nuclei in challenging conditions, indicating potential for improving diagnostic workflows.

Conclusion

Deep learning models, particularly U-Net and Detectron2, provide accurate and efficient nuclei segmentation in cervical cytology WSIs. Despite domain shifts affecting performance, these models offer promising tools for automated screening and diagnostic applications, supporting the development of reliable AI-driven cytology solutions

EACR25-0756

A Smart Platform for Cancer Research: Integrating Consensus Meta-Analysis of Omics Data with Ontology-Based Network Analysis

S. Yoon¹

¹*Sookmyung Women's University, Biological sciences, Seoul, Korea (Republic of)*

Introduction

The rapid growth of omics and ontology data, coupled with advancements in large language models (LLMs) and deep learning, has opened new opportunities for data-driven drug target and biomarker discovery. By integrating these technologies, we aim to streamline cancer research through comprehensive data mining and network-based analysis.

Material and method

We integrated diverse omics and ontology datasets from public sources into the Q-omics data mining platform [1]. Meta-analysis and data consensus were performed across datasets and incorporated into Q-omics' smart databases. A LLM-powered "Text-to-Data Mining" interface was implemented, enabling researchers to perform complex analyses without computational expertise. For functional insights, we developed NetCrafter [2], a novel ontology-based network analysis algorithm, and incorporated it into the Q-omics workflow. Graph neural networks (GNNs) such as message-passing neural networks (MPNNs) were used to identify network hotspots, facilitating drug target discovery.

Result and discussion

We identified over 29 billion significant cross-associations across heterogeneous datasets, encompassing over 1 billion multi-modal omics data points. Consensus analysis on cross-associated data across pan-cancer datasets provides a valuable resource for identifying reliable drug targets, biomarkers, and underlying mechanisms. Genes with tumor-specific

overexpression and unfavorable prognoses show high consistency across cancer lineages. Lineage consensus in gene perturbation data (CRISPR/shRNA) demonstrates strong reproducibility, reinforcing the reliability of functional screening approaches. In addition, advanced data mining applications within Q-omics enable the identification of synthetic lethal gene pairs and tumor-specific neoantigens, supporting novel therapeutic strategies. Ontology-based network analysis provides immediate functional insights from gene lists derived from RNA/protein expression or perturbation experiments (CRISPR/shRNA). Ontological networks highlight pan-cancer consensus functions associated with drug response and patient survival and serve as valuable input for MPNN models, aiding hotspot identification for drug target discovery.

Conclusion

By integrating multi-omics meta-data with LLMs and deep learning, Q-omics pioneers an innovative "Text-to-Data Mining" platform, enabling researchers to effortlessly identify anticancer targets, biomarkers, and mechanistic insights—without computational expertise. As omics datasets expand and AI technology advances, Q-omics [1] serves as a transformative resource, driving progress in cancer research and drug development.

Panoptic Segmentation and Spatial Analysis of Whole Slide Images: A Unified Open-Source Framework

O. Lehtonen¹, N. Nordlund¹, S. Salloum¹, A. Virtanen², S. Hautaniemi¹

¹*University of Helsinki, Research Programs Unit, Helsinki, Finland*

²*University of Helsinki, Department of Pathology, Helsinki, Finland*

Introduction

Histopathological features like tissue architecture, nuclear morphology, and stromal organization are key prognostic factors in cancer. However, extracting these features from hematoxylin & eosin (H&E) stained Whole Slide Images (WSIs) reproducibly remains challenging. Existing computational tools prioritize AI-driven predictive modeling but lack structured feature extraction tools directly linked to biological and clinical insights. Panoptic segmentation, which simultaneously segments nuclei and tissues, offers a powerful yet underutilized solution. In this work, we present two open-source Python libraries, cellseg_models.pytorch, for panoptic segmentation of WSIs, and cellseg_gsontools for spatially resolved and clinically relevant feature extraction at WSI scale.

Material and method

We demonstrate the utility of our Python libraries by extracting clinically relevant biological phenomena in two use-cases. First, we characterize the spatial heterogeneity of desmoplastic reaction in the stromal compartment of a high-grade serous ovarian cancer (HGSC), a phenomenon linked to EMT and poor outcomes in HGSC. Additionally, we examine immune

infiltration patterns in Human Papilloma Virus (HPV)-induced cervical intraepithelial neoplasia grade 2 (CIN2), where immune activation influences the lesion regression potential due to the viral etiology of the disease. For these analyses, we utilized 50 H&E-stained WSIs from HGSC omental tissue sections from the DECIDER trial (NCT04846933) and 163 CIN2 diagnostic biopsies collected as routine diagnostic biopsies at the Helsinki University Hospital. Panoptic segmentation models were applied to delineate nuclei and tissues, enabling spatially resolved feature extraction. Stromal organization in HGSC was assessed through clustering of tissue intensity and collagen fiber orientation features, while immune infiltration in CIN2 was quantified through immune cell densities within lesions and at the lesion-stroma interface.

Result and discussion

Our results demonstrate that `cellseg_models.pytorch` and `cellseg_gson tools` enable robust extraction of interpretable histopathological features at the whole-slide scale. By leveraging these tools, we successfully quantified clinically relevant features in both HGSC and CIN2. These examples showcase the versatility of our framework in spatial histopathological analysis, extending beyond HGSC and CIN2 to studying tumor microenvironments, stromal remodeling, immune infiltration, and morphometric changes in diverse disease contexts.

Conclusion

Our computational framework provides a scalable and interpretable solution for extracting spatially resolved histopathological features from WSIs, addressing a key gap in digital pathology. By integrating panoptic segmentation with structured spatial analysis, we enable reproducible quantification of tissue organization, immune infiltration, and stromal remodeling.

EACR25-0789

Comprehensive machine learning analysis of high-dimensional radiomics datasets by PYRAMID

S. Romagnoli¹, M. Betti², D. Maraghelli³, S. Bicchi², M. Palma⁴, S. Malinconi¹, L. Malorni⁴, S. Di Donato⁴, M. Bartolucci⁵, M. Benelli¹

¹*University of Florence, Department of Experimental and Clinical Biomedical Sciences, Florence, Italy*

²*Azienda USL Toscana Centro, Italy, Prato-Pistoia Medical Physics Department, Prato, Italy*

³*Azienda USL Toscana Centro - Ospedale Santo Stefano, Radiologia, Department of Diagnostic Imaging, Prato, Italy*

⁴*Azienda USL Toscana Centro, Italy, Department of Medical Oncology, Hospital of Prato, Prato, Italy*

⁵*Azienda USL Toscana Centro, Italy, Department of Diagnostic Imaging, Prato, Italy*

Introduction

The identification of novel quantitative imaging biomarkers, including those derived from radiomics, facilitates personalized medicine. Radiomics has been successfully applied to predict patient outcomes, histopathological and molecular features. However, the absence of standardized protocols for its analytical process, spanning from data transformation to predictive modeling, poses a significant challenge in establishing

uniform and reproducible approaches. To address these issues, we present PYthon Radiomics And MachIne learning Data analysis (PYRAMID), a Python framework for a reproducible radiomics analysis workflow.

Material and method

PYRAMID is a python framework for radiomics analysis, built on scikit-learn and imbalanced-learn, providing a comprehensive machine learning workflow. It comprises five modules: DaTrax (data transformation/normalization), SLIC (class imbalance handling), FeatX (feature selection), HyperTune (model training), and PREDICT (validation). By implementing several state-of-the-art methods in each module, a complete PYRAMID run tests up to 16,200 method combinations (pipelines). PYRAMID was evaluated on multiple TCIA and RadiomicsHub datasets, benchmarking AUC, F1, and average precision (AP) against results from original papers and challenges.

Result and discussion

Here, we report on the application of PYRAMID to the RADCURE dataset, including pre-treatment CT scans from patients with head and neck cancer. Considering 2,175 patients with available tumor segmentation and clinical information, we extracted 851 radiomics features per patient by pyradiomics and split the dataset into training ($n = 1,605$) and validation ($n = 570$) sets. Using radiomics-only features to predict the binarized 2-year survival, we applied PYRAMID evaluating all possible pipelines. Considering the top 5% pipelines in terms of F1-score, a median AUC of 0.75 (0.68-0.78) and median AP of 0.40 (0.30-0.47) on the validation set were obtained exceeding the performance of baseline radiomics model of the challenge (AUC = 0.71, AP = 0.33). These pipelines were enriched for robust scaling and uniform distribution transformation for data preprocessing, AllKNN for sampling, and Gradient Boost and ElasticNet for ML. Notably, pipelines lacking data transformation or class imbalance correction were significantly underrepresented in the top performing 5%, highlighting the importance of preprocessing of radiomics data.

Conclusion

PYRAMID is a toolkit for standardized radiomics workflow analysis. Applied on RADCURE, it achieved performance superior to original results, enabled the identification of best-performing methods and pipelines and suggested best-practice strategies. Further results from additional publicly available datasets, spanning various classification tasks and imaging types, will be presented at the congress.

EACR25-0836

Developing an artificial intelligence model for clinical benefit prediction in breast cancer

A. Murmu^{1,2}, A. Rácz³, B. Győrffy^{1,2,4}

¹*Semmelweis University, Department of Bioinformatics, Budapest, Hungary*

²*HUN-REN Research Center for Natural Sciences, Institute of Molecular Life Sciences, Budapest, Hungary*

³*HUN-REN Research Center for Natural Sciences, Institute of Materials and Environmental Chemistry, Budapest, Hungary*

⁴University of Pecs, Department of Biophysics, Pecs, Hungary

Introduction

Understanding the complex interplay of features influencing treatment outcomes is crucial for prognostic modelling and clinical decision making. We aimed to analyze the clinical benefit of adjuvant chemotherapy in breast cancer patients at 5-year survival and establish a web-based novel tool.

Material and method

We utilized the Surveillance, Epidemiology, and End Results database to retrieve data of breast cancer patients after the year 2000. The inclusion criteria were adult patients (≥ 18 years) with available overall survival data. After excluding incomplete records, duplicate patient ID's and censored data for 5 years, 1,090,297 cases with 18 parameters were analyzed. We developed a gradient boosting machine learning model using chemotherapy and non-chemotherapy breast cancer patient groups to predict the clinical benefit from adjuvant chemotherapy. These models were trained to estimate the survival event probabilities of breast cancer patients.

Result and discussion

The gradient boosting model demonstrated high accuracy of 0.77 and 0.84, balanced accuracy of 0.81 and 0.87 and AUC of 0.86 and 0.91 in chemotherapy and non-chemotherapy models, respectively. Sensitivity was 0.83 and 0.84 and the specificity reached 0.71 and 0.84 in chemotherapy and non-chemotherapy models, respectively. Among all the parameters, lymph node positivity was found to be the most important parameter in both the chemotherapy and non-chemotherapy models. Internal test validation showed that the gradient boosting model could predict 82% of the correct cases in the chemotherapy model and 69% of the correct cases in the non-chemotherapy model. Our web-based platform was set up at www.recurrenceonline.com/clinical to enable real-time predictions.

Conclusion

Our online tool offers a user-friendly interface for real-time monitoring of the clinical benefit of adjuvant chemotherapy in breast cancer patients. The algorithm has the potential to be used in clinical settings and assist clinicians in making more informed treatment decisions.

EACR25-0970

Artificial intelligence-based pathological analysis for Gleason grade and tumor quantification in prostate cancers

T. Kwak¹, C. Lee², W. Park³, J. Ku⁴, J. Cho¹, H. Chang¹, K. Kim⁵, B. Kang⁵, S. Kim¹, H. Ha⁵

¹Deep Bio Inc., Seoul, Korea (Republic of)

²Inje University Busan Paik Hospital, Department of Urology, Busan, Korea (Republic of)

³Seegene Medical Foundation, Department of Pathology, Busan, Korea (Republic of)

⁴Dongnam Institute of Radiological & Medical Sciences Korea Cancer Center Hospital, Department of Urology, Busan, Korea (Republic of)

⁵Pusan National University Hospital, Department of Urology, Busan, Korea (Republic of)

Introduction

Prostate cancer poses diagnostic challenges due to its multifocal nature and often small tumor volumes. The global shortage of pathologists exacerbates these issues, resulting in inconsistent and delayed diagnoses. While artificial intelligence (AI)-based image analysis has demonstrated the potential to improve diagnostic accuracy in various areas, its application in whole radical prostatectomy (RP) specimens remains underexplored. This study evaluates the clinical feasibility of AI-based pathological analysis for Gleason grading and tumor quantification, aiming to enhance prostate cancer diagnosis.

Material and method

We enrolled patients who underwent RP from 2011 to 2021 with more than one year of follow-up. Patients with fewer than 10 specimen slides or cancers other than prostatic adenocarcinoma were excluded. All slides were digitized and analyzed using an AI-based algorithm. Algorithm-based outputs, including International Society of Urological Pathology (ISUP) grade groups (GGs), tumor volumes (TVs), and percent tumor volumes (PTVs), were compared to those obtained by pathologists. We evaluated their prognostic performance for predicting biochemical progression-free survival (BPFS) in comparison with pathologist assessments.

Result and discussion

A total of 29,646 H&E-stained slides from 992 patients were analyzed. Post-RP, 348 patients experienced biochemical recurrence, with 178 occurring within 1 year. Pathologists identified cancer in 986 cases and assigned GGs (pGG) to 980. The AI-based algorithm identified cancer and assigned GGs (aGG) to all cases. GGs by pathologists and by the algorithm showed fair agreement (linear-weighted kappa: 0.374). Their prognostic performance for predicting BPFS showed little difference, with concordance index (c-index) of 0.654 and 0.644 for pGG and aGG, respectively ($p = 0.52$). Median TV and PTV determined by pathologists (pTV, pPTV) were 3.8 mL and 15.0%, while those calculated by the algorithm (aTV, aPTV) were 1.0 mL and 3.7%, respectively. Their Pearson correlation coefficient was 0.830 for TV and 0.846 for PTV. In predicting BPFS, algorithm-based TV and PTV measurements demonstrated superior performance compared to pathologist-based correspondences, with c-index of 0.657 and 0.672 against 0.622 and 0.641, respectively.

Conclusion

The AI-based algorithm and pathologists showed comparable power for predicting BPFS while the algorithm exhibited superior performance in tumor quantification, suggesting its potential as an effective tool for enhancing pathological diagnosis and prognosis.

EACR25-0985

Machine Learning Algorithms for Prediction of Bone Metastasis Risk in Patients with Lung Cancer

R. Luk¹, S. Choi¹, J. Cheung¹

¹The University of Hong Kong, Department of Orthopaedics and Traumatology, Hong Kong, Hong Kong, China

Introduction

Lung cancer is the leading cause of cancer deaths in Hong Kong, accounting for 26.1% of all cancer deaths in 2023. The cause is often metastasis, even in patients who have had their primary lung tumours resected.

Approximately 30% to 40% of patients with advanced lung cancer are estimated to experience bone metastases. The aim of this study was therefore to optimise the accuracy and explainability of machine learning models to identify lung cancer patients with high risk for bone metastasis.

Material and method

The patient cohort comprised 1864 patients diagnosed with primary lung malignancy at a territory-wide tertiary referral centre between 2016 and 2021. A total of 25 variables, spanning sociodemographic, clinical, pathological, and treatment information, were considered as potential predictors of bone metastasis. The outcome was binary, indicating the presence or absence of bone metastasis followed up for a minimum of 1 year. All patient health records were extracted from the clinical management system (CMS) of the hospital. For optimisation of model performance and explainability, this study utilised various ensemble machine learning techniques, including Random Forest and Boosting methods. The performance of these ensemble methods was compared to two simpler baseline models, logistic regression and radial basis function (RBF) kernel support vector machine (SVM), which have shown the highest performance out of other commonly used machine learning classifiers. Principal component analysis (PCA) was performed for dimensionality reduction and feature importance, and probability calibration was performed to enhance model usability.

Result and discussion

Both Random Forest and Boosting type ensemble methods outperformed the baseline models across all three primary evaluation metrics. PCA also revealed that lung cancer histological type, T-staging, American Joint Committee on Cancer staging, differentiation grade and lymphovascular staging were the five input features with the greatest contribution to explained variance in the prediction of bone metastasis.

Conclusion

The optimised accuracy and interpretability of the machine learning models developed in this study can enable clinicians to better understand the parameters used to generate the prediction, which is key to its implementation within a clinical setting. The analysis and identification of feature importance can also allow for more targeted collection of input variables, resulting in heightened model cost-effectiveness.

EACR25-1047

Single-nuclei transcriptome profiling reveals vascular endothelial cell heterogeneity induced by VEGFA/BRAF targeting in murine melanoma model

R. Chiarelli¹, S. Parab¹, V. Sarlo¹, S. Capellero¹, L. Palmiotto¹, A. Bartolini¹, D. Cantarella¹, E. Grassi¹, F. Bussolino¹, V. Comunanza¹

¹Candiolo Cancer Institute, FPO – IRCCS, 10060

Candiolo (TO), Italy

Introduction

Malignant melanoma is an aggressive cancer, with high risk of metastasis and mortality. The introduction of targeted therapies and immunotherapy has represented the most significant advances in the treatment of melanoma; however, the onset of resistance remains a challenge to overcome. Vascular Endothelial Growth Factor A (VEGFA) is a key promoter of tumor angiogenesis and immunosuppression and is an attractive target for combinatorial therapy. We have demonstrated that VEGFA removal improved the antitumor efficacy of BRAF inhibitor (BRAFi), through vessel normalization and M1-macrophages and CD8+ T cells infiltration, boosting immune checkpoint blockade. Single cell biology is a powerful tool to decipher cancer cell heterogeneity and complex tumor microenvironment (TME) at a molecular level. However, this approach requires enzymatic cell dissociation that can influence cellular coverage. By contrast, single nucleus RNA sequencing (snRNA-seq) has substantial advantages including compatibility with frozen samples and the elimination of a dissociation-induced, transcriptional stress response.

Material and method

Single-nuclei transcriptome profiling was conducted on samples obtained from D4M syngeneic melanoma model at varying treatment regimen. We performed high-quality snRNA-seq from 8 frozen tissue specimens, a biological replicate for each condition, that were preserved in liquid nitrogen. Approximately 10,000 nuclei were partitioned in each snRNA-seq experiment using used 10x Genomics technology and sequenced (150 bp PE) by the Illumina NextSeq 500 platform. The integrated Seurat object consisted of 37,104 high-quality nuclei (8,510 from control; 10,920 from BRAFi; 4,549 from anti-VEGFA; 13,125 from BRAFi + anti-VEGFA). Raw sequencing data were processed using Cell Ranger and analyzed with the Seurat package in R. Cell-cell interaction based on ligand-receptor expression levels was investigated using CellChat bioinformatic tool. We used Azimuth and loupeR for cell annotation.

Result and discussion

In this study, we have used single snRNA-seq as a profiling strategy to further investigate how VEGFA targeting regulates the TME in melanoma, with the aim to identify cellular and molecular changes that regulate the interplay between different cell populations.

Unsupervised Seurat-based clustering identified 20 clusters which were further annotated into six major cell types (malignant, myeloid, dendritic, T cells, fibroblasts, endothelial, adipocytes). We found significant heterogeneity within melanoma cancer cells (9 clusters) and myeloid cell (5 clusters) that display distinct global transcriptional program and different enrichment in different condition.

Conclusion

The current study offers a deep insight into the biology of melanoma highlighting TME reprogramming through target therapy treatment, underlying further discovery of new TME biomarkers which may be potentially druggable.

EACR25-1099

Investigating molecular evolution of tumor heterogeneity at recurrence unveils patient-specific trajectories

B. Nosirov¹, A. Lipsa¹, H. Allahverdi¹, Y. Yabo², K. Grzyb³, T. Kaoma⁴, R. Toth⁴, A. Skupin⁵, P. Nazarov⁴, A. Golebiewska⁴

¹Luxembourg Institute of Health, Cancer Research, Luxembourg, Luxembourg

²Uniklinikum Erlangen, Neurochirurgie, Erlangen, Germany

³Luxembourg Institute of Health, Department of Infection and Immunity, Luxembourg, Luxembourg

⁴Luxembourg Institute of Health, Cancer Research, Luxembourg, Luxembourg

⁵University of Luxembourg, LCSB, Belval, Luxembourg

Introduction

Tumor heterogeneity is one of the major barriers to the treatment of many tumor types. In glioblastoma (GBM) – the most aggressive brain tumor – the survival of patients following standard therapy is around 14 months, largely due to the inherent heterogeneity and phenotypic plasticity. Investigations of paired primary-recurrent tumours and preclinical models derived thereof using multi-omics profiling can provide clinically relevant insights into tumour evolution at the individual patient level.

Material and method

To understand the impact of treatment on the intratumoral heterogeneity of tumor cells, we applied bulk and single-cell RNA-seq, spatial transcriptomics, epigenomics (DNA methylation arrays), genomics (targeted DNA-seq) and proteomics (LC-MS) in GBM patient-derived orthotopic xenograft models generated from 8 longitudinally matched treatment naïve and treatment-exposed recurrent patient tumors. We performed comprehensive integrative multi-omics analysis including state-of-the-art machine learning tools to assess the molecular evolution of GBM tumors at recurrence.

Result and discussion

Multi-omics analysis revealed a presence of diverse molecular profiles, representing various genetic, epigenetic and transcriptomic subtypes of glioblastomas observed in patients. A machine learning-based independent component analysis (ICA) identified independent biological signals from heterogeneous cellular populations representing distinct biological processes that drive glioblastoma recurrence, without relying on prior knowledge of cell types or states.

Conclusion

Our GBM PDOX models provide a platform for high-quality pre-clinical research and improved clinical relevance in the development and testing of novel therapeutics.

EACR25-1175

Unified Whole Genome Sequencing for Hematological Malignancies

S. Truong¹, J. Han¹, A. Crawford¹, S. Catreux¹, S. Kim¹, S. Daniel¹, D. Barfield¹, R. Mehio¹

¹Illumina Inc, San Diego, United States

Introduction

Acute myeloid leukemia (AML) or myelodysplastic syndromes (MDS) rely on genetic testing and molecular profiling for risk stratification. Comprehensive genomic analysis of hematologic malignancies requires the evaluation of multiple variant types, including small variants (single nucleotide variants and insertions/deletions < 50 bp), copy number alterations (CNAs), structural variants (SVs) such as translocations, Internal Tandem Duplications (ITD) and loss of heterozygosity (LoH) calculation. Chromosomal evaluation by karyotyping, microarray, and FISH, and sequencing methods such as single gene and gene panel testing are currently employed to detect across these variant classes, resulting in high costs, high operational complexity, need to support multiple molecular technologies, and potential for conflicting results. Enabled by continued sequencing cost reductions, recent studies using tumor-only whole-genome sequencing (WGS) have demonstrated that a single assay can provide results that are equivalent to or better risk stratification than conventional testing approaches with lower sample failure rates (Duncavage et al., 2021).

Material and method

We present a complete solution for analysis and interpretation of hematological whole genome samples. The workflow leverages DRAGEN(TM) secondary analysis to detect all variant types relevant to hematological malignancy research. To establish performance of the pipeline, we performed PCR free WGS at an average ~220 X coverage on reference cancer cell lines and 53 AML clinical samples.

Result and discussion

VAF LoD was established for small variants and SVs at 5% and 7.3%, respectively. We observed an overall accuracy of > 95%, correctly calling 73/73 clinically relevant small variants (including 4 FLT3-ITD), structural variants, and > 96% of copy number events across this cohort. SV and CNA evaluation included 2 inversions sized approximately 45 and 56 Mb in length, 8 translocations, 22 CNAs ranging from 4.5 Mb to 100 Mb, and 7 whole chromosome events. The secondary analysis results are directly ingested into Connected Insights for variant interpretation, automatic curation including AML subtyping and risk stratification based on common guidelines such as WHO 2022 and ELN 2022. Evidence maps and decision trees can be tailored to a laboratory's preference based on clinical trials or hem-specific sources such as CKB, OncoKB and more. Powerful visualizations including interactive Circos plots enable exploring of complex structural rearrangements.

Conclusion

The DRAGEN Heme pipeline is a tumor only WGS pipeline for genomic profiling of hematological malignancy samples. The analytical performance of this approach resulted in high accuracy for variants commonly assessed in AML samples. We demonstrate its ease of use to advance hematological malignancy clinical research and its accessibility for all labs looking to drive informatics forward.

EACR25-1184

Predicting drug response from omics data using MultiOmic2Drug

F. Saab¹, M. Rohbeck², D. Saur¹

¹DKFZ|TUM, Translational Cancer Research and Experimental Cancer Therapy, Munich, Germany

²DKFZ, Heidelberg, Germany

Introduction

Recent clinical trials have proven the importance of leveraging patients' molecular profiles (omics) for the personalisation of cancer treatments (Sicklick et al. 2019; Rodon et al., 2019). However, the complex and heterogeneous nature of omics motivates the application of deep learning methods. These methods hold great promise in uncovering biomarkers and patterns that are essential for the treatment of hard-to-treat cancers, such as pancreatic ductal adenocarcinoma (PDAC). PDAC is considered to be a lethal cancer, associated with a very low 10-year survival rate of 5%. In this work, we present MultiOmic2Drug (MO2D), a deep learning neural network aimed at the prediction of drug response through the integration of multiple omic layers.

Material and method

As a proof of concept, our model, MO2D, was trained using molecular data of pan-cancer cell lines deposited in Depmap (cancer dependency map). In particular, we used copy number variation (CNV), transcriptomics and proteomics (MS/MS) data of the cancer cell lines in combination with in-vitro drug response results.

Result and discussion

By inspecting the latent space, we assessed that the model has learnt to predict the drug response.

Quantitatively, the model is being evaluated with a MSE (Mean Squared Error) loss and the performance ranges between 0.15 and 0.3 on unseen data.

Conclusion

Our MO2D demonstrated through its latent space its ability to learn the drug response. Additionally, we will externally validate MO2D on validation datasets, and the predictions of MO2D will be tested in-vitro.

EACR25-1225

DTFD-MIL-CN: A Cost-Effective and Accurate Deep Learning Model for Hormone Receptor-Positive, HER2-Negative Breast Cancer Distant

Recurrence Risk

Q. Liuliu¹, C. Shuyue², Y. Jian¹, Y. Zixuan¹, S. Mengwu¹, T. Geng³, Y. Jialiang³, H. Ping-an², Y. Peng¹

¹Department of Medical Oncology, National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; Department of VIP Medical Oncology, National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; Beijing, China

²Zhejiang Sci-Tech University, Hangzhou City, Zhejiang Province, China

³Geneis Beijing Co., Ltd., Beijing, 100102, China, Beijing, China

Introduction

EndoPredict is a multigene assay that effectively assesses the long-term recurrence risk in patients with hormone receptor (HR)-positive, HER2-negative breast cancer. This tool aids in identifying low-risk patients who may safely forgo chemotherapy while guiding high-risk patients toward more aggressive treatment strategies. However, its high cost limits widespread clinical application. This study aims to develop a deep learning model that integrates clinical features and hematoxylin and eosin (HE)-stained pathological images to stratify breast cancer patients into risk categories, providing a cost-effective alternative to EndoPredict.

Material and method

This study included patients diagnosed with early-stage HR-positive, HER2-negative breast cancer who underwent EndoPredict testing at multiple oncology centers, including the Cancer Hospital, Chinese Academy of Medical Sciences, between January 2021 and June 2024. A total of 295 cases were collected, of which 254 were retained after excluding samples with poor-quality pathological images or missing clinical data. A deep learning model, DTFD-MIL-CN (Double-Tier Feature Distillation Multiple Instance Learning with Clinical and Nuclear Features), was employed, incorporating a dual-attention learning mechanism and hierarchical classification structure for feature modeling. Specifically, ResNet-50, pre-trained on a large-scale image dataset, was used to extract 1,024-dimensional feature vectors from HE-stained image patches. Additionally, a HoVer-Net-based model was applied to extract nuclear features, including eccentricity, equivalent diameter, and Euler number. These morphological features were then integrated with clinical variables such as age, estrogen receptor status, and progesterone receptor status to construct a multimodal analytical framework.

Result and discussion

A ten-fold cross-validation strategy was implemented to maximize sample utility and enhance model robustness. Specifically, 80% of the dataset was used for cross-validation, while the remaining 20% served as an independent test set. During cross-validation, the model demonstrated strong performance, achieving an average area under the curve (AUC) of 0.852. Furthermore, the model weights from the best-performing fold were applied to the independent test set, yielding an AUC of 0.846, indicating favorable classification performance.

Conclusion

The DTFD-MIL-CN model effectively predicts distant recurrence risk in HR-positive, HER2-negative breast cancer patients. Compared to EndoPredict, it offers a more cost-effective alternative with high accuracy and generalization capability. This model holds promise as an efficient and economical tool for individualized risk assessment in patients with early-stage Luminal-type breast cancer, thereby supporting clinical decision-making and optimizing treatment strategies.

EACR25-1229

Deep transfer learning for predicting BRAF V600E mutation status in colorectal

cancer using image-derived features associated with microsatellite instability

S. Arslan¹, C. Bass¹, S. Wolf¹, F. Ntelemis¹, A. Geraldes¹, J. Schmidt¹, D. Harrison², J. Kather³, P. Pandya¹, N. Kumar¹

¹Panakeia Technologies Limited, Cambridge, United Kingdom

²University of St Andrews, School of Medicine, St Andrews, United Kingdom

³Dresden University of Technology, Else Kroener Fresenius Center for Digital Health, Dresden, Germany

Introduction

Microsatellite instability (MSI) and BRAF V600E mutation are key molecular biomarkers in colorectal cancer (CRC) with significant implications for diagnosis, prognosis, and treatment. MSI results from mismatch repair system defects, leading to genetic hypermutability and increased mutation burden. MSI and the BRAF V600E mutation often co-occur due to shared molecular pathways, highlighting a complex biological relationship between these biomarkers. Transfer learning repurposes pre-trained models for related tasks, allowing the extraction of relevant features for new biomarkers from pathology images. We hypothesise that histomorphological patterns associated with MSI, as extracted through deep learning (DL) from digitised haematoxylin and eosin (H&E)-stained pathology slides, may harbour relevant features indicative of BRAF V600E mutational status.

Material and method

We utilised a DL model pre-trained for predicting MSI status on whole slide images (WSIs) of H&E-stained primary CRC slides ($n = 1707$). This model was used to extract image-based features for a separate cohort of 701 CRC WSIs with known MSI and BRAF V600E status. A multi-layer perceptron classifier was trained on the image-derived features using 5-fold cross-validation. The model's performance was assessed using the area under the receiver operating characteristic curve (AUC). The statistical association between MSI and BRAF V600E mutation was evaluated with a chi-squared test.

Result and discussion

The BRAF V600E mutation was present in 14.98% (105/701) of the cohort. MSI-high tumours accounted for 12.84% (90/701) of the cases. Among these, 63.33% (57/90) harboured the BRAF V600E mutation, compared to just 7.86% (48/611) in MSI-low and stable cases. The chi-squared test ($\chi^2 = 185.25$, $p < 1e-05$) confirmed a statistically significant relationship between MSI and BRAF V600E mutation. The strength of this relationship was quantified using Cramér's V, which indicated a moderately strong association ($V = 0.51$). Using transfer learning, we achieved an average AUC of 84.77% ($\pm 3.14\%$), with values ranging from 80.95% to 88.20% across 5 folds. These results suggest that MSI-related histomorphological features identified with DL are informative of BRAF V600E mutation status.

Conclusion

This study highlights the potential of deep transfer learning for capturing morphological patterns associated with MSI and BRAF V600E mutation using only H&E-stained WSIs. The ability to extract biologically relevant

features from pathology slides enables rapid, cost-effective biomarker assessment, which could enhance clinical management and inform treatment decisions. Future work will investigate the biological interplay between MSI and the BRAF V600E mutation, investigating the role of DL in bridging the gap between morphology and underlying molecular mechanisms.

Novel clustering of glioblastoma patients with EGFR mutation by unsupervised machine learning

C. Gavira-O'Neill¹, J. Pastor Ruiz², C. Ramírez Castillejo², S. Casas Tintó³

¹CTB-UPM / ISCIII-IIER, Madrid, Spain

²UPM, Madrid, Spain

³ISCIII-IIER, Madrid, Spain

Introduction

Glioblastomas (GB) are a subtype of brain tumors originating in glial cells. The most malignant primary brain tumor, five-year survival rates lie at only 6.9% and average survival is estimated at 15 months with standard treatment (surgery plus radio and/or chemotherapy). However, there is great heterogeneity amongst patients, with survival ranging from some months after diagnosis to years post-surgery. The desire to classify these phenotypically diverse cases has led to extensive research into the molecular background of GB patients. This includes the identification of several frequently occurring mutations, such as in PI3K, EGFR or TP53. Alterations in expression of epidermal growth factor receptor (EGFR) have been found in over 50% of GB cases. Over-expression of the gene is associated to more aggressive GB, with multiple mechanisms leading to EGFR pathway activation. The existence of different variants, and incomplete understanding of all the signaling pathways that are affected as a consequence, have limited the applications of treatments targeting this protein.

Material and method

The presented project applies unsupervised machine learning methods to transcriptomic data of GB patients to specifically cluster these altered EGFR patients.

Result and discussion

Application of our clustering algorithm has identified several subgroups of cases with differential patterns in tumor-associated biological processes. Geneset enrichment analysis (GSEA) shows significant differences in stemness, oxidation state, neuronal function and tumor expansion pathways.

Conclusion

Elucidating the biological basis that separates these patients can lead to better understanding of tumor progression as well as of the differences in response to treatments, with a final goal of more personalized tumor management.

EACR25-1252

MetaAnalysisOnline's Network Tool: Simplifying Network Meta-Analysis for All Researchers

J. Fekete^{1,2}, O. Menyhart^{1,2}, B. Győrffy^{1,2,3}

¹Semmelweis University, Department of Bioinformatics, Budapest, Hungary

²HUN-REN Research Centre for Natural Sciences, Oncology Biomarker Research Group, Institute of Molecular Life Sciences, Budapest, Hungary

³University of Pécs, Department of Biophysics, Pécs, Hungary

Introduction

Network meta-analysis (NMA) is a powerful statistical method that enables indirect comparisons of multiple treatments by integrating data from various studies. However, conducting NMA often requires advanced statistical expertise and specialized software, creating barriers for researchers and clinicians. This study introduces metaanalysisonline.com etwork, a user-friendly web-based platform designed to streamline network meta-analysis without requiring programming skills.

Material and method

MetaAnalysisOnline.com supports NMA using both fixed-effects and random-effects models. The platform automates complex calculations and provides essential visualization tools, including treatment rankings, league tables, inconsistency and heterogeneity tests, and split comparisons. The system integrates statistical methodologies from the netmeta package in R, ensuring accuracy and transparency. The web-based interface allows users to input study results, define treatment networks, and generate interactive visualizations without coding expertise.

Result and discussion

The online tool is freely accessible and allows researchers to input data directly from commonly used spreadsheet applications such as Excel. It generates key outputs such as network and forest plots, funnel plot, and league tables to compare multiple treatments effectively. In addition, the platform performs sensitivity analyses and inconsistency assessments to ensure the robustness of findings. By providing comprehensive statistical outputs and interactive visualizations, MetaAnalysisOnline.com enhances the interpretation of complex treatment networks.

Conclusion

Metaanalysisonline.com simplifies network meta-analysis by automating statistical calculations and visualization, making advanced evidence synthesis more accessible and reproducible for researchers and clinicians.

Spatial Transcriptomics Reveals Immune-Tumor Interactions Associated with Pembrolizumab Response in NSCLC

L. Kalson¹, M. Baardwijk², R. Wurm³, A. Stubbs², L. Brcic⁴

¹Medical University of Graz, Otto Loewi Research Center, Graz, Austria

²University Medical Center Rotterdam, Department of Pathology and Clinical Bioinformatics, Erasmus MC, Rotterdam, Netherlands

³Medical University of Graz, Department of Internal Medicine, Graz, Austria

⁴Department of Pathology, Medical University of Vienna, Vienna, Austria

Introduction

Immunotherapy has transformed the treatment landscape for non-small cell lung carcinoma (NSCLC), yet predicting which patients will respond to immune checkpoint inhibitors (ICIs) remains a major clinical challenge. Despite the use of PD-L1 expression as a main predictive biomarker, its power is limited. This highlights the need for better patient stratification strategies. Spatial transcriptomics (ST) offers a novel approach by integrating histology with spatially resolved whole-transcriptome profiling, preserving tissue architecture and enabling in-depth characterization of the tumor microenvironment (TME). This study aims to identify transcriptomic and spatial patterns of immune and tumor cells associated with pembrolizumab response in PD-L1 high NSCLC patients.

Material and method

A total of 16 NSCLC patients (PD-L1 ≥ 50%) treated with pembrolizumab as a first line therapy were selected divided into responders (n = 8) and non-responders (n = 8). In each group, there were 4 adenocarcinoma and 4 squamous cell carcinoma samples. FFPE small biopsy samples were analyzed using 10x Genomics Visium spatial transcriptomics, integrating H&E-stained sections to ensure accurate spatial mapping. Space Ranger, scampy, squidpy, and cell2location were used for spatial clustering and immune cell deconvolution. TLS characterization, immune exclusion assessment, and spatial proximity mapping of immune-tumor interactions was performed.

Result and discussion

Responders exhibited fragmented tumor architecture, with cancer cells interspersed among immune cells, suggesting immune-mediated tumor disruption. In contrast, non-responders displayed dense tumor clusters, potentially creating immune-privileged niches. T cells in responders localized within tumor regions, enhancing tumor-immune interactions, whereas in non-responders, T cells were confined to stromal areas, indicating an immune-excluded phenotype. Plasma cell enrichment in responders suggests a B-cell-mediated antitumor response, whereas myeloid-dominated non-responders may exhibit immunosuppressive signaling, limiting ICI efficacy.

Conclusion

Spatial transcriptomics reveals key tumor-immune architectural differences that may influence pembrolizumab response in NSCLC, even in small diagnostic biopsies. Understanding immune infiltration patterns, tumor fragmentation, and myeloid-driven suppression could refine patient stratification and guide immuno-therapy strategies. Further validation is needed to establish these features as predictive biomarkers for immunotherapy efficacy.

EACR25-1257

Machine Learning Meets Man's Best Friend: Uncovering Prognostic Factors in Canine Mammary Tumors

H. Scheel¹, J. Zobolas^{2,3}, T. Lien⁴, F. Lingaas¹, H. Bergholtz²

¹Faculty of Veterinary Medicine, Norwegian University of Life Sciences, Department of Preclinical Sciences and Pathology, Ås, Norway

²Institute for Cancer Research, Oslo University Hospital, Department of Cancer Genetics, Oslo, Norway

³Faculty of Medicine, University of Oslo, Oslo Centre for Biostatistics and Epidemiology (OCBE), Department of Biostatistics, Oslo, Norway

⁴Oslo University Hospital, Department of Pathology, Oslo, Norway

Introduction

Canine mammary tumors (CMTs) are the most prevalent type of cancer in dogs. Approximately 45% of canine mammary carcinoma cases result in metastasis and death within one year after diagnosis, although survival time can vary greatly between dogs. This variation is attributed to the highly heterogeneous nature of the disease, which presents with diverse clinical manifestations, histopathological subtypes and molecular properties. Currently, prognosis for CMT patients is primarily based on histopathologic examination and TNM staging, which includes assessment of tumor size, lymph node involvement and metastasis. While molecular markers such as estrogen receptor (ER) protein levels and gene expression are recognized as prognostic factors of CMT, they are not routinely used in clinical settings for CMTs as they are for human breast cancer.

Material and method

In this study, we applied a machine learning approach to a publicly available dataset of 146 canine mammary tumors to explore prognostic factors, particularly the potential of gene expression data to improve survival predictions. We assessed prognostic factors including gene expression and clinical data such as age, breed, ER status and lymphatic invasion. Three Cox proportional hazard models with different data types were fit: one with only clinical variables (Clinical model), one with gene expression data (GEX) and one combining both data types (Clinical + GEX). To evaluate the models' risk discrimination capabilities, we used Uno's C-index and the time-dependent Area Under the Curve (ROC-AUC). We performed differential gene expression analysis, and gene set enrichment analysis (GSEA) to investigate gene expression differences between risk groups established using the Clinical model.

Result and discussion

Our results indicated that risk discrimination was most effective at 6 months post-diagnosis, with the Clinical model outperforming the other two models, indicating the essential role of clinical data in survival prediction. At this time point, the median ROC-AUC was 0.811 for the Clinical model, 0.727 for the GEX model, and 0.768 for the Clinical + GEX model. The GSEA revealed significant differential expression of 24 out of 50 Hallmark signatures between the two risk groups, highlighting key pathways involved in canine mammary tumor pathogenesis.

Conclusion

Clinical data is crucial for predicting the survival of individuals with CMT while addition of gene expression offers limited extra value. Moreover, risk groups identified through prognostication based on clinical

variables show significant differences in the expression of Hallmark signatures.

EACR25-1306

Enhancing Mutational Signature Detection in Whole Exome Sequencing: Insights from Esophageal Squamous-Cell Carcinoma

K. Yilmaz¹, B. Otu², A. Acar¹

¹Middle East Technical University, Biological Sciences, Ankara, Turkey

²Middle East Technical University, Graduate School of Informatics, Ankara, Turkey

Introduction

Mutational signatures represent distinct mutation patterns that arise from biological processes such as DNA damage, repair mechanisms, and environmental factors. These signatures play a crucial role in cancer research, offering insights into tumor etiology, early detection, and potential therapeutic targets. Whole genome sequencing (WGS) is the gold standard for identifying mutational signatures due to its comprehensive genomic coverage. However, whole exome sequencing (WES), which is widely used in clinical settings due to its cost-effectiveness, presents challenges in accurately capturing these signatures due to its lower mutation detection capacity. Enhancing WES's ability to reliably identify mutational signatures is essential for expanding its clinical applicability.

Material and method

In this study, we analyzed 552 esophageal squamous-cell carcinoma (ESCC) samples to assess the differences in mutational signature detection between WGS and WES. We generated down-sampled WES data from the WGS samples to simulate real-world exome sequencing conditions. Mutational signatures were identified and compared across three major signature types: single base substitutions (SBS), insertions and deletions (ID), and doublet base substitutions (DBS). We evaluated the detection sensitivity of WES relative to WGS and examined the extent of information loss across different signature classes.

Result and discussion

Our analysis revealed that WES exhibited a 50% reduction in detection sensitivity across all mutational signature types compared to WGS. This loss of sensitivity was observed for SBS, ID, and DBS signatures, indicating a significant limitation in using WES for comprehensive mutational signature analysis.

Conclusion

These results highlight the need for advanced methodologies, such as deep learning approaches, to improve the precision and sensitivity of mutational signature identification in WES, ultimately enhancing its clinical utility.

Deciphering the Molecular Impact of Asbestos: Gene Expression Profiles in Malignant Pleural Mesothelioma

D. Rosati¹, B. Maurizi¹, V. Serio¹, D. Maffeo¹, A. Rina¹, M. Palmieri¹, A. Giordano², E. Frullanti¹

¹University of Siena, Dept. of Medical Biotechnologies, Siena, Italy

²Sbarro Institute for Cancer Research and Molecular Medicine and Center for Biotechnology, Department of Biology, Philadelphia, United States

Introduction

The incidence of malignant pleural mesothelioma (MPM) has risen significantly due to extensive asbestos exposure, particularly since the mid-20th century. Despite advancements in cancer therapies, a definitive cure for MPM remains elusive, largely because the molecular mechanisms driving asbestos-related carcinogenesis are not yet fully understood. This exploratory study investigates gene expression alterations specifically associated with mesothelioma patients who have a documented history of asbestos exposure, aiming to provide a foundation for future research focused on identifying novel prognostic and predictive biomarkers.

Material and method

Publicly available RNA sequencing datasets were analyzed using a bioinformatics pipeline to perform differential gene expression analysis. Furthermore, functional enrichment analysis was conducted to identify significantly overrepresented Gene Ontology (GO) terms related to biological processes, molecular functions, and cellular components, offering insights into the molecular pathways implicated in MPM pathogenesis.

Result and discussion

The analysis identified a set of differentially expressed genes (DEGs) in MPM patients with confirmed asbestos exposure, along with key enriched GO terms. These biological annotations highlight processes such as ion homeostasis and oxidative stress response, shedding light on the cellular disruptions triggered by asbestos exposure.

Conclusion

The findings of this study enhance our understanding of the molecular alterations underlying asbestos-induced carcinogenesis in MPM. By pinpointing specific DEGs and enriched GO categories, this research provides a valuable basis for future studies aimed at discovering biomarkers and therapeutic targets to improve patient outcomes.

EACR25-1395

Pan-cancer analysis of signaling pathways regulatory connection with pyrimidine metabolism and its chemoresistance role

V. Ramesh¹, M. Demirdizen¹, L. Pinna¹, T. Doktor¹, F. Benso², M. Siddiqui¹, P. Ceppi¹

¹University of Southern Denmark, Department of Biochemistry and Molecular Biology, Odense, Denmark

²University of Turin, Department of Oncology, Orbassano, Italy

Introduction

Cancer is often characterized with the accumulation of mutations and deregulated signaling pathways or metabolic processes, which in turn facilitates uncontrolled proliferative ability to the cell with high

dependency on nucleotide metabolisms. Notably, aberrant expression levels in the rate-limiting enzymes of pyrimidine metabolism (PyMet) attributes 80% of cancer types, and the understanding of the intricate signaling pathways or metabolic processes behind PyMet is quite limited. Therefore, a comprehensive portrait of the signaling pathways and metabolisms connections with PyMet is essential to exploit therapeutic strategies for cancer.

Material and method

A pan-cancer analysis of PyMet's interaction with signaling pathways and metabolic processes was performed using a pathway-based approach in around 10,000 gene expression profiles of 32 cancer types utilizing a large collection of gene-sets representing signaling pathways and metabolic processes. The identified interactions were further validated in vitro using pyrimidine metabolic inhibitor (brequinar) treatments and genetic knockdowns. In addition, PyMet inhibition was explored for the synergistic activity with commonly used chemotherapeutic drugs such as cisplatin and doxorubicin using cell lines and mouse derived KrasG12D p53Δ/Δ lung tumor organoids to improve chemosensitivity of the drugs.

Result and discussion

Pan-cancer analysis with pathway-based approach has identified a strong inter-dependency of regulatory connections of PyMet including TERT, MTOR, DAX1, HOXA1, TP53 and TNC which in turn was tightly linked to chemoresistance. These PyMet-signaling interactions were further validated in vitro by inhibiting thymidylate synthase activity using knockdown approach and with brequinar treatment. Strikingly, chemoresistance gene signatures of widely used clinical drugs such as doxorubicin and cisplatin showed an inverse association pattern with brequinar treatment profile. In fact, brequinar treatment in cell lines and mouse-derived lung tumor organoids displayed a synergistic sensitization of cells to chemotherapeutic drugs implying targeting PyMet can overcome chemoresistance in cancer.

Conclusion

The study highlights the complex signaling and metabolic cascades governing pyrimidine metabolism and its role in chemoresistance, and thereby providing an effective tool for advancing PyMet targeting strategy in cancer. The analysis as an accessible resource is available at: www.pype.combio.sdu.dk

EACR25-1406

Single Cell Transcriptomics Reveals Hallmark Enrichment in Luminal A and Triple Negative Breast Cancers

O. Menyhart¹, Z. Dobolyi¹, B. Győrffy¹

¹Semmelweis University, Department of Bioinformatics, Budapest, Hungary

Introduction

The cancer hallmark framework offers valuable insights into the mechanisms underlying tumor diversity. To explore how these hallmarks differ among breast cancer (BC) subtypes and normal samples, we analyzed single-cell RNA-seq data of Luminal A (LumA), triple-negative breast cancer (TNBC), and normal tissues. We also

assessed gene expression trajectories and cell-cell communications that may influence tumorigenesis.

Material and method

Single-cell RNA-seq data with 10x Genomics protocols were utilized from NCBI GEO. In total, we integrated 47 LumA samples (164,091 cells), 24 TNBC samples (82,456 cells), and 16 normal breast samples (63,241 cells) into datasets. Data were processed using the Python scanpy pipeline; cell types were annotated via the CellMarker2.0 database, and tumor cells were identified with inferCNV. The CancerHallmarks.com platform was utilized to characterize cancer hallmark gene enrichment in the top 5000 genes. Pseudotime analyses with Monocle3 captured differentiation trajectories, and cell-cell communication networks were inferred with CellChat V2.

Result and discussion

Cell type distributions revealed unique micro-environments: LumA contained abundant epithelial and cytotoxic T cells, whereas TNBC had a higher proportion of B cells, macrophages, and cancer stem cells (CSCs). The proportion of tumor cells was 31% in LumA and 23% in TNBC samples. Tumor cells were characterized by distinct hallmark enrichment: in LumA, the hallmarks “reprogramming energy metabolism” and “resisting cell death” were particularly enriched ($p < 0.0001$), while in TNBC, additional hallmarks, including “evading immune distraction”, “tumor-promoting inflammation” and “replicative immortality” were also significant ($p < 0.01$). Subclustering of CSCs identified two principal groups in LumA and four in TNBC, reflecting broader heterogeneity in TNBC. Pseudotime trajectories showed that key mitochondrial and ribosomal genes, as well as MALAT1, FTH1, TPT1, and EEF1A1, vary significantly along differentiation pathways in both LumA and TNBC. CellChat V2 detected marked shifts in signaling pathways such as MK and VISFATIN and immune-related signals (e.g., CXCL, CCL, IL2) between normal and tumor cells. These suggest that tumor cells shift communication dynamics, favoring angiogenesis and reduced immune visibility, potentially enhancing tumor survival.

Conclusion

We demonstrate distinct hallmark enrichments and altered signaling pathways by integrating single-cell gene expression data from multiple BC subtypes. Our findings underscore the importance of investigating dynamic cell states and communication networks.

EACR25-1409 Enabling Clinical and Early-Phase Drug Development Applications through Single-Sample Tumor Archetype Assignment

M. Lütge¹, S. Nassiri²

¹*Roche Pharma Research and Early Development, Oncology Discovery, Zurich, Switzerland*

²*Roche Pharma Research and Early Development, Oncology Discovery, Basel, Switzerland*

Introduction

Tumor archetypes provide a biologically driven framework for classifying solid tumors through the lens of the tumor microenvironment (TME). Emerging studies have identified pan-cancer TME subtypes and established their association with overall survival, response to immunotherapy, and specific genomic alterations, highlighting the potential of TME classification for refining patient stratification and optimizing precision oncology strategies. However, computational approaches for deriving tumor archetypes are often tailored to specific datasets or require a representative input cohort as a preprocessing step, limiting their applicability to individual samples or small cohorts, which are common scenarios in clinical practice and early-phase trials.

Material and method

We adopted as our working model the pan-cancer taxonomy proposed by Bagaev et al., which categorizes tumors into four distinct TME subtypes: immune-enriched, fibrotic, immune-enriched and fibrotic, and desert. Focusing on colorectal, lung, and breast cancer, and using RNA-seq data from TCGA and Roche clinical trials, we systematically assessed the robustness and generalizability of Bagaev tumor archetypes across indications and cohorts. We further trained a set of indication-specific single-sample machine learning classifiers that leveraged within-sample pairwise gene expression relationships to assign archetype labels to out-of-sample and previously unseen data.

Result and discussion

The replicability of tumor archetypes and their associated gene signature enrichment profiles varied across indications and cohorts. Moreover, the assigned archetype label for a given sample was highly dependent on the cohort's composition. This is problematic, as archetype assignment should not be influenced by the specific cohort in which samples are evaluated. We found that our classifiers achieved robust and reliable results comparable to cohort-based clustering outcomes when all four archetypes were well-represented, and particularly excelled in settings with limited samples or under-represented archetypes. In cases of disagreement, our classifiers showed stronger alignment with H&E evaluation of TME features and maintained performance despite batch effects and variable sequencing depths, underscoring their practical utility for real-world clinical applications.

Conclusion

We offer a robust and generalizable framework for TME-based tumor archetype assignment in individual patients. This framework addresses the limitations of cohort-dependent methods, making it particularly well-suited for clinical settings and early-phase drug development applications. Future work will focus on addressing TME gene signature redundancies and exploring the interpretability and utility of soft-assignments using class-label probabilities.

EACR25-1476 Linking *in situ* phenotyping of intestinal stem cells to functional analyses of patient-derived organoids as a risk

stratification strategy during follow-up monitoring of CRC patients

⁵*University of Lübeck, Lübeck Institute of Experimental Dermatology, Lübeck, Germany*

⁶www.outlive-crc.uni-luebeck.de/projekte, Lübeck, Germany

Introduction

Intestinal stem cells (ISCs) are crucial for high-turnover tissue regeneration and homeostasis of the colonic crypt, however, their dysregulation is a major factor in developing colorectal cancer (CRC). Two types of ISCs have been identified: cycling LGR5+ SCs at the base and a reserve pool of SCs in the +4 position of the crypt. To maintain cell proliferation and self-renewal, SCs express high levels of β-Catenin, a central component of the Wnt signaling pathway. Here, we aim to phenotype the colonic SC compartment at both the single-cell level *in situ* and the functional level *ex vivo* to identify CRC patients at high risk of recurrence during follow-up monitoring.

Material and method

In situ phenotyping of ISCs was performed using the spatial single-cell proteomics Immuno-Oncology panel (CosMxTM from Bruker). Colonic tissues of patients during CRC follow-up versus normal controls were analyzed. Therefore, ISCs were defined as Vimentinneg β-Cateninpos cells, and the two subtypes were distinguished based on their spatial position within the crypt. To link these data to functional analyses, the *ex vivo* proliferative potential of ISCs was studied using patient-derived 3D organoids (PDOs). PDOs were generated from colonic crypts that were isolated from biopsy samples collected during regular follow-up colonoscopies. The proliferation and differentiation of PDOs were analyzed using live cell imaging and RNA sequencing, respectively.

Result and discussion

In-depth characterization revealed different phenotypes of Vimentin neg β-Catenin pos ISCs between follow-up CRC patients and controls. In preliminary experiments, these phenotypes could be functionally validated using PDO cultures.

Conclusion

Our findings suggest that the proliferative capacity of colonic PDOs highly depends on the phenotype of the ISC compartment. In the long term, characterizing the stem cell profile could contribute to risk stratification of CRC follow-up patients and identification of therapeutic or metabolic targets for the prevention of recurrences as part of tertiary prevention.

EACR25-1478

Good Models or Good Riddance: A Guide for Researchers on Choosing Optimal Cell Lines for Translational Ovarian Cancer Research

A. McCabe¹, O. Zaheed¹, S. McDade², K. Dean¹

¹*University College Cork, School of Biochemistry and Cell Biology, Cork, Ireland*

²*Queen's University Belfast, School of Medicine, Dentistry and Biomedical Sciences, Belfast, United Kingdom*

Introduction

Epithelial ovarian cancer (EOC) poses a significant global health challenge, accounting for over 200,000 deaths per year. EOC comprises five histological subtypes that respond differently to chemotherapy and have distinct prognoses. EOC cell lines serve as essential tools for cancer research; however, subtype specificity and molecular similarity to primary tumours are often overlooked, hindering applications in preclinical research. Here, we address the challenge of selecting appropriate EOC cell line models for subtype-specific research. We also identify long non-coding RNAs (lncRNAs) upregulated in high-grade serous ovarian carcinoma (HGSOC) cell lines. A subset of these lncRNAs demonstrated strong correlations with genes involved in the epithelial-to-mesenchymal transition (EMT).

Material and method

Non-negative matrix factorization (NMF) was performed on 56 EOC cell lines. The mutational, copy number and gene expression landscapes of these cell lines was then characterized. The gene expression profiles of these 56 cell lines were compared with those of 93 primary tumour samples, stratified by subtype. Differential gene expression analysis was performed to identify deregulated lncRNAs in HGSOC cell lines. Finally, Spearman's correlation test was carried out to identify lncRNAs displaying a similar expression pattern to 37 EMT-related genes.

Result and discussion

Non-negative matrix factorization separated 56 EOC cell lines into five stable clusters. The five groups of cell lines identified by NMF each shared the major mutational and copy number characteristics of each of the five subtypes of ovarian cancer, suggesting that these groupings were reflective of histological subtype. Integration of gene expression data identified EOC cell lines most suited to transcriptomic studies. We also highlight that A2780, used in over 90% of EOC preclinical studies, is an unsuitable model of ovarian carcinoma of any subtype. We then focused on HGSOC cell lines to identify potential therapeutic or diagnostic biomarkers. lncRNAs have been highlighted as auspicious biomarkers in cancer diagnosis and prognosis, due to their tissue-specific expression and stability in circulation. We identified 229 lncRNAs differentially expressed in HSGOC cell lines compared to control samples. Interestingly, nine of these lncRNAs displayed similar expression patterns to several EMT-related genes, marking them as prospective candidates for *in vitro* diagnostic and prognostic testing.

Conclusion

Ultimately, this study underscores the critical importance of selecting subtype-specific EOC cell line models for computational and laboratory-based investigations. Additionally, we pinpointed subtype-specific lncRNAs exhibiting strong correlations with EMT-related genes. A greater understanding of the diverse subtypes of ovarian will lead to more targeted therapies, novel diagnostics and increased survival for patients affected by EOC.

EACR25-1565

Artificial Intelligence-Based Polyp Size Measurement: Multinational Validation Across Endoscopic Datasets

S. Kim¹, S. Jang^{2,3}, H. Im¹, J. Im¹, B. Kim¹

¹*Seoul National University College of Medicine, Internal Medicine and Liver Research Institute, Seoul, Korea (Republic of)*

²*Seoul National University Graduate School, Interdisciplinary Program in Bioengineering, Seoul, Korea (Republic of)*

³*Seoul National University Graduate School, Integrated Major in Innovative Medical Science, Seoul, Korea (Republic of)*

Introduction

Colon polyp size measurement is crucial for predicting colon cancer risk. However, precise measurement remains challenging due to variability among clinicians and non-calibrated equipment. Recent studies have aimed to improve accuracy by incorporating Artificial Intelligence (AI) models. However, the models have not been extensively validated across diverse clinical datasets. This study evaluates an AI-based colon polyp size measurement system using real-world clinical data from multiple countries.

Material and method

The Real-Colon (Italy, UK, USA, Austria, Japan), PICCOLO (Spain), and SNUH (Korea) datasets were utilized, with polyp sizes validated by gastro-enterologists. Paired images, including standard and instrument-referenced frames, were measured by three physicians. A CASCADE model generated segmentation masks. Depth maps were created using a deep learning estimation model and underwent iterative grid optimization for each dataset. These maps were converted into 3D point clouds, from which 2D projections were derived to calculate colon polyp diameters.

Result and discussion

We conducted binary classification at 5 mm and 10 mm clinical thresholds using three datasets: Real-Colon (131 polyps, 2,097 images), PICCOLO (68 polyps, 2,968 images), and SNUH (76 polyps, 165 images). The system showed robust performance across all datasets. At the 5 mm threshold, accuracies were 80.96% (F1: 0.8812) for PICCOLO, 81.29% (F1: 0.4988) for Real-Colon, and 76.97% (F1: 0.7246) for SNUH. At the 10 mm threshold, accuracies were 72.57% (F1: 0.7140) for PICCOLO, 98.06% (F1: 0.5176) for Real-Colon, and 90.91% (F1: 0.7368) for SNUH.

Conclusion

This study marks the first comprehensive evaluation of a colon polyp size measurement algorithm on multi-

institutional data from various countries, demonstrating its broad applicability across diverse clinical settings and populations, and confirming the potential for clinical application of AI-based polyp size assessments across varied datasets.

EACR25-1570

Prediction of Rectal Cancer Complete Response to Chemoradiotherapy by Multiscale Imaging and Deep Learning Analyses (PRECORMIDEL)

C. Sarmiento¹, D. Accardi², J. Azevedo², M. Castillo-Martin², L. Vanneschi¹

¹*NOVA Information Management School, Lisbon, Portugal*

²*Champalimaud Foundation, Lisbon, Portugal*

Introduction

Colorectal cancer (CRC) is the third most common cancer worldwide, accounting for 9.6% of cancer-related deaths. Among CRC, rectal cancer (RC) has significant morbidity and mortality. Neoadjuvant chemoradiotherapy (nCRT) is a standard treatment for locally advanced RC, yet response to therapy varies among patients. Pathological response to nCRT is a critical prognostic factor, but its prediction remains a challenge. Biomarkers have been explored, but their clinical applicability is limited. We hypothesize that key features within patient biopsies can predict treatment response and that deep learning (DL), as a powerful and unbiased analytical approach, can effectively analyze histological images to make these predictions.

Material and method

This study applies DL algorithms to predict nCRT response using high-resolution Hematoxylin and Eosin (H&E) images from 20 cases (10 "responder" patients with persistent complete response after nCRT, and 10 "non-responders" who had to undergo salvage surgery) of a larger dataset of 120 patients identified in the Watch&Wait cohort of the Champalimaud Foundation. Image preprocessing involved patch extraction, followed by patch-level classification using pretrained ResNet18 and VGG19. Patient-level predictions were generated through a majority-vote aggregation. The model performance was assessed using accuracy, F1 score, precision, and recall at both patch and patient levels. These metrics allow for evaluating the model's ability to correctly classify both individual patches and patient outcomes.

Result and discussion

Preliminary results show that ResNet18 outperforms VGG19, achieving an accuracy of 87%, F1 score of 88%, precision of 99%, and recall of 78%. The superior precision of ResNet18 underscores its ability to reduce false positives, while recall values indicate room for improvement in minimizing false negatives. These results are supported by a dataset with well-defined, high-resolution images acquired through consistent protocols. Despite the small sample size, the reliability of ResNet18's predictions suggests that our data-driven methodology plays a key role. Analyzing the whole dataset, incorporating immunohistochemistry images, and

refining model architectures will be key to improving performance.

Conclusion

These preliminary findings demonstrate the potential of DL for predicting nCRT response in RC, with ResNet18 showing strong performance across key metrics. The high quality and rigor of the dataset likely contribute more to these results than model complexity alone. While the results are promising, further validation with external datasets is necessary. This approach could pave the way for personalized treatment strategies by identifying patients most likely to respond to nCRT while also providing insights into the cellular mechanisms underlying these response differences.

EACR25-1610

Development of a mathematical model for early prediction of relapses in colorectal cancer

M. Sánchez-Díez¹, J. Pastor¹, C. Ramírez-Castillejo¹

¹*Universidad Politécnica de Madrid, Madrid, Spain*

Introduction

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths and the third most common cancer worldwide. While primary tumors are effectively managed in most cases, approximately 20–40% of patients experience recurrence within the first two to three years after treatment. Cancer stem cells (CSCs) are most responsible for relapse due to their unique characteristics, including their low division rate, their self-renewal capacity, and their ability to evade the primary tumor, travel through the bloodstream (due to its epithelial-mesenchymal transition capacity), and colonize other locations, both proximally and distally (metastasis). Although several biomarkers have been described in the literature for the detection of CSCs, none are exclusive to this cell population. This limitation highlights the need for a combination of biomarkers to improve early relapse prediction.

Material and method

The presented project applies supervised machine learning methods to generate a mathematical model for relapse prediction. The expression levels of a combination of CSCs biomarkers together with the clinicopathological characteristics of the patients were the inputs for the developed mathematical model.

Result and discussion

Different supervised machine learning models were applied to develop a mathematical model for relapse prediction, with Logistic Regression yielding the best results. This model achieved a specificity of 82.4% and a sensitivity of 82.6%, offering reliable predictive capabilities. We also analyzed the contribution of each biomarker to the model to better understand their roles in relapse prediction.

Conclusion

The development of a mathematical model for early relapse prediction contributes to advancing precision medicine and improving the quality of life for colorectal cancer patients by enabling more targeted and effective interventions, maximizing response rates, minimizing unnecessary treatments, and reducing side effects.

EACR25-1680

Deciphering the Role of Stress Granules: Dampening Inflammation in Cancer through Mitochondrial RNA Sequestration

A. Kaizeler¹, V. Morais¹, N. Barbosa-Morais¹

¹*Gulbenkian Institute for Molecular Medicine, Lisbon, Portugal*

Introduction

Stress granules (SGs) are dynamic, membraneless cytoplasmic assemblies formed in response to various cellular stressors, including hypoxia, nutrient deprivation, and chemotherapy, that are commonly encountered in the tumour microenvironment. Initially linked to global translational suppression, SGs are now recognized for their role in the selective sequestration of proteins and mRNAs, a process that modulates stress responses and influences cell survival. In cancer, SGs have been associated with metastasis and chemoresistance, highlighting their potential impact on tumour progression.

Material and method

We performed an unbiased analysis of publicly available transcriptomes of SGs, collected by either differential centrifugation or proximity RNA labelling, from diverse human cell types, stress conditions, and isolation methodologies. To address methodological discrepancies and elucidate the functional implications of SG composition, we developed, using machine learning, an SG gene signature technique. This signature was subsequently employed to assess prognostic outcomes in cancer survival and therapeutic response.

Result and discussion

Our analyses suggest that SG transcript profiles derived via differential centrifugation are strongly influenced by inherent methodological biases, resulting in minimal concordance with datasets obtained through proximity labelling. Notably, the former naturally biases for heavier and consequently longer RNAs. Despite these methodological challenges, after removal of that bias, an enriched sequestration of mitochondrially encoded RNAs in SGs was consistently observed across studies. We hypothesize that these RNAs have immunogenic properties and that their sequestration within SGs mitigates the immunogenic response, thereby reducing inflammation and apoptosis. While the machine learning-derived SG gene signature was often elevated in tumours compared to normal tissues, its performance as a prognostic tool was not superior to that of random gene sets, a limitation of many other cancer-related signatures. This suggests that, although SG-mediated dampening of the inflammatory response may contribute to cancer cell survival and therapy resistance, its translation into a robust prognostic marker remains challenging.

Conclusion

This study highlights the dual challenges of methodological variability and biological complexity in SG research. Our findings support a model in which SGs selectively sequester immunogenic mitochondrially encoded RNAs, attenuating inflammatory responses and apoptosis, which may promote tumour progression. While our developed SG signatures imply the presence of these structures in cancer tissues, its limited prognostic

performance calls for further refinement and the need for standardised isolation techniques to clarify the precise role of SGs in cancer biology.

EACR25-1696

A semi-automated approach for detecting minimal residual disease with single-tube by flow cytometry in pediatric acute myeloid leukemia

T. Fernandes Nunes^{1,2}, R. Mendonça de Pontes¹, A. Silva Dias¹, S. Mendes Alves Leal¹, I. Quezado Soares Magalhães³, J. Martins Córdoba³, R. Camargo¹, F. Magalhães Furtado^{3,1,4}

¹*Children's Hospital of Brasilia, Laboratory of Translational Research, Brasilia, Brazil*

²*University of Brasília, Faculty of Medicine, Brasília, Brazil*

³*Children's Hospital of Brasilia, Department of Oncohematology, Brasília, Brazil*

⁴*Sabin Diagnosis and Health, Brasilia, Department of Hematology, Brasília, Brazil*

Introduction

Acute Myeloid Leukemia (AML) demands precise diagnostics and prognostics. Flow cytometry (FC) is essential for identifying neoplastic markers, while Minimal Residual Disease (MRD) detection in Bone Marrow (BM) evaluates treatment response. This study explores the use of the semi-automated t-SNE algorithm with HOVON single-tube FC for MRD detection in pediatric AML, comparing its accuracy and efficiency to manual analysis.

Material and method

This retrospective study analyzed cytomorphological markers in leukemic cells from 8 pediatric AML patients at a Brazilian public hospital between 2021-2024. Children aged ≤ 18 years with AML who maintained positive MRD ($\geq 0.1\%$ blasts in the BM) were included. Clinical data were collected by reviewing medical records. Acquisition for MRD detection in BM samples was performed using an FACSCanto cytometer, using a combination of monoclonal antibodies. In this study, BM aspirates were prepared for cytometric analysis by centrifugation or massive lysis of red blood cells with ammonium chloride solution, known as Bulk Lyse, increasing the sensitivity of the method and allowing the recovery of enough leukocytes to perform the labeling and acquisition of ≥ 1.5 million cells per tube. The 5 control samples were labeled with a combination of 46 specific monoclonal antibodies, totaling 6 tubes (8 colors) to identify residual leukemic cells and differentiate normal/residual cells regenerating in the BM during treatment. The 8 test samples were labeled only from a single tube adapted from the HOVON group to the panel used for monitoring MRD in AML. FlowJo software was used to apply the automated data clustering methodology by t-SNE. The local ethics committee approved the study.

Result and discussion

Analyses were performed on 8 patients, 1 male and 7 female. The mean age was 10.75 years and 5 BM aspirates from children with AML were included as

controls. Single-tube analysis (CD7/CD13/CD34/CD117/CD33/HLA-DRA/CD45) facilitated the characterization of myeloid compartments at immature stages, including pre-leukemic CD34/CD33 stem cells associated with leukemia recurrence. The inclusion of CD56 as a cross-lineage marker proved useful for detecting MRD. The automated cluster mapping methodology, specifically t-SNE, successfully identified expected MRD populations, demonstrating consistency with manual gating results. Control samples showed no MRD populations, aligning with this methodology. A comparison of manual and semi-automated analyses revealed a 100% agreement between t-SNE and manual gating results. Statistical evaluation showed no significant differences in mean detection rates and Pearson's correlation indicated no bias between the methods.

Conclusion

The findings support the integration of t-SNE methodology into monitoring workflows. This study highlights t-SNE as a complementary tool, providing clinicians with a risk stratification method based on machine learning.

EACR25-1735

Accelerating real world data collection using Large Language Models in rare neoplasms, a bone sarcoma example

P. Teterycz¹, S. Rynkun², B. Szostakowski³, M. Wągrodzki⁴, P. Rutkowski³, M. Rosińska²

¹*Maria Skłodowska-Curie National Research Institute of Oncology, Department of Soft Tissue/Bone Sarcoma and Melanoma, Digital Medicine Centre, Warsaw, Poland*

²*Maria Skłodowska-Curie National Research Institute of Oncology, Digital Medicine Centre, Warsaw, Poland*

³*Maria Skłodowska-Curie National Research Institute of Oncology, Department of Soft Tissue/Bone Sarcoma and Melanoma, Warsaw, Poland*

⁴*Maria Skłodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland*

Introduction

Real-world data collection in oncology poses many challenges due to an extensive number of important variables, the rapidly changing treatment landscape, and mostly unstructured source data. Large Language Models (LLMs) have proven capable of extracting information across various domains, yet their size and computational requirements still limit their practical use. However, the popularization of smaller LLMs' variants and model quantization methods have opened doors for local, controlled inference without the necessity for substantial computing infrastructure. This study evaluates the performance of multiple small LLMs as information extractors on Polish language free-text medical notes.

Material and method

Electronic health records (EHRs) of 302 consecutive bone sarcoma patients treated in a reference center between 2016 and 2022 have been selected. 5 variables (pathology type, tumor size, localization, grade, and type of primary resection) for each EHR have been extracted by an oncologist experienced in sarcoma treatment.

4 LLMs (Llama 3.1 8B, DeepSeek-R1 8B, Mixtral 8x7B,

Bielik-11B-v2.3-Instruct) have been chosen for the study, with the temperature set to 0. A zero-shot prompting technique with or without additional background information has been used to query the models with the task of returning the value for a given variable using an XML tag. Accuracy was defined as a percent of values concordant with the human-extracted values.

Additionally, among non-concordant values, we distinguished valid results, i.e., of expected format and containing a keyword/phrase from per-variable, expert-devised list. Finally, we've designed a voting strategy that selects the value obtained in more than half of valid results as the ensemble result.

Result and discussion

The average accuracy across the models ranged between 19.2% and 34.2%, with performance on distinct prompts varying greatly. In particular, the tumor localization values turned out to be the easiest to assess by LLMs, with accuracy up to 70.4%. The models had better accuracy when given background information (OR: 1.31, 95% CI: 1.25-1.38). The majority of non-concordant values were non-valid values. Applying the voting strategy improved performance significantly, with 75.8% overall accuracy.

Conclusion

Our study highlights the potential of using lightweight LLMs to automate data extraction from oncologic notes, which could significantly accelerate clinical research. A singular, small LLM is not yet sufficient for real use cases in non-English settings; however, prompt engineering and ensemble methods can greatly improve performance.

EACR25-1741

Pan-Cancer Analysis Identifies Dorsomorphin Dihydrochloride as an Anticancer Drug Targeting the Notch Signaling Pathway

E. Kubat Oktem¹

¹Istanbul Medeniyet University, Molecular Biology and Genetics, Istanbul, Turkey

Introduction

Cancer is characterized by the uncontrolled and continuous division of cells. Identifying specific biomarkers for tumor treatment has become increasingly important, particularly with the discovery of oncogenes and tumor suppressor genes. Various biochemical signaling pathways contribute to cancer development, and one critical pathway is the Notch signaling pathway.

Material and method

This study applies advanced bioinformatics approaches to analyze transcriptome and clinical data from nine tumor types in TCGA, focusing on two main goals: identifying biomarkers linking Notch signaling to carcinogenesis and exploring the potential of drug repositioning to target this pathway.

Result and discussion

The results reveal CA4, CFD, DPT, FHL1, TMEM100, TMEM132A, and VEGFD as critical biomarkers associated with Notch signaling in tumorigenesis. In particular, dorsomorphin dihydrochloride was successfully repositioned as a drug targeting pan-cancer

Notch biomarkers, offering a promising therapeutic strategy for cancers influenced by this pathway.

Conclusion

This study highlights the significant role of drug repositioning, demonstrating how existing drugs can be repurposed to target key biomarkers like those involved in Notch signaling. In precision medicine, these biomarkers, combined with repositioned drugs like dorsomorphin dihydrochloride, hold the potential to revolutionize patient-specific therapies, reducing both the time and cost of developing new treatments.

EACR25-1799

Proteomic Analysis of the Pd(II) Complex-Induced Changes in HeLa Cervical Cancer Line

V. Ralić¹, M. Petković¹, J. Žakula², L. Korićanac², M. Nešić¹, I. Popović¹, K. Davalieva³

¹Vinča Institute of Nuclear Sciences, Department of Atomic Physics, Belgrade, Serbia

²Vinča Institute of Nuclear Sciences, Department of Molecular Biology and Endocrinology, Belgrade, Serbia

³Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology "Georgi D Efremov", Skopje, North Macedonia

Introduction

Palladium(II) complexes have emerged as potential anticancer agents due to the metal core similarity with widely used platinum(II) complexes. However, the precise molecular mechanisms remain unclear. In this study, we investigate the effects of a Pd(II) complex on HeLa cells at the protein level.

Material and method

HeLa cells were treated with 50 µg/ml dichloro(1,2-diaminocyclohexane)palladium(II), [Pd(dach)Cl₂] for 48 hours, followed by comparative proteomics analysis using label-free data-independent LC-MS/MS acquisition coupled with ion mobility. A bioinformatics approach using STRING and Cytoscape plug-in ClueGO was applied to perform functional enrichment analysis of the proteins with statistically significant differential abundance, highlighting key cellular processes and molecular pathways affected by treatment.

Result and discussion

We have identified 121 differentially abundant proteins (Anova < 0.05) in Pd(II) treated HeLa cells compared to controls. An enrichment analysis of GO annotations indicated ATP hydrolysis activity and RNA binding as top molecular functions. The most affected biological processes were RNA splicing, protein-RNA complex organization, and cytoplasmic translation. KEGG pathways enrichment revealed a significant association with the spliceosome and ribosome pathways, suggesting RNA processing and stability disruptions. Identification of hub genes in the protein-protein interaction network of differentially abundant proteins revealed that the top 6 highly essential proteins in this network were ribosomal (RPL4, RPS9, RPL32, RPS15A, RPS25, RPL36AL).

Conclusion

This study provides novel insights into the changes in HeLa cell proteins induced by a Pd(II) complex. The enrichment of RNA-processing pathways suggests a potential mechanism of action, warranting further

investigation into the therapeutic relevance of Pd(II) complexes in cancer treatment.

EACR25-1837

MOKCa-3D Database: Functional and structural analysis of gain-of-function and loss-of-function missense mutations in cancer

B. Haile¹, A. Cinar², F. Banini², K. Zhikova², F. Gallagher², C. Richardson³, E. Pearl²

¹University of Sussex, Brighton, United Kingdom

²University of Sussex, United Kingdom

³The Institute of Cancer Research, United Kingdom

Introduction

Determining the functional consequence of missense mutations acquired in the development of cancer is critical to the understanding of the evolution and the therapeutic vulnerabilities of an individual tumour. Over three million unique missense mutations have been reported in the COSMIC database of cancer somatic mutations, with little functional annotation accompanying each mutation. We have designed the MOKCa-3D database [1] to enable the contextualization and interpretation of cancer somatic missense mutations including the structural impact of the mutation on the 3D structure, and whether the mutation results in a gain or loss of the protein's function.

Material and method

For each protein, a sequence feature viewer enables interactive visualization of the amino acid sequence, missense mutations, post-translational modification sites (PTMs), protein domains, active sites, binding sites, protein-protein interaction sites, and mutational frequency. The mutation-level page concisely presents functional insights for each individual mutation, and an interactive MOL star viewer highlights mutated residue on an AlphaFold protein structural model. The SAAP structural impact analysis pipeline was used to identify the structural impact of the mutation.

Result and discussion

MOKCa-3D concisely presents functional insights and structural impacts of cancer somatic missense mutations enabling users to interpret their functional consequences.

Conclusion

MOKCa-3D is freely accessible and easy to navigate, making it usable by the widest range of researchers.

The S-RACE Platform: Empowering Healthcare Real-World Data with Artificial Intelligence (AI) Using a Cloud-Based Approach

A. Traverso¹, C. Tacchetti¹, A. Esposito², S. Barbieri¹, A. Corvaglia¹, A. Dimonte¹, E. Draetta¹, B. Fabiani¹, D. Tiano¹, M. Agazzi³

¹Università Vita-Salute San Raffaele, Milano, Italy

²Università Vita-Salute San Raffaele, Italy

³IRCCS Ospedale San Raffaele, Milano, Italy

Introduction

Prognostic and predictive clinical decision support systems based on Real-World Evidence (RWE) data are crucial in clinical research. These systems help clinicians optimize therapeutic choices, reduce adverse events, and enhance personalized medicine. AI plays a key role in these advancements, as machine learning algorithms uncover hidden patterns beyond human capability, leading to novel clinical insights. However, the clinical translation of such algorithms depends heavily on data quality. RWE data are often unstructured, sparse, and poorly curated, requiring extensive manual processing. To address this, we developed an end-to-end data engineering pipeline to import RWE from our IT system and create machine learning models to tackle urgent clinical questions.

Material and method

The S-RACE Cloud-based platform, developed with Microsoft, has three main functionalities: a universal data platform (ingestion), a clinician AI hub (exploration), and a data science lab (modeling). The universal data platform lets investigators select patient cohorts, define data sources, and retrieve DICOM images. An on-prem anonymization engine processes data before securely transferring it. AI technologies, including Microsoft Cognitive Health Services, use natural language processing (NLP) and medical ontologies to extract relevant clinical information. Processed RWE, standardized using FHIR, are stored in a data lake and linked to specific use cases. Preliminary analyses are conducted via Microsoft Power BI, while data modeling is performed using Microsoft Azure Machine Learning Studio. Explainability techniques enhance model interpretability, and standardized templates automate documentation. Validated models will be shared internally and with the broader clinical and research communities via the clinician AI hub.

Result and discussion

We have integrated five major hospital IT systems into the platform including electronic health records, PACS, blood lab tests, pathology and cancer registries leading to a total of 5000 cancer patients' data imported. Currently, ten clinical use cases (prostate cancer, metastatic lung cancer, colorectal cancer, pancreatic cancer, liver cancer, lung cancer screening, diabetes, multiple sclerosis, cardiovascular diseases) are active, with AI models under development and validation. One oncological case study has been concluded: we have developed one web-based risk score to preoperatively predict kidney cancer mortality [1].

Conclusion

The S-RACE platform is a scalable AI-driven solution to leveraging RWE in clinical decision-making. By integrating hospital IT systems, automating data processing, and enabling AI modeling, the platform enhances research and fosters data-driven personalized medicine. Future work will focus on expanding validated AI models and facilitating their clinical adoption.

⁵Laboratório de Instrumentação e Física Experimental de Partículas and Faculdade de Ciências da Universidade de Lisboa, Departamento de Física, Lisboa, Portugal

Introduction

Gold nanoparticles (AuNPs) can enhance radiotherapy effects in tumors without raising patient dose, being Monte Carlo simulations (MCS) a very useful tool to study the effect of AuNPs as radiosensitizers.

Material and method

Voxelized cell geometry of GBM cell model was implemented on TOPAS MC, and MCS results estimated the SF using local effect model (LEM) and microdosimetric kinetic model (MKM). Different concentrations of AuNPs were evaluated. Additionally, DNA damage caused by direct and indirect interactions during the physical and chemical stages was assessed. Strand breaks (SBs) on opposite DNA strands within 10 base pairs were classified as double-strand breaks (DSBs); otherwise, they were single-strand breaks (SSBs). DSBs were categorized as direct (both SBs from direct interactions), indirect (both from indirect interactions), or hybrid (one direct, one indirect).

Result and discussion

Regarding the survival fraction, the results, obtained using LEM, were benchmarked against experimental results, demonstrating a good agreement. The SF obtained either in the absence or in the presence of AuNPs with LEM were compared with the ones obtained using MKM. The study showed that selecting the appropriate domain size is crucial in MKM, as it directly affects the calculation of the microdosimetric quantity y^-_D (dose-mean lineal energy). Four domain sizes were considered: 5, 10, 15, and 20 nm. The percentual difference in SF at 2 Gy between LEM and MKM follows a consistent trend, regardless of the irradiation type. The highest difference is observed when the domain size is set to 5 nm, decreasing as the domain size increases. This difference is also more pronounced in the presence of AuNPs compared to cases where no AuNPs were considered. Furthermore, the differences obtained for X-ray irradiation are significantly larger than those observed for Co-60 exposure. The results of MCS for DNA damage demonstrate that X-rays, in combination

with AuNP, induce a substantial increase in DSBs, with nearly four times higher DSBs production. This increase is primarily driven by indirect mechanisms. In contrast, after γ -ray exposure, the production of DSB does not increase so significantly as for the X-ray exposure. In this case, the indirect damage is negligible. These results agree with the experimental findings.

Conclusion

The results reinforce the potential of AuNPs as effective radiosensitizers, particularly for kilovoltage X-ray therapy. The findings highlight the importance of optimizing parameters in advanced radiobiological models, such as MKM, to better understand the micro- and nanoscale effects of AuNPs.

⁴Queen's University Belfast, The Patrick G Johnston Centre for Cancer Research, Belfast, United Kingdom

Introduction

Prostate cancer is a leading cause of cancer-related mortality, with disease heterogeneity complicating risk stratification and treatment decision-making. AI models developed using gene expression or digital histopathology have demonstrated significant prognostic value for cancer patients. However, the biological interpretation of these AI models, and the integration of these multi-modal data types, could enhance clinical applicability and prognostic value, respectively. This research aims to use functional genomics to improve AI model explainability, and deep learning to refine prostate cancer risk stratification.

Material and method

This study will utilise two in-house prostate cancer cohorts: the FASTMAN cohort, which includes 466 locally advanced patients, and the FIR cohort, which consists of 159 intermediate-risk patients. This study will also utilise the 499 patients within the TCGA-PRAD cohort. Self-supervised learning (SSL) will be used on digital prostate histopathology whole-slide images (WSIs) to extract morphological features without reliance on extensive annotations. Functional genomics through gene expression will be used to biologically interpret the ArteriaAI Prostate Test, and hypertension status. SSL-derived histopathology features, gene expression, and clinicopathological factors will be integrated using deep learning autoencoders for patient subgroup discovery.

Result and discussion

Through the exploration of different methods within the analysis pipeline of SSL methods in digital histopathology, we will provide a benchmark for other researchers to avail to, as well as developing SSL-derived histopathology features for our curated prostate cancer patient cohorts. The biological interpretation of the ArterAI Prostate Test will enhance its explainability for greater trust towards future use in clinical practice. Hypertension status was significantly associated with better outcomes in disease progression and overall survival for locally advanced prostate cancer patients treated with radiotherapy and ADT. We anticipate that the integration of the described multimodal data types will reveal novel patient subgroups with improved patient stratification.

Conclusion

Through SSL digital histopathology analysis, functional genomics, and multimodal data integration, this research aims to enhance risk stratification and characterize the underlying biology associated with prognostic AI models and hypertension status in prostate cancer patients

Unravelling HR-positive, HER2-negative Breast Cancer and its Tumor Microenvironment Heterogeneity Using Spatial Transcriptomics

B. Karakose¹, M. Serra¹, N. Van Renne¹, F. Lifrange², D. Venet¹, D. Vincent¹, G. Rouas¹, D. Larsimont³, F. Rothe¹, C. Sotiriou¹

¹*Institut Jules Bordet, Breast Cancer Translational Research Dept., Brussels, Belgium*

²*CHU de Liège - Sart Tilman Site, Liege, Belgium*

³*Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet, Dept. of Pathology, Brussels, Belgium*

Introduction

HR-positive, HER2-negative (HR+/HER2-) breast cancer exhibits significant molecular and cellular heterogeneity, influencing prognosis and treatment response. We applied spatial transcriptomics (ST) to dissect tumor microenvironment (TME) heterogeneity and its impact on clinical outcomes.

Material and method

Spatial transcriptomics (Visium 10X) was performed on 86 HR+/HER2- of no special type of frozen tumor samples, and relative H&E slides were morphologically annotated. Single-cell deconvolution of ST spots was performed to increase the resolution of Visium data. Tumor and TME compartments were identified using morphological annotation, and differences in the abundance of deconvoluted cell types between two intrinsic molecular subtypes, LumA and LumB, were investigated. Unsupervised clustering of spatially resolved transcriptomes was performed to identify distinct spatial subtypes across samples. Differential gene expression and pathway enrichment analyses were conducted to explore functional differences among clusters.

Result and discussion

As expected, LumB tumors exhibited worse relapse-free survival compared to LumA tumors ($p = 0.012$). Distinct spatial patterns emerged between LumA and LumB subtypes. LumA tumors were more enriched for CXCL12+ endothelial cells, naive B cells, and multiple CAF subtypes across both tumor and TME zones compared to LumB tumors, whereas LumB tumors exhibited higher infiltration of exhausted T cells (LAG3+), CXCL10+ macrophages, and lipid-associated macrophages (FABP5+) within TME regions compared to LumA tumors. Unsupervised clustering revealed 24 distinct clusters with different transcriptomic patterns, cellular compositions and histological features. Clusters that were significantly associated with poor prognosis are validated using external datasets METABRIC and SCAN-B. Cluster 6, present in all patients, was enriched in stromal cells, epithelial cells, and fat tissue. Cluster 11, (78 patients), represents areas of necrosis and fat tissue within the tumor and was enriched in lipid-associated macrophages, inflammatory response and IFN- α /IFN- γ signaling pathways. Similarly, Cluster 12 (71 patients), consists of tumor regions exhibiting necrosis, associated with IFN- γ stimulated macrophages and enriched in IFN- α /IFN- γ signaling, suggesting immune activation in response to tumor cell death. Lastly, cluster 17 (seven patients) marked tumor regions. These findings highlight the role of intra-tumor heterogeneity and immune composition in prognosis.

Conclusion

These findings enhance the understanding of the TME in HR+/HER2- breast cancer, highlighting its critical role in tumor progression. Further validation is needed to determine how these spatial clusters and immune interactions influence treatment response and long-term patient outcomes.

Introduction

Given that ovarian cancer is often diagnosed at an advanced stage, there is a high demand for translational studies discovering advanced clinical biomarkers. The aim of the study was to develop prognostic models for

High-Grade Serous Ovarian Cancer (HGSOC) Overall Survival (OS) based on the multilayered omics networks.

Material and method

A non-TCGA-related (The Cancer Genome Atlas Program) independent Polish patient cohort constituted of 66 women with HGSOC, and 43 non-HGSOC controls. Multiomic analyses covering: Whole Exome (WES), total RNA, smallRNA and methylome (RRBS) sequencing, were performed on Illumina platform for each of the samples, and standardized data processing was applied. To reduce the dimensionality of data, networks of correlated profile modules were created using WGCNA (Weighted Correlation Network Analysis). Time-to-event analyses related to OS were performed utilizing log-rank tests and multivariate Cox PH models. Feature selection and modelling were conducted using machine learning approaches. A performance of the binary classifier for survival during follow-up period was assessed using AUROC, with internal cross-validations (CV) using LOOCV and 5-fold CV.

Result and discussion

The mortality rate was 35% with median follow-up ca. 4.5 years. 12% of patients carried heterozygous germline pathogenic BRCA1/2 variants. Network analysis allowed for identification of 28 RNA and 15 miRNA WGCNA modules. Final prognostic model for OS was developed using Cox regression with elastic net regularization ($\alpha = 0.5$; $\lambda = 0.18$), and following variables were selected in the order of importance: M15 RNA module, M3 miRNA module, BRCA1/2 germline status, BMI, and two cell signatures. Co-expression and interactome data reveal that RNA module M15 is driven by RAD21, responsible for DNA repair and playing an oncogenic role, while miRNA module M3 is miR-4516 related - targeting genes involved in cell cycle regulation and p53 signalling pathway (FDR-adjusted p-value = 0.03). Patients stratified by the median model outcome differed significantly in their hazard ratios (HR = 9.1; p = 0.004; 95% CI = 2.0-40.9). Median survival time in the high-risk group was 33 mo. (95% CI = 18-40 mo.), whereas in the low-risk group median survival was not reached (NR; 95% CI = 66-NR mo.). Selected features were fuelled into logistic regression model for mortality prediction during post-surgery follow-up period, which was characterised by AUC = 0.74 (95% CI = 0.62-0.975).

Conclusion

Multiomic network-based approach allows for development of significantly prognostic models in oncology setting. Obtained results highlight the cell cycle-related pathways, whose expressional aberrations are associated with survival outcomes in HGSOC. In the next steps of model development we are planning to incorporate additional multiomic layers including different genome-wide DNA methylation features.

EACR25-2023

integrative Molecular Tumor Board (iMTB): A Decision-Support Tool for Precision Cancer Medicine in iCAN

R. Kumari¹, W. Wang¹, T. Luck¹, L. Gerber¹, S. Kuusela¹, C. Sarmento¹, E. Pitkänen^{1,2}, S. Nakken³, V. Pietiäinen¹

¹*University of Helsinki, Institute for Molecular Medicine Finland - FIMM, HiLIFE – Helsinki Institute of Life Science, iCAN Digital Precision Cancer Medicine Flagship, Helsinki, Finland*

²*University of Helsinki, Applied Tumor Genomics Research Program, Research Programs Unit, Helsinki, Finland*

³*Oslo University Hospital, Department of Tumor Biology, the Institute for Cancer Research, Oslo, Norway*

Introduction

As part of the Finnish digital cancer precision medicine flagship (iCAN) initiative, a substantial collection of molecular profiling and clinical data is being gathered from individual cancer patients (current participants: n = 3811). To identify clinically relevant and actionable results from molecular data of each patient and to present the findings in a concise and well-structured report, we have established a reporting platform, integrative Molecular Tumor Board (iMTB). This system consolidates clinically relevant molecular profiling findings and facilitates the integration of these findings to the Biobank and clinical workflows.

Material and method

The iMTB currently leverages the Personal Cancer Genome Reporter (PCGR) tool (Nakken et al., 2018) for exome sequencing data, analyzing somatic mutations, copy number alterations (amplifications and deletions), and germline variants. Additionally, new modules have been integrated for RNA-seq data and cancer fusion proteins. The iMTB operates in a pan-cancer framework within iCAN but is also adaptable for other translational studies. Within iCAN, iMTB reports have been implemented across various cancer types, including pediatric cancers, urological cancers, rare tumors, breast cancer, and ovarian cancer.

Result and discussion

This workflow is currently being piloted for pediatric solid tumors (n = 86) and rare cancers (n = 113) at the Helsinki University Hospital (HUS) through the iCAN Flagship initiative and associated studies. At the request of clinicians and with the patient's consent, the iMTB reports are delivered to clinics via the Helsinki Biobank (HBB). Our pilot study highlights the translational impact of molecular profiling, such as identifying pathogenic germline variants to be further validated in diagnostic laboratories. These findings demonstrate that iMTB addresses a critical gap, enhancing Helsinki Biobank's and the research community's ability to effectively translate research findings into clinical practice, ultimately benefiting the patients.

Conclusion

Looking ahead, we aim to further enhance the iMTB tool through open science collaborations and continuous development. This initiative will continue to support the visualization of complex omics data, streamline research efforts, and facilitate the translation of preclinical cancer research into clinically applicable tools, ultimately advancing precision medicine and improving patient outcomes.

⁵State University of Feira de Santana, Department of Technology, Feira de Santana, Brazil

Introduction

Oral squamous cell carcinoma (OSCC) is the most prevalent malignant neoplasm in the oral cavity, accounting for approximately 95% of cases. In Brazil, it poses a significant public health challenge due to its high incidence, morbidity, and mortality, particularly in advanced stages with metastasis. Effective therapeutic options remain limited, underscoring the need for novel molecular targets and drug repositioning strategies. This study aims to identify biomarkers and therapeutic targets associated with metastatic OSCC using bioinformatics approaches.

Material and method

Transcriptomic data from The Cancer Genome Atlas (TCGA) and Gene Expression Omnibus (GEO) were analyzed to distinguish tumor (OSCC) and non-tumor samples. We applied the Limma-Voom statistical method to identify differentially expressed genes between tumor and non-tumor samples. Subsequently, we performed gene co-expression network analysis to detect gene modules highly correlated with clinical relevance. Protein-protein interaction analysis was conducted with the modules of interest, followed by functional characterization of each module through gene ontology and signaling pathway analyses.

Result and discussion

Preliminary findings revealed distinct co-expression modules associated with tumor progression, invasion, and metastasis. Specific modules, particularly those enriched in migration-related genes, extracellular matrix remodeling, and epithelial-mesenchymal transition, were strongly correlated with OSCC aggressiveness. Overlap analysis with a curated metastasis-associated gene panel further confirmed the relevance of these findings.

Conclusion

Future steps include implementing machine learning models to predict drug-target interactions facilitating the identification of candidate drugs for therapeutic repositioning. Integrating bioinformatics and AI-driven approaches enhances precision oncology efforts, providing insights into OSCC molecular mechanisms and developing more effective treatment strategies.

EACR25-2052

Unveiling the spatial regulation of chemoresistance in ovarian cancer

S. Palomino Echeverria¹, T. Belova², I. Launonen¹, P. Hsieh², A. Vähärautio¹, M. Kuijjer², A. Färkkilä¹

¹University of Helsinki, Helsinki, Finland

²University of Oslo, Oslo, Norway

Introduction

High-grade serous ovarian cancer (HGSC) is the most aggressive subtype, causing over 150,000 deaths annually. Its genetic heterogeneity complicates classification and drives chemoresistance, worsening clinical outcomes (ref). Beyond genetics, the tumor microenvironment (TME) promotes chemoresistance through immune evasion, angiogenesis, and cell interactions. Transcriptional and post-transcriptional networks further shape tumor adaptation. A comprehensive understanding requires integrating multiple omics approaches. Traditional omics technologies, when analyzed independently, provide valuable but limited insights, capturing only individual layers of tumor biology, while spatial omics can add context by preserving molecular organization. However, multimodal data integration faces challenges like resolution differences, tissue misalignment, and spatial variability. Overcoming these barriers is key to deciphering HGSC progression and therapeutic resistance.

Material and method

We utilize a dataset from Launonen et al. comprising 22 HGSC tumor samples (treatment-naïve and chemotherapy-treated) from 16 patients, analyzed with t-CyCIF imaging, scRNA-seq, and bulk RNA-seq. To integrate multimodal data and identify biologically relevant patterns, we will employ CAVACHON from Hsieh et al., a probabilistic learning framework based on a generalized hierarchical variational autoencoder. This method integrates prior biological knowledge about the relationships between different data types and allows the extraction of variability specific to each modality while capturing their interdependencies. CAVACHON will be applied to integrate scRNA-seq and t-CyCIF data, enabling cell clustering, modality-specific differential expression analysis, and disentangling of shared and modality-specific molecular programs. As a final step, bulk RNA-seq will be used to validate the results.

Result and discussion

We analyzed 22 tumor samples from 16 patients, identifying 6,402,172 cells with t-CyCIF and annotating 68,019 single cells with scRNA-seq. Seven major cell types – B cells, CD4+ and CD8+ T cells, regulatory T cells, myeloid cells, stromal cells, and tumor cells – were consistently shared across both modalities. Applying CAVACHON, we aim to uncover non-canonical cell clusters with unique regulatory patterns, providing insights into tumor heterogeneity, chemoresistance, and immune evasion. Integrating spatial and molecular data will further elucidate spatially confined tumor cell states and microenvironmental influences on disease progression.

Conclusion

This study leverages spatial omics, multimodal integration, and network analysis to dissect aberrant tumor cell states and their TME interactions. By identifying chemoresistant subpopulations and characterizing spatially confined molecular programs, we aim to reveal therapeutic vulnerabilities, advancing precision oncology for HGSC.

EACR25-2056

Machine Learning-Driven Drug Repositioning for Oral Squamous Cell Carcinoma: A Predictive Approach Using Affinity2Vec

⁸*D'Or Institute for Research and Education (IDOR), Center for Biotechnology and Cell Therapy, Salvador, Brazil*

Introduction

Drug repositioning aims to identify new therapeutic applications for existing drugs, offering advantages such as reduced development time, cost savings, and lower risks, as these drugs have already undergone clinical trials. Artificial intelligence (AI) has advanced this field in recent years by processing large volumes of data and integrating scientific studies, medical records, and molecular information to uncover relevant patterns. In this study, we explore the application of machine learning to identify promising drug candidates for Oral Squamous Cell Carcinoma (OSCC). By leveraging state-of-the-art computational techniques, we aim to discover novel drug candidates through an in-depth analysis of drug-target interactions.

Material and method

We curated a comprehensive dataset using publicly available drug-target affinity data from ChEMBL to achieve this. This allowed us to explore a broad spectrum of drug classes and target families, potentially uncovering new repositioning opportunities. We applied stringent filtering criteria to refine the dataset and focus on molecular interactions relevant to our objectives. Specifically, we selected data points that met the following criteria: classified as binding assays, originating from *Homo sapiens*, involving single proteins as targets, and containing non-null pChEMBL values and maximum clinical trial phase information. We implemented Affinity2Vec, a model designed to predict

drug-target affinity scores using a regressor based on the Extreme Gradient Boosting (XGBoost) algorithm. This model takes as input an embedding representing a drug-target pair, which is generated by concatenating two distinct representations:

(i) the drug representation obtained via the Seq2Seq algorithm applied to the SMILES 2D structure of the drug and

(ii) the protein representation derived from the ProtVec algorithm applied to the FASTA sequence of the protein.

Result and discussion

The regressor was trained on 15,364 drug-target affinity scores from our dataset. Once trained, the model was used to predict the affinities between all 3,340 drugs and the 31 OSCC-related target proteins, resulting in a ranked list of 103,540 drug-protein pairs based on predicted affinity scores. The model achieved a mean squared error of 1.05 in the training set and a concordance index of 0.722. Finally, using the trained model, we generated a ranked list of predicted affinities for the 31 target proteins across the 3,340 drugs in our dataset.

Conclusion

In conclusion, in silico tools enabled the identification and ranking of promising drugs for repositioning in treating oral squamous cell carcinoma. Additionally, the database containing target-drug activities could be utilized to train future OSCC research models.

EACR25-2076

Gene expression profile in colon cancer therapeutic resistance and its relationship with the tumor microenvironment

P. Doria¹, G. Rocha^{2,1}, V. Bertoni¹, M. Araújo-Pereira¹, R. Guindalini², C. Gurgel^{2,1}

¹*Gonçalo Moniz Institute, Oswaldo Cruz Foundation (IGM-FIOCRUZ/BA, Brazil), Laboratory of Pathology and Molecular Biology, Salvador, Brazil*

²*D'OR Institute for Research and Education (IDOR), Salvador, Brazil, Center for Biotechnology and Cell Therapy, Salvador, Brazil*

Introduction

Colon cancer is a common disease, treated with few chemotherapeutic agents with similar treatment sequencing despite its heterogeneity. A significant proportion of patients are diagnosed with metastasis, and resistance to antineoplastic drugs is associated with disease progression and therapeutic failure. It is known that the tumor microenvironment plays an essential role in cancer progression, contributing to processes that may be associated with therapeutic resistance mechanisms in colon cancer. In this study, we aim to identify a gene expression signature and its relationship with immune cell infiltration in colon cancer, contributing to the identification of potential resistance biomarkers.

Material and method

An in silico study was conducted using RNA-seq data from The Cancer Genome Atlas Program (TCGA) samples, subdivided into two groups (treatment-resistant and non-resistant), taking into account the molecular subgroups (CMS1, CMS2, CMS3, and CMS4). The following algorithms were used:

i. Limma was applied to identify differentially expressed genes;

- ii. WGCNA was applied to construct co-expression networks;
- iii. CIBERSORT was applied to estimate the proportion of infiltrating immune cells; and iv. TIMER was applied to explore the relationship between core genes and immune cell content.

Result and discussion

Twenty differentially expressed genes (DEGs) were found, with 18 related to the group considered resistant to oncologic treatment and presenting poorer overall survival. T CD4 memory resting cells and M0 and M2 macrophages were found in more significant proportions in the analyzed samples and more infiltrated in the tumor microenvironment, the higher the expression of some of these resistance DEGs. Additionally, these genes correlate with biological aspects of neuronal differentiation, axogenesis, and synaptic transmission.

Conclusion

The gene expression signature suggests the presence of differentially expressed synaptic membrane genes, which may be involved in neuronal pathways that influence the tumor microenvironment, potentially serving as future biomarkers. Furthermore, the presence of M0 and M2 macrophages and T CD4 memory resting cells suggests a potential interaction that may play a role in therapeutic resistance.

Evaluating computational and enzymatic strategies for artifact removal in FFPE-derived NGS data

W. Plonka¹, D. Kostka¹, A. Lalik², M. Kimmel³, R. Jaksik¹

¹Silesian University of Technology, Department of Systems Biology and Engineering, Gliwice, Poland

²Silesian University of Technology, Biotechnology Centre, Gliwice, Poland

³Rice University, Poland

Introduction

Formalin-fixed, paraffin-embedded (FFPE) samples are invaluable in biomedical research and clinical diagnostics, particularly in genomic studies such as next-generation sequencing (NGS). However, the formaldehyde fixation process introduces DNA damages, primarily through deamination of cytosines to uracil, which by sequencing can be recognized as modifications of the C>T or G>A type that can confound mutation detection. To mitigate these effects, computational tools such as ideafix, microSEC, FFPolish, and SOBdetector have been developed to filter out sequencing artifacts.

Material and method

In this study, we evaluated the effectiveness of these tools across three datasets: (1) 36 matched WES FFPE and fresh-frozen samples from TCGA, (2) 21 matched WGS samples from CGCI, and (3) our custom WES dataset, including fresh-frozen samples, formalin-treated samples, both treated and untreated with the NEBNext® FFPE DNA Repair v2 Module. All samples were analyzed using the four computational tools, and filtered results were compared against fresh-frozen samples as the gold standard using som.py. We considered only variants with DP > 10 in our analysis.

Result and discussion

Our results indicate that SOBdetector achieved the highest sensitivity for somatic SNV detection, while FFPolish demonstrated the highest precision. However, the high precision of FFPolish came at the cost of an elevated false-positive rate in the artifact detection process. This effect was particularly pronounced in the classification of variants from fresh-frozen samples, where a significant proportion were identified as artifacts. Importantly, enzymatic repair using NEBNext outperformed all computational methods, demonstrating its effectiveness in mitigating fixation-induced damage. Additionally, our findings reveal that formalin fixation leads to an increase in C>A or C>T variants in WES data, with some specificity to cancer type, and that the unamplified WGS showed no clear variant preference.

Conclusion

Together, these results emphasize the necessity of both enzymatic and computational artifact removal strategies to improve the accuracy of FFPE-based genomic analyses, ultimately enhancing mutation detection in cancer genomics.

EACR25-2134

Spatially resolved OMICs defines specific immune-tumor niches in esophageal adenocarcinoma responders to neoadjuvant chemotherapy

⁷IRCCS San Raffaele Scientific Institute, Department of Gastrointestinal Surgery, Milan, Italy

Introduction

Esophageal adenocarcinoma (EAC) is a highly aggressive malignancy, with neoadjuvant chemotherapy (nCT) followed by surgery as the standard of care. However, fewer than 30% of patients achieve a pathological complete response (CR), which is strongly associated with improved survival. A deeper understanding of the tumor microenvironment (TME) in responders (CRs) and non-responders (NRs) is critical for patient stratification and therapeutic advancements.

Material and method

Building on our prior discovery that pre-existing immunity correlates with nCT response, we performed single-cell spatial transcriptomics (1000 x Spatial Molecular Imager-SMI) on treatment-naïve EACs ($n = 3$ CRs vs. $n = 3$ NRs) and profiled two independent EAC cohorts ($n = 75$) using multiplexed immunofluorescence (mIF), digital spatial transcriptomics (DSP), and bulk RNA sequencing (RNAseq).

Result and discussion

Our SMI analysis revealed distinct immune-tumoral niches exclusively enriched in CR tumors, characterized by dense clusters of dendritic cells (DCs), T and B cells, and granulocytes, supporting a robust pre-existing immune activation state. In contrast, NR tumors exhibited augmented M2-like macrophages, pro-tumoral cancer-associated fibroblasts, endothelial cells, and proangiogenic signatures, driven by distinct ligand-receptor interactions and spatial organization. These findings were further corroborated by DSP analysis of 20 EACs, which confirmed heightened neutrophil degranulation and DC activity in CRs, while NRs displayed dominant angiogenic and lipid metabolism signatures. Notably, immune cells in CRs showed upregulation of antigen presentation, immune activation, and M1-like differentiation pathways, whereas NRs were enriched for immunosuppressive pathways and M2-like macrophage signatures. Ongoing integration with mIF and bulk RNAseq (> 50 EACs) aims to further delineate these immune landscapes.

Conclusion

This study uncovers previously unrecognized features of the immune microenvironment in EAC responders, marked by clusters of antigen-presenting cells cross talking with adaptive (T and B cell) and innate (granulocyte) immune responses, in stark contrast to the immunosuppressive, pro-angiogenic, and lipid metabolism-driven TME in NRs.

⁷*Gazi University, Department of Medical Pathology, Faculty of Medicine, Ankara, Turkey*

Introduction

Fusion transcripts (FTs) are chimeric RNA molecules formed either through chromosomal rearrangements or as a result of transcriptional events. These transcripts have been increasingly recognized for their crucial role in

tumorigenesis. Hepatocellular carcinoma (HCC), a leading cause of cancer-related mortality, remains poorly understood in terms of its FT landscape. Therefore, this study aims to systematically identify and characterize tumor-specific FTs in HCC. By uncovering novel fusion events and assessing their impact on gene expression, we aim to establish a comprehensive framework for understanding their role in HCC progression.

Material and method

Eight independent datasets comprising 328 samples in our meta cohort were analyzed using STAR-Fusion, identifying tumor-specific FTs. Differential gene expression (DEG) analysis was conducted between HCC tumors and normal adjacent liver tissues (NAT) to identify key fusion partners in the meta cohort. Validation of key fusion partners was performed using an in silico cohort of 436 samples and two wet lab validation cohorts comprising 42 samples. The expression patterns of fusion partner genes were further examined both in silico and in vitro to determine their potential role in tumorigenesis.

Result and discussion

We detected 4268 FTs in HCC and 2762 FTs in paired NAT samples. Among these FTs that are expressed in either tumor or NAT tissues, 124 of them exist in at least five samples (recurrent FTs). Importantly, a total of 81 recurrent FTs were exclusively detected in tumor samples. Upon analyzing the FTs found at least five times in tumor samples but absent in paired NAT samples, we identified a total of 15 FTs; among the identified fusion partners, 72% were protein-coding genes, 17% were classified as noncoding RNAs, and 11% were pseudogenes. DEG analysis revealed that fusion partner genes, including liver-associated genes such as ALB, APOA2, IGF2, MT2A, SERPINA1 and H19, were frequently involved in fusion events and significantly downregulated in HCC tumors compared to NAT.

Detailed characterization of FTs shows that they have variants with distinct structural modifications that may impact their functional output, and some of them are significantly associated with more aggressive HCC phenotypes. These findings were confirmed with an in silico cohort. Wet lab validation experiments with patient samples verified reduced levels of fusion partners.

Conclusion

This study provides a comprehensive analysis of the FT landscape in HCC, identifying novel tumor-specific fusions and characterizing their expression patterns. The downregulation of key fusion partner genes in aggressive HCC suggests their relevance as potential biomarkers. These findings highlight FTs as promising diagnostic and prognostic biomarkers for HCC, which may ultimately contribute to improved patient management and therapeutic strategies.

This study is supported by the TUBITAK project, 120C216.

EACR25-2256

TNMv2: online tool to perform stage specific gene expression analysis

Á. Bartha¹, D. Müller¹, B. Győrffy¹

¹*Semmelweis University, Department of Bioinformatics, Budapest, Hungary*

Introduction

We present an updated version of TNMplot, a web-based platform integrating RNA-Seq and gene-chip data from 56,938 samples. TNMplot enables users to select a gene and tumor type for comprehensive gene expression analysis, supporting over 20 tumor types with publication-ready visualizations.

Material and method

RNA sequencing data were sourced from the Genomic Data Commons (GDC), including adult tumor samples from TCGA, pediatric samples from the TARGET project, and normal reference data from the GTEx portal. Gene chip-based data, comprising over 33,000 manually curated samples, were obtained from the NCBI GEO database. TNMplot facilitates differential expression analysis across normal, primary tumor, and metastatic tissues, supported by an expanded clinical dataset for stage-specific tumor analysis.

Result and discussion

The updated platform offers advanced tools, such as a pan-cancer dot matrix for simultaneous visualization of multiple tissue types and genes. It also includes correlation analysis between pairs of genes or multiple genes, along with correlation profile computation. The platform provides a unique feature for identifying progression-related genes through the recently added stage-based expression comparison. This analysis includes data from over 4,500 patient samples, encompassing breast ($n = 2,331$), colorectal ($n = 648$), skin ($n = 82$), prostate ($n = 61$), and lung ($n = 1,399$) cancer cases. The tool also has the ability to analyze gene expression using both RNA-seq and gene chip approaches, enabling internal validation across diverse patient populations. In addition to stage-specific expression estimation, this dual-platform capability is unique among comparable tools.

Conclusion

In conclusion, the updated TNMplot platform provides a comprehensive starting point for transcriptomic analysis for oncology-related basic, pharmacological, and translational research.

EACR25-2265

Unraveling Osteosarcoma Heterogeneity: molecular subtyping of early-stage osteosarcoma

L. Bojić¹, J. Pejić¹, M. Milivojević¹

¹*University of Belgrade, Institute of Molecular Genetics and Genetic Engineering, Belgrade, Belgrade, Serbia*

Introduction

Osteosarcoma (OS) represents a highly heterogeneous bone malignancy. Identifying molecular subtypes can improve the understanding of tumor biology and contribute to future targeted therapies.

Material and method

Non-negative matrix factorization (NMF) was used to classify 102 OS samples, derived from patients who did not have metastases and did not receive chemotherapy, into three subtypes (S1, S2, S3) based on gene expression profiles. Identification of key biological processes and hub genes associated with each subtype was done using functional enrichment analysis and weighted gene coexpression network analysis (WGCNA). Tumor micro-

environment (TME) analysis was conducted using ESTIMATE and CIBERSORT algorithms.

Result and discussion

S1 exhibited enrichment in cell cycle regulation and RNA metabolism processes, S2 in extracellular matrix organization and angiogenesis, and S3 in translation, ribosome biogenesis, and immune evasion. WGCNA identified subtype-specific gene modules. Processes enriched in the S1 group of OS are mostly connected to cellular transport, Golgi apparatus organelle functions, and cytokinesis, while the S2 correlated modules have shown enrichment mostly in extracellular matrix organization, adhesion, platelet-derived growth factor and integrin-mediated signaling. S3 subtype has shown considerable enrichment in Golgi apparatus processes, response to endoplasmic reticulum stress and bone forming processes such as ossification, bone development, etc. Analysis of the ESTIMATE score revealed differences between groups, with the lowest score exhibited by the S1 group, indicating poor prognosis for this subtype. CIBERSORT algorithm results showed different fractions of immune cells in each subtype, and correlation analyses highlighted distinct immune cell interactions in each subtype. S1 had more T follicular helper cells, eosinophils, and CD8 T cells, with the lowest M2 macrophage fraction. S2 had more resting mast cells, memory B cells, resting NK cells, and activated dendritic cells but fewer T gamma delta cells. Correlation analysis showed co-infiltration of naive T cells, T gamma delta cells, and resting dendritic cells in S1, while CD8 T cells correlated with neutrophils. In S2, activated NK and mast cells were linked, whereas S3 showed co-infiltration of M0 macrophages and naive CD4 T cells.

Conclusion

This study identifies three distinct OS subtypes with unique molecular signatures and immune profiles, providing potential biomarkers and therapeutic targets for personalized treatment strategies.

EACR25-2278

Assessing the maturation stages of PMN-MDSC to dissect the immunosuppressive mechanisms within TME

S. Forcelloni¹, M. Bilotta¹, P. Fiore¹, L. Moretta¹, P. Vacca¹, N. Tumino¹

¹*Bambino Gesù Children Hospital IRCCS, Innate Lymphoid Cells Unit, Roma, Italy*

Introduction

The tumor microenvironment (TME) presents significant obstacles to the success of cancer therapies, and understanding its complexities is crucial for developing more targeted therapies. One of the key immuno-suppressive cellular subsets in the TME consists of myeloid-derived suppressor cells (MDSCs), especially the polymorpho-nuclear (PMN) type. PMN-MDSCs are immature neutrophils that primarily reside in the bone marrow (BM). In pathological conditions like cancer, infection, or

inflammation, these cells migrate to the peripheral blood (PB) and inflamed tissues. PMN-MDSCs suppress the immune system by blocking the activity of important immune cells, like T cells and NK cells, thereby promoting tumor growth and enabling immune evasion. High levels of MDSCs in tumors are associated with worse prognosis and resistance to cancer immunotherapy.

Material and method

PMN-MDSCs were isolated from peripheral blood and bone marrow of healthy donors mobilized with the stimulating factor G-CSF, as well as from peripheral blood of lung tumor patients. After isolating peripheral blood mononuclear cells, PMN-MDSCs were separated using immunomagnetic beads and prepared for single-cell RNA sequencing (scRNA-seq). Data analysis was performed using custom scripts based on Scanpy and Seurat tools.

Result and discussion

This study aims to understand the differentiation and immunosuppressive function of PMN-MDSCs. Based on their origin (i.e., healthy donor bone marrow, healthy donor peripheral blood, or peripheral blood from tumor patients), we identified different subpopulations of MDSCs, each with distinct gene expression patterns and immunosuppressive characteristics. By combining RNA-velocity and pseudotime analyses on integrated scRNA-seq data, we observed that PMN-MDSCs in the bone marrow show the highest level of cellular plasticity, proliferation, and stemness-related properties. In contrast, PMN-MDSCs from the peripheral blood of lung cancer patients appear to be more differentiated and acquire more mature immunosuppressive traits.

Conclusion

In this study, we identified distinct subsets of PMN-MDSCs that express specific genes related to immunosuppression. By comparing PMN-MDSCs from healthy donor bone marrow, healthy donor peripheral blood, and peripheral blood from lung tumor patients, we were able to reconstruct the differentiation trajectory of these cells in relation to their immunosuppressive functions.

EACR25-2312 Modelling Somatic Alterations with Protein Language Models

²*Conway Institute, University College Dublin, Dublin, Ireland*

Introduction

Cancer is a genetic disease where somatic alterations accumulate in a cell and result in uncontrolled proliferation and invasiveness. Some genes are much more likely to be altered and are used in the clinic to guide prognosis and treatment. Yet, there is a large variability in the way in which patients respond to treatment even when carrying alterations in well-known genes. The cause of this variability is unknown, part of it comes from the complexity that arises in somatic alterations. Some genes like KRAS are mutated in several cancers, yet some prognostic differences have been reported depending on the protein position and the substitution amino acid. Furthermore, sometimes the

mutant gene is also amplified, making it hard for mathematical models to capture these intricacies. Some artificial intelligence models known as protein language models have been proposed to model germline alterations. By training on millions of protein sequences, they are able to determine accurately if a variant is likely to be pathogenic. Here, we propose using pre-trained protein language models to generate embeddings for somatic alterations that can be used to build machine learning models for cancer.

Material and method

In order to repurpose protein language models, we built a custom somatic embedding layer that combines fusions, mutations and copy number alterations to combine somatic alterations. We applied our somatic embedding layer in a transformer architecture and fine-tuned the embeddings of the protein language models using publicly available datasets of drug response in cell-lines and progression free survival in pancreatic, colon and breast cancer.

Result and discussion

We show that our architecture can be used to predict drug response and survival in publicly available datasets more accurately than other models. Our architecture is able to not only capture subtle differences between similar substitutions, like in the case of KRAS mutants, but also to combine the effect of multiple alterations on the same cell or patient. Furthermore, using explainable AI techniques, we were able to dissect why our model's predictions.

Conclusion

Our results show the potential applications of artificial intelligence to model somatic alterations in cancer. While in this work we focus on two problems, drug response in cell-lines and progression free survival, our architecture has the potential to be applied to other settings, including patient stratification and optimal treatment prediction.

EACR25-2347

Leveraging SHAP Values from Machine Learning and Mutational Signatures in Supervised Clustering to Enhance Disease-Specific Survival Prognosis in Endometrial Carcinoma

I. Salido-Guadarrama¹, S. Romero-Cordoba²

¹*Instituto Nacional de Perinatología, Bioinformatics and Statistical Analysis, Mexico City, Mexico*

²*Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, Departamento de Medicina Genómica y Toxicología Ambiental, Mexico City, Mexico*

Introduction

Endometrial carcinoma is a leading cause of gynecologic cancer deaths, with prognosis varying significantly. Current risk stratification tools are limited, prompting the need for more precise methods. This project applies machine learning and SHAP values to improve the interpretability of mutational signatures, identifying clinically relevant subgroups. By integrating biological insights with machine learning, it aims to enhance patient stratification and guide personalized therapeutic strategies, improving survival outcomes.

Material and method

Somatic mutation data from 448 endometrial carcinoma (UCEC) samples in TCGA were analyzed using the COSMIC mutational signature framework via the SigProfilerAssignmentR package. Four machine learning models – Random Forest, Support Vector Machines, Logistic Regression, and LightGBM – were trained on clinical variables and mutational signature exposures. LightGBM achieved the best performance based on accuracy and AUC metrics. SHAP values quantified each mutational signature's contribution to survival predictions, offering interpretability. These values were clustered using DBSCAN, with parameters optimized for clinical and biological relevance. Stability analysis identified robust cluster configurations. Clinical and demographic characteristics of clusters were compared using ANOVA or chi-square tests, while survival differences were assessed via Kaplan-Meier analysis and log-rank tests.

Result and discussion

DBSCAN clustering of SHAP values identified four distinct groups (C1–C4). Cluster C1 exhibited enrichment in Signature SBS6, associated with mismatch repair deficiency. Clinically, C1 demonstrated better DSS outcomes compared to other clusters (log-rank $p < 0.01$). Additionally, patients in C1 were characterized by lower age at diagnosis but higher BMI, suggesting unique biological pathways influencing prognosis. Clustering based on SHAP values demonstrated enhanced resolution and interpretability compared to clustering performed directly on original mutational signature exposures. SHAP-based clustering captured clinically meaningful subgroups that aligned with known biological mechanisms, such as the prognostic impact of SBS6 enrichment. The integration of SHAP values into clustering workflows provides a novel approach to stratify endometrial carcinoma patients by leveraging both machine learning interpretability and biological relevance.

Conclusion

This study underscores the utility of explainable machine learning techniques in oncology research. By combining mutational signature analysis with SHAP-based clustering, we identified biologically and clinically relevant subgroups that improve survival prognosis in endometrial carcinoma. Future work should explore integrating additional omics data to further enhance predictive accuracy and clinical applicability.

EACR25-2357

Tumor Growth Dynamics and Telomere Maintenance in Sarcoma: Insights from 3D Spheroid Models

K. Ostojic¹, V. Žnidar², D. Lozina¹, I. Urlić¹, I. Rubelj³, M. Huzak²

¹*Faculty of Science, Department of Biology, Zagreb, Croatia*

²*Faculty of Science, Department of Mathematics, Zagreb, Croatia*

³*Ruder Bošković Institute, Department of Molecular Biology, Zagreb, Croatia*

Introduction

Sarcomas are a diverse group of malignant tumors originating from mesenchymal tissues, characterized by rapid growth, metastatic potential, and significant heterogeneity in clinical behavior and molecular profiles. Despite advancements in treatment, mortality remains high, particularly in metastatic cases, underscoring the importance of early detection. To understand tumor progression, we focused on the avascular phase, where limited nutrient diffusion leads to gradients, hypoxia, and necrosis—better replicated by 3D spheroid models than traditional 2D cultures, enabling detailed cancer stem cell (CSC) study. CSCs play a key role in tumor initiation, maintenance, and recurrence, sustaining immortality through telomere maintenance mechanisms, including telomerase-dependent mechanisms or alternative lengthening of telomeres (ALT). This study aims to deepen understanding of tumor biology and CSCs, with potential applications in developing more precise therapies.

Material and method

This study utilized patient-derived sarcoma spheroids to examine tumor growth dynamics, telomere maintenance, and length. The cells were cultured under restrictive conditions, with growth monitored over time using confocal microscopy to obtain high-resolution Z-sections. The resulting images were processed in ImageJ, binarized, and 3D volume reconstruction was performed using ReViMS software. Relative telomere length was assessed through qPCR by comparing amplified telomeric sequences to a reference single-copy gene. Telomerase presence was evaluated using the qRT-PCR method.

Result and discussion

This study employed a method utilizing precise 3D reconstruction to enhance volumetric assessments by accurately capturing the irregular morphology of spheroids, accounting for subtle shape variations caused by uneven proliferation, cell death, and mechanical constraints. Unlike previous studies that relied on diameter-based approximations assuming a spherical shape, this method offers a more accurate representation of spheroid volume. The spheroids varied in size from tens to hundreds of μm , displaying characteristic irregular shapes. The inflection point in spheroid growth was successfully identified, with growth subsequently following a sigmoidal (S-shaped) curve, consistent with patterns observed in existing literature. Additionally, telomere length and telomerase activity were assessed.

Conclusion

We reconstructed spheroid volumes from 2D Z-slice images, providing key data on tumor growth and aggressiveness. Integrating these volume measurements into predictive models could offer insights into therapy resistance and tumor progression, particularly concerning CSCs. Monitoring telomere dynamics and immortality mechanisms enhances our understanding of cancer biology, highlighting the importance of 3D spheroids in developing personalized therapeutic strategies to improve patient outcomes.

EACR25-2412

YOLO-based approach for breast cancer tumour detection and segmentation in MRI scans

A. Staścak¹, M. Bambyněk¹, M. Kaszuba², S. Student³, M. Jarząb⁴, D. Borys¹

¹Department of Systems Biology and Engineering, Faculty of Automatic Control, Electronics and Computer Science, Silesian University of Technology, Gliwice, Poland

²Radiology and Diagnostic Imaging Department, Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice, Poland

³Biotechnology Centre, Silesian University of Technology, Gliwice, Poland

⁴Breast Cancer Center, Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice, Poland

Introduction

YOLOv11 is one of the latest versions in the YOLO (You Only Look Once) model series, designed for fast and accurate real-time object detection. It introduces architectural improvements, such as advanced feature extraction and optimised training processes, resulting in higher precision with fewer parameters. YOLOv11 is particularly useful in medical image analysis, supporting tasks like instance image classification. The application of this model for automatic detection and subsequent segmentation of breast cancer tumours in MRI scans has the potential to support early diagnosis and enhance treatment effectiveness.

Material and method

For training, validation, and testing, 75 MRI images from patients with diagnosed breast cancer from the National Oncology Institute of Maria Skłodowska-Curie (Gliwice branch) were used. Tumour regions in the scans were annotated and verified by two specialists from oncology and breast radiology. The images were converted from the DICOM format to PNG for network training. The regions of interest were labelled using the LabelImg tool. Data augmentation techniques, such as image rotation, were applied while simultaneously recalculating the coordinates in the annotation files. The dataset was then divided using a stratified split with a 70/15/15 ratio for training, validation, and testing, ensuring better model generalisation. Object detection model performance was evaluated using the F1 curve, precision-recall metrics, and accuracy. After detection, segmentation was conducted using the Fuzzy C-Means Clustering method on the tumour regions identified by the network. Additionally, a DICOM RTSTRUCT file was generated, containing the segmented region of interest with the FCM mask applied, enabling direct visualization of the detected area within the original examination.

Result and discussion

The results confirmed the effectiveness of YOLOv11 in identifying tumour regions in breast MRI scans, achieving high detection precision. Moreover, applying FCM-based segmentation to the detected areas allowed for precise tumour region delineation, detailed analysis of tumour structure and determination of subtypes. Generating DICOM RTSTRUCT files facilitated seamless integration with medical systems, enhancing clinical usability.

Conclusion

In conclusion, combining YOLOv11 with segmentation techniques and appropriate data processing represents a valuable step toward supporting breast cancer diagnosis based on MRI scans, enabling precise tumour detection and analysis.

Funding: Excellence Initiative – Research University Program, project number: 32/014/SDU/10-22-71(AS).

EACR25-2422

Characterizing Aggressiveness of Prostate Cancer with Large-scale DNA Organization Image Analysis

F. Inaba¹, M. Keyes², M. Guillaud¹, C. MacAulay¹

¹BC Cancer Research Centre, Integrative Oncology, Vancouver, Canada

²BC Cancer Agency, Radiation Oncology, Vancouver, Canada

Introduction

Prostate cancer is a pathologically heterogeneous disease, in that patients may present with cancers that require timely treatment or may have indolent disease. In the absence of a reliable prediction method, risk assessment for disease progression and metastasis has been challenging. Typically, all grading and risk assessment is based on pathologist observation of prostate tissue architecture, PSA, and tumor stage; less emphasis has been placed on individual cell morphological characteristics. Here, we demonstrate that large-scale DNA/chromatin organization (LDO) in prostate cancer cells of patients with more advanced cancers is altered and can be used to identify patients of Gleason scores (GS) of 6 and 9, independent of other clinical variables.

Material and method

Using a multiple instance learning approach, binary labels were assigned to each nucleus in a patient core needle biopsy by a random forest classifier, and the proportion of nuclei predicted to be associated with advanced prostate cancer was used to determine each patient's GS (GS 6 or GS 9). Our patient cohort consists of 60 patients, (38 with GS6, 22 with GS9) of which 25% of patients were assigned to the holdout set. The performance of the training patient classification was computed using a 5-fold cross validation. For each train/test split in the cross-validation, the classifier was trained on the training set and then used to generate scores for the patients in the test fold.

Result and discussion

Patients in the training set were classified with a balanced accuracy of 0.851, and an F1-score of 0.815. This performance also translated to the patients in the holdout set, where the balanced accuracy and F1-scores of patient classification was 0.857 and 0.833 respectively. In multiple instance approaches where labels are assigned to each instance, there exists the risk of not being able to learn meaningful discriminations, especially if the number of nuclei critical in the patient classification is scarce. However, the consistently high balanced accuracy and F1-scores in the training patients and holdout set suggest that the classifier was able to capture the patterns of LDO necessary for patient classification.

Conclusion

We demonstrate that leveraging large-scale DNA/chromatin organization (LDO) provides a robust method for discriminating GS6 and GS9 patients independent of other clinical variables. The high balanced accuracy and F1-scores across both the training and holdout sets suggest that the critical patterns in LDO are effectively captured by the nuclear classifiers. Future studies will apply the trained classifiers to patients with GS7 and GS8 to visualize how nuclear chromatin organization may change over the course of disease progression.

EACR25-2465

The effect of common germline variants on tumor mutation burden and mutational signatures activity

A. Ravid¹, H. Ladany¹, Y. Maruvka¹, A. Gusev²

¹*Technion, Haifa, Israel*

²*Dana Farber Cancer Institute, Boston, United States*

Introduction

A major component in tumorigenesis is the accumulation of somatic mutations, driven by both stochastic and systematic mutational processes, which leave distinct mutational signatures in the genome. While external and random factors contribute to these processes, inherited germline variants may also modulate their activity. However, the extent to which common germline single nucleotide polymorphisms (SNPs) influence tumor mutational burden (TMB) and mutational signatures remains largely unexplored, mainly due to the lack of a large enough dataset sufficient to detect such a weak association. Here we suggest a novel method we call GroupSig that can aggregate panel sequencing data and overcome the small amount of mutations observed in each single sample. We used that to investigate the association between genotypes in common germline variants and TMB and mutational signature activity across multiple cancer types using large-scale genomic datasets.

Material and method

We analyzed data from two cohorts: a dataset of 35,000 tumor samples from the Dana-Farber Cancer Institute (DFCI) panel sequencing cohort and a dataset of 10,000 tumor samples from The Cancer Genome Atlas (TCGA) whole-exome sequencing (WES) cohort. To address the challenge of low somatic mutation counts in panel sequencing, we developed GroupSig, a novel approach that aggregates mutations across patient groups stratified by SNP genotype, creating "super patients" to enable the use of mutational signature fitting tools. We first conducted a genome-wide association study (GWAS) in the DFCI dataset, analyzing the effect of genotype on TMB, while accounting for group sizes. We filtered SNPs based on a genome-wide significance threshold ($p < 5 \times 10^{-8}$). We then tested if the significant SNPs were correlated with the activity of specific signatures. We then repeated the analysis on the smaller TCGA dataset (~10,000) as a validation set without GroupSig, as there is a sufficient number of mutations per sample.

Result and discussion

Application of GroupSig to the DFCI cohort enabled the fitting of grouped somatic mutations data to the profiles of known single substitution signatures. We found 79

genomic loci that correlated with high TMB in the DFCI dataset and that were validated also in the TCGA dataset. Of those, 3 loci were correlated with the activity of specific signatures.

Conclusion

This study provides evidence that common germline SNPs influence mutational processes in cancer, advancing the research on hereditary cancer risk. The GroupSig approach enables large-scale assessment of these associations, even in panel sequencing datasets with low mutation counts per sample. Our findings enhance the understanding of genetic contributions to tumorigenesis and may inform cancer risk assessment and personalized therapeutic strategies.

EACR25-2486

RabAnalyser: a computational framework to measure the cell-to-cell variability of Rab GTPases organization

S. Tealdil¹, C. Campa²

¹*Polytechnic of Turin, DIMEAS, Torino, Italy*

²*Italian Institute for Genomic Medicine, Candiolo, Italy*

Introduction

Cancer cell evolution depends on cell-to-cell heterogeneity arising from genetic and non-genetic variations, which facilitate adaptation to dynamic environments. While genomic alterations contribute to this variability, additional factors such as spatial architecture and metabolic diversity further shape cellular behaviour. Rab proteins, the largest subfamily of small GTPases, orchestrate intracellular trafficking by localizing to membrane-bound organelles and cycling between active and inactive states. In their active form, Rab proteins cluster on membranes, regulating organelle positioning, tethering, and fusion. The continuous remodelling of these organelles during cellular processes generates variability in their spatial organization, reflecting heterogeneity in Rab cluster patterns among cells. However, computational strategies to measure the heterogeneity of Rab cluster patterns are lacking.

Material and method

Here, we developed RabAnalyser, an image-based computational framework designed to investigate heterogeneity of Rab cluster patterns at the single-cell level. It extracts quantitative features from fluorescence microscopy images, capturing key attributes of Rab cluster organization. A minimal yet robust set of 11 features was identified, integrating conventional intensity and size assessments with novel geometric and spatial positioning metrics. By employing the Kolmogorov-Smirnov statistic, RabAnalyser detects distinct cell subpopulations based on Rab cluster patterns and generates as outputs: UMAP-based clustering, statistical analysis, and machine learning-based classification.

Result and discussion

We applied RabAnalyser to analyse glioblastoma cells treated with an anti-mitotic agent known to alter Rab11 distribution. Imaging of 1000 cells revealed two primary subpopulations distinguished by the elongation of Rab11 clusters, with nearly equal cells. Upon treatment, an additional subpopulation emerged, increasing overall heterogeneity and redistributing cells into three groups

characterized by differences in Rab11 cluster elongation and spatial density. These findings indicate that antimitotic treatment induces heterogeneity within isogenic cells, underscoring the role of Rab cluster organization in cellular response to perturbation.

Conclusion

This study demonstrates that RabAnalyser provides a robust methodology for quantifying cell-to-cell heterogeneity in fluorescence microscopy images with spotty signals. Moreover, the emergence of distinct subpopulations in response to treatment suggests that analysing Rab cluster organization offer insights into organelle arrangement and their implications in cancer. The elongation of Rab11 clusters may reflect underlying tubulation processes, highlighting a potential link between organelle architecture and cancer progression.

EACR25-2501

Site-specific validation of the GRANT model for renal cell carcinoma (RCC) cancer-specific survival (CSS) after surgery

P. Scuri¹, A. Larcher², A. Traverso¹, G. Musso², U. Capitanio², F. Montorsi², A. Esposito¹, C. Tacchetti¹, A. Salonia¹

¹University Vita-Salute San Raffaele, Milano, Italy

²IRCCS San Raffaele Hospital, Milano, Italy

Introduction

This study evaluates the GRANTs model's performance, a prognostic score for RCC from 2017, using three implementations on two different cohorts: a rule-based approach as in the original paper and two Cox Proportional Hazards (PH) models. The assessment covers two patient cohorts

Material and method

Inclusion: RCC patients post-partial or radical nephrectomy. Exclusion: metastasis at diagnosis, metachronous cancer, Von Hippel–Lindau disease, bilateral synchronous carcinoma, neoadjuvant therapy, total cold ischemia. Follow-up data were censored at five years; patients lacking cause of death information or dying from non-kidney cancer causes were excluded. These criteria were applied to HSR (IRCCS Ospedale San Raffaele) (2536 patients) and Firenze (Azienda Ospedaliero-Universitaria Careggi) (670 patients) datasets. The rule-based GRANT model was used to determine risk groups and it was externally validated using Kaplan–Meier survival curves and log-rank tests on both cohorts. Two Cox PH models using GRANT variables underwent 100 Monte Carlo Cross Validation (MCCV) simulations for site-specific validation. These models differed by GRANT variables being binarized or continuous (e.g., age > 60 vs. continuous). We compared them using survival metrics (e.g., C-index) across cohorts. Risk stratification enabled comparison with the rule-based GRANT on the Firenze dataset.

Result and discussion

The rule-based GRANT model provided statistically significant stratification in both datasets. The Cox PH model with continuous variables showed higher C-index values than the binarized variant in both internal (HSR) and external (Firenze) validations. Among the three

models post-stratification on the Firenze dataset, the Cox PH model with continuous variables exhibited superior performance.

Conclusion

Comparison of GRANT model versions demonstrates the effectiveness of site-specific validation, with site-specific Cox PH models outperforming the rule-based version, particularly when validated on a similar demographic. The use of continuous over binarized variables enhanced prediction accuracy. While the rule-based model historically allows ready application, modern web applications enable rapid deployment of machine learning models in real-world settings

EACR25-2527

Radiomics-based classification of tumour subtypes in breast cancer using MRI imaging

D. Borys¹, A. Staśczak¹, M. Bambynek¹, M. Kaszuba², S. Student¹, M. Jarząb²

¹Silesian University of Technology, Gliwice, Poland

²Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice, Poland

Introduction

MRI and mammography are the primary imaging examinations for the diagnostic detection of breast cancer. Those modalities also can be used not only by specialists but also by computer-aided systems that allow analysis to be carried out automatically, quickly and objectively and, above all, reproducibly and accurately. Radiomics features, that are calculated based on diagnostic images, can provide additional information that is not visible even to experienced specialists. They can also form the foundation for building diagnostic support systems based on classifiers.

Material and method

For training, validation, and testing, 75 MRI images from patients with diagnosed breast cancer from the National Oncology Institute of Maria Skłodowska-Curie (Gliwice branch) were used, who were scanned using a standard contrast agent. Tumour delineation, defining region of interest for the subsequent analysis, was performed using two step approach with detection phase based on deep learning YOLO (v11) network and final detailed segmentation in the detected area by local classification algorithm based on fuzzy c-means algorithm. Tumour regions in the scans in the training and validation of YOLO network step were annotated and verified by two specialists from oncology and breast radiology. T1-related subtractive MRI images were used to determine the ROI. T1 and T2 images were used furthermore, together with ROI definition interpolated to the corresponding space as an input to pyRadiomics (v3.1.0) Python module to compute a set of 100 radiomics features for each image set.

Result and discussion

The dataset was then divided using a stratified split with a 70/15/15 ratio for training, validation, and testing for the classification of two classes that relate to two breast cancer subtypes: Class first was subtype 1, which corresponds to the solitary tumour, and class 2 corresponds to subtypes 2, 3 and 4 (grouped, separated and replaced tumours). Other subtypes were discarded

from the analysis. Classical algorithms for classification were tested, including logistic regression, support vector machines, and random forests. Results of the model comparison are presented by the model's accuracy, precision, sensitivity and specificity.

Conclusion

In conclusion, combining YOLOv11 with segmentation techniques and appropriate data processing allowed us to calculate radiomics features and build and train classification models to stratify different cancer subtypes in breast cancer using MRI T1, T2 and subtraction images.

EACR25-2597

POSTER IN THE SPOTLIGHT

IRE1 signaling in Triple Negative Breast Cancer

B. Pasat¹, A. Samali¹, A. Chatzioannou², A. Gorman¹

¹*University of Galway, Galway, Ireland*

²*Biomedical Research Foundation of Academy of Athens, Athens, Greece*

Introduction

IRE1 is a protein that senses the presence of endoplasmic reticulum stress. It is constitutively active in several cancers, including triple-negative breast cancer (TNBC). Its RNase activity allows it to cleave CUGCAG sequences found inside stem loops. Among its well-known targets is XBP1 mRNA, which has two such sequences and whose cleavage leads to the formation of an active transcription factor called XBP1s. As XBP1s has the ability to facilitate the progression of TNBC, IRE1 presents itself and its downstream targets as promising candidates for therapeutic interventions. Additionally, IRE1 can cause the degradation of other RNA molecules (including mRNAs, miRNAs, lncRNAs) in a process known as Regulated IRE1-dependent decay (RIDD).

Material and method

Omics datasets encompassing mRNA, miRNA, proteins, and metabolic products were generated from the TNBC cell line MDA-MB-231 following treatment with MKC866, an IRE1 inhibitor, at multiple time points. These datasets were analyzed using MultiOmics-Integrator, a Nextflow pipeline previously developed and published by the authors of this abstract [1]. The analysis included detailed isoform switching, RNA-seq, proteomics, and lipidomics investigations. Additionally, to further focus on IRE1 signaling, we predicted novel XBP1 and RIDD candidates, incorporating recent advancements in the field.

Result and discussion

The results provide valuable insights into IRE1 signaling in the context of TNBC pathology. By integrating data across multiple omics layers, several novel candidates downstream of the XBP1 and RIDD axis were identified. These candidates play key roles in metabolism, migration, and survival of TNBC cells. Additionally, we examined their behavior in single-cell datasets to better understand their impact on tumor microenvironment formation. Experimental validation of these candidates is currently underway. The robustness of the signature was evaluated using BRCA cell lines, and its prognostic

potential was assessed through survival analysis with TCGA samples.

Conclusion

We focused on identifying novel downstream targets of IRE1/XBP1 and IRE1/RIDD signaling pathways. We believe that our work will aid in deciphering the role of IRE1 in TNBC progression and characterization.

Detection of Circulating Tumour DNA (ctDNA) with ddPCR and NGS in Liposarcoma

M. Wong¹, M. Openshaw¹, M. Tarabichi², U. GK³, A. Desai⁴, A. Beggs¹

¹*University of Birmingham, Institute of Cancer and Genomic Science, Birmingham, United Kingdom*

²*Université libre de Bruxelles, IRIBHM, Brussel, Belgium*

³*University of Leeds, Bioinformatics, Leeds, United Kingdom*

⁴*Queen Elizabeth University Hospital, Midlands Abdominal Retroperitoneal Sarcoma Unit, Birmingham, United Kingdom*

Introduction

Cell-free DNA (cfDNA) is naturally released during cell death processes like apoptosis or necrosis. In the tumour context, it is known as circulating tumour DNA (ctDNA). We harness the power of ddPCR to determine the copy number variation (CNV) of mouse double minute 2 (MDM2) and cyclin-dependent kinase 4 (CDK4) gene amplifications, which is one of the molecular characteristics of both well-differentiated liposarcomas (WDLPS) and dedifferentiated liposarcomas (DDLPS).

Material and method

Demographic data for all included patients were included in a prospective cross-sectional analysis. A total of 32 adult patients with primary and recurrent retroperitoneal sarcomas were assessed. Blood samples were collected prospectively during treatment. cfDNA was isolated from plasma and quantified. All patients who had tumour in situ during blood sampling and were histologically positive for MDM2 amplification via immunohistochemistry (IHC) were selected for inclusion in this study. A total of 15 plasma-derived DNA samples (Eleven non-paired samples plus four paired samples – pre- and post-surgery) were included between June 2023 - June 2024. ctDNA detection and copy number determination were performed using Bio-Rad QX200 Droplet Digital PCR (ddPCR) (Bio-Rad Laboratories) and Oxford Nanopore Technologies (ONT).

Result and discussion

MDM2 was detectable in both tissue tumour samples and plasma-derived samples (ctDNA). The average concentration was 2.5 ng/μl and 5 ng/μl, respectively. A duplex MDM2:RPP30 ddPCR assay revealed one sample had an amplified copy number of 18.9, which was confirmed by ONT. This positive sample occurred in a

patient who had unresectable disease, therefore, open and close laparotomy (stage AJCC IIIB). The remainder negative copy number samples were staged AJCC IB. For the longitudinal paired samples, there was no difference in CNV, however the median follow-up was only 40-month. On the other hand, a repeated experiment with duplex CDK4:RPP30 assay yields a lower amplified copy number of 9.87 for the same sample (E01), but overall consistent findings compared to MDM2 assay.

Conclusion

Analysis of ctDNA is a novel approach for cancer screening, diagnosis, monitoring treatment response, and identifying mutations. Our analysis shows that ctDNA detection is possible in patients with both retroperitoneal WDLPS and DDLPS using liquid biopsy ddPCR and NGS approaches, however this appears to be restricted to patients with locally advanced disease. A larger sample size to improve sensitivity in ctDNA MDM2 and CDK4 detection is required for clinical utility.

EACR25-0110

The systemic inflammation response index (SIRI) may identify less toxic treatments for specific advanced pancreatic adenocarcinoma patients

R. del Campo-Pedrosa¹, A. Martín-Carnicero², A. González-Marcos³, A. Martínez⁴

¹Encore Lab SL, Data Department, Logroño, Spain

²Hospital San Pedro, Medical Oncology Department, Logroño, Spain

³Universidad de La Rioja, Department of Mechanical Engineering, Logroño, Spain

⁴Center for Biomedical Research of La Rioja (CIBIR), Angiogenesis Group, Logroño, Spain

Introduction

The systemic inflammation response index (SIRI) has been recently proposed as a prognosis biomarker which could predict oncological outcome for advanced pancreatic ductal adenocarcinoma (PDAC). The aim of this study was to try to validate SIRI in an independent cohort through univariate and multivariate analysis considering confounding factors.

Material and method

A retrospective cohort of 132 advanced and metastatic PDAC patients was collected between 2010 and 2021. Kaplan-Meier, along with univariate and multivariate Cox regression, was used to test association between overall survival (OS) and SIRI values at diagnosis, as well as to assess chemotherapy (FOLFIRINOX, Gemcitabine plus Nab-paclitaxel and Gemcitabine alone) outcomes by SIRI levels (defined as neutrophil x monocyte/lymphocyte, with a threshold of $10^9/L$).

Result and discussion

Baseline SIRI presented a non-statistically significant tendency ($p = 0.066$) of prognostic OS value on univariate analysis, which did not prevail (HR (95% CI): 1.227 (0.851-1.769), $p = 0.273$) in the presence of risk factors such as ECOG2 (HR (95% CI): 2.632 (1.501-4.615), $p = 0.001$) and liver metastases (HR (95% CI): 1.451 (1.011-2.083), $p = 0.043$). According to individualized treatments, patients with low SIRI levels had similar outcomes when comparing chemotherapy

regimens whereas patients with high SIRI levels presented a non-statistically significant tendency ($p = 0.065$) of performance similar to the general population, where FOLFIRINOX and Gemcitabine plus Nab-paclitaxel had similar outcomes and both were better than Gemcitabine alone. Our findings indicate that SIRI lacks statistically significant prognostic value in PDAC. Nevertheless, consistent with the original report, we found that patients with low SIRI levels showed no significant differences in survival related to treatment regimens, suggesting that the Gemcitabine treatment, which is less toxic, could be preferred for this group. However, for high SIRI levels, contrary to prior research claiming FOLFIRINOX superiority, no statistically significant differences were found.

Conclusion

We were not able to confirm the prognostic value of SIRI in either the univariate or the multivariate analyses. Nevertheless, we believe that further studies could help confirm its role in guiding treatment, especially in identifying less toxic regimens for patients with low SIRI levels.

EACR25-0111

The Monocyte/Hemoglobin Ratio as a New Prognostic Biomarker in Patients with Advanced Pancreatic Adenocarcinoma

R. del Campo-Pedrosa¹, A. Martín-Carnicero², A. González-Marcos³, A. Martínez⁴

¹Encore Lab SL, Data Department, Logroño, Spain

²Hospital San Pedro, Medical Oncology Department, Logroño, Spain

³Universidad de La Rioja, Department of Mechanical Engineering, Logroño, Spain

⁴Center for Biomedical Research of La Rioja (CIBIR), Angiogenesis Group, Logroño, Spain

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is currently one of the deadliest cancers. It is generally diagnosed at very advanced stages, resulting in a low survival rate for patients. In this context, it is crucial to find new tools that can predict the survival of patients with advanced PDAC in the presence of known risk factors, such as diabetes and liver metastases.

Material and method

Retrospective information was collected from 126 patients diagnosed with advanced and metastatic PDAC who were treated with chemotherapy at University Hospital San Pedro (Spain). Optimal cut-off points were calculated for several macrophage-based ratios: neutrophil-lymphocyte ratio (NLR), lymphocyte-monocyte ratio (LMR), platelet-lymphocyte ratio (PLR), neutrophil-hemoglobin ratio (NHR), lymphocyte-hemoglobin ratio (LHR), monocyte-hemoglobin ratio (MHR) and platelet-hemoglobin ratio (PHR). Using Kaplan-Meier curves and the log-rank test, these ratios were related to overall survival (OS), evaluated along with risk variables by the Cox proportional hazards multivariate model and validated by logistic regressions.

Result and discussion

Patients with LMR ≥ 2.38 ($p = 0.034$) and MHR < 70.87 ($p < 0.001$) showed a higher probability of survival in univariate analysis but only MHR retained prognostic power (HR (95% CI): 2.852 (1.699–4.788), $p < 0.001$) in the presence of risk factors such as ECOG grade, diabetes, and liver metastases. MHR also remained significant ($p = 0.0140$) in logistic regression. Stratified by diabetes or by liver metastases, only MHR was prognostic in both groups ($p < 0.001$, $p = 0.002$). Current research shows controversial results regarding the prognostic power of traditional macrophage-based ratios, rarely evaluated with these risk factors, highlighting the need for novel biomarkers. Hemoglobin levels, used as indicators of treatment tolerance, have been studied in colorectal cancer (MPR), lung cancer (ferritin-to-hemoglobin), and others (hemoglobin/red cell ratios), but in PDAC few references are available. For instance, hemoglobin was used as part of the HALP index (hemoglobin, albumin, lymphocytes, and platelets), showing relevance in PDAC resected cases. However, to the best of our knowledge, the prognostic value of hemoglobin in advanced and metastatic PDAC populations has not been studied, despite its demonstrated role in other cancers.

Conclusion

The new MHR ratio has shown better prognostic power than other macrophage ratios in the presence of risk factors associated with PDAC. This ratio could be used as a prognostic biomarker at diagnosis in clinical practice to aid in medical treatment decisions.

EACR25-0157

miRNAs in Serum and Extracellular Vesicles as Potential Biomarkers of Metastatic Disease in Clear Cell Renal Cell Carcinoma

H. Ayoubian¹, A. Zaccagnino¹, M. Stöckle¹, K. Junker²

¹Saarland University, Department of Urology and Paediatric Urology, Homburg, Germany

²Saarland University Medical Center and Saarland University, Department of Urology and Paediatric Urology, Homburg, Germany

Introduction

There is still a lack of blood-based biomarkers for renal cell carcinoma (RCC). miRNAs including exosomal miRNAs, play a pivotal role in the detection of several types of cancers. Our prior research demonstrated a decrease in the levels of miR-451a, miR-10b-5p, the let-7 family, and miR-30c in primary metastatic tumors. In this study, we aimed to evaluate the significance of these miRNAs in both serum and serum extracellular vesicles (EV) for detecting clear cell RCC (ccRCC) and their potential as biomarkers of metastatic disease.

Material and method

EVs were isolated from the serum of ccRCC patients, including 13 non-metastatic, 33 metastatic (20 metachronous (metachr), 10 synchronous (syn)) as well as 18 healthy individuals, using the Size Exclusion Chromatography (SEC) kit according to the manufacturer's recommendations. The miRNeasy kit was employed to isolate miRNA from both serum and its EVs. The quality and quantity of EV isolation were analyzed using western

blot for exosome markers and nanoparticle tracking analyser for size evaluation. The expression levels of miRNAs (Let7c, miR-451a, miR-30c-5p, miR-126-3p; references: miR-361-5p, miR-1228-3p) in serum and its EVs were investigated using TaqMan real-time PCR techniques.

Result and discussion

The expression levels of miR-451a, let-7c, miR-30c-5p, and miR-126-3p showed significant differences between tumor patients and healthy controls. Let-7c and miR-126-3p were significantly decreased ($p \leq 0.05$) in serum of metachr patients compared to those with non-metastatic ccRCC whereas no significant differences were found between syn and non-metastatic ones. All 4 miRNAs were significantly lower expressed in metachr compared to healthy controls. Analysing miRNAs from EVs, let-7c and miR-126-3p showed significant differences between tumor patients and healthy controls. There was a significant lower expression ($p \leq 0.05$) of miR-451a and let-7c in EVs from all metastatic and in metachr compared to non-metastatic patients, and all 4 miRNAs differed between syn and non-metastatic patients.

Conclusion

We confirmed that miRNA expression of metastatic tumor tissues is reflected in liquid biopsy. Our results suggest that certain miRNAs in serum and their EVs could serve as promising minimally invasive diagnostic and prognostic markers in ccRCC.

EACR25-0160

miR-7974: A predictor of poor prognosis and link to autophagy in ER+ breast cancer

S. Eneh¹, J. Hartikainen^{1,2,3}, S. Heikkilä⁴, R. Sironen^{1,2,5}, M. Tengström⁶, V. Kosma^{1,2,7}, S. Ahuja¹, A. Mannermaa^{1,2,7}

⁴University of Eastern Finland, Institute of Biomedicine, School of Medicine, Kuopio, Finland

⁵Kuopio University Hospital, Department of Clinical Pathology, Kuopio, Finland

⁶Kuopio University Hospital, Cancer Center, Department of Oncology, Kuopio, Finland

⁷Kuopio University Hospital, Biobank of Eastern Finland, Kuopio, Finland

Introduction

Patients with estrogen receptor-positive (ER+) breast cancer (BC) generally have better survival rates than those with ER-negative early BC; however, individual prognoses can vary greatly. Therefore, identifying biomarkers to detect patients who may require more aggressive treatment is crucial. MicroRNAs (miRNAs), a class of small non-coding RNAs, regulate gene expression and have been linked to cancer progression, making them promising candidates for diagnosis and

prognosis. In this study, we investigate miR-7974, a less-explored miRNA, and its potential role in ER+ BC.

Material and method

We extracted total RNA from 204 breast tissue samples from the Kuopio Breast Cancer Study cohort using the mirVana™ miRNA Isolation Kit. We prepared small RNA sequencing libraries with the TruSeq® Small RNA Library Prep Kit and sequenced them on an Illumina MiSeq sequencer. To investigate the correlation between miR-7974 and clinical features, as well as patient outcomes in breast cancer (BC), we used bioinformatics tools like DESeq2 and multivariate survival analyses. To study the functional role of miR-7974 in MCF-7 at the molecular and cellular levels, we utilized in vitro methods, including Western blot, qPCR, and miRNA pull-down assays, alongside in ovo chick chorioallantoic membrane (CAM) assay. Additionally, the direct target of miR-7974 was validated using another BC cell line, MDA-MB-453.

Result and discussion

Our findings show that the upregulation of miR-7974 was significantly ($P = 8.93 \times 10^{-6}$) higher in invasive local BC cases ($n = 182$) compared to benign cases ($n = 22$). The multivariate survival analyses revealed that the high expression of miR-7974 was significantly ($P < 0.05$) associated with poorer relapse-free survival (RFS) and BC-specific survival (BCSS) compared to the low expression in all invasive local BC cases. Additionally, high expression of miR-7974 was linked to poorer RFS in ER+ patients, with a hazard ratio (HR) of 8.70 and a 95% confidence interval (CI) of 3.28–23.06 ($P = 1.37 \times 10^{-5}$). We also found that miR-7974 is involved in genes related to autophagy. Specifically, MAP1LC3B, a key gene involved in autophagy, was found to be a direct target of miR-7974 ($P < 0.05$) in MCF-7 cells. Overexpression of miR-7974 in these cells resulted in anti-proliferative effects, reducing cell growth in both in vitro and in ovo models.

Conclusion

Our results suggest that miR-7974 could be a valuable prognostic biomarker for poor outcomes in ER+ BC, potentially improving survival predictions. The dual role of autophagy helps explain the mechanism behind poor survival, alongside the tumor-suppressive effect observed in both in vitro and in ovo models with high miR-7974 expression. Further research is needed to fully understand miR-7974's role in autophagy regulation and its downstream effects.

EACR25-0245

Immunohistochemistry expression of HER2, Ki-67, and Sialyl-Tn as biomarkers of poor prognosis from patients with gastric adenocarcinoma in Southeastern Mexico

O. Pacheco-Can¹, D. Williams-Jacquez², A. Gutiérrez-Solis¹, A. Avila-Nava¹, R. Chim-Ake¹, A. Molina-Alavez³, K. Sánchez-Pozos⁴, R. Lugo¹

de Yucatán, IMSS-Bienestar, Department of Pathological Anatomy, Merida, Mexico

³Hospital Regional de Alta Especialidad de la Península de Yucatán, IMSS-Bienestar, Department of Oncology, Hematology and Chemotherapy, Merida, Mexico

⁴Hospital Juarez de Mexico, Research Division, Mexico City, Mexico

Introduction

Gastric cancer (GC) is one of the most common cancer types worldwide. Adenocarcinoma is the most frequent type of tumor in GC. Southeast Mexico has the highest rate of comorbidities in all of Mexico. In clinical practice, diagnostic and prognostic biomarkers are scarce; hence, besides the great proportion of the undiagnosed population, some affected subjects do not receive the correct treatment. The Human Epithelial Growth Factor Receptor 2 (HER2) is related to the invasion and progression of tumors, and its expression in GC is around 7–34%. Ki-67 is associated with cell proliferation and poor prognosis in patients with GC; Ki-67 is considered an excellent predictor of GC recurrence. Finally, the expression around 77% of Sialyl-Tn (sTn) is also considered a marker of low survival and high mortality in GC. Thus, the present study aims to determine the expression of HER2, Ki-67, and sTn expression as biomarkers of poor prognosis in patients with gastric adenocarcinoma who attended a reference hospital in Southeast Mexico.

Material and method

221 patients with gastric adenocarcinoma were identified, but only 30 were selected after applying inclusion criteria. All selected patients had endoscopic or gastrectomy biopsies, showing 16 intestinal and 14 diffuse adenocarcinoma subtypes. Four slides with tumor tissue were obtained from each patient. An immunohistochemistry assay was performed to assess the expression of HER2, Ki-67, and sTn, and the staining of Hematoxylin & Eosin. One specialized pathologist determined the identification and the degree of differentiation.

Result and discussion

In general, overexpression of the HER2 receptor in patients with gastric adenocarcinoma was 56.7%. Likewise, HER2 showed overexpression in the intestinal subtype (62.5%), even higher than diffuse adenocarcinoma. Ki-67 expression was predominantly expressed in the diffuse subtype (62.5%). Interestingly, all diffuse adenocarcinomas with Ki-67 expression showed poor differentiation in the tissue, most of them with advanced tumor stage and high phenotypic heterogeneity. Otherwise, sTn showed an expression of 73.3% in patients with gastric adenocarcinoma, and 72.7% of them had died. We observed that patients with sTn positive in diffuse adenocarcinoma increase 1.2-fold the risk of dying. Co-expression of three biomarkers increases 2.2-fold the risk of mortality. The expression of biomarkers was independent of the tumor stage.

Conclusion

The presence of three biomarkers in gastric adenocarcinoma indicated a poor prognosis. HER2 was overexpressed in intestinal adenocarcinoma. Ki-67 and sTn were predominantly expressed in diffuse adenocarcinoma poorly differentiated. Therefore, our findings suggest that the presence of sTn positive might be

considered a mortality biomarker for patients with gastric adenocarcinoma in Southeast Mexico.

EACR25-0249

Genome-scale cell-free DNA methylation analysis for early detection and monitoring of lung cancer

E. Rodger¹, M. Ezegbogu¹, M. Yassi², M. Hillock¹, B. Brockway³, R. Kumar³, G. Reid¹, M. Parry², A. Chatterjee¹

¹*University of Otago, Department of Pathology, Dunedin, New Zealand*

²*University of Otago, Department of Mathematics and Statistics, Dunedin, New Zealand*

³*University of Otago, Department of Medicine, Dunedin, New Zealand*

Introduction

Lung cancer accounts for 1.8 million deaths globally every year. Due to lung cancer's non-specific symptoms, which overlap with other respiratory illnesses (e.g., tuberculosis, asthma, pulmonary emphysema, and fibrosis), most patients present at the hospital with an advanced stage of malignancy. This is responsible for poor patient survival and drives inequities in outcomes. We and others have shown that alterations in DNA methylation are not only tissue- and cancer-type specific, but, because of their abundance, can enable earlier tumour detection with high sensitivity and specificity. Although mutational studies involving cell-free DNA (cfDNA) have experienced considerable progress in their technical and clinical applications, some challenges persist. Alternatively, cfDNA methylation analysis is emerging as a promising biomarker for early lung cancer detection and management, especially when tissue biopsies and low-dose computed tomography (LDCT) scans are unsuitable or inconclusive. We aim to identify blood-based cfDNA methylation markers that can improve early detection and prognosis of lung cancer.

Material and method

In this study, we analysed the cfDNA methylomes of lung cancer patients to determine the tissue of origin and applied this information to lung cancer diagnosis and prognosis. Using cell-free reduced representation bisulfite sequencing (cfRRBS), we have prepared genome-scale methylation libraries from 6–10 ng of plasma-derived cfDNA obtained from lung cancer patients at either early or late-stage, and non-malignant controls (patients with respiratory illness, but not cancer).

Result and discussion

The resulting sequencing data was passed through our in-house bioinformatics pipeline, yielding an average of three million high-quality CpGs per sample. We used deep-learning-powered models for tissue deconvolution and correlated these findings with the clinical presentation of the patients. Differential methylation analysis revealed a subset of regions that were highly discriminatory between 1) lung cancer and non-malignant controls and 2) early and late-stage lung cancer. These promising results suggest that a highly sensitive, tumour-specific methylation signature could enable the earlier detection of lung cancer compared to the current standard of care.

Conclusion

We have successfully demonstrated that blood-based cfDNA methylation biomarkers can accurately detect the presence of lung cancer, even at an early stage. Future work will focus on extending these findings and developing a clinically relevant cfDNA-based methylation test that can be used to complement current screening and treatment monitoring strategies.

⁵*Novartis, Basel, Switzerland*

Introduction

Human epidermal growth factor receptor 2-positive (HER2+) metastatic breast cancer (mBC) is an aggressive BC form treated in first line with dual HER2 blockade (trastuzumab and pertuzumab antibodies). This regimen was shown to recruit and activate immune cells in the tumor microenvironment (TME), enhancing tumor clearance. However, not all patients benefit from this therapy, and resistance develops often, highlighting the need to identify immune biomarkers of response. Since tumor-associated immune cells can migrate from circulation to the TME, blood may serve as an accessible source of biomarkers to predict response to anti-HER2 therapy. Characterizing the immune landscape of responders and non-responders could guide personalized treatments and uncover new immunotherapy targets for improved patient outcomes.

Material and method

Peripheral blood mononuclear cells (PBMC) from 8 HER2+ mBC female patients undergoing standard-of-care treatment with trastuzumab, pertuzumab and docetaxel at the Portuguese Institute of Oncology (IPOLFG) were analysed via scRNA-seq. A direct comparison between responder and non-responder patients was performed to identify putative response biomarkers at the levels of immune population frequency, functional gene expression signatures and pathways, and cell-cell communication networks.

Result and discussion

We used a unique biobank of PBMC samples from HER2+ mBC patients, collected before and along 5 years of treatment with dual HER2 blockade, to perform an in-depth transcriptomic analysis of the peripheral immune landscape of HER2+ mBC at the single-cell level. Comparison between response groups revealed responders to be enriched in circulating monocytes,

dendritic cells (DC) and central memory CD8+ T cells before the start of treatment. Upregulation of biological pathways related to antigen presentation, IFN-g signalling, and cytotoxicity was found in monocytes and NK cells from responder patients, while non-responders were enriched in pathways typically associated with poor prognosis such as hypoxia and vascular wound healing. Co-upregulation analysis revealed gene signatures shared by DC and monocytes in non-responders, and by T and B cells in responders, and highlighted KLF9 as a potential biomarker of poor response given its upregulation in both myeloid and lymphoid populations in non-responder patients.

Conclusion

With the first scRNA-seq peripheral immune profiling of HER2+ mBC patients, we show that responder and non-responder patients may be distinguished before the start of treatment. PBMC composition and gene expression profile support the potential of blood as a source of tumor-associated immune biomarkers for therapy assignment. Monocyte, DC and CD8+ T cell subsets are highlighted as potentially significant players in the clinical response to anti-HER2 antibodies, which prompts the need for further investigation into their dynamics in the TME of HER2+ breast cancers.

Czech Metastatic Colorectal Cancer Patients: their Copy Number Variation and Clinical Response to Chemotherapy and Bevacizumab

J. Stranska¹, K. Bartakova¹, Z. Rozankova¹, L. Kotkova¹, J. Vrbkova¹, P. Flodr², H. Jurtikova¹, B. Liznerova¹, J. Drabek¹

¹*Faculty of Medicine and Dentistry, Palacky University Olomouc, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic*

²*Faculty of Medicine and Dentistry, Palacky University Olomouc, Institute of Clinical and Molecular Pathology, Olomouc, Czech Republic*

Introduction

Bevacizumab (Avastin®) is a humanized monoclonal antibody targeting vascular endothelial growth factor A (VEGF-A), inhibiting angiogenesis in metastatic colorectal cancer (mCRC). It is primarily used in patients with RAS mutations, where cetuximab or panitumumab are ineffective. Although bevacizumab is established in mCRC treatment, no definitive DNA biomarker for its efficacy exists. Somatic mutations in NRAS, BRAF, and PIK3CA have been studied but lack validation as predictive markers. We hypothesize that somatic copy number variations (CNVs) might be key biomarkers for bevacizumab efficacy.

Material and method

We analyzed 30 mCRC patients from University Hospital Olomouc, divided into two groups based on progression-free survival (PFS): poor responders (PFS ≤ 9 months) and good responders (PFS ≥ 10 months). DNA was isolated from FFPE samples and quantified by qPCR. CNV analysis was performed using the OncoScan FFPE Assay Kit, which applies molecular inversion probes technology to detect CNVs in FFPE-derived DNA. The

data was processed using OncoScan Console and R software for segmentation and GISTIC 2 analysis. Functional annotation of genes was done using the DAVID database.

Result and discussion

Good responders showed amplifications in the 18p11.32 region and deletions in chromosomes 1p36.33, 8p11.22, 10q11.23, 14q32.33, 16p13.3, and 20p12.1. Poor responders exhibited amplifications at 8q24.21, 14q12, and 19q13.2, with no deletions above the threshold. Functional annotation revealed that good response genes were involved in ATPase activity, neuronal signaling, and transcription regulation. Poor responders had amplified genes linked to immune regulation (IFNL1, IFNL2, IFNL3), MAPK signaling (MAP3K10, MAP4K1), and differentiation (EID2, SIRT2). Genes like AGRN, MAPK8, and ARHGAP22 from good responders have been linked to angiogenesis and treatment resistance, while DVL1 and MYC in poor responders are associated with tumor proliferation.

Conclusion

This study suggests that CNVs detected by OncoScan technology could serve as biomarkers for predicting bevacizumab response in mCRC. Identifying genes linked to angiogenesis, tumorigenesis, and proliferation (e.g., AGRN, MAPK8, MYC, and DVL1) requires further validation in larger cohorts. Such findings could lead to personalized therapies, improving mCRC treatment outcomes. Future studies will validate these results using high-throughput methods like PCR to confirm their clinical utility.

EACR25-0354

Colorectal cancer patients comprehensive genomic profiling using TruSight Oncology 500

Z. Rozankova¹, M. Skopova¹, P. Stejskal¹, S. Mlcochova², L. Tovarkova¹, M. Khoylou¹, M. Hajduch¹

¹*Faculty of Medicine and Dentistry, Palacky University Olomouc, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic*

²*University Hospital, Laboratory of Experimental Medicine, Olomouc, Czech Republic*

Introduction

Comprehensive genomic profiling (CGP) provides testing of hundreds of pan-cancer biomarkers with tumor markers specific for individual tumor types. This approach brought the possibility of single nucleotide variants (SNV), insertions and deletions (INDELS), copy number variations (CNV), fusions and splice variants detection in DNA and RNA at one time, and tumor mutational burden (TMB) and microsatellite instability (MSI) additionally. The aim of this study was to validate TruSight Oncology 500 HT (TSO500) NGS assay using different types of samples and different types of bioinformatician analysis.

Material and method

We enrolled 513 colorectal cancer patient samples and commercial reference DNA standard in this study. The input amount was 40 ng of gDNA (derived from FFPE and RNA-later tissue samples). All samples were mechanically fragmented prior to library preparation. Sequencing libraries were prepared using DNA Unique

Dual Indexes. After quality control of all libraries, sequencing on the Illumina NovaSeq 6000 was performed. Bioinformatic analysis was performed using two approaches for secondary and tertiary analysis – Velsera Pierian and Illumina Connected Insights (ICI).

Result and discussion

The results showed that the TSO500 HT kit provides high sensitivity and specificity in detecting tumor markers in patients with colorectal cancer. The average total number of reads obtained was 118 thousand with an average coverage per human genome of 271, with a minimum coverage of 124, and a maximum coverage of 1127 that corresponded with different types of input material. It was found that biomarkers were significantly elevated in samples with higher amounts of cancer cells.

Conclusion

The use of the TSO500 HT kit offers new possibilities for non-invasive diagnosis and monitoring of colorectal cancer. The high reproducibility and robustness of the kit in clinical settings indicate that this tool can be valuable for personalized treatment and monitoring of oncology patients. Furthermore, the results of this research can contribute to the further development of diagnostic methods for colorectal cancer and similar oncological diseases.

⁶University of Dundee, Division of Molecular and Clinical Medicine, School of Medicine, Dundee, United Kingdom

Introduction

The development of EGFR-targeting drugs for gastro-esophageal adenocarcinoma (GEA) treatment has been hampered by negative results from phase II/III clinical trials testing EGFR inhibitors in combination with chemotherapy. These failures could be explained by the lack of patient selection due to the absence of reliable predictive markers of response. However, preclinical and clinical findings indicate the effectiveness of EGFR blockade in GEA patients harboring EGFR gene amplification, promising a reassessment of EGFR as a therapeutic target in GEA within the context of a precise patient selection. Retrospective analyses also suggest that

a subset of EGFR non-amplified GEA patients might benefit from EGFR targeting, highlighting the urgent need for predictive biomarkers of sensitivity.

Material and method

We screened 27 GEA primary cancer cell lines and 10 Patient-Derived Xenografts for sensitivity to anti-EGFR drugs. The molecular characterization of these models was performed to uncover potential predictive biomarkers of response. Identified biomarkers were then validated by IHC and RNA in situ hybridization in samples from patients enrolled in the COG clinical trial.

Result and discussion

Our analysis identified both in vitro and in vivo a subset of GEAs lacking EGFR gene amplification, but sensitive to EGFR inhibition. The molecular characterization of these models revealed overexpression of the EGFR ligands amphiregulin (AREG) or epiregulin (EREG) in the drug-sensitive group. To assess the translational significance of these findings, we conducted a post-hoc analysis on tumors from patients enrolled in the COG trial who were treated with the EGFR inhibitor gefitinib. Importantly, we detected a significant correlation between overall survival (OS) and AREG/EREG expression level (HR: 0,5827; CI:0,3445-0,9854, P = 0,0439). Moreover, overexpression of EGFR ligands had no predictive power in the presence of KRAS mutations.

Conclusion

We propose AREG or EREG overexpression as a new predictive marker to identify a subgroup of GEA patients who could benefit from EGFR inhibition.

EACR25-0386

LGALS3BP's role in bladder cancer: a potential urinary biomarker and therapeutic target

⁴University, DSMOB, Chieti, Italy

⁵Mediapharma, Mediapharma, Chieti, Italy

⁶Vancouver Prostate Centre, Vancouver Prostate Centre, Vancouver, Canada

⁷University, DSMOB, Chieti, Canada

Introduction

Bladder cancer remains a major public health challenge, necessitating improved diagnostic and therapeutic strategies. Liquid biopsy, leveraging urinary biomarkers, offers a non-invasive approach for early detection by capturing disease-specific molecular changes. Targeted therapies, particularly antibody-drug conjugates (ADCs), are also advancing precision medicine in bladder cancer treatment. LGALS3BP (Galectin-3-binding protein), is a secreted glycoprotein involved in various biological processes such as immune modulation, cell adhesion, and tumor progression. Elevated circulating LGALS3BP levels are linked to various cancers, making it a promising candidate also as urinary biomarker for liquid biopsy. Additionally, LGALS3BP is emerging as a

potential ADC therapy target in combination with immune checkpoint inhibitors (ICIs).

Material and method

Immunohistochemical analysis of paraffin-embedded tissues was conducted to quantify LGALS3BP expression in bladder cancer tissues. An in-house ELISA assay was developed and used to assess urinary circulating LGALS3BP levels in both healthy controls and bladder cancer patients. A panel of eight commercially available bladder cancer cell lines was utilized for in vitro characterization of LGALS3BP expression and its glycosylation status. Therapeutic studies were performed using xenograft models.

Result and discussion

LGALS3BP expression was significantly elevated in bladder cancer tissues and correlated with disease progression. Its overexpression was confirmed in urothelial cancer cell lines, with variations in glycosylation patterns. Notably, treatment with Kifunensine, a mannosidase inhibitor, enhanced 1959 therapeutic antibody reactivity, suggesting that LGALS3BP glycosylation may influence antibody recognition and protein function. Urinary LGALS3BP levels were markedly higher in patients than in healthy individuals. Of note, in-house ELISA developed by our group, based on the 1959 therapeutic antibody, demonstrated promising accuracy (67% sensitivity, 79% specificity), highlighting LGALS3BP as a potential urinary biomarker. Lastly, therapeutic studies performed with 1959-sss/DM4 confirmed LGALS3BP as an effective target for ADC therapy in bladder cancer.

Conclusion

The findings presented here strongly position LGALS3BP as a promising candidate for bladder cancer research, highlighting its potential both as a urinary biomarker and as a therapeutic target.

Introduction

Microtubules (MTs) are crucial components of the cytoskeleton and play direct roles in essential cellular processes, such as cell division and migration, intracellular transport and stress response. Taxanes (paclitaxel and docetaxel), which act by stabilizing MTs, are widely used in neoadjuvant chemotherapy (NAT) for breast cancer (BC) patients. Despite their undeniable clinical success, responsiveness is not guaranteed and taxanes bare significant side effects. We have recently identified deviations in the levels of two post-translational modifications (PTMs) of tubulin, namely α -tubulin acetylation and detyrosination, that correlate with or influence cancer cell response to taxanes in vitro, respectively. To validate these findings and determine the clinical significance of this “tubulin code” in BC, we are conducting a retro-spective clinical study to test the predictive, prognostic and therapeutic value associated with α -tubulin acetylation and/or detyrosination for precision oncology. If successful, this will allow patient stratification, towards improved therapeutic choices and outcomes.

Material and method

We have established a robust immunohistochemistry (IHC) protocol and scoring system for assessing the levels of α -tubulin acetylation and detyrosination in formalin-fixed paraffin embedded patient material. For this study, histological cuts from naïve tumor biopsies from BC patients (any molecular sub-type) who underwent NAT regimens that included taxanes were collected, along with relevant clinical and histopathological data. When available, surgically removed post-NAT material from the same patients was also analyzed.

Result and discussion

Using our established methodology, the levels of α -tubulin acetylation and detyrosination will be classified as highly positive, positive, or negative, based on visual assessment by pathologists and quantitative digital analysis. The correlation between tubulin PTM levels and the response to taxanes in NAT (complete pathological response, partial or no response), as well as other clinical and pathological factors, will be analysed. Sensitivity and specificity of the biomarkers will be evaluated using receiver operating characteristics (ROC) curve analyses.

Conclusion

With this approach, we have generated preliminary results and shown that the study of tubulin PTM levels in BC is feasible and may represent new biomarkers of therapy response. If successful, our study will enable more informed and personalized therapeutic choices for patients, by pinpointing the good and the weak responders to taxane-based therapy. We envision that our findings will establish the grounds for personalized taxane dosage-optimization and improved therapeutic efficacy, while opening the possibility to manipulate these tubulin PTMs as new therapeutic targets for enhanced treatment of specific breast cancer sub-types, with special attention to triple negative breast cancer.

EACR25-0394

Detection of high molecular weight DNA contaminations in cell-free DNA samples

A. Dorn¹, W. Pike²

¹Agilent Technologies, Cell and Biomolecular Analysis Division, Waldbronn, Germany

²Agilent Technologies, Cell and Biomolecular Analysis Division, Ankeny, United States

Introduction

Cell-free DNA (cfDNA) is a critical component in translational research, facilitating the identification of biomarkers and mutations through noninvasive methods. However, its low yield, complex fragmentation, and potential contamination with high molecular weight (HMW) DNA present challenges for next-generation sequencing (NGS) workflows. Quality assessment of cfDNA is essential, requiring visualization of fragmentation patterns and contamination.

Material and method

Plasma samples were processed using different cfDNA extraction kits. The extracted cfDNA samples were analyzed with the Cell-free DNA ScreenTape assay and the High Sensitivity D1000 ScreenTape assay on the Agilent TapeStation system as well as with the High Sensitivity DNA kit on the Agilent 2100 Bioanalyzer system.

Result and discussion

Total DNA and cfDNA concentration of various samples were compared. Despite some samples having a higher total DNA amount, there was no correlation with cfDNA concentration. Electropherogram comparisons of different samples revealed the presence of HMW DNA, which is also reflected in lower %cfDNA scores. Other QC methods used in comparison were unable to accurately display and quantify HMW DNA contaminations, thus failing to correctly assess cfDNA quality.

Conclusion

The Agilent TapeStation system, utilizing the Cell-free DNA ScreenTape assay, offers an objective and reliable qualification of cfDNA samples. It provides the % cfDNA quality score, indicating the proportion of cfDNA relative to HMW DNA contamination, thus ensuring accurate assessment of cfDNA quality before NGS library preparation and sequencing. Other QC methods might overlook HMW DNA contamination, leading to inaccurate yield estimations and potentially compromising downstream experiments. Accurate quantification of cfDNA, including HMW DNA contamination, is essential for reliable NGS library preparation and results.

⁵Te Whatu Ora Health New Zealand - Waitaha Canterbury, Department of Urology, Christchurch, New Zealand

⁶Precision Urology, Department of Urology, Dunedin, New Zealand

Introduction

Prostate cancer (PCa) represents a major health burden globally, with over 1.4 million annual diagnoses and almost 400,000 PCa-related deaths. Current approaches to PCa screening and diagnosis are suboptimal, creating challenges for the accurate detection of clinically important PCa. Hence, there is an urgent need for novel, accessible, and clinically deployable biomarkers to optimise PCa care. Circulating tumour DNA (ctDNA) is a minimally invasive, highly specific technology that identifies the presence of a tumour using plasma-derived cell-free DNA (cfDNA). DNA methylation changes are a universal hallmark of cancer that dynamically influence gene expression. We, and others, have shown that ctDNA-based epigenetic alterations are higher in number, potentially enabling earlier tumour detection than genetic mutation analysis. Analysis of the cell-free DNA methylome, therefore, represents an exciting avenue for the development of highly accurate biomarkers for early PCa detection.

Material and method

In this multicentre, prospective discovery study, we have performed whole-genome scale DNA methylation profiling of matched patient blood and prostate biopsy tissue samples. Men scheduled to undergo prostate biopsy for clinical suspicion of PCa were recruited from several localities across New Zealand, with matched pre-biopsy peripheral blood samples and prostate biopsy tissue collected for molecular profiling. Unbiased, whole-genome scale DNA methylation profiling for both plasma cfDNA and tissue samples was performed using cell-free reduced representation bisulfite sequencing (cfRRBS).

Result and discussion

Over 200 differentially methylated regions (DMRs) differentiating malignant from benign and healthy samples have been identified from early profiling results of cfDNA samples, demonstrating significant discriminatory power for PCa detection at very early-stage disease. PCa-specific DMRs have also been identified from prostate tissue samples – interestingly, however, the most predictive tissue-derived DMRs cluster distinctly from those detected in cfDNA, even in matched patient samples.

Conclusion

Early profiling results show promise for cfRRBS as a discovery approach for cell-free DNA-based methylation biomarkers, with high prospective utility in the setting of PCa detection. Profiling results will be further refined and correlated to clinical and histopathological features of disease severity to generate a blood-based, targeted methylation panel for early and accurate PCa detection.

Liquid Biopsy-Based Biomarkers for Predicting Radiotherapy Response in

Locally Advanced Head and Neck Squamous Cell Carcinoma

A. Saeed¹, N. Othman¹, H. Ghafour², N. Mahmood³

¹Zhianawa cancer center, Radiation oncology,

Sulaymaniyah, Iraq

²Zhianawa cancer center, Medical physics,

Sulaymaniyah, Iraq

³University of Sulaimani, Biology, Sulaymaniyah, Iraq

Introduction

Radiotherapy (RT) is frequently used to treat head and neck squamous cell carcinoma (HNSCC), however resistance is still a significant problem. Treatment choices and patient outcomes may be influenced by trustworthy biomarkers that forecast RT response. Exosomal RNA and circulating tumor DNA (ctDNA) have become attractive liquid biopsy-based biomarkers for tracking tumor dynamics and therapy effectiveness. Exosomal RNA and ctDNA signatures are examined in this work as potential indicators of RT response in locally progressed HNSCC.

Material and method

60 HNSCC patients undergoing adjuvant or definitive radiation therapy participated in a prospective research. Samples of plasma were taken before, during, and after RT. NGS (ultra-deep next-generation sequencing) was used to monitor ctDNA levels and TP53, NOTCH1, and HRAS mutations. Furthermore, the expression of genes linked to immunity and hypoxia was examined in exosomal RNA. Tumor regression, locoregional control, and progression-free survival (PFS) were all associated with biomarker dynamics.

Result and discussion

Shorter PFS and greater recurrence rates ($p < 0.01$) were linked to persistent ctDNA detection after RT. The 2-year locoregional control was considerably better in patients with ctDNA clearance mid-RT (HR = 0.42, $p = 0.003$). Poor response was associated with high exosomal RNA production of VEGF and HIF1A, suggesting that tumor hypoxia contributes to radioresistance. Additionally, patients with lower amounts of exosomal PD-L1 mRNA demonstrated better RT response and immune activation.

Conclusion

The potential of ctDNA and exosomal RNA as real-time indicators for RT response prediction in HNSCC is demonstrated by this work. High exosomal hypoxia markers and persistent ctDNA post-RT may be used as markers of radioresistance to inform individualized treatment plans. To enhance patient outcomes, future research should look into incorporating liquid biopsy-driven adaptive RT techniques.

Bioinformatics Unit, Badalona, Spain

⁴Catalan Institute of Oncology, Medical Oncology Department, Badalona, Spain

Introduction

Cisplatin-based neoadjuvant chemotherapy (NAC) followed by radical cystectomy is the standard treatment for muscle-invasive bladder cancer (MIBC). However, NAC use is limited due to its modest impact on survival, patient comorbidities, and lack of predictive biomarkers. Tumor-educated platelets (TEPs) have emerged as potential biomarkers for cancer diagnosis and treatment response through liquid biopsy. TEPs, functionally altered by tumors, internalize and transport tumor-derived mRNA, reflecting its genetic profile. This study aims to identify a TEP mRNA-based predictive signature of NAC response in MIBC patients.

Material and method

Pre-NAC blood samples from 50 MIBC patients (T2-4N0/+M0) were collected from two Spanish hospitals, along with 12 diagnostic tumor tissue samples for TEP-tumor gene expression correlation. Blood samples from 10 healthy donors served as controls. Total RNA from platelets and FFPE tissues was extracted using the mirVana™ miRNA Isolation Kit and Maxwell RSC RNA FFPE Kit (Promega), quantified via NanoDrop (Thermo Fisher). Gene expression was analyzed using the NanoString nCounter Human Tumor Signaling 360 Panel. Data preprocessing and normalization were performed in R (v4.3.1), and differential expression analysis was conducted using limma within the NanoTube framework ($|FC| > 1.2$, $p < 0.05$, $q < 0.1$) to compare complete responders (ypT0N0) and non-responders ($yp \geq T2$). Gene set enrichment analysis was performed with fgsea (implemented within NanoTube) on pathway and hallmark gene sets provided by NanoString with the panel annotation.

Result and discussion

We identified nine genes – CDCP1, SOX7, EXO1, ANGPT2, BRCA1, GREM1, GRHL2, TNS4, and FGFR2 – that were significantly overexpressed in TEPs from non-responsive MIBC patients compared to responsive patients. Notably, these genes exhibited similar expression patterns between responsive patients and the control group, suggesting their association with treatment resistance. Among them, GREM1 was the most overexpressed gene ($FC = 2.29$; $q\text{-value} = 5.4e-4$) in the TEPs of non-responders versus responders. Furthermore, our exploratory functional enrichment analysis revealed that cancer hallmarks such as evading growth suppressors, activating invasion and metastasis, and sustaining proliferative signaling, along with pathways related to the cell cycle and epithelial-mesenchymal transition, were significantly enriched in the TEPs of non-responsive patients.

Conclusion

This prospective study highlights the potential of TEPs as a non-invasive liquid biopsy tool for predicting NAC response in MIBC. We identified nine overexpressed genes in non-responders, with GREM1 showing the strongest discriminative power. TEP RNA profiles effectively distinguished between responders and non-

responders, suggesting their utility as predictive biomarkers to guide treatment decisions. Further validation in larger cohorts is warranted.

EACR25-0520

Serum metabolomic profiling unveils a metabolite marker panel for early detection of colorectal cancer

Y. Liu¹, W. Wan², E. Tan¹

¹*Singapore General Hospital, Colorectal Surgery, Singapore, Singapore*

²*Singapore General Hospital, Department of Pathology, Singapore, Singapore*

Introduction

Early detection of colorectal cancer (CRC) is critical for identifying the disease at a curable stage. Current screening methods, such as invasive colonoscopy and stool-based tests, face limitations due to low to moderate uptake and compliance. Minimally invasive blood-based approaches, particularly those analyzing tumor-derived or tumor-relevant metabolites, offer a promising alternative for CRC screening. This study aims to identify serum metabolite markers for early-stage CRC detection and evaluate their diagnostic potential, both individually and in combination.

Material and method

In this case-control study, untargeted metabolite profiling using liquid chromatography-mass spectrometry (LC-MS) was performed on serum samples from 32 pairs of stage I/IIA CRC patients and age-, gender-matched controls with colonoscopy-verified no evidence of disease (NED). Differences in serum metabolite levels between cases and controls were analyzed by using Mann-Whitney U test. Receiver operating characteristic (ROC) curves were constructed for assessment of assay sensitivity and specificity. Multivariate logistic regression models, followed by ROC analysis, were used to evaluate the assay performance of metabolite combinations.

Result and discussion

A total of 59 metabolites were differentially expressed between CRC cases and NED controls, with 31 upregulated and 28 downregulated. Notably, nine upregulated metabolites exhibited substantially higher serum levels in CRC cases as compared to controls ($P < 0.001$). ROC analysis confirmed the discriminative power of these metabolites, with area under the curve (AUC) values ranging from 0.732 to 0.887 ($P \leq 0.001$). Combinations of two or more metabolites yielded higher AUCs and improved sensitivities as compared to individual metabolites. A five-metabolite panel demonstrated particularly strong diagnostic performance, achieving a sensitivity of 96.9% while maintaining a specificity of 90%. This represented a significant improvement over the sensitivities of the individual markers (59.4%, 50.0%, 46.9%, 53.1% and 46.9%, respectively) at the same specificity (all $P \leq 0.001$).

Conclusion

The identified five-metabolite serum panel shows promise to be developed into a minimally invasive, blood-based test for early detection of colorectal cancer.

Further validation in larger cohorts is warranted to confirm its clinical utility.

Introduction

Plasma cell-free DNA (cfDNA) analysis to track estrogen receptor 1 (ESR1) mutations is highly beneficial for the identification of tumor molecular dynamics and the improvement of personalized treatments for patients with metastatic breast cancer (MBC). Plasma-cfDNA is, up to now, the most frequent liquid biopsy analyte used to evaluate ESR1 mutational status. Circulating tumor cell (CTC) enumeration and molecular characterization analysis provides important clinical information in patients with MBC. In this study, we investigated whether analysis of CTCs and circulating tumor DNA (ctDNA) provide similar or complementary information for the analysis of ESR1 mutations.

Material and method

We analyzed both plasma-cfDNA ($n = 90$) and paired CTC-derived genomic DNA (gDNA; $n = 42$) from 90 MBC patients for seven ESR1 mutations using the ddPLEX Mutation Detection Assay (Bio-Rad, Hercules, CA, USA).

Result and discussion

Eight out of 90 (8.9%) plasma-cfDNA samples tested with ddPCR were found positive for one ESR1 mutation, whereas 11/42 (26.2%) CTC-derived gDNA samples were found positive for at least one ESR1 mutation. Direct comparison of paired samples ($n = 42$) revealed that the ESR1 mutation rate was higher in CTC-derived gDNA (11/42, 26.2%) than in plasma-cfDNA (6/42, 14.3%) samples.

Conclusion

Our results, using this highly sensitive ddPLEX assay, reveal a higher percentage of mutations in CTC-derived gDNAs than in paired ctDNA in patients with MBC. CTC-derived gDNA analysis should be further evaluated as an important and complementary tool to ctDNA for identifying patients with ESR1 mutations and for guiding individualized therapy.

Do small extracellular vesicles within serum of different thyroid pathologies express the same miRNA as those isolated from tissue-on-chip?

H. Beattie¹, T. Haigh², V. Green³, M. Wade¹, J. England⁴, J. Greenman¹

¹University of Hull, Centre for Biomedicine, Hull, United Kingdom

²York and Scarborough Teaching Hospitals NHS Trust, Otorhinolaryngology, York, United Kingdom

³University of Hull, Centre for Biomedicine, Hull, United Kingdom

⁴Hull University Teaching Hospitals, Otorhinolaryngology, Hull, United Kingdom

Introduction

Following the successful isolation and characterisation of small extracellular vesicles (sEV) released from thyroid cancer, Graves' disease, and benign thyroid tissue maintained on a tissue-on-chip device, these were analysed for miRNA content to determine any differences in the profile between pathologies. Now, the serum from patients of these pathologies has been analysed to identify if the miRNA profiles detected in sEV released from tissue-on-chip can be found within the blood. For the tissue-on-chip analysis, there was a cohort of 30 patients; thyroid cancer (n=10), Graves' disease (n = 10), and benign thyroid (n=10). For the serum analysis, where blood was available, a sample from the same patient was used. So far, a total of 6 serum samples per pathology have been analysed to identify potential miRNA biomarkers.

Material and method

Thyroid biopsies from 30 patients were sliced using a vibratome before being incubated on 8 separate tissue-on-chip devices with constant perfusion in EV depleted medium for 6 days. Effluent coming from the devices was collected and pooled prior to differential ultracentrifugation to isolate sEV. RNA was extracted using the miRNeasy Micro Kit (Qiagen) prior to qRT-PCR analysis. Serum from patients also underwent ultracentrifugation to isolate sEV, prior to qRT-PCR. qRT-PCR analysis of the serum sEV was completed using the panel of miRNA identified from sequencing of sEV isolated from tissue-on-chip samples.

Result and discussion

Four miRNAs were seen to be significantly differentially expressed in Graves' vs. Benign tissue-on-chip sEV: miR-7-5p ($p < 0.025$), miR-382-5p ($p < 0.025$), miR-435-5p ($p < 0.023$), miR-129-5p ($p < 0.026$). Five miRNAs were differentially expressed in Cancer vs. Benign sEV: miR-375-3p ($p < 0.002$), miR-382-5p ($p < 0.008$), miR-146b-5p ($p < 0.017$), miR-432-5p ($p < 0.000$), miR-129-5p ($p < 0.008$). To date, qRT-PCR analysis of serum has demonstrated the presence of several miRNAs of interest, including miR-7-5p and miR-432-5p. It is clear there needs to be an improvement in RNA extraction, to allow reliable qRT-PCR detection; this should enable the measurement of miRNA present at low concentrations.

Conclusion

Tissue-on-chip technology developed at the University of Hull has allowed the isolation of tissue specific sEV

which demonstrate distinct miRNA biomarker profiles between thyroid pathologies. qRT-PCR has been used to validate the miRNA identified using RNA sequencing. Some markers have been identified by qRT-PCR in serum samples, but additional optimisation of the extraction protocol is currently ongoing. The identification of these miRNA biomarkers of thyroid disease could provide a non-invasive thyroid cancer and disease progression analysis tool in the future.

THOR Methylation signatures in liquid biopsies for early breast cancer detection

C. Cardoso¹, D. Pestana¹, J. Apolónio¹, N. Silva¹, N. Nunes², U. Tabori², P. Castelo-Branco¹

¹University of Algarve, Algarve Biomedical Center Research Institute, Faro, Portugal

²SickKids, Toronto, Canada

Introduction

Breast Cancer (BC) is the leading cause of cancer-related death among women worldwide. The incidence of BC in young women (<40 years old) is rising, revealing the need to develop and implement new strategies for BC diagnosis beyond current imaging-based approaches. In most BC cases, cancer cells reactivate the telomerase enzyme through upregulation of human Telomerase Reverse Transcriptase (hTERT) gene, acquiring limitless self-renewal capacity and supporting tumor progression. One mechanism responsible for this reactivation is the hypermethylation of a specific region within the hTERT promoter, called TERT Hypermethylated Oncological Region (THOR). Our group showed that THOR is significantly hypermethylated in malignant breast tissue when compared to benign tissue (40.23% vs. 12.81%). Liquid biopsy is a minimally invasive approach that provides real-time information about tumor status, particularly through circulating cell-free DNA analysis. We aim to identify THOR DNA methylation patterns exclusive to BC that could be used as liquid biopsy-based biomarkers to detect BC through a simple blood test.

Material and method

DNA derived from 59 BC tissue samples, 60 healthy breast tissue samples and 47 healthy blood samples was bisulfite treated, followed by PCR amplification of THOR region and sequenced using Illumina Next generation MiSeq. The raw DNA methylation data of the THOR region was processed through a multistep bioinformatic pipeline: data quality control and poor bases trimming, alignment, incomplete bisulfite conversion reads filtration, methylation extraction, and complete reads selection. Then, we quantified the THOR methylation patterns present in the BC tissue, healthy breast tissue and healthy blood. We selected the THOR methylation patterns exclusively detected in the BC tissue but never detected in both healthy breast tissue and healthy blood samples, thus considered BC specific. This analysis was performed in BASH, and in R.

Result and discussion

Comparing BC and healthy breast tissue samples, we identified 450 BC-specific THOR methylation patterns that were never detected in healthy breast tissue. After comparing it with healthy blood samples, we found that 19 THOR methylation patterns remained exclusive to BC

(sensitivity = 15%–75%; specificity = 100%). Notably, we also identified a panel of 13 BC-specific THOR methylation patterns present in 58 out of the 59 BC tissue samples (sensitivity = 98%, specificity = 100%).

Conclusion

Our findings underscore the potential of THOR methylation signatures to be used as a highly sensitive and specific biomarker for breast cancer detection.

EACR25-0547

STRN4/Zinedin is a favourable prognostic indicator for patients with colon cancer

O. Wickstead¹, A. Li¹, T. Martin¹, R. Hargest¹, D. Miller², R. Allemann², Q. Dou³, W. Jiang¹

¹*Cardiff University, School of Medicine, Cardiff, United Kingdom*

²*Cardiff University, School of Chemistry, Cardiff, United Kingdom*

³*Wayne State University, Karmanos Cancer Institute, Detroit, United States*

Introduction

Striatin-4 (STRN4) is a member of the STRIPAK (striatin-interacting phosphatase and kinase) complex, and regulates multiple cellular processes such as cell differentiation, growth and metabolism. STRN4 has been implicated in tumorigenesis through its involvement in the Hippo signalling pathway, autophagy, and anti-tumour immunity via the STING pathway. Its role in colon cancer remains poorly understood and its clinical relevance has not been established; it is crucial therefore to determine the clinical significance of STRN4.

Material and method

Post-surgical colon tissue samples, including 90 tumour and 79 non-cancerous tissues were obtained from patients at the University Hospital of Wales. The samples were homogenised and underwent reverse transcription to generate cDNA for transcriptional analysis. STRN4 expression was assessed across the cohort and results stratified according to clinicopathological parameters including tumour differentiation stage, TNM stage, Dukes stage, presence of metastasis, and patient survival. Expression levels were analysed based on patients' EGFR (epidermal growth factor receptor) status.

Result and discussion

STRN4 expression was significantly reduced in higher-grade tumours compared with lower-grade tumours ($p = 0.031$) and increased with higher TNM stages ($p = 0.06$, $p = 0.0079$, $p = 0.0039$ for TNM1 vs. TNM2, TNM3, and TNM4, respectively). In survival-based analysis, patients with high STRN4 levels had significantly greater overall survival than those with low expression ($p = 0.041$ by Kaplan-Meier model, hazard ratio (HR) = 0.416, 95% confidence interval (CI): 0.174–0.994). Stratification of patients by EGFR status showed that the survival benefit of STRN4 was more pronounced in patients with high EGFR expression ($p = 0.020$) compared with those with low EGFR ($p = 0.552$). STRN4 expression had a more profound impact on predicting disease-free survival (DFS) of colon cancer patients; high STRN4 expression was associated with significantly improved DFS ($p = 0.007$, HR = 0.331, 95% CI: 0.142–0.770). Multivariate analysis identified STRN4 ($p = 0.009$) and TNM staging

($p = 0.027$) as significant independent predictors of DFS with better outcomes in cases of high EGFR expression. High levels of STRN4 were associated with reduced metastasis potential for colon cancer patients (DMFS $p = 0.015$, HR = 0.342 (95% CI 0.137–0.854)) and may also indicate increased sensitivity of patients to chemotherapies.

Conclusion

The present study is the first to demonstrate that high STRN4 expression in human colon cancer is a favourable prognostic factor, associated with improved overall, disease-free, and distant metastasis-free survival. The stronger prognostic value in patients with high EGFR expression suggests a potential therapeutic implication of STRN4, warranting further investigation into STRN4 as a clinical biomarker and therapeutic target in colon cancer. Ethical approval reference number: SJT/C617/08.

EACR25-0608

Integrating tumor fraction, next generation sequencing and qPCR analysis in liquid biopsy of EGFR-mutated non-small cell lung cancer patients

E. Lazzarini¹, L. Santarelli¹, A. Padovan², S. Potente³, L. Bao², C. Romualdi³, V. Guarneri², L. Bonanno², S. Indraccolo²

¹*Veneto Institute of Oncology IOV-IRCCS, Basic and Translational Oncology Unit, Padova, Italy*

²*University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy*

³*University of Padova, Department of Biology, Padova, Italy*

Introduction

Tumor fraction (TF) assessment in liquid biopsy (LB) is increasingly used to evaluate the actual presence of circulating tumor DNA (ctDNA). False negative LB results in fact are often associated to low or undetectable TF. The aim of our study is to evaluate the integration of TF assessment into the diagnostic workflow of non-small cell lung cancer (NSCLC) LB, with a particular focus on its utility in the interpretation of cases testing negative for actionable gene mutations, such as EGFR mutations, to enhance diagnostic accuracy.

Material and method

We collected LBs from a cohort of 30 newly diagnosed NSCLC patients, carriers of EGFR mutations determined by routine tissue analysis and enrolled in the ongoing REM trial. Plasma EGFR mutations were identified both by Next Generation Sequencing (NGS) with the 77-gene Avenir Expanded Panel and the real time Cobas EGFR Mutation Test v2 (Roche). TF was assessed by shallow whole genome sequencing (sWGS) using the KAPA HyperPrep Kit (Roche) and SAMURAI plus ichorCNA algorithms.

Result and discussion

Across 30 LB samples, sWGS revealed a mean TF of $7.0\% \pm 1.0\%$ (median = 0.0%; range 0.0 to 43.4%). TF was detectable in 13 out of 30 samples (44%), with a mean TF of $16.2\% \pm 11.1$ (median = 0.1%, range 2.1 to 43.4%). In all cases with detectable TF, EGFR mutations were detected both by the Avenir and Cobas test, with a median VAF of 21.6%. Moreover, the Avenir test

detected a second EGFR mutation in two patients and EGFR amplifications in three patients. TF was undetectable in 17 out of 30 liquid biopsies (56%). However, EGFR mutations were still identified in 15 out of these 17 TF-negative samples using the Cobas and Avenio tests, with a median VAF of 1.25%. Three samples tested negative by both methods. Notably, two patients with undetectable TF carried two EGFR mutations with VAFs of 12.4 and 14.6%, in the absence of gene amplifications, according to the results of Avenio NGS test, suggesting that EGFR mutations can still be detected even in cases with no measurable TF. This apparently false negative TF determination might be attributed to intrinsic limitations of TF calculation, which primarily relies on the detection of genomic aneuploidy and can be affected by a low presence of copy number alterations.

Conclusion

These study highlights the superior sensitivity of NGS and qPCR tests in detecting EGFR mutations, even in cases with undetectable TF, underscoring the limitations of TF assessment by sWGS and emphasizing the need for an integrated multi-modal approach in LB analysis of lung cancer samples.

Disclosure. Unconditioned research support: AstraZeneca.

EACR25-0611

The Impact of Circulating Malignant Tumour Cells on Tumour Recurrence in Oral Squamous Cell Carcinoma

A. Alkandari¹, S. Choi²

¹*Ministry of Health, Oral & Maxillofacial Surgery, Kuwait, Kuwait*

²*University of Hong Kong, Orthopaedics & Traumatology, Hong Kong, Hong Kong, China*

Introduction

Oral squamous cell carcinoma (OSCC) is a serious and debilitating disease, with surgical resection the mainstay of treatment. The extent to which surgical resection of OSCC disseminates cancer and is associated with metastasis is currently unknown. The aim of this study was to determine changes in numbers of malignant cells released into the systemic circulation immediately following tumour removal and over the first seven post-surgical days and to relate these numbers with cancer recurrence or metastasis over a 3-year post-surgical follow-up period.

Material and method

Patients identified at a single centre with histopathologically confirmed OSCC and who were scheduled to undergo resective surgery were invited to join the study. Peripheral blood from 54 patients were sampled at baseline (before induction of anaesthesia of the planned surgery), when the surgeon declares that the tumour had been resected, and at post-surgical day 1 and day 7. Blood was processed for circulating tumour malignant cell enumeration within 48 hours of blood taking using an immunofluorescent *in situ* hybridisation technique. White blood cells were stained CD45+, DAPI+ (4',6-diamidino-2-phenylindole) but circulating tumour malignant cells were stained CD45-, DAPI+. Clinical information at baseline and up to 3-years post-surgical treatment, including cancer recurrence or metastasis were

retrieved from the clinical management system. Spearman's correlation was used to look at relationships between outcome and tumour cell count at various timepoints.

Result and discussion

A total of 54 patients with mean (SD) age of 65.94 (11.26) years, were studied. Tumours were at various stages (I to IV) and occurred in anatomical sites including tongue, buccal mucosa and floor of mouth. Patients were followed up for recurrence, metastasis, or death for between 3 to 5 years post-surgery. 16 patients had passed away (mean age 71.00) at project census. Circulating tumour cells and circulating tumour-derived endothelial cells were detected in all but two patients. The number of circulating tumour cells, and circulating tumour-derived endothelial cells were higher at the post-surgical day 1 and day 7 timepoints, but these increases were not statistically significant. Results showed that there is no association between the number of circulating malignant cells and the clinical-pathological stage of the tumour. Presence of circulating malignant cells at any timepoint during the tumour resection journey is predictive of recurrent/metastatic disease at up to 5 years of patient follow-up, although there was no direct correlation between number of cells and disease status at 5 years.

Conclusion

Patients with any circulating malignant cells in their peripheral blood at any time during the surgical journey should be given heightened surveillance with regard to detecting recurrent/metastatic disease

EACR25-0664

Evaluation of a novel protein-based assay for multi-cancer early detection

N. Walter¹, B. von und zu Zwerger²

¹*University Hospital Regensburg, Department for Psychosomatic Medicine, Regensburg, Germany*

²*Private Practice, Naturopathy, Garmisch-Partenkirchen, Germany*

Introduction

Early cancer detection is critical for improving patient survival, however, current diagnostic methods often lack sensitivity, especially for asymptomatic or early-stage malignancies. Liquid biopsy technologies have emerged as promising alternatives, yet challenges remain, particularly due to the low abundance of circulating tumor DNA (ctDNA). This study evaluates the Carcimun® test, a protein-based assay, for its ability to differentiate cancer from non-malignant inflammatory conditions.

Material and method

A prospective, single-blinded study included 172 participants, categorized as healthy ($n = 80$), cancer patients ($n = 64$, nine distinct types including lung, colorectal, and pancreatic, bile duct, liver, esophageal, stomach, gastrointestinal stromal, and peritoneal cancer, stage I-III), and individuals with inflammatory conditions (fibrosis, sarcoidosis, pneumonia) or benign tumors ($n = 28$). Plasma samples were analyzed using the Carcimun® test, measuring protein-based changes via optical extinction. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were

determined, with a predefined extinction threshold of 120 units as a cut-off for malignancy. Statistical analysis was conducted using ANOVA and post-hoc testing.

Result and discussion

The Carcimun® test demonstrated high accuracy (95.4%), with sensitivity (90.6%) and specificity (98.2%), effectively differentiating cancer from non-malignant conditions. The PPV was 96.7%, indicating a high probability that individuals testing positive truly have cancer. The NPV was 94.6%, suggesting a strong ability to rule out malignancies when test results fall below the extinction threshold. Cancer patients exhibited significantly elevated extinction values (315.1 vs. 23.9 in healthy individuals, $p < 0.001$). Importantly, the test distinguished between inflammatory and malignant cases ($p < 0.001$), addressing a major limitation of previous liquid biopsy methods. Coagulation disturbances may affect extinction readings, potentially resulting in false-positive or false-negative findings.

Conclusion

The Carcimun® test presents a highly sensitive and specific approach to cancer detection, with enhanced differentiation from inflammatory conditions. By expanding inclusion criteria to non-malignant diseases, this study underscores the test's real-world applicability in early cancer screening. Further large-scale validations and longitudinal studies are warranted to optimize its integration into clinical practice.

EACR25-0689

Prognostic Potential of ctDNA Methylation in Prostate Cancer: Predicting Biochemical Recurrence and Overall Survival in Localized and Metastatic Disease

J. Chung¹, D. Kim², M. Jung², H. Cho³, J. Cha³, K. Han³, S. Lee⁴, Y. Kim⁵

⁴LepiDyne Inc, R&D center, LepiDyne Inc, Seoul, Korea (Republic of)

⁵Yonsei University, Interdisciplinary program of integrated OMICS for Biomedical Science, Seoul, Korea (Republic of)

Introduction

Circulating tumor DNA (ctDNA) methylation has emerged as a pivotal epigenetic biomarker reflecting tumor progression and treatment resistance. This study evaluates whether ctDNA methylation levels can serve as a prognostic marker for biochemical recurrence (BCR) in localized prostate cancer (LPCa) and overall survival (OS) in metastatic castration-resistant prostate cancer (mCRPC). Additionally, we investigate the interplay between ctDNA methylation and circulating tumor cells (CTCs) to provide deeper insights into tumor biology.

Material and method

Blood samples from 157 prostate cancer patients were analyzed, including LPCa ($n = 73$) and mCRPC ($n = 84$). Three key ctDNA methylation markers (C2orf, APC, HAPLN3) were quantified, alongside CTC enumeration and transcriptional profiling of AR, AR-V7, PSA, and PSMA. Correlations between ctDNA methylation burden and CTC transcriptomic activity were examined. Kaplan-Meier survival analysis was used to evaluate the prognostic value of ctDNA methylation in predicting BCR in localized disease and OS in mCRPC patients.

Result and discussion

ctDNA methylation was detected in 61.7% of LPCa and 96.8 % of mCRPC patients, showing a stepwise increase with disease progression ($P < 0.05$). Both CTC counts and CTC-derived gene expression (AR, AR-V7, PSA, PSMA) increased with advancing disease stage ($P < 0.05$). Notably, elevated ctDNA methylation levels were significantly associated with higher CTC transcriptional activity, suggesting its role as a surrogate marker of tumor aggression. In LPCa, APC methylation independently predicted BCR (HR, 2.6, 95% CI 1.05-6.45; $P = 0.039$). In mCRPC, elevated ctDNA methylation levels correlated with worse OS (HR, 3.63, 95% CI 1.84-7.18; $P < 0.001$).

Conclusion

Our findings support ctDNA methylation as a dynamic prognostic biomarker that reflects CTC transcriptional activity and tumor progression. Its ability to predict biochemical recurrence in localized disease and survival outcomes in mCRPC patients underscores its clinical relevance. Integrating ctDNA methylation profiling into liquid biopsy strategies could refine risk stratification and treatment decision-making in prostate cancer management.

EACR25-0699

Identification of Histopathological and Molecular alterations associated with High-risk Oral leukoplakia: A prospective study

R. Chavda¹, D. Rai², K. Mahajan², J. Gawde¹, S. Rane³, N. Mittal³, S. Pimple⁴, M. Mahimkar¹

¹Advanced Centre for Treatment, Research and Education in Cancer, Cancer Research Institute, Navi Mumbai, India

²Advanced Centre for Treatment, Research and Education in Cancer, Department of Preventive Oncology, Mumbai, India

³Tata Memorial Hospital, Department of Pathology, Mumbai, India

⁴Tata Memorial Hospital, Department of Preventive Oncology, Mumbai, India

Introduction

Oral leukoplakia (OL) is the most common oral potentially malignant disorder with 30% to 50% lifetime risk to develop oral squamous cell carcinoma (OSCC). In clinic, histological grading remains the gold standard to identify lesions at risk of progression into OSCC but is subjective with unreliable outcome prediction. Moreover, the significance of individual histological characteristics

and underlying molecular alterations associated with progressive OL remains unexplored. Additionally, prospective studies with comprehensive understanding are lacking.

Material and method

The Institutional Ethics Committee approved the study protocol and signed informed consent was obtained from all the participants. This study included 498 OL tissue and blood samples. Pathologists SR and NM designed an assessment form featuring the architectural and cellular changes in OL cases. Haematological parameters were noted at the time of enrolment. DNA was extracted from OL tissues, and the presence of HPV was detected. The copy number was evaluated for 15 genes using DD-PCR. Follow-up at regular intervals of 6 months was done, and clinical outcomes were recorded as free of disease, persistence of lesion, recurrence of lesion, and malignant transformation (MT).

Result and discussion

The mean follow-up period was 31.73 months. In the histopathological assessment of 25 cellular and architectural features, we observed a significant association of dyskeratosis, nuclear hyperchromatism, enlarged nucleoli, and irregular epithelial stratification in both recurrence of lesion and MT. Additionally, an abnormal form of mitosis was observed in MT. Interestingly, inflammation occurrence and intensity (mild, moderate and severe) in tissue and low platelet to lymphocyte ratio in blood were strongly associated with MT. All cases were negative for HPV. Using DD-PCR, we identified novel prognostic biomarkers to stratify high-risk leukoplakia patients. Through this information, we provide a model to identify progressive lesions.

Conclusion

Collectively, this prospective study provides a comprehensive understanding of individual histopathological features, along with CNAs associated with the disease progression. Our findings may aid to stratify high-risk OL patients and determine the prognosis of precancerous lesions, thus helping in clinical management.

Tumor educated platelets in diagnostics and monitoring of childhood brain tumors

A. Holmström¹, M. Talka², S. Långström³, M. Kankainen², P. Valle³, A. Karppinen⁴, S. Kyölä², A. Anttonen², V. Pentikäinen³, K. Eloranta³

¹*Children's Hospital, Helsinki University Hospital and University of Helsinki, Pediatric Research Center, Helsinki, Finland*

²*Diagnostic Center, Helsinki University Hospital, Helsinki, Finland, Division of Clinical Genetics, Helsinki, Finland*

³*Children's Hospital, Helsinki University Hospital, Helsinki, Finland, Division of Hematology-Oncology and Stem Cell Transplantation, Helsinki, Finland*

⁴*Helsinki University Hospital, Helsinki, Finland, Department of Neurosurgery, Helsinki, Finland*

Introduction

The most common solid tumors in pediatric patients are brain tumors, which also have the highest mortality rate

among childhood malignancies. Brain tumor diagnosis highly relies on molecular profiling of the tumor tissue supported with radiological imaging. However, biopsy is not always feasible due to the location of the tumor and radiological imaging is not a precise diagnostic method limiting the follow-up of minimal residual disease. To enable safer and repeatable follow-ups while capturing tumor heterogeneity, analyzing tumor-induced alterations in blood could provide cost-effective and precise monitoring, with the potential for microscopic disease detection. Previous research has shown that platelet RNA expression is altered in cancer patients. Moreover, transcriptomic changes in platelets have been used to distinguish different tumor types and monitor tumor progression. In this study, we investigated platelet RNA expression to assess its potential in pediatric brain tumor diagnostics and follow-up.

Material and method

Blood was collected into EDTA tubes from both pediatric brain tumor patients ($n = 24$), and healthy controls without known history of tumor ($n = 27$), all aged between 0–18 years old, at the New Children's Hospital in Helsinki, Finland. All samples were processed within 2 h from collection with platelet isolation by double centrifugation and CD45+ leukocyte depletion. RNA was extracted from platelets, and its integrity and quantity was determined. RNA sequencing (RNA-seq) libraries were constructed from 1 ng of total RNA. Rsubread was used to assign RNA-seq reads to human reference genome, NCBI nuclear rRNA gene models, and to determine read counts per genes. Differentially expressed genes (DEGs) were analyzed using DESeq2 and pathway analysis was made using Enrichr.

Result and discussion

Two high-grade gliomas, five low-grade gliomas, one atypical teratoid rhabdoid tumor, and eight healthy controls (HC) were included in the pilot analysis. We observed differential expression of 42 genes (FDR < 0.1) in platelet RNA (brain tumors vs. HC), of which 37 were upregulated and five downregulated. The majority of DEGs were associated with regulation of immune system. Furthermore, our results indicated that gene expression signature of TEPs may discriminate the aggressive pediatric CNS malignancies from low grade tumors. Confirmatory analyses with expanded cohort are currently ongoing.

Conclusion

The results of pilot analysis demonstrated that pediatric brain tumor patients have altered TEP transcriptome which could be utilized in diagnosing brain tumors and monitoring disease. Overall, TEPs are a new promising diagnostic approach which could potentially be used in combination with other approaches to enable more precise and less riskful diagnostics in the future.

EACR25-0765

Extracellular nicotinamide phosphoribosyltransferase (eNAMPT) in ascitic fluid as a potential biomarker for Ovarian Cancer development and recurrence

F. Gorini¹, C. Coada², G. Ambra³, A. Perrone⁴,

P. Hrelia¹, S. Angelini¹, G. Ravegnini¹

¹University of Bologna, Pharmacy and Biotechnology - FABIT, Bologna, Italy

²University of Bologna, Medical and Surgical Sciences, Bologna, Italy

³University of Piemonte Orientale, Pharmaceutical Sciences, Novara, Italy

⁴IRCCS Azienda Ospedaliero-Universitaria of Bologna, Bologna, Italy

Introduction

Ovarian cancer (OC) is one of the most lethal cancers worldwide. Currently, treatment options are limited to surgery and systemic chemotherapy, but around 80% of patients experience disease relapse and treatment resistance. Despite research advancements, the mechanisms underlying OC recurrence and chemotherapy resistance remain poorly understood. Thus, new insights are needed to identify patients at higher risk of recurrence and to develop more personalized therapeutic strategies. Nicotinamide phosphoribosyltransferase (NAMPT) plays a crucial role in the biosynthesis of NAD from nicotinamide. Extracellular NAMPT (eNAMPT), secreted outside the cell, exerts cytokine-like functions and mediates pro-inflammatory conditions by activating signaling pathways. eNAMPT is involved in various tumorigenic processes, including DNA repair, gene expression regulation, proliferation, invasion, stemness, metastasis, angiogenesis, immune modulation, and drug resistance, making it a promising target for anti-cancer strategies. In this context, the present project aims to evaluate the presence of eNAMPT in the ascitic fluid of OC patients in order to analyze its potential role in OC development and recurrence.

Material and method

eNAMPT levels were evaluated in the ascitic fluid of 42 OC patients treated at the Gynecologic Oncology Unit of the IRCCS in Bologna, at the time of diagnostic laparoscopy and prior to any treatment, using a commercially available sandwich enzyme-linked immunosorbent assay (ELISA) for human eNAMPT (AdipoGen), starting from 100 µl of samples. The amounts of eNAMPT were analyzed and their association with clinical features, prognosis, and therapy response was evaluated.

Result and discussion

Of the 42 samples, 25 showed values higher than 4 ng/ml on a range between 0 and 8 ng/ml (as maximum value), with 19 patients with an expression higher than 6. At the moment, follow-up is too short to have enough events to determine an effect of eNAMPT level on Progression Free Survival. However, eNAMPT level inversely correlates with CA125, a protein often elevated in blood of OC patients and used as biomarker ($p = 0.02$).

Conclusion

High levels of eNAMPT were observed in ascitic fluid samples suggesting that ascites - which is produced in large volumes in OC - is particularly enriched in eNAMPT, and that it is an excellent biological source to elucidate the role of eNAMPT.

⁵Clinica Universitária de Neurocirurgia, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal., Lisboa, Portugal

Introduction

Medulloblastoma (MB) is the most common malignant brain tumor in children. It can disseminate within the central nervous system, particularly in Group 3 tumors, significantly worsening patient prognosis. While current therapies are effective for treating primary MB tumors, disseminated disease remains incurable, underscoring the urgent need for novel and more effective treatments. Recent findings suggest a potential association between a particular axis and MB progression. Based on these findings, we hypothesize that a molecule associated with this axis can be a prognostic marker in MB and its targeting can be a promising strategy to treat metastatic MB.

Material and method

To test our hypothesis, we analyzed the clinical relevance of the expression of a specific gene in MB patients using the R2: Genomics Analysis and Visualization Platform, specifically investigating its association with metastasis and patient survival. Additionally, we overexpressed this particular gene in ONS76 MB cells to evaluate its functional role in cell proliferation and migration. Using these cells, we developed an orthotopic mouse model to study the effects of gene overexpression in tumor invasion, dissemination, and survival. Moreover, we performed an in-silico drug screen to identify potential inhibitors for this molecule and validated their efficacy through both in vitro and in vivo assays.

Result and discussion

Our analysis revealed that elevated expression of this gene is significantly associated with dissemination and poorer survival outcomes in Group 3 MB patients. In vitro, gene overexpression enhanced cell proliferation and migration. In vivo, it resulted in greater MB tumor invasion and dissemination, as well as reduced survival in mice. Through our in-silico drug screen, we identified three inhibitors which were tested. Among these, a lead candidate emerged as the most promising, effectively suppressing the target expression, reducing cell proliferation and migration, and blocking its signaling pathway. Importantly, this compound also significantly reduced tumor burden in treated mice.

Conclusion

Our results suggest this molecule could be a prognostic marker for MB, particularly in patients with Group 3 tumors. Furthermore, the effective inhibition of this molecule in vitro and in vivo, shows potential as a therapeutic strategy for metastatic disease.

Changing the paradigm of liquid biopsy storage without cold chain. In-vitro validation of a preservative medium for circulating tumor HPV-DNA stabilization

C. Senti¹, I. Triva², M. Ibrahim Hamoude², C. Sabelli¹

¹*Copan Italia S.p.A., Scientific Affairs, Brescia, Italy*

²*Copan Italia S.p.A., Microbiology Laboratory, Brescia, Italy*

Introduction

Human papillomavirus (HPV) has been demonstrated to be released into the bloodstream as circulating tumor DNA (ctHPV-DNA) which may potentially used as prognostic and predictive biomarker for HPV-related malignancies including cervical cancer (CC) and head and neck squamous cell carcinomas (HNSCCs). Despite its potential clinical applications, the analysis of ctDNA for diagnostic procedures remains challenging due to its low concentration, fragmentation into short DNA lengths, blood hemolysis and the rapid degradation within a few hours if not properly preserved. In this study, we evaluated the preservative performance of eNAT® medium (Copan Italia, Brescia) for ctHPV-DNA in artificial human plasma samples under in-vitro setting.

Material and method

Serial dilutions of HeLa cells (ATCC*229) were prepared from a stock suspension (10^{-1} to 10^{-6}) in Dulbecco's phosphate-buffered saline (dPBS). HeLa DNA containing HPV 18 was extracted from 60 μ L of each dilution using NIMBUS platform (Hamilton). DNA quantification was performed with Nanodrop spectrophotometer and Qubit dsDNA High Sensitivity (HS) assay (Thermo Fisher Scientific). A qPCR titration assay (Allplex HPV-HR, Seegene) was subsequently conducted to determine the optimal DNA concentration that best mimicked the characteristics of ctHPV-DNA. HeLa DNA from the 10^{-2} dilution was selected as an inoculum for stability testing. 2:1 dilution ratio of artificial human (ah) plasma (Biochemazon) and eNAT® (ahPlasma:eNAT) was prepared in six replicates by mixing 360 μ L of artificial human plasma with 180 μ L of eNAT®. Into each replicate, 54 μ L of the 10^{-2} HeLa DNA dilution was inoculated, yielding a final dilution of 10^{-3} . DNA extraction, quantification and amplification were performed following the same protocol at baseline (T0) and after two weeks (T2w) of storage at room temperature (RT) of 25°C.

Result and discussion

Regarding ctHPV-DNA stability analysis, Hela DNA samples inoculated in a 2:1 dilution ratio of ahPlasma: eNAT exhibited an average Ct of 30,1 ($\sigma = 0,21$) at T0 and an average Ct of 30,2 ($\sigma = 0,5$) after 2 weeks, indicating consistent ctHPV-DNA preservation at RT (25°C) without the need of cold-chain storage.

Conclusion

Based on preliminary findings, eNAT® medium appears to be a suitable option for long-term storage and transport of human plasma samples for subsequent circulating tumor DNA molecular analysis, potentially facilitating the sample management avoiding the need of cold chain storage and shipment. Further investigations are ongoing to assess the preservation efficiency of eNAT® with additional circulating tumor DNA targets in a clinical setting.

³*CNRS/University of Limoges/CNRS-ERL 7004, University of Technology of Troyes, XLIM Research Institute, UMR 7252/Light, Nanomaterials & Nanotechnologies (L2n), CNRS-ERL 7004, Troyes, France*

⁴*University of Limoges, IRCCER UMR CNRS 7315, Limoges, France*

Introduction

Glioblastoma (GBM) is among the most prevalent and aggressive brain tumors, with a poor median survival rate despite advancements in diagnosis. The complexity of this cancer is due to the tumor heterogeneity, which makes patient follow-up and management particularly difficult. To overcome this issue, the identification of circulating biomarkers in liquid biopsies is crucial in GBM patients.

Material and method

A new method of liquid biopsy based on the analysis of the contents of extracellular vesicles (EVs) is currently emerging. Previous studies have shown that the truncated variant of EGFR (EGFRvIII), present in 40% of GBMs, is released in circulating EVs of patients' plasma. As EGFRvIII is constitutively active, it plays a role in tumorigenesis and contributes to chemoresistance. However, early detection of EGFRvIII in EVs derived from liquid biopsy is not suitable with clinical routine applications due to the complexity for isolating EVs from plasma with current technologies. Furthermore, they lack sensitivity for detecting biomarkers at low concentrations in patients' blood. To overcome these challenges, Surface Plasmon Resonance (SPR) is being explored as a real-time detection method. This approach enables the detection of EVs and their surface components without the need for extensive purification steps which makes a promising solution for biomarkers detection in clinical routine.

Result and discussion

Our preliminary technological developments on SPR method have permitted to functionalize the SPR sensor surface to capture EVs. Moreover, our optimized approach enhances the sensitivity of EVs biomarkers detection, such as CD63 and CD81, thereby overcoming

one of the main limitations of liquid biopsy analysis in clinical practice.

Conclusion

Our aim is now to improve the sensitivity of SPR technology for the detection of circulating biomarkers such as EGFRvIII in EVs derived from human glioblastoma. The early detection of very low concentrations of biomarkers in blood will be a major tool for monitoring patients.

EACR25-0849

Advancing Multi-Cancer Early Detection: High-Performance cell-free RNA Profiling with the Flomics Liquid Biopsy Platform

J. Curado¹, P. Sanders¹, L. Gonzalez¹, L. Sanchez¹, M. Weber¹, P. Monteagudo¹, J. Lagarde¹, P. Simón-Extremera², S. Panadero³, P. Catalina³

¹Flomics Biotech, S.L., Barcelona, Spain

²Leitat Technological Center, Health and Biomedicine, Barcelona, Spain

³Andalusian Public Health System Biobank, Granada, Spain

Introduction

Liquid biopsies are increasingly important diagnostic tools for early cancer detection due to their high sensitivity and minimal invasiveness, with cell-free RNA (cfRNA) emerging as a promising biomarker. At Flomics Biotech we developed a high-quality cfRNA-Seq platform that profiles human plasma cfRNA in a robust and reproducible manner. Our platform combines optimized laboratory protocols for Next-generation Sequencing of plasma RNA with state-of-the-art bio-informatics and machine learning (ML) classification methods to identify cancer-related RNA biomarker signatures. Here we used our cfRNA-Seq platform in the LiquiDx pre-clinical study with the aim of developing a multi-cancer early detection test.

Material and method

We used our cfRNA-seq platform to profile the cfRNA in plasma samples from over 1,000 individuals (median age = 64 years) recruited in collaboration with 9 international clinical partners. The cohort consists of patients with colorectal, lung, breast, pancreatic or prostate cancer, or non-cancer diseases of the same organs, and healthy individuals. Early and late stage patients were recruited for each cancer type, with 22% of patients having stage I cancer. We isolated total RNA from 1 ml of plasma and sequenced at an average depth of 36M reads per sample with Illumina technology. Using the cfRNA-seq data we identified differentially expressed genes (DEGs), performed gene set enrichment analysis (GSEA), and trained an ML classifier to predict patient status and cancer tissue of origin. We employed a stratified 4-fold cross-validation strategy that maintains class balance across training and validation splits, and optimized the model's hyperparameters.

Result and discussion

We identified 114 DEGs ($|\log_{2}FC| > 1$, FDR < 0.05), with GSEA revealing enrichment of metastasis, inflammation, and proliferation-associated genes in cancer patient cfRNA profiles. For cancer vs healthy classification, our ML classifier achieves a mean area

under the ROC curve of 0.92 ± 0.01 , and a sensitivity of 83% at 90% specificity. For classification of different cancer types, at 90% specificity our ML classifier achieves a sensitivity ranging from 69% for breast cancer to 99% for prostate cancer. In contrast to other liquid biopsy-based technologies, our platform maintains a high performance level in detecting stage I cancer patients (80% sensitivity), reinforcing its great potential as a cancer early detection tool.

Conclusion

The Flomics cfRNA-Seq platform delivers high-quality cfRNA data and robust biomarker identification, demonstrating transformative potential in cancer early detection across multiple cancer types and stages, particularly in stage I where cancer detection is more challenging. The platform's high performance and minimal invasiveness position it as a revolutionary tool to improve global cancer diagnostics.

Non-Invasive Detection of Circulating mRNA Markers in Colorectal Diseases

V. Vymetalkova¹, K. Balounova¹, A. Valickova¹, A. Uttarilli¹, J. Horak¹, V. Makajevova², L. Sojka², J. Jungwirth³, J. Kral⁴, J. Bruha⁵

¹Institute of Experimental Medicine, Czech Academy of Sciences, Department of Molecular Biology of Cancer, Prague, Czech Republic

²Thomayer Hospital, Department of Surgery, Prague, Czech Republic

³St. Anne's Sanatorium, Prague, Czech Republic

⁴Institute for Clinical and Experimental Medicine, Department of Gastroenterological Methods, Prague, Czech Republic

⁵University Hospital Pilsen, Department of Surgery, Pilsen, Czech Republic

Introduction

Colorectal adenomas (CRA) are abnormal epithelial growths and key precursors to colorectal cancer (CRC). Their timely removal significantly reduces CRC risk, a major global health burden with nearly 1.9 million new cases annually. Early detection strategies, particularly non-invasive biomarkers, are critical for improving patient outcomes. This study aimed to identify and validate mRNA markers for CRA and CRC using a multi-phase approach.

Material and method

In the discovery phase, next-generation sequencing (NGS) was used to analyze transcriptome profiles in CRA (n = 16), incident CRC (n = 10), and cancer-free individuals (CFI, n = 10). We identified 10 genes deregulated between adenomas and adjacent tissues and 8 differentially expressed among tumor tissue, surrounding tissue, and healthy mucosa. For validation, we used RT-qPCR in an expanded cohort (CRA n = 48, CRC, and CFI n = 51). CRC patients were stratified by stage (n = 48 per stage). The most promising markers (CEMIP1, TACSTD2, SP5 and VWA2 specific to CRA, and KRT80, CLDN2, and CEMIP1 to CRC) were then analyzed in liquid biopsies (plasma and stool) from CRA (n = 30), CRC (n = 36), and CFI (n = 51). In CRC patients, plasma markers were assessed at diagnosis and

~10 days post-surgery to evaluate their potential to reflect tumor burden reduction.

Result and discussion

Multi-level validation confirmed differential expression of key mRNA markers in tissues and biofluids, supporting their non-invasive detection potential. Plasma and stool analyses showed significant expression changes, with certain transcripts decreasing post-surgery (CEMIP1), indicating responsiveness to tumor resection. These findings suggest that selected mRNA markers could serve as sensitive and specific biomarkers for early detection of CRA and CRC.

Conclusion

This study demonstrates the feasibility of transcriptomic biomarkers in liquid biopsies for non-invasive CRC screening. The integration of NGS-based discovery with RT-qPCR validation provides a robust framework for identifying clinically relevant markers. Future research should assess their diagnostic utility in larger, independent cohorts.

EACR25-0868

The expression of the tight junctional protein complex Occludin (OCLN) and Zonula Occludens 1 (ZO-1) in human colon cancer and assessment of disease progression and therapeutic responses

Q. Tian^{1,2}, C. Wang², A. Li², M. McKenna², J. Benedikt¹, R. Hargest², W. Jiang², T. Martin²

¹School of Engineering, Cardiff University, Cardiff, United Kingdom

²School of Medicine, Cardiff University, Cardiff, United Kingdom

Introduction

Occludin (OCLN) is a membrane integral protein located at the apical membrane region of epithelial and endothelial cells. Together with its anchorage membrane subcoat protein, Zonula Occludens (ZO-1), it contributes to the formation and function of the tight junction and is key to the regulation of paracellular permeability and cell-cell adhesion. The role of the tight junction and its constitutive molecules in cancer are under intense investigation, with Occludin being postulated to have a possible role in colon cancer by defining a subclass of patients. In the present study, we investigated the expression pattern of Occludin together with ZO-1 and attempted to establish relevance in clinical colon cancer.

Material and method

A cohort of colon cancer tissues with matched normal (control) tissues were assessed for transcript levels of Occludin and Zonula Occludens-1 (ZO-1). Expression levels in relation with patient's pathological factors, tumour staging, prognosis and clinical outcome were evaluated.

Result and discussion

Colon cancer tissues exhibited an aberrant expression pattern for both Occludin and ZO-1, compared with normal tissues ($p < 0.001$ by Mann-Whitney U test). High levels of Occludin in colon tumours were associated with a shorter overall survival (OS), distant metastasis

free survival (DMFS) and disease-free survival (DFS) of the patients. Similarly, high levels of ZO-1 also showed a connection with survival outcomes (OS, DFS and DMFS). There was little association with local recurrence. Owing to their biological roles in maintaining the integrity of tight junctions, the expression of Occludin and ZO-1 was also considered in combination, it was found that patients with high expression of both Occludin and ZO-1 had a much poorer survival (OS 58.8%) than those without high expression (OS 85.7%) and those with only one of the proteins highly expressed (OS 70.8%). Further stratification of the patients by EGFR and Her2 status revealed that whilst EGFR status did not contribute to prediction, high expression of Her2 and Occludin identified the group with poorest overall survival (25%).

Conclusion

Expression of the Occludin/ZO1 complex is aberrant in human colon cancer with this aberrant pattern linked to clinical outcome. Moreover, Her2 status contributes to the survival model, implicating this complex as a putative prognostic in colon cancer.

²DNATECH, Lisboa, Portugal

³i3S, Porto, Portugal

Introduction

Understanding the factors that influence therapeutic response and prognosis is crucial for improving the management of HER2-positive breast cancer (HER2+ BC). Despite the success of neoadjuvant therapy (NAT), predicting pathological response and long-term outcomes remains a major challenge. Tumor-infiltrating lymphocytes (TILs) have emerged as immune biomarkers associated with response to NAT and prognosis. At the same time, redox biology plays a fundamental role in shaping the cancer cell phenotype and the tumor microenvironment. However, the extent of their impact on HER2+BC progression and treatment outcomes is still unclear. This study aims to investigate the interplay between immune infiltrates and oxidative stress in HER2+BC, integrating bioinformatics to identify redox-related genes linked to prognosis and immune modulation.

Material and method

Surgically resected specimens from 30 patients with early HER2+ BC who underwent neoadjuvant chemotherapy with trastuzumab and pertuzumab were analysed for TILs (hematoxylin-eosin) and the oxidative damage biomarker 3-nitrotyrosine (3-NT, immunohistochemistry). To explore the associations between the expression of redox-related genes with tumor microenvironment cell populations and patient survival, a bioinformatics study using the TCGA dataset and the GEPIA and TIMER2.0 platforms was performed.

Result and discussion

TILs score correlated positively with tumor size, both at diagnosis and after NAT. 3-NT scores correlated with tumor size at diagnosis and TILs score. Based on the associations identified between TILs, clinical features and oxidative damage, a bioinformatics analysis was conducted to explore redox-related genes that could be critical for HER2+BC prognosis. We identified 53 redox-related genes for which dysregulated expression is associated with survival, with 43 genes associated with higher hazard ratios (HR) and 10 with lower HR. Some of these genes are associated with a higher abundance of specific immune cell populations infiltration. Genes are mostly related to oxidative phosphorylation, response to oxidative stress, and regulation of transcription. Four main pathways are shared by some of the genes identified: HMOX1, TP53-mediated translational control, regulation of PTEN transcription, and VEGFA-VEGFR2 signalling.

Conclusion

This study provides novel insights into the interplay between redox biology and tumor immunity in HER2+ BC. The identification of redox-related genes associated with survival and immune modulation suggests potential prognostic biomarkers. Further research should validate these findings, paving the way for more precise and personalized therapies. EACR25-0899

Age and Microenvironment Matter: When Survivin Becomes a Predictor of Poor Outcomes in Neuroblastoma

F. Brehm Pinhatti¹, S. Marques¹, S. Elifio-Esposito¹

¹Pontifícia Universidade Católica do Paraná, Graduate Program in Health Science, School of Medicine and Life Sciences, Curitiba, Brazil

Introduction

Survivin is a key protein involved in tumor progression and therapy resistance, yet its prognostic significance in neuroblastoma remains underexplored. This study aimed to evaluate the association between survivin expression and clinical outcomes in a cohort of neuroblastoma patients, with detailed analyses focusing on a subset of cases with malignant tumors.

Material and method

Clinical and pathological data from 66 patients diagnosed with neuroblastoma and treated at Pequeno Príncipe and Erasto Gaertner hospitals, Curitiba, Brazil, between 1990 and 2016 were collected. Immunohistochemical staining on tissue microarray slides was used to assess survivin expression in the nucleus and extracellular matrix/cytoplasm. Expression was quantified through color morphometry or hotspot scoring.

Result and discussion

In the total cohort, the median age at diagnosis was 17.5 months. Abdominal mass or pain (35.9%) was the most frequent clinical manifestation. Tumors were most commonly located in the adrenal gland (50.8%), with 42.3% classified as INSS stage 4. Bone marrow infiltration occurred in 27% of cases, residual recurrence

in 21.3%, and 30.3% of patients died from the disease. Survivin expression was observed in benign and malignant tumors, with significantly higher levels in malignant cases ($p < 0.001$). In the subset of 45 malignant tumors, high survivin expression was associated with progression (HR = 7.74, $p < 0.001$) and mortality (HR = 5.83, $p < 0.001$). Kaplan-Meier analyses demonstrated reduced progression-free and overall survival in patients with high survivin expression, particularly in those with metastatic disease or bone marrow involvement. Stratified analyses revealed distinct patterns of survivin expression and clinical impact across different patient subgroups. High survivin (score >2) was paradoxically associated with lower progression rates ($p = 0.043$) in patients <18 months, whereas in older patients, high survivin correlated with significantly higher progression ($p = 0.001$) and overall worse outcomes ($p = 0.003$). In patients with bone marrow infiltration, high survivin expression (>2) was associated with significantly worse survival outcomes ($p = 0.048$) and increased risk of progression ($p = 0.012$). These findings highlight survivin as a prognostic biomarker with context-dependent effects, emphasizing the need for tailored therapeutic strategies based on patient-specific tumor characteristics.

Conclusion

Survivin expression serves as a significant biomarker for neuroblastoma, correlating with aggressive clinical features and poor outcomes. However, its prognostic impact varies by age, metastatic status, and bone marrow involvement. These findings underscore the complexity of survivin's role in neuroblastoma and the necessity for further research to refine its application as a prognostic and potential therapeutic target.

EACR25-0972

Prognostic and therapeutic implications of tumor heterogeneity captured by longitudinal ctDNA in advanced high-grade serous ovarian carcinoma

M. Nguyen¹, J. Oikkonen¹, Y. Li¹, J. Hynninen², S. Hautaniemi¹

¹University of Helsinki, Faculty of Medicine, Helsinki, Finland

²Turku University Hospital, Department of Obstetrics and Gynecology, Turku, Finland

Introduction

Circulating tumor DNA (ctDNA) offers advantages in clinical trials and cancer treatment monitoring due to its minimally invasive nature and sampling accessibility. Beyond these benefits, ctDNA can provide a snapshot of tumor heterogeneity, and longitudinal measures can guide therapeutic strategies. While these benefits are evident in many cancer types, they are not well characterized for high-grade serous carcinoma (HGSC), the most lethal subtype of ovarian cancer. This study leverages real-world data from the longitudinal, multi-region, observational, prospective DECIDER trial to investigate the potential of longitudinal ctDNA analysis in advanced-stage HGSC.

Material and method

We collected 35 treatment-naïve plasma samples and 80 matched patient tissue biopsies from 35 patients. Plasma samples were sequenced using either whole-exome sequencing (WES) at 500x coverage or a 1000x targeted panel of over 500 cancer-related genes, while tissue samples were sequenced using either whole-genome sequencing (WGS) at 45x coverage or a 200x targeted panel. For longitudinal analysis, 150 plasma samples collected during primary treatment were sequenced with shallow whole-genome sequencing (sWGS) at a coverage of 0.4x from 30 patients. Mutational profiles were called using GATK4, and ichorCNA was used for longitudinal ctDNA analysis, providing ctDNA fractions and copy number profiles.

Result and discussion

Our results demonstrate that ctDNA captures tissue heterogeneity, revealing distinct clonal populations within individual tumors. Furthermore, ctDNA contains specific tissue mutational profiles, suggesting a complementary benefit to tissue biopsies. During primary treatment response monitoring, patients with decreasing ctDNA levels had better prognoses, while those with stable ctDNA fractions experienced shorter progression-free intervals. Notably, ctDNA levels indicated a greater reduction in patients who received chemotherapy plus bevacizumab compared to chemotherapy alone; however, this observation is limited by the small cohort size.

Conclusion

The ctDNA biopsy technique demonstrated advantages in both diagnosis and treatment monitoring for advanced HGSC patients, particularly in detecting genomic variants missed by tumor biopsies due to heterogeneity. Longitudinal ctDNA monitoring highlighted therapeutic responses, suggesting its potential as a dynamic biomarker for treatment efficacy. This study provides a foundation for larger investigations. We are expanding the cohort to further investigate the potential of ctDNA as a predictive biomarker for treatment response, and to explore its role in guiding personalized treatment strategies in HGSC. This expanded study will provide greater statistical power to validate the trends observed in this small cohort and enable more definitive conclusions regarding the clinical utility of ctDNA in managing HGSC.

EACR25-1009

Biomarkers for neo-adjuvant treatment in locally advanced rectal cancer: preliminary results from a comprehensive characterization of the biological features of good and poor response

A. Huerta-Hernandez¹, I. Labiano¹, I. Caseda¹, N. Irazabalbeitia^{2,1}, E. Mata³, J. Zabalza⁴, A. Lecumberri^{1,5}, M. Alsina^{1,5}, J. Suarez⁶, R. Vera³
¹Navarrabiomed-IdiSNA, Oncobiona Group, Pamplona-Iruña, Spain

³Hospital Universitario de Navarra (HUN)-IdiSNA, Department of Medical Oncology-Oncobiona Group, Pamplona-Iruña, Spain

⁴Hospital Universitario de Navarra (HUN), Department of Radiology, Pamplona-Iruña, Spain

⁵Hospital Universitario de Navarra (HUN)-IdiSNA, Department of Medical Oncology, Pamplona-Iruña, Spain

⁶Hospital Universitario de Navarra (HUN), Department of Surgery, Pamplona-Iruña, Spain

Introduction

Locally advanced rectal cancer (LARC) is treated with neoadjuvant therapy (NAT) followed by surgery. Watch & wait (w&w) strategies pursuing organ preservation are starting to be adopted for patients responding to NAT. Magnetic Resonance Imaging (MRI) plays a pivotal role in the response assessment. However, this approach alone is not optimal for identifying responding patients and novel biomarkers to complement clinical response evaluation are needed. We report preliminary results from a larger study proposing a comprehensive characterization of LARC patients to describe biomarker signatures of response to NAT that could help to select patient who could benefit from w&w strategies.

Material and method

Upon signature of the informed consent, biological specimens and clinical data were collected before and after NAT. Blood circulating immune cells, MRI diffusion weighed imaging (DWI) parameters and the gut microbiome were evaluated. Patients were grouped according to pathological Mandard Tumor Regression Grade (TRG) as responders (R; TRG 1-2) and non-responders (NR; TRG 3-5). Differences between sexes were assessed.

Result and discussion

By February 2025, 55 patients were included, 29 had TRG assessment. The immune cell evaluation in R showed an increase of the early myeloid suppressor (CD11b+, CD14-, CD66b-, CD33+, HLADR-) and Fc ϵ RI α expressing cells from basal to post-NAT sample, while they remained unchanged in NR. PDL1 expressing myeloid cells did not change in R but decreased in NR. Regarding lymphoid cells, R showed higher levels of CD4+PD1+ cells after NAT. Additionally, NR showed a significant increase in CD8+CD4- cells and KLRL1+ CD28- subpopulation from basal to after NAT, which was not observed in R. MRI-based assessment showed high sensitivity but low specificity to detect complete responses. In DWI parameters, the change in the skewness of the signal from basal to post-NAT MRI was higher in R. The basal microbiome profile and diversity indexes were similar in R and NR, while particular genus, such as the butyrate producing bacteria genus Blautia was increased in R. Sex related differences were assessed. Basal CD3+, CD4+ and KLRL1-CD28+ expressing CD8+ cells were elevated in females, while total myeloid cells (CD11b+) were decreased. Basal MRI skewness and kurtosis were lower in females. Finally, female feces were enriched for particular bacteria genus such as Eisenbergiella and Frisingicoccus.

Conclusion

These preliminary results suggest distinctive biological and radiological characteristics of NAT-responders LARC patients, as well as sex-related differences. This study is ongoing and further analyses will clarify the importance of these biomarkers.

EACR25-1069

Sex-Based Differences in Colorectal Cancer Patients: a Multi-Omics Perspective on Primary and Surrogate Tissues

⁸University of Turin, Department of Clinical and Biological Sciences, Italy

Introduction

Colorectal cancer (CRC) stands out as a global health challenge, ranking as the third most common cancer and the second in mortality worldwide. Studies on microRNA (miRNA) and metabolite profiles in human feces and plasma offer promising insights into physiological and pathological conditions and some of them show sex-dependent expression patterns. However, an extensive evaluation of such patterns in relation to CRC is lacking. In addition, the emerging concept of a 'sex hormone-gut microbiome axis' further suggests that sex-specific variations in gut microbiota composition may contribute to differential cancer susceptibility. This study investigates the sex-specific variations between CRC patients and healthy individuals by integrative analysis of fecal miRNA and metagenome profiles and plasma metabolome.

Material and method

Multi-omic profiles (transcriptome and metagenome) from fecal samples of 335 healthy individuals ($F = 213$, $M = 142$) and 332 CRC/adenoma patients ($F = 132$, $M = 200$) from four different European cohorts were analyzed. Plasma metabolomic data from two of these cohorts were also available. In addition, miRNA and gene expression data from tumor/adenoma tissues matched with adjacent mucosa ($n=154$) were integrated. Public data from Roadmap Epigenome Project, GTEx, curated MetagenomicData, and GEO were also integrated.

Result and discussion

Significant sex-based differences in fecal miRNA expression and microbiome composition were observed in healthy subjects and CRC patients. Distinct patterns were also identified in circulating metabolites that correlated with sex-specific disease manifestation. Specifically, 7 fecal miRNAs, 15 microbial species, and 11 circulating metabolites showed significantly different levels among healthy men and women under 50 years (adj. $p < 0.05$). Moreover, 37 miRNAs, 8 bacteria and one circulating metabolite were observed to be

differential expressed between healthy women stratified by age, including *Phocaeicola massiliensis*, acylcarnitine 13:0 and miR-200b-3p, a well-known CRC-related miRNA, whose levels were increased in young women with respect to both men and postmenopausal women. In CRC patients, 43 fecal miRNAs, 15 microbial species, and 4 circulating metabolites were associated with different levels in men compared to women (adj. $p < 0.05$). Of interest, miR-200b-3p was downregulated in CRC females compared to CRC males though without any significant evidence.

Conclusion

This study provides evidence of putative sex-based differences in molecular and microbial profiles associated with CRC. Further investigation is currently ongoing to fully elucidate the interaction between specific miRNAs, bacterial communities and metabolites, particularly focusing on the role of estrogens in female subjects. Understanding these sex-specific differences could have important implications for early cancer detection and personalized treatment approaches.

EACR25-1089

Expression of the BMP antagonist Noggin in gastric cancer clinical cohort and its association with drug treatment

M. Alamri¹, W. Jiang¹, L. Ye¹

¹Cardiff University, Cancer and genetics, Cardiff, United Kingdom

Introduction

Noggin is a secreted antagonist that regulates bone morphogenetic protein (BMP) signalling. Our recent study showed that Noggin promoted the proliferation of gastric cancer cells through upregulation of EGFR. Together with the profound role played by BMPs in stomach development and gastric cancer, further study of their therapeutic potential is provoked. In the present study, we aimed to explore the impact of Noggin on patients' responses to neoadjuvant chemotherapy and to investigate cancer cells' responses to chemotherapy drugs *in vitro*.

Material and method

The transcript level of Noggin was examined in a clinical cohort comprising tumour tissue and paired adjacent normal gastric tissue from patients who underwent neoadjuvant chemotherapy, utilising real-time PCR. Overexpression and knockdown of NOG in gastric cancer cell lines were conducted using lentiviral vectors. The expression of the NOG gene was confirmed at the mRNA and protein levels. Different chemotherapy drugs, including 5-fluorouracil, Oxaliplatin, Docetaxel and Ebirubucin, were tested to examine Noggin's impact on the drug response.

Result and discussion

Noggin transcript levels were higher in normal adjacent tissues ($n = 86$, median = 162.2), $p < 0.001$ compared to its expression (median = 21.9) in tumour tissues ($n = 87$). Higher levels of Noggin expression appeared to be associated with short overall survival (OS), with a log rank $p = 0.095$. A multivariate analysis revealed that Noggin, EGFR and HER4 were associated with poor response to the neoadjuvant chemotherapy. Interestingly,

further analysis showed that higher Noggin expression was significantly associated with poor OS in those patients with HER2 low expression tumours ($p = 0.039$). Overexpression of Noggin in AGS cells presented a good response to Docetaxel and Oxaliplatin similar to the control, but remarkably less responsive to the treatment with 5-Fu.

Conclusion

Higher expression of Noggin in gastric cancer was associated with poor response to neoadjuvant chemotherapy and also shorter OS in those patients with HER2-negative tumours. Overexpression of Noggin resulted in a resistance to 5-Fu.

EACR25-1091

AKT3 as a candidate biomarker of platinum response in epithelial ovarian cancers

E. Azzalini¹, D. Tierno¹, S. Romano¹, V. La Fauci¹, A. Baldutti², R. Bulla², S. Bonin¹

¹*University of Trieste, Department of Medical Sciences, Trieste, Italy*

²*University of Trieste, Department of Life Sciences, Trieste, Italy*

Introduction

Globally, ovarian cancer represents the 8th most common cancer in women. The standard treatment involves surgical intervention, followed by platinum- and taxane-based chemotherapy. However, patients typically relapse and succumb to the disease within 5 years from diagnosis. A significant advancement in patients' survival has been observed with the integration of PARPi into clinical practice. However, the absence of biomarkers to predict platinum response remains a limitation, as platinum sensitivity is a crucial criterion for determining patients' eligibility for PARP maintenance therapy. AKT isoforms (AKT1, AKT2, AKT3) are emerging as interesting prognostic markers and potential targets in EOC due to their distinct roles in cancer biology. In this study we examined the expression of these isoforms at the mRNA level in relation to cisplatin resistance in 11 EOC cell lines of different histotypes.

Material and method

EOC cell lines were cultured in 96 well plates and exposed to cisplatin (range 5–160 μ M) for 24 hours. Thereafter, the cell viability was evaluated by the Presto Blue method, and the IC₅₀ was subsequently determined. From each cell line, RNA was extracted, and the expression levels of AKT isoforms were evaluated through RT-ddPCR. Cell lines genomic data were retrieved from the CCLE database and HRD status determined based on the presence of mutations in genes that confer a Genomic Instability Score (GIS) > 42 (Barnicle A. et al. *Genome Med.* 2024 Dec 18;16:145).

Result and discussion

The results demonstrated that AKT1 and AKT2 exhibited no correlation with cisplatin response, while AKT3 exhibited a strong linear correlation with IC₅₀ values ($R^2 = 0.72$; $p = 0.001$), suggesting an isoform-specific role for AKT3 in mediating cisplatin resistance. AKT1 and AKT2 were overexpressed in HGSC cell lines, while AKT3 expression remained consistent across different histotypes, showcasing its potential as a biomarker for

platinum response in all EOC. Furthermore, AKT3 was significantly under-expressed in HRD cell lines compared to HRP ($p = 0.01$), suggesting its potential as a biomarker not only for platinum resistance but also as a surrogate for HR status.

Conclusion

This study has identified AKT3 as a promising biomarker capable of predicting response to platinum and PARPi therapy. It may also represent a new and targetable molecule for patients resistant to chemotherapy, who have limited treatment options and a poor prognosis.

EACR25-1131

Development of tumor-specific EV-miRNA signatures to improve lung cancer early detection (EV-miR-Test)

A. Saponaro^{1,2}, V. Manuti¹, E. Murgo¹, G. Savino², M. Marasco², T. Colangelo^{2,1}

¹*Cancer Cell Signaling Unit, IRCCS Fondazione Casa Sollievo della Sofferenza, ISBReMIT - Istituto Di Medicina Rigenerativa, San Giovanni Rotondo (FG), Italy*

²*C.R.E.A.T.E. - Center for Research and Innovation in Medicine, Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy*

Introduction

Lung cancer (LC) is the deadliest cancer worldwide, causing ~2 million deaths annually. The two primary subtypes are non-small-cell lung cancer (NSCLC, ~85%) and small-cell lung cancer (SCLC, ~15%). Due to late-stage diagnoses and the lack of effective early screening, LC has a low 5-year survival rate of less than 15%. Liquid biopsies have emerged as a promising, non-invasive alternative to tissue biopsies, analyzing circulating tumor cells (CTCs), cell-free DNA (cfDNA), and extracellular vesicles (EVs) in bodily fluids. EVs, abundant and stable carriers of molecular cargos like microRNAs (miRNAs), are critical for understanding cancer biology as they regulate cancer development, progression, and resistance to therapies. Additionally, cell-free miRNAs (cf-miRNAs) are highly stable and tissue-specific, making them promising candidates for LC diagnosis and prognosis.

Material and method

To identify a tumor-specific EV-miRNA signature, a global miRNA expression profiling was performed on early-stage NSCLC patients' plasma samples compared to healthy controls. EVs were isolated using ultracentrifugation and immunoaffinity beads, followed by characterization via Nanoparticle Tracking Analysis and Immunoblotting. Epithelial cell-specific EVs (EP-EVs), enriched for EpCAM+ markers, were captured using an EpCAM antibody. This profiling method was extended to compare miRNA signatures in tumor and normal lung cells, further distinguishing epithelial-origin (EP-EV-miRNAs) from inflammatory-origin (TME-EV-miRNAs). Tumor-specific EV-miR signature was validated through Calibration, Validation, and Clinical groups, while functional assays investigated EV-miRNAs roles in NSCLC cell proliferation, migration and invasion.

Result and discussion

A new EV-miRNA signature was identified, distinguishing LC patients from healthy individuals. The origin of LC-derived EV-miRs (epithelial vs. inflammatory) was elucidated. The analysis of the functional role of EP-EV-miRs and TME-EV-miRs in NSCLC provided insights into their involvement in cancer progression, revealing that dysregulated EV-miRNAs enhanced cell proliferation and invasion in NSCLC cell lines compared to controls.

Conclusion

EV-miRNA could serve as non-invasive biomarkers for monitoring LC progression over time. Developing an accurate, tumor-specific EV-miR Test may reduce false positives in NSCLC screening and refine risk assessment, especially for individuals selected for LDCT screening. Clarifying EV-miRNA origins and functions could lead to an effective early detection test for NSCLC, improving diagnosis, survival rates, and treatment outcomes while potentially lowering healthcare costs.

EACR25-1189

Unraveling the Impact of Genetic Ancestry on Breast Cancer Neoadjuvant Chemotherapy Response: A Comprehensive Analysis

M. Guevara-Nieto¹, C. Orozco-Castaño², R. Parra-Medina³, J. Zabaleta⁴, L. Lopez-Kleine⁵, A. Combita⁶

¹*Instituto Nacional de Cancerología, Cancer Biology / Translational Oncology, Bogota, Colombia*

²*Instituto Nacional de Cancerología, Cancer Biology Research Group, Bogota, Colombia*

⁴*Louisiana State University Health Science Center, Interdisciplinary Oncology, New Orleans, United States*

⁵*Universidad Nacional de Colombia, Statistics, Bogota, Colombia*

⁶*Instituto Nacional de Cancerología, Translational Oncology, Bogota, Colombia*

Introduction

Breast cancer (BC) presents a public health challenge, particularly with low response rates to neoadjuvant chemotherapy (NAC). Colombia's diverse lineage includes indigenous American (IA), European, and African American (AA) ancestries. Genetic ancestry influences gene expression related to tumor risk, progression and drug metabolism. However, the impact of ancestry on NAC response is unclear. This study aimed to predict NAC effectiveness by exploring gene expression patterns, genetic ancestry, and survival factors linked to NAC non-response in Colombian women with invasive BC.

Material and method

An integrative transcriptome, and survival analysis was conducted on 144 samples of BC female patients belonging to Colombian NCI population and candidates for NAC. Patients either responded or did not respond to NAC. To estimate genetic ancestry, genotyping of 106 ancestry informative markers was performed from non-tumoral DNA. Molecular intrinsic subtypes were classified into Luminal A, LuminalB/Her2+, LuminalB/

Her2+, HER2 enriched, and TNBC. Further prognostic validation was conducted in other cohorts. Analyses were performed comparing ancestry as a covariate in differential expression model.

Result and discussion

Non-responders had a higher proportion of advanced tumors and significantly lower survival rates than responders. Subtype-specific variations in European and Indigenous American ancestry proportions were associated with treatment response. Non-responders in Luminal B displayed higher IA ancestry. Subtype grouping with ancestry as a covariate revealed distinct transcriptional profiles and pathway activation patterns, particularly in HER2-enriched and Luminal A subtypes, suggesting the molecular mechanisms of chemotherapy resistance. Key oncogenic differentially expressed genes (DEGs) were identified, including FGF10 and WT1 in Luminal A and HLF in Luminal B/HER2-positive patients. Prognostic validation confirmed the relevance of DEGs, such as WT1, CLEC3A, PRRC1, and TPD52, in BC. Higher levels of IA ancestry were associated with varying survival trends across subtypes. This highlights the prognostic significance of tumor stage, identifies distinct pathway activation patterns associated with chemotherapy resistance and genetic ancestry, and identifies subtype-specific oncogenic DEGs.

Conclusion

This study provides valuable insights into chemotherapy response in Colombian BC patients by integrating clinical, genetic ancestry, and molecular data. This study underscores the importance of examining diverse populations to gain new insights and reduce disparities in BC treatment outcomes. This study stresses the importance of tailored treatment approaches and calls for additional validation through larger studies involving multiple ancestries as well as functional research to enhance precision oncology efforts across diverse groups.

EACR25-1212

Predicting Second-Line Chemotherapy Outcome in Advanced Pancreatic Cancer: A Machine Learning Approach Using PBMC-Based Biomarkers - Translational Findings from the PREDICT Trial

A. Lahusen¹, M. Lutz², M. Karthaus³, P. Fung-Yi⁴, M. Kirchner⁵, A. Tannapfel⁶, A. Stenzinger⁵, T. Eiseler¹, S. Räth⁷, T. Seufferlein¹

⁴*University Hospital Essen, Bridge Institute for Experimental Tumor Therapy, Essen, Germany*

⁵*University Hospital Heidelberg, Molekularpathologisches Zentrum, Heidelberg, Germany*

⁶*Ruhr-Universität Bochum, Institute of Pathology, Bochum, Germany*

⁷*AIO-Studien-gGmbH, Berlin, Germany*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest cancers, especially in advanced stages. The PREDICT trial (NCT03468335), a phase IIIb/IV study, aimed to predict second-line treatment success for advanced PDAC (aPDAC) using clinical data profiles. This translational research explored how first-line chemotherapy (CTX) response could predict second-line CTX outcome, using PBMC-based liquid biomarkers and machine learning (ML).

Material and method

The study stratified patients into two groups based on short or long second-line CTX (Nal-IRI/5-FU/FA) time to treatment failure (S-/L-TTF2; n = 10 each) after Gem-nabPac first-line CTX. RNA profiling of microdissected PDAC tissue used NanoString™ PanCancer IO360. Differentially regulated genes guided PBMC screening from second-line CTX-naïve patients at protein (flow cytometry, FC) or RNA (RT-qPCR) levels. FC data underwent R-based single-cell clustering with ML-based back-gating of most differential clusters (HyperGates, HGs). Classical ManualGates (MGs) were also created. Feature selection used Weka-based WrapperSubsetEval with eight classifiers. The best-performing classifier/ subset was used for binary classification (S-/L-TTF2 and S-/L-OS) on training (n = 66) and validation (n = 16) PREDICT datasets. This subset was further validated in an external (n = 30) cohort with different first-line and second-line treatment regimens.

Result and discussion

Transcriptome analysis revealed increased inflammation, immune cell activation/infiltration (e.g. activated CD8 T cells), and immune exhaustion in L-TTF2 compared to S-TTF2 tumors. Therefore, circulating PBMCs from second-line CTX-naïve aPDAC patients were screened. Analysis of eight FC panels (19 candidates) revealed 1198 differential clusters with corresponding HGs and 881 MGs. Feature selection, combining FC with RT-qPCR results and clinical parameters, identified a best performing minimal predictive signature (TTF2Pred) of 5 HGs and 2 MGs for 7 PBMC surface protein markers (CXCR4, CD8, CD4, CD62P, CD307b, CD45, CD121b). ML using kernel logistic regression successfully predicted S- and L-TTF2 binary groups (ROC-AUC > 0.90 and accuracy > 87% for training/validation). Further, TTF2Pred showed prognostic value for S- and L-OS binary class prediction (ROC-AUC = 0.80, accuracy = 75%). External validation confirmed performance, revealing highest specificity (Score = 0.96) for patients receiving first-line Gem-nabPac CTX (ROC-AUC = 0.86, Accuracy = 90%).

Conclusion

This study identified a favorable tumor immune micro-environment in L-TTF2 aPDAC patients, characterized by CD8 T cell-inflamed ("hot") tumor tissues prior to second-line CTX. A 7-marker circulating PBMC-based liquid biomarker panel was developed for early prediction of second-line CTX success after first-line Gem-nabPac CTX in aPDAC patients. These findings aim to advance personalized treatment strategies for aPDAC patients.

EACR25-1235

Exploring cfDNA copy number profiles to characterize disease stages in pancreatic adenocarcinoma

L. Abreu de Carvalho¹, N. Vandenbussche², G. Wieme², B. Parton², B. Lintermans², S. Ribeiro³, A. Hoorens⁴, K. Geboes³, F. Berrevoet¹, K. Claes²

¹Ghent University Hospital, Department of General and Hepato-Pancreat-Biliary Surgery and Liver Transplantation, Ghent, Belgium

²Ghent University Hospital, Ghent University, Center for Medical Genetics Ghent, Department of Biomolecular Medicine, Ghent, Belgium

³Ghent University Hospital, Department of Gastroenterology, Ghent, Belgium

⁴Ghent University Hospital, Department of Pathology, Ghent, Belgium

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer-related mortality due to its aggressive biology and late-stage diagnosis. Surgery offers the only chance of cure, yet early recurrence by undetected systemic disease often undermines its benefit. Additional biomarkers are needed to improve prognostication and guide treatment strategies. Circulating tumor DNA (ctDNA) offers a non-invasive method of disease characterization. This study investigates circulating free DNA (cfDNA) copy number profiles across PDAC stages using shallow whole genome sequencing (sWGS).

Material and method

We analyzed 121 cfDNA samples from 54 PDAC patients using sWGS. Copy number profile abnormality (CPA) scores were determined using WISECONDOR, and tumor fractions (TF) were assessed with ichorCNA. We evaluated the ability of these markers to distinguish between resectable, borderline/locally advanced, and metastatic PDAC, comparing their performance to CA19-9 levels and imaging.

Result and discussion

Patients with resectable tumors (n = 27) exhibited significantly lower CPA scores (0.65 ± 0.35 vs 3.47 ± 1.7 ; $p < 0.0001$) and TF ($3.6 \pm 1.9\%$ vs $15.1 \pm 8.0\%$; $p = 0.0002$) compared to those with metastatic disease (n = 8). Patients with borderline/locally advanced tumors (n = 13) and those found to have early metastatic disease diagnosed during exploratory surgery (n = 6) had CPA (0.61 ± 0.21) and TF ($3.3 \pm 1.1\%$) values similar to resectable cases. Both markers showed no clear correlation with CA19-9 but, in some patients, discriminated better between disease stages than CA19-9.

Conclusion

sWGS of cfDNA offers a cost-effective, non-invasive tool that identifies patients with metastasized PDAC and may serve as a complement to CA19-9 and imaging for disease characterization. In this small cohort, markers could not predict unresectability. Further investigations are underway to determine whether specific genomic alterations correlate with prognosis and could aid in detecting early metastatic disease.

EACR25-1236**Elevated monocyte-lymphocyte ratio as a prognostic and predictive biomarker of poor response to radio-immunotherapy in advanced cancer: correlation with immune and metabolic dysregulation**

D. Morel¹, A. Levy¹, L. Bouarroudj¹, R. Sun¹, C. Massard¹, Y. Loriot¹, E. Deutsch¹

¹Gustave Roussy, Villejuif, France

Introduction

Growing evidence indicates that the myeloid/lymphoid imbalance plays a pivotal role in the polarization (pro- or anti-tumor) of the immune response following radiation therapy (RT). The monocyte-lymphocyte ratio (MLR) – determined from routine blood count – is a readily accessible inflammatory biomarker that has exhibited promising efficacy in predicting the response to immunotherapy, but its clinical adoption is hindered by its apparent lack of specificity.

Material and method

We prospectively collected sequential paired tumor and blood samples from pan-cancer patients treated in two clinical trials (SABR-PDL1 NCT02992912; ABIMMUNE NCT03212469) that evaluated combinations of immunotherapy with concomitant RT. Samples were obtained i) at baseline, ii) after the start of immunotherapy, before RT, and iii) after RT. Patients from the SABR-PDL1 trial were divided into two cohorts: Discovery and Validation #1. ABIMMUNE was used as a second, independent, Validation cohort (#2). The Discovery cohort was subjected to a comprehensive integrative analysis that encompassed RNA sequencing of biopsies, as well as proteomic and metabolomic analysis of paired serums.

Result and discussion

We collected sequential blood and/or tumor data from N = 182 patients (Discovery N = 55; #1 N = 80; #2 N = 47). We confirmed that the baseline MLR was predictive of treatment response in the Discovery cohort with an AUC = 0.68 (P = 0.0029). A baseline MLR threshold of 0.75 effectively identified patients at risk for reduced PFS (log-rank Hazard Ratio (HR) = 2.6, 95% CI [1.1-6.2]; Pval = 0.0014) and OS (HR 4.2, 95% CI [1.3-13.0]; Pval < 0.0001). Unresponsive patients had a significant increase of MLR after radiotherapy (p = 0.0009, compared to baseline). Using the 0.75 threshold in Validation cohorts #1 and #2, we confirmed the predictive value of baseline MLR for PFS (#1: HR 1.9, 95% CI [1.1-3.4]; Pval = 0.0054; #2: HR 2.7, 95% CI [1.2-6.1]; Pval = 0.0017) and OS (#1: HR 2.9, 95% CI [1.5-5.7]; Pval < 0.0001; #2: HR 3.1, 95% CI [1.5-6.7]; Pval = 0.0004). An elevated MLR was linked to tumor dysregulations in pathways involved in inflammatory response, myeloid differentiation, lymphocyte activation and metabolism, including bile acid and fatty acid metabolisms. The proteomic analysis of serums showed that the MLR correlated with >30 inflammation-related chemokines, among which CXCL8, TGFA, TGFB1, FSTL3 and CCL23 (all p < 0.0001). The MLR strongly correlated with circulating IL6 (p < 0.0001) and CSF1 (p < 0.0001). Last, the MLR reliably reflected the

significant dysregulations characterizing unresponsive patients regarding circulating metabolites: tryptophan derivatives, bile acids and carnitine metabolites.

Conclusion

In advanced cancer, the MLR is strongly linked to a detrimental inflammation-based loop that feeds a tumorigenic myelopoiesis with the sustained production of IL6, CSF1 and suppressive metabolites. A baseline MLR > 0.75 is predictive of pan-cancer poor prognosis.

Introduction

Colorectal cancer (CRC) develops over a long time, often arising from precursor lesions which can progress to malignancy. While genetic aberrations driving to CRC are well-known, alterations in microRNA (miRNA) expression within these precursor lesions are less explored, despite their potential as biomarkers. Using transcriptomic data, we aimed to provide a comprehensive characterization of the miRNA profiles in tissue from non-advanced (nAA) and advanced (AA) adenoma and matched adjacent mucosa samples. We also investigated whether the identified tissue altered profiles are reflected in stool miRNA levels, which can represent non-invasive biomarkers for cancer prevention.

Material and method

RNA-seq and sRNA-seq were performed in adenomas tissues (nAA = 20, AA = 30) and adjacent mucosa collected at colonoscopy in a cross-sectional study. sRNA-seq was also performed in stool from the same patients and from colonoscopy-negative controls (n = 87). Paired differential expression (DE) analyses were performed comparing nAA and AA to their adjacent mucosa to identify subtype-specific alterations at miRNA (DEMs) and gene (DEGs) level. Correlations analyses were performed between the expression levels of DEMs and their validated targets, as well as functional enrichment analyses. Samples from an additional cohort recruited in the CRC screening program (nAA = 29, AA = 80 and controls = 54) will be analyzed to validate findings.

Result and discussion

In adenoma tissues, 647 miRNAs were detected, while 345 were identified in stool samples, with 116 of them detected in both biospecimens. DE analyses revealed 112 miRNAs and 1,803 genes commonly dysregulated across adenoma subtypes. Compared to nAA, which showed 33 DEMs and 547 DEGs, AA showed a higher

dysregulation, with 162 DEMs and 1,950 DEGs, mainly upregulated. Functional miRNA enrichment analyses highlighted dysregulation in several pathways, including inflammatory response, G2M checkpoint inhibition and EMT programs. A set of genes related to these pathways and targeted by upregulated miRNAs was found to be downregulated in AA tissues. In stool samples 60 miRNAs were uniquely DE in AA, while 47 were specific to nAA. However, 28 miRNAs were commonly altered in both subtypes with seven showing a progressive dysregulation from healthy to nAA and AA. Hierarchical clustering on nAA-DEMs in stool identified two distinct clusters of patients reflecting the adenoma subtype. Finally, in AA, four miRNAs were dysregulated in both tissue and stool samples, particularly miR-10a-3p resulted constantly upregulated, respectively compared to adjacent mucosa and stool of healthy individuals.

Conclusion

The miRNA landscape of precancerous lesions reflects the heterogeneity between nAA and AA, both in tissues and stool samples. Further analyses will refine our characterization, focusing on other features of adenomas, such as villosity and dysplasia.

EACR25-1284

Differential protein expression in platelets collected from glioma patients and healthy controls: A Comparative Study

⁴Haukeland University Hospital, Neurosurgical, Bergen, Norway

⁵University of Bergen, Biomedisin. Proteomics., Bergen, Norway

⁶Haukeland University Hospital, Oncology, Bergen, Norway

⁷University of Bergen, Biomedicine, Bergen, Norway

Introduction

Glioblastoma (GBM) is the most aggressive and most common type of primary brain tumor in adults. Standard multimodal treatment fosters event free survival for approximately 7 months and extends overall survival (OS) to only 15 months. Due to the risk of biopsy complications, the histology verification of the tumor is not always possible. Therefore, in many cases the treatment is based on MRI findings and exclusion of other malignancy in CAT. A confirmative liquid biopsy would provide additional and useful support for clinical decision making and patient counselling. To date no liquid biopsy for GBM is available. Platelets interact with tumor cells in multiple ways, including direct contact, release of cytokines, and uptake of tumor-derived extracellular vesicles (EVs). These interactions cause modifications in platelet RNA and protein profiles, yielding tumor educated platelets (TEPs) that reflect specific tumor characteristics. Our study aim to use proteomic analysis to identify differential protein expression in platelets collected from glioma patients

compared to healthy controls, identifying potential biomarkers for glioma diagnosis and therapeutic monitoring

Material and method

Platelet samples were collected from 14 glioma patients and 14 matching healthy controls. Platelets were isolated using differential centrifugation to minimize contamination with other blood components. Protein extraction and quantification were performed, followed by analysis using mass spectrometry-based proteomics. Protein identification and quantification were conducted with Label-Free Quantification (LFQ-DIA) techniques, and differentially expressed proteins were statistically validated. Bioinformatic tools were employed to analyze pathways and functional annotations related to identified proteins.

Result and discussion

Out of the 3,444 proteins identified and quantified, 463 were differentially expressed between glioma patient platelets and those from healthy controls. Reactome Pathway analysis, gene ontology enrichment, and protein-protein interaction studies revealed that these proteins are involved in key pathways, including vesicle-mediated transport, Cyclin B: Cdk1 complex inactivation, apoptosis, lipid metabolism, cell cycle regulation, glutathione synthesis and recycling, platelet activation, signaling, aggregation, and overall signal transduction.

Conclusion

The study identifies a distinct proteomic profile in platelets from glioma patients compared to healthy individuals, suggesting that platelets in glioma may harbor unique proteins characteristics related to tumor biology. These findings support the potential of platelets as a source of biomarkers for glioma detection, confirmation of diagnosis and monitoring. Future studies with larger cohorts are warranted to validate these proteins as diagnostic markers and explore their mechanistic roles in glioma progression.

EACR25-1357

Investigation of miRNAs expression in Bulgarian patients with early-stage and advanced laryngeal cancer as a prognostic biomarker

G. Stancheva¹, V. Petkova¹, S. Kyurkchiyan²,

L. Dimitrov³, D. Popova⁴, R. Kaneva¹, T. Popov³

⁴Medical University of Sofia, Department of Ear-Nose and Throat/Clinic of Ear- Nose and Throat, UMHAT "Tsarica Yoanna-ISUL", Sofia, Bulgaria

Introduction

Laryngeal squamous cell carcinoma (LSCC) is an aggressive malignancy with poor prognosis, which despite modern treatment protocols, novel molecular markers are required to improve survival. miRNAs, small

non-coding RNAs, are involved in various pathological processes, as well as hypoxia. The aim of the study was to investigate the expression levels, discriminative pattern and correlation between hypoxic miRNAs as a biomarker in plasma distinguishing early stage from advanced laryngeal carcinoma.

Material and method

The expression of miR-144-3p, a hypoxia-related miRNA, was evaluated in 20 early-stage tumours and corresponding normal laryngeal samples, whereas miR-31-3p and miR-196a were evaluated in 20 early-stage plasma samples compared with plasma samples from healthy persons by quantitative real-time polymerase chain reaction (qRT-PCR) analysis. Total RNA isolation, reverse transcription and real-time qPCR were performed with miRNeasy kit, TaqMan™ MicroRNA Reverse Transcription Kit, and TaqMan™ Gene Expression Assay (Applied Biosystems). SPSS v19 (IBM) was used in statistical analysis, and p-value less than 0.05 was taken as significant.

Result and discussion

In the current study, we observed increased expression levels of tumor suppressor gene miR-144-3p (44%, p=0.01) in tumor tissue in comparison with paired normal tissue. In advanced laryngeal tumours, data showed in previous study, miR-144-3p was significantly dysregulated in peritumor mucosa with a pattern of expression consistent with paired tumor samples thus revealing a signature of field cancerization. In early-stage laryngeal tumours (T1, T2) miR-144-3p expression did not reveal such association. Investigation of miR-31-3p and miR-196a expression levels in plasma samples revealed a significant dysregulation of miR-31-3p (69.1% overexpressed, p=0.01) compared to levels of healthy peoples. The ROC curve analysis showed that miR-31-3p can distinguish group of patients with laryngeal tumor from healthy peoples with sensitivity of 66.7% and specificity of 72.2% (AUC = 0.706; 95% CI: 0.523-0.888; p = 0.045) whereas miR-196a did not.

Conclusion

The current findings suggest that miR-31-3p potentially could take a key role as a noninvasive biomarker not only in advanced but in early-stage laryngeal cancer as well. These results may contribute to future studies on elucidating the mechanisms of contribution of hypoxic miRNAs to LSCC.

⁶Cancer Genomics & Systems Biology Lab, Biotecnologie Mediche, University of Siena, Si, Italy

Introduction

Cancer remains the second leading cause of mortality worldwide, emphasizing the urgent need for non-invasive methods to rapidly characterize tumor profiles and monitor treatment responses. Whole-exome sequencing (WES) of cell-free DNA (cfDNA) via liquid biopsy has emerged as a powerful approach to detecting clinically relevant genetic alterations and identifying novel biomarkers associated with therapeutic resistance. This study leverages WES of cfDNA in patients with advanced metastatic cancers to explore its potential in personalized oncology.

Material and method

cfDNA was extracted from 72 samples of 53 patients diagnosed with metastatic cancers across 11 distinct histological subtypes. The samples were prepared using the Illumina® Cell-Free DNA Prep Kit and sequenced on the NovaSeq Xplus platform, achieving sequencing coverage between 163X and 485X. Secondary analysis was conducted using Illumina Connected Analytics®, while variant annotation was performed using Illumina Connected Insights® software. Only clonal mutations with a variant allele frequency (VAF) above 1% were considered, and germline variants (MAF > 1%) were excluded. Variants with allele frequencies between 40-60% or > 95% were classified as "putative germline." To evaluate treatment response over time, longitudinal sampling was conducted in selected patients.

Result and discussion

cfDNA extraction yielded an average input of 119 ng (range: 7.26-792 ng). To date, 35 samples, at different timepoints, from 20 patients have undergone WES analysis, revealing 330 likely pathogenic/pathogenic variants across 230 genes, with an average of nine mutations per sample. The identified mutations provided insights into the aggressive progression observed in these patients. Notably, 14 patients were longitudinally monitored, enabling the correlation of cfDNA-derived mutation profiles with imaging-based assessments of treatment response. In these cases, liquid biopsy results demonstrated evolving mutational landscapes that aligned with either tumor progression or regression. The ability to track these genetic changes in real-time underscores the value of cfDNA WES in precision oncology.

Conclusion

This study highlights the potential of WES of cfDNA as a robust tool for detecting key genetic alterations in metastatic cancers and dynamically monitoring tumor evolution. The identification of driver mutations and resistance-associated alterations provides critical insights that can guide therapeutic decision-making. By facilitating a deeper understanding of cancer biology, this approach supports the development of more targeted and

effective treatments for metastatic patients, ultimately advancing personalized oncology strategies.

Establishing a plasma protein signature for clear cell renal cell carcinoma

H. Lakshminarayanan¹, D. Rutishauser¹, P. Schraml¹, H. Bolck¹, H. Moch^{1,2}

¹University Hospital and University of Zurich,
Department of Pathology and Molecular Pathology,
Zurich, Switzerland

²University Hospital Zurich, Department of Pathology
and Molecular Pathology, Zurich, Switzerland

Introduction

Clear cell renal cell carcinoma (ccRCC) is the most lethal urological malignancy, with 30% of patients presenting with de novo metastasis in the clinic and an additional 30% further developing recurrent metastasis during disease progression. Current diagnostic and prognostic methods rely primarily on histopathological characterization, which limits early detection and intervention for recurrent metastasis.

Material and method

This study employs liquid biopsy to enhance prognostication and clinical management of ccRCC patients across two sub-cohorts to identify biomarkers for localized and metastatic ccRCC, utilizing longitudinal plasma proteomics. We collected plasma samples from ccRCC patients before surgery (PRE-OP), after surgery (POST-OP), and at longitudinal follow-up time points. Using data-independent mass spectrometry, we analyzed the depleted plasma samples to identify biomarker candidates. Next, we employed network analysis to identify protein modules potentially contributing to the disease phenotype. Finally, we assessed the utility of our candidate proteins as biomarkers.

Result and discussion

Our network analysis approach identified protein modules enriched in matrix remodeling and metabolic dysregulation pathways, perpetuating the ccRCC phenotype. First, we identified five proteins involved in angiogenic and immune responses as biomarker candidates for localized ccRCC. These proteins demonstrated high diagnostic performance, discriminating pre-operative samples from post-operative samples in our localized cohort. Next, we identified six proteins previously implicated in cancer metastasis as biomarker candidates for metastatic ccRCC. These candidates effectively distinguished metastatic from high-grade non-metastatic ccRCC patient plasma samples in our cohort.

Conclusion

These findings underscore the utility of plasma proteomics in biomarker discovery. Further validation of these signatures could inform clinical decision-making, enabling early detection and real-time longitudinal monitoring for ccRCC patients.

EACR25-1397

Novel Blood-Based mRNA Biomarkers: A Promising Approach for Non-Invasive Colorectal Cancer Screening

M. Eiras¹, D. Pinto¹, D. Santos¹, J. Soares², M. Gonzalez Santos¹, L. Santos¹, M. Dinis Ribeiro³, L. Lima¹

¹Research Center of IPO Porto (CI-IPOP), Portuguese Oncology Institute of Porto, Experimental Pathology and Therapeutics Group, Porto, Portugal

²Research Center of IPO Porto (CI-IPOP), Portuguese Oncology Institute of Porto, Experimental Pathology and Therapeutics Group, Porto, Portugal

³Research Center of IPO Porto (CI-IPOP), Portuguese Oncology Institute of Porto, Precancerous Lesions & Early Cancer Management Group, Porto, Portugal

Introduction

Colorectal cancer (CRC) is the third most common cancer globally and the second leading cause of cancer-related deaths. Despite advancements in screening, the preferred non-invasive method, the Fecal Immunochemical Test (FIT), has significant limitations, particularly its low sensitivity for detecting pre-cancerous lesions and high false-positive rates. Colonoscopy, while the gold standard for diagnosis, is invasive, costly, and often associated with low patient adherence. Blood-based biomarkers offer a promising alternative, as they provide a minimally invasive approach that could enhance patient compliance and improve early CRC detection. Therefore, there is an urgent need for more accurate and reliable blood-based biomarkers to optimize screening strategies and reduce CRC-related mortality. This study evaluates the clinical potential of mRNA biomarkers in blood-based samples, including plasma and peripheral blood mononuclear cells (PBMCs), for enhancing CRC screening.

Material and method

Following RNA-sequencing analysis and literature review, three mRNA targets – CEACAM6, PRDX6, and NAA60 – were selected for evaluation. PRDX6 and NAA60 were assessed in RNA extracted from PBMCs of 100 individuals, while all three genes were analyzed in plasma RNA samples from 80 individuals who underwent screening colonoscopy. Expression levels were measured using real-time PCR with TaqMan probes.

Result and discussion

All three biomarkers exhibited differential expression across clinical groups. In plasma, CEACAM6 and PRDX6 effectively discriminated CRC lesions, with CEACAM6 achieving an AUC of 0.82 (sensitivity: 89%, specificity: 75%) and PRDX6 an AUC of 0.76 (sensitivity: 63%, specificity: 93%). NAA60 demonstrated strong performance in detecting high-grade dysplasia (HGD) lesions (AUC: 0.73, sensitivity: 81%, specificity: 67%). Notably, CEACAM6 outperformed FIT in CRC detection, while NAA60 surpassed FIT in detecting advanced adenomas. Similarly, in PBMCs, NAA60 distinguished HGD from non-lesion (NL) samples (AUC: 0.83, sensitivity: 88%, specificity: 70%) and exhibited strong discrimination between samples from individuals where non-relevant findings were present in the colonoscopy (no lesions and low-grade dysplasia) and advanced lesions (HGD and CRC) (AUC: 0.78, sensitivity: 92%, specificity: 57%).

Conclusion

These preliminary findings highlight the potential of CEACAM6, PRDX6, and NAA60 as promising blood-based biomarkers for CRC screening. NAA60, in particular, demonstrated a strong performance in

distinguishing advanced precancerous lesions and cancer, making a good candidate for CRC screening. However, further validation in larger, independent cohorts is essential to confirm these findings. Additionally, future studies should explore the combination of these biomarkers to improve overall diagnostic accuracy and optimize non-invasive CRC screening strategies.

EACR25-1404

Aberrant miRNA expression in papillary thyroid carcinoma— clinical applications

N. Mehterov¹, M. Gevezova¹, B. Nonchev², A. Sacconi³, G. Blandino⁴, V. Sarafian¹

¹*Medical University-Plovdiv, Department of Medical Biology, Plovdiv, Bulgaria*

²*Medical University-Plovdiv, Department of Endocrinology and Metabolic Diseases, Plovdiv, Bulgaria*

³*IRCCS Regina Elena National Cancer Institute, Biostatistics and Bioinformatics, Rome, Italy*

⁴*IRCCS Regina Elena National Cancer Institute, Department of Research, Advanced Diagnostic, and Technological Innovation, Rome, Italy*

Introduction

MicroRNAs (miRNAs) are single-stranded RNA molecules that act as global regulators of gene expression and thus appear as valuable molecules for early diagnosis, monitoring and prognosis in cancer. Thyroid cancer (THCA) are common malignant diseases with increased incidence in the last decade. The aim of the present study is to establish a personalized transcriptional profile of miRNAs in biological material obtained via fine-needle aspiration biopsy (FNAB) from normal, benign, malignant, and metastatic tissues of patients with papillary thyroid carcinoma (PTC).

Material and method

Bioinformatics Analysis: Based on data from The Cancer Genome Atlas (TCGA), a panel of 10 miRNAs was identified as potentially clinically relevant for PTC.

Molecular Biology Methods: miRNA expression was analyzed in tissue samples obtained via ultrasound-guided FNAB from benign, malignant, and metastatic thyroid nodules of patients with PTC ($n = 38$), and the results were compared with normal tissue.

Result and discussion

Our findings demonstrate that let-7b-5p, miR-146b-5p, miR-182-5p, miR-339-3p, miR-423-5p, miR-450b-5p, miR-484, miR-874-3p, and miR-142-3p exhibit altered expression between normal and tumor tissue.

Additionally, miR-142-3p, miR-146b-5p, let-7b-5p, miR-182-5p, and miR-484 show significant expression differences between benign and malignant nodules. The cumulative expression of the 10-miRNA panel demonstrates diagnostic potential and can be used as a biomarker for distinguishing tumor from normal tissue with $AUC = 0.984$, sensitivity = 92%, and specificity = 97%.

Conclusion

The investigated miRNA panel represents a reliable diagnostic tool for PTC and could facilitate a personalized clinical and therapeutic approach. The identification of a novel, specific miRNA profile in PTC

could provide valuable insights into the malignant and invasive potential of the tumor, as well as its histological characteristics, thereby complementing routine diagnostics. Furthermore, the correlation between an individual's transcriptional profile and their clinical outcome may offer a predictive value for treatment response and disease prognosis.

EACR25-1417

What Drives the Expansion of Mutant Clones in Non-Malignant Gastrointestinal Tissues, and How Is This Related to Cancer Initiation?

F. Maruf^{1,2}, H. Misetic^{1,2}, F. Ciccarelli^{1,2}

¹*Barts Cancer Institute, Queen Mary University of London, Centre for Cancer Evolution, London, United Kingdom*

²*Francis Crick Institute, Cancer Systems Biology Laboratory, London, United Kingdom*

Introduction

Throughout life, adult stem and progenitor cells accumulate genetic alterations that can enhance cellular fitness. These alterations lead to the clonal expansion of their progeny and the progressive populating of the tissue. Mutant cells may expand into clonal populations without necessarily progressing to cancer, even when harbouring mutations in well-known cancer-related genes (cancer drivers). This study aims to identify mutant genes that drive clonal expansion in non-cancerous tissues (somatic drivers) and understand their roles in tissue homeostasis and disease initiation, including cancer. The gastrointestinal (GI) system, frequently exposed to endogenous and exogenous mutagenic factors, accumulates somatic mutations at a high rate due to its rapid cell turnover, making it an ideal model for studying somatic evolution. Our preliminary analysis focused on compiling a comprehensive dataset of somatic mutations in non-cancerous GI tissues, identifying damaging exonic and splicing mutations, and mapping them to known somatic and cancer drivers.

Material and method

By integrating and curating multiple literature sources, we compiled whole-genome and whole-exome sequencing data from 4,205 samples across 12 GI tissue types (appendix, caecum, colon, duodenum, ileum, jejunum, liver, oesophagus, pancreas, rectum, small intestine, and stomach) from 297 individuals. We observed substantial variability in mutation burden across tissues, with the appendix, ileum, and small intestine exhibiting the highest mutation loads, particularly in samples from diseased donors. This variability persisted when considering gene-level mutations, with the median number of mutated genes ranging from 5 to 35, and when focusing on damaging mutations, where the median number of affected genes ranged from 2 to 10.

Result and discussion

Notably, over 70% of samples lacked mutations in known somatic drivers, and nearly 50% lacked mutations in known cancer drivers, underscoring the need for new approaches to identify genetic alterations that drive clonal expansion in non-cancerous tissues. The candidate

driver RHPN2 was the most frequently mutated gene across eight GI organ sites, while mutations in known false positives such as TTN, CSMD1, and DNAH5 were also prevalent, likely due to their length and sequence composition biases. Among somatic drivers, NOTCH1 was the most frequently mutated, consistent with recent literature.

Conclusion

In conclusion, our analysis of non-cancerous GI tissues provides valuable insights into the landscape of somatic mutations and their potential role in clonal expansion. While the low prevalence of mutated somatic drivers is notable, it also highlights the need for further research to identify novel drivers of clonal expansion in non-malignant tissues.

EACR25-1423

Investigating the sheddase (s) responsible for HAI-1 ectodomain release in bladder cancer cell lines

A. Saeed^{1,2}, A. Myumyun¹, E. Yuksek Tekben¹, D. Ward¹, R. Bryan¹

¹*Bladder Cancer Research Centre, Institute of Cancer and Genomic Sciences, University of Birmingham, United Kingdom*

²*Anatomy and Pathology Department, College of Veterinary Medicine, University of Sulaimani, Iraq*

Introduction

Hepatocyte growth factor activator inhibitor-1 (HAI-1) is a transmembrane protein with a fundamental role in regulating serine protease activity in the tumour microenvironment through inhibitory Kunitz domains in its extracellular domain (ECD). We have previously demonstrated that high-risk non-muscle invasive bladder cancer (NMIBC) patients with high urinary levels of HAI-1 ECD have worse outcomes. However, the mechanism of HAI-1 ECD shedding in bladder cancer (BC) is unknown. The aim of this study is to explore the role of 4 metalloproteinases in HAI-1 shedding, proliferation and migration in BC cell lines

Material and method

HAI-1 shedding was measured in three cell lines (T24, VM-CUB-1, and 5637) in non-stimulated and phorbol ester-stimulated cells in the presence of matrix metalloproteinase (MMP) inhibitors or siRNA knockdown of ADAM 10, ADAM 17, MMP 7, and MMP 14. The effects of MMP inhibitors and knockdowns on HAI-1 shedding, migration, and proliferation were investigated.

Result and discussion

T24 showed the lowest HAI-1 expression and shedding, VM-CUB-1 intermediate, and 5637 had the highest expression as well as shedding. Marimastat and ADAM 10/17 inhibitors significantly suppressed HAI-1 shedding ($p < 0.01$). Among the MMP knockdowns, ADAM 17 exhibited the most significant decrease in HAI-1 shedding, followed by MMP 7. Cellular migration was decreased by ADAM 17 knockdown, whereas the proliferation was reduced by both MMP 14 and ADAM 17 knockdown ($p < 0.05$). Similarly, Marimastat and ADAM 10/17 inhibitors reduced the proliferation capacity of VM-CUB-1 ($p < 0.05$).

Conclusion

Across BC cell lines, higher cytoplasmic HAI-1 expression correlates with higher ECD shedding. MMP inhibitors block shedding, and inhibitor selectivity implicates ADAM17. ADAM 17 sheds HAI-1 ECD and is also closely associated with cellular migration and proliferation.

EACR25-1443

Osteosarcoma biomarker discovery in plasma extracellular vesicles using a targeted proteomics approach

S. Sinha¹, V. Sarhadi², M. Alam², R. Seppänen-Kaijansinkko², P. Siljander³, T. Salo²

¹*University of Helsinki, Department of Oral and Maxillofacial Diseases, Molecular and Integrative Biosciences, Helsinki, Finland*

²*University of Helsinki, Department of Oral and Maxillofacial Diseases, Helsinki, Finland*

³*University of Helsinki, Molecular and Integrative Biosciences, Helsinki, Finland*

Introduction

Osteosarcoma (OS) is an aggressive cancer of the bone, predominantly affecting adolescents and older adults. Generally, OS is diagnosed based on imaging tests and confirmed by biopsy, which is often invasive and painful. Till date, there are no established biomarkers for OS. Plasma-derived extracellular vesicles (EVs) are a promising form of liquid biopsy and involve a less invasive procedure for patients. Here, we used a targeted proteomics approach to screen plasma EVs for the presence of potential protein biomarkers of OS and therefore evaluate the diagnostic utility of plasma EVs. Additionally, we tested two commonly used EV isolation methods, ultracentrifugation (UC) and size exclusion chromatography (SEC), to determine which one is better for proteomic analysis.

Material and method

OS patient ($n = 15$) and healthy control ($n = 24$) plasma samples were obtained from the Helsinki biobank. OS cell lines ($n = 7$) were derived from patient biopsies or commercially sourced. EVs were isolated from plasma and from cell culture conditioned media by UC or SEC. The suitability of both methods for plasma EV isolation were assessed in terms of purity and yield. EVs were characterised by nanoparticle tracking analysis, electron microscopy, and Western blotting for CD9, CD63 and Hsp70 expression. Plasma EVs were analysed by a proximity extension assay (Olink) for the absolute quantitation of selected cytokines and immune surveillance-related molecules ($n = 89$). Proteomics results will be further validated with plasma EVs and OS cell line EVs using Western blotting.

Result and discussion

Both UC and SEC yielded an adequate amount of EVs from plasma. In SEC, plasma EV particles did not elute at the expected fractions and EV markers were present throughout all fractions. UC-isolated EVs were richer in protein than SEC-isolated EVs and therefore we chose them for further analyses. Based on proteomics, 18 out of 89 proteins were differentially expressed in OS-derived plasma EVs compared to controls. MMP1, CCL25 and TREM1 expression was significantly higher in OS-EVs than in controls.

Conclusion

UC was a more reliable method than SEC for the isolation of EVs from plasma. Several proteins were differentially expressed in OS compared to control plasma. Based on these findings, plasma EVs may have a diagnostic role in OS.

Exosomal miRNAs in Breast Cancer cancerogenesis: the EsomiR Study Update

B. Cardinali¹, A. Stella¹, S. Coco¹, A. Sciuotto¹, L. Zinoli¹, F. Boccardo², A. Rubagotti³, G. Chiorino⁴, P. Ostano⁴, L. Del Mastro¹

¹*IRCCS Ospedale Policlinico San Martino, Oncology and Hematology, Genoa, Italy*

²*University of Genoa, DIMI - Internal Medicine Department, Genoa, Italy*

³*University of Genoa, DISSAL - Department of Health Sciences, Genoa, Italy*

⁴*Fondazione Edo ed Elvo Tempia, Laboratory of Cancer Genomics, Biella, Italy*

Introduction

One of the key challenges in Breast Cancer (BC) prevention is identifying women who are at a higher risk of developing the disease, who might benefit from intensive monitoring and/or chemoprevention. This retrospective, single-center, case-control, study seeks to explore the potential of miRNAs derived from extracellular vesicles (EV-miRNAs) as early biomarkers for detecting women at an increased risk of developing BC. To achieve this purpose, EV-miRNAs from cyst fluid of women with Gross Cyst Disease of the Breast (GCDB) – a benign condition linked to a 2-4 times greater likelihood of developing BC – were analyzed.

Material and method

Cyst fluid samples were chosen from a cohort of 600 patients diagnosed with GCDB between 1985 and 1993, some of whom subsequently developed BC. EV-miRNAs were extracted using the Serum/Plasma exoRNeasy Midi Kit (Qiagen) and quantified by QubitTM using the microRNA Assay Kit (Thermo Fisher Scientific). The EV-miRNome was evaluated by microarrays on the Agilent platform using the SurePrint Human miR Microarrays 8×60 K. MiRNA validation was conducted by RT-qPCR using the miRCURY LNA miRNA SYBR Green qPCR Kit (Qiagen) in the Mastercycler ep realplex.

Result and discussion

A total of 118 samples (58 cases/60 controls) were analysed. Class comparison (Cases vs Controls) was performed to identify differentially expressed EV-miRNAs and subsequently a Logistic regression with LASSO penalization, combined with k-fold cross-validation ($k = 10$), identified 9 miRNAs (miR-3194-5p, miR-4713-3p, miR-6763-5p, miR-4443, miR-6872-3p, miR-769-3p, miR-5195-3p, miR202-3p, miR-6076) and two clinical variables (family history and menopausal status) associated with the risk of developing BC. RT-PCR confirmed the expression of 6 miRNAs out of those (miR-4443, miR-6763-5p, miR-3194-5p, miR202-3p, miR-6076 and miR-6872-3p). The best multivariate model built on these data included clinical variables, age

and three miRNAs (miR-4443, miR-3194-5p, miR-6763-5p) and demonstrated good predictive power [AUC 0.65 (95% CI: 0.54–0.75)]. Further analyses are ongoing to improve the results.

Conclusion

To the best of our knowledge, this study represents the first attempt to identify an EV-miRNA-based BC risk signature using liquid biopsy from cyst fluid. The ultimate goal of this project is to implement this signature into clinical use by prospectively testing it on plasma samples from breast cancer patients.

EACR25-1507

Prognostic value of tumour-infiltrating immune cells in patients with nasopharyngeal carcinoma

J. Ma¹

¹*Ministry of Health Holdings, Singapore, Singapore*

Introduction

Nasopharyngeal carcinoma is of low incidence rate worldwide but is endemic in East Asia, Southeast Asia and Northern Africa. Majority of the endemic cases are associated with infection by Epstein-Barr Virus (EBV), implying the interaction between genetic and environmental factors, viral infection and host immune system in the pathophysiology of NPC. Patients with primary NPC respond well to radiotherapy with or without chemotherapy. However, some patients, especially those with locally advanced NPC are at significant risk for disease recurrence. For this group of patients, addition of immunotherapy may bring clinical benefit as was demonstrated in several clinical trials. It is therefore important to identify biomarkers that prognosticate disease relapse and overall survival.

Material and method

In this study, we curated a panel of 16 markers for characterisation of TME of NPC. This panel includes 6 immune cell markers: T helper cells (CD4), cytotoxic T cells (CD8), regulatory T cells (FOXP3), B cells (CD20), NK cells (CD56), tumour associated macrophages (CD163); epithelial cell marker EpCAM; immune checkpoint molecules: PD1, PDL1, PDL2; other prognostic or functional markers: EBER, CD38, CD39, CD103, CD137, Ki67. With multiplex immunohistochemistry (IHC) staining and subsequent quantification of a cohort of 50 patients with treatment-naïve primary NPC, we quantified the immune cell populations in different stages of the disease, compared the expression of biomarkers in patients with and without recurrent diseases, and examined their prognostic value in overall survival (OS) and time-to-progression (TTP).

Result and discussion

We noted that NPC samples are heavily infiltrated by T cells, B cells, NK cells, and myeloid cells and the immunophenotypes vary with disease status. Moreover, expression of certain markers, e.g., CD163, CD8, and CD103 significantly differs between patients who developed recurrent diseases and those who did not, suggesting the prognostic value of these molecules. Indeed, we noted prolonged overall survival in patients with low proportions of CD163+ or PD1+ CD8+ cells, and high proportion of CD103+, HLA-DR+ or Ki67+

cells. We also observed delayed disease progression in patients with increased infiltration of CD4+, CD8+, CD103+ or Ki67+ cells. Notably, we identified CD103 as an independent prognostic marker for improved overall survival.

Conclusion

We depicted the TME of primary NPC by IHC staining with a curated panel of antibodies. We demonstrated that CD103 is a significant prognostic marker for OS. Patients with low CD103 expression may benefit from upfront treatment intensification.

Introduction

Colorectal cancer (CRC) is one of the most prevalent malignancies of the gastrointestinal tract worldwide, with nearly 2 million new cases diagnosed annually. Colonoscopy remains the gold standard for CRC diagnosis; however, its invasiveness, associated discomfort, and lack of routine implementation often lead to late-stage detection. Therefore, there is an urgent need for non-invasive, sensitive, and specific biomarkers for early diagnosis. MicroRNAs (miRNAs), small non-coding RNA molecules, play a crucial role in gene expression regulation and can act as oncogenes or tumor suppressors. MiRNAs are present in a variety of biological fluids, further highlighting their potential as minimally invasive biomarkers in diagnostics. The study analysed the miRNA profile in the serum of CRC patients compared to healthy controls (HC) to identify new diagnostic biomarkers for this cancer.

Material and method

We obtained serum samples from 100 CRC and 100 HC patients. A miRNA was isolated from the serum, then levels of 798 miRNAs were analysed using NanoString nCounter technology. The Ingenuity Pathway Analysis software was used to select potential targets. The STRING database and the Cytoscape programme were used to generate protein-protein interaction networks and to identify hub genes. Functional analysis of target genes was performed using the online databases (KEGG, g:Profiler, and Enrichr). Receiver Operating Characteristic (ROC) analysis was used to assess the

diagnostic value of miRNAs. A logistic regression model for the combined miRNAs in the panel was created using Weka software.

Result and discussion

Our data showed 11 miRNAs with significantly changed expression in CRC group compared to HC ($|FC| \geq 1.5$, FDR ≤ 0.05). The logistic regression model for the three miRNAs combined showed significantly greater diagnostic utility (AUC = 0.958, with 90.7% specificity and 95.6% sensitivity) than each miRNA analysed separately. The indicated target transcripts are involved in pathways leading to tumorigenesis. The results obtained showed serum miRNA profile which is characteristic for patients with CRC. Novel model with three miRNAs that distinguish CRC patients from HC patients with high sensitivity and specificity. The results of this research will be used to prepare a patent application.

Conclusion

Our findings suggest that circulating miRNAs might have a pivotal role in diagnosis of CRC. The development of an IVDR test based on serum miRNA expression could significantly enhance and facilitate the diagnosis of this cancer.

Introduction

Circulating nucleic acids in blood plasma offer a promising approach for minimally invasive cancer detection. While most research has focused on cell-free DNA, the broader range and dynamic, on-demand production of RNA make cell-free RNA an interesting cancer biomarker resource as well.

Material and method

We applied mRNA capture sequencing to analyze blood plasma cfRNA from 266 cancer patients and cancer-free controls (discovery n = 208, 25 locally advanced to metastatic cancer types; replication n = 58, 3 cancer types). We identified fusion transcripts and performed cellular deconvolution, differential abundance, and gene set enrichment in cancer compared to control groups. We

also developed a new case-specific approach that compares an individual patient's cfRNA profile to a reference control population to identify biomarker tail genes - transcripts that deviate by more than three standard deviations from the reference distribution and show some recurrence among patients. The number of biomarker tail genes per sample was used for binary cancer/control classification and performance was assessed by 10x 5-fold cross-validation.

Result and discussion

Our findings revealed both cancer type-specific and pan-cancer cfRNA alterations, but high heterogeneity among patients and cohorts limited the identification of robust cancer biomarkers at the group level. Our biomarker tail gene concept addresses this challenge by comparing individual profiles to a set of reference profiles. The number of biomarker tail genes in a plasma sample effectively distinguished ovarian and prostate cancer patient samples from controls (mean AUC of 0.901 and 0.964, resp.). We also validated this concept in independent cohorts of 65 plasma donors (two lymphoma types) and 24 urine donors (bladder cancer), confirming its potential of leveraging individual patient alterations for cancer detection. To further evaluate the cancer specificity of these signals, we are currently expanding our analyses to include a cohort of non-malignant diseases (n = 150).

Conclusion

Our findings highlight the heterogeneity of cfRNA alterations among cancer patients and suggest that focusing on case-specific changes could facilitate cancer detection.

EACR25-1533

Feasibility of tracking multiple primary cancers (MPCs) using tumor-informed circulating tumor DNA (ctDNA) assays

S. Sudhaman¹, K. Manage¹, H. Youngberg¹, S. Woods¹, J. Ortiz¹, S. Bristow¹, M. Krainock¹, A. Rodriguez¹, M. Liu¹

¹Natera, Inc., Austin, United States

Introduction:

Approximately 10-25% of cancer patients (pts) develop MPCs, often metachronous, resulting from environmental exposures, prior therapies, and inherited genetic factors. Monitoring individual tumor progression is challenging due to the lack of sensitive biomarkers and tumor-specific imaging characteristics that can distinguish between recurrences and MPCs. This study demonstrates the feasibility of individually monitoring MPCs using a tumor-informed ctDNA assay.

Material and method

This retrospective analysis used real-world data from commercial ctDNA testing in pts with MPCs who had a personalized, tumor-informed, mPCR-NGS ctDNA assay (SignateraTM, Natera, Inc.) designed for each primary tumor. Pt treatment and the collection of longitudinal blood samples were at the treating physician's discretion. Clinicopathologic information for ctDNA analyses was collected retrospectively from Natera's commercial database. The patterns of tumor-specific ctDNA results for each pt were summarized.

Result and discussion

In total, 41 pts with MPCs underwent ctDNA monitoring for two (40 pts) or three (1 pt) primary tumors. Tumor A included breast (21.9%, n = 9), gastrointestinal (GI) (31.7%, n = 13), genitourinary (GU) (14.6%, n = 6), gynecologic (gyn) (4.9%, n = 2), skin (14.6%, n = 6), sarcoma (2.4%, n = 1), lung cancer (7.3%, n = 3), and unknown histology (2.4%, n = 1). Stage distribution for Tumor A was: stage I: 5 (12.2%), stage II: 8 (19.5%), stage III: 20 (48.8%), stage IV: 6 (14.6%), and unknown: 2 (4.9%). Tumors B and C comprised of GI (38.6%, n = 17), gyn (20.5%, n = 9), breast (13.6%, n = 6), skin (13.6%, n = 6), GU (4.5%, n = 2), lung (4.5%, n = 2), hematological cancer (2.3%, n = 1), and unknown histology (2.3%, n = 1). Stage distribution for Tumor B was: stage I: 8 (18.2%), stage II: 5 (11.4%), stage III: 16 (36.4%), stage IV: 10 (22.7%), and unknown: 5 (11.4%). Among these, 17 pts had multiple primary tumors originating in the same organ. Analysis of clinical data was performed for 33 pts, including one with three primary tumors. The median follow-up was 14.5 months for Tumor A and 2.7 months for Tumor B/C. A total of 302 ctDNA tests were performed: 241 for Tumor A and 61 for Tumor B. Among 33 pts, one tested ctDNA negative in both tumors, while 4 pts tested positive for both tumors at some point. 12 pts tested positive for Tumor A but were consistently negative for tumor B. Lastly, 16 pts were positive for Tumor B or C but serially negative for Tumor A.

Conclusion

This study demonstrates the feasibility of real-time tracking of MPCs using tumor-informed ctDNA assays. Reliable assessment of tumor-specific molecular disease burden during surveillance and treatment monitoring can be critical for timely and informed clinical management decisions and personalized treatment plans.

EACR25-1548

ddPCR as molecular approach to assess MSI-H status in PDAC EUS-FNB samples

M. Piano¹, E. Boldrin¹, L. Moserle¹, N. Salerno¹, G. Peserico², M. Biasin³, A. Rosato¹, A. Scapinello³, A. Fantin², M. Curtarello¹

¹Veneto Institute of Oncology IOV-IRCCS, Immunology and Molecular Oncology Diagnostics Unit, Padova, 35128, Italy

²Veneto Institute of Oncology IOV-IRCCS, Gastroenterology Unit, Padova, 35128, Italy

³Veneto Institute of Oncology IOV-IRCCS, Anatomy and Pathological Histology Unit, Padova, 35128, Italy

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive disease with poor prognosis. Biopsy evaluation is crucial to determine surgical and treatment options. Endoscopic Ultrasound Fine Needle Biopsy (EUS-FNB) can collect adequate tissue for diagnostic purposes, which could be suitable to perform molecular analysis to improve new personalized treatments. The effectiveness of immunotherapy in treating tumors with high microsatellite instability (MSI-H) has been demonstrated in various cancer types. In PDAC, the prevalence of MSI-H is estimated to be around 1–2% of

patients by using immunohistochemistry (IHC), different types of PCR based methods or NGS. Aiming to improve MSI-H detection in PDAC EUS-FNB, droplet digital PCR (ddPCR) technology was used to better stratify patients that could be eligible for immunotherapy.

Material and method

Formalin-fixed-paraffin-embedded (FFPE)-DNA extracted from 43 PDAC EUS-FNB were evaluated for their adequacy in terms of quantity and quality by using the Qubit dsDNA High Sensitivity Assay Kit and the Agilent TapeStation 4200 respectively. MSI-H status was assessed by ddPCR which is based on the analysis of five microsatellites marker loci (BAT-25, BAT-26, NR-21, NR-24 and MONO-27). Samples were also evaluated for the mismatch repair system deficiency (dMMR) analyzing MLH1, MSH2, MSH6 and PMS2 proteins by IHC.

Result and discussion

FFPE-DNA amount, obtained from PDAC EUS-FNB samples, ranged between 35 and 1955 ng in 25 µL of final elution volume. The median concentration was 11.3 ng/µL (range 1.4–78.2). DNA Integrity Number (DIN) median value was 3.1 (range 1–5.9). The fragments average length, defined at the main peak by TapeStation analysis, was 1694 bp (range 384–10,445). The quantity and quality of the DNA was adequate to perform molecular analysis. MSI-H/dMMR status was first assessed using IHC staining, a widely used method for detecting the dMMR phenotype in various types of tumors, and all samples resulted to be microsatellite stable (MSS). However, one of the IHC's drawbacks is that it is restricted in detecting the absence/presence of the four traditional MMR proteins, but not the functional consequences of aberrations at the genomic level, then may not accurately reflect the MMR system status. To overcome the IHC limitations, MSI-H status was also evaluated at the molecular level by using the highly sensitive ddPCR method, and has been detected in 16.28% of cases, compared to the 1–2% frequency detected by traditional techniques.

Conclusion

This study suggests that ddPCR can enhance the detection of MSI-H phenotype in PDAC, resulting in a better selection of patients who might be eligible for immunotherapy and may be excluded by conventional diagnostic methods. This finding is crucial in patients with advanced disease, in which the pancreatic biopsy is the only tissue source to perform diagnostic evaluation.

EACR25-1591

Computational screening for promising protein biomarkers and predictive performance evaluation for lung cancer

Z. Li¹, O. Blyuss², A. Zaikin¹

¹University College London, London, United Kingdom

²Queen Mary University of London, London, United Kingdom

Introduction

Lung cancer is a leading cause of cancer-related mortality worldwide, with early detection being critical for improving survival rates. Protein biomarkers offer a promising alternative for lung cancer screening due to their potential for non-invasive detection and ability to

reflect disease progression. However, identifying reliable protein biomarkers remains a significant challenge due to the uncertainty of tumour biology and the need for robust validation. Currently, there are no universally accepted protein biomarkers for lung cancer screening and most biomarkers that have been assessed to date are not measured in the pre-diagnostic setting, not allowing for evaluating early detection performance. Furthermore, the benefits of incorporating long screening history are unclear and require further investigation.

Material and method

In this study, we analysed a unique population screening data from 248 participants (98 cases and 150 controls) with 94 protein biomarkers, the samples of which go as far as 5 years before final diagnosis. Therefore, the dataset is pre-diagnostic as well as longitudinal. To address the limitations of dataset size, we implemented a novel repeated splitting strategy using LASSO to systematically identify promising biomarkers. As a proof of concept, we then used the selected biomarkers to train the longitudinal machine learning models and evaluate the value of incorporating long screening history.

Result and discussion

CEACAM5, MUC-16, CXL17, WFDC2, hK14 and CPE were identified as promising biomarkers for lung cancer screening. We also showed that the longitudinal analysis using LSTM neural networks gave rise to an ROC AUC score of approximately 0.886 and sensitivity (0.8) of 0.774 based on the current data. However, the real benefit of conducting longitudinal analysis still needs to be further investigated.

Conclusion

In this work, we presented a novel computational methodology for biomarker screening and identified 6 promising protein biomarkers for lung cancer based on a unique long time-span screening dataset. The longitudinal analysis using LSTM neural networks achieves a desirable predictive performance in terms of ROC AUC and sensitivity (0.8).

EACR25-1609

Identification of novel diagnostic biomarkers as therapeutic targets in prostate cancer

N. Bhummaphan¹, C. Puttipanyalears²

¹Chulalongkorn University, College of Public Health Sciences, Bangkok, Thailand

²Chulalongkorn University, Faculty of Medicine, Bangkok, Thailand

Introduction

Prostate cancer (PCa) is the most common cancer and the second-leading cause of cancer-associated death in males. PCa is considered one of the most prevalent malignancies globally, and metastasis is a major cause of death. Despite advances in screening for early detection of PCa, a large portion of men continue to present with advanced PCa. In general, prostate-specific antigen (PSA) is a protein produced in the prostate gland. The PSA test measures the level of PSA in the blood as a gold standard for screening tools for prostate cancer; however, PSA has low efficiency and usually results in a false-positive test. Other methods to screen PCa, such as MRI scans, phenotypic and molecular tests, such as Formalin-fixed

paraffin-embedded (FFPE) tissues, are not good enough for detection because of late-stage diagnosis, high invasiveness, and expense. Due to many limitations, a novel of PCa screening for diagnosis is required. Peripheral blood mononuclear cells (PBMCs) can provide an inexpensive, less invasive, and highly accurate method. This study aims to discover a potential novel biomarker for PCa screening, utilizing the gene expression of the PBMCs.

Material and method

Data have been searched from the NCBI, GEO database of gene expression in PCa patients and healthy donors' PBMCs were collected. As a result, GSE153514, GSE16120, and GSE46602 were found. All genes from the three GSE groups were intersected with upregulated genes that have been identified. A statistical significance test was conducted in the gene expression of each data set and p-values < 0.001 have been selected. Then, PBMC from a total of 45 healthy donors, and 45 PCa cancer donors were collected. Quantitative RT-PCR (qRT-PCR) was performed in cDNA from all blood samples.

Result and discussion

The relative mRNA expression value of CU1 gene of the PCa group was significantly higher than the healthy group with a significance value. The sensitivity and specificity of this gene as a screening tool were 77.1% and 81.8% respectively. Moreover, the expression of CU1 significantly impacts the cancer progression of prostate cancer cells. The high expression of CU1 was correlated with the cell proliferation and metastatic behavior in PC-3 prostate cancer cell lines.

Conclusion

In conclusion, a novel biomarker CU1 has high potential as a candidate upregulated gene, which could be further investigated as biomarkers and the molecular mechanism to develop as a therapeutic target for PCa.

⁴The Wellbeing Services County of Central Finland, Jyväskylä, Finland

⁵Tampere University, Department NEON S, Faculty of Medicine and Health Technology, Tampere, Finland

⁶University of Jyväskylä, Department of Biological and Environmental Science, Jyväskylä, Finland

Introduction

Lynch Syndrome (LS) is an inherited cancer predisposition syndrome caused by a pathogenic mutation in one of the DNA mismatch repair genes (path_MMR): MLH1, MSH2, MSH6, or PMS2. It causes a lifetime elevated cancer risk for various cancers. The cancer risk

depends on the path_MMR gene where MLH1 is known to cause the highest cancer risk. Even with high cancer risk, all carriers don't develop cancer, highlighting the possibility that the cancer risk can be impacted via lifestyle choices. Current risk assessment methods consider sex, age, and path_MMR gene variant but lack individual systems biology markers, which lifestyle choices may influence. Vigilant surveillance and innovative strategies for early detection and precise risk stratification are pivotal for effective risk mitigation in individuals with LS. Our study examined the systemic biology of currently healthy LS carriers by harnessing the multi-omics integration of circulating microRNAs (cmiRs) and circulating metabolites (cMets) to assess their potential in predicting future cancer risk. Both cmiR and cMet levels can be influenced by various factors, including lifestyle choices.

Material and method

Multi-omics data was combined with information on whether the study subject developed cancer (n = 17) or not (n = 99) during a 5.8-year surveillance. Single- and multi-omics data analysis approaches were employed to identify systemic cancer-predicting biomarkers, including Principal Coordinate Analysis, Sparse Partial Least Squares, Weighted Correlation Network Analysis, and the Lasso Cox regression survival model.

Result and discussion

Our study revealed a cmiR cluster associated with upcoming cancer. These cmiRs regulate key signaling pathways related to cancer progression, like PI3-Akt. Notably, the levels of certain metabolites, such as low-density lipoprotein (LDL), and very low-density lipoprotein (VLDL) were elevated in carriers of the MLH1 gene variant compared to carriers of the MSH2 and MSH6 variants. Lipid metabolism dysfunction is connected to a higher risk of tumorigenesis. Additionally, we built a survival model, where three biomarkers hsa-miR-101-3p, hsa-miR-183-5p, and triglycerides in high-density lipoproteins (HDL_TG) were indicators of increased cancer risk.

Conclusion

This study provided insights into systems biology in LS and identified promising cancer biomarkers for evaluation of early-stage cancer risk detection, an alternative tool besides current risk assessment methods.

²Barretos Cancer Hospital, Molecular Oncology Research Center, Barretos, Brazil

³Barretos Cancer Hospital, Pathology Department, Barretos, Brazil

⁴Barretos Cancer Hospital, Oncology Department, Barretos, Brazil

Introduction

Lymph node metastasis is a pivotal event in melanoma progression, directly impacting prognosis and therapeutic decision. Despite advances in molecular profiling, predictive biomarkers for nodal involvement remain scarce. Unraveling the transcriptional differences between metastatic and non-metastatic tumors may illuminate key molecular drivers and enhance risk stratification. This study aimed to identify differentially expressed genes (DEGs) associated with lymph node metastasis and to develop a predictive model for metastatic risk assessment in melanoma.

Material and method

Thirty-five melanoma patients with formalin-fixed paraffin-embedded (FFPE) tumor samples containing at least 60% neoplastic cells were analyzed. Total RNA was extracted using the RNeasy Mini Kit and profiled using the NanoString nCounter® Human Immunology v2 Panel. Data normalization and differential expression analysis were conducted using the nSolver Advanced Analysis module, with subsequent statistical validation in R (v4.3.1). DEGs were identified based on a significance threshold of $p < 0.01$ and a \log_2 fold change ≥ 2 . A logistic regression model incorporating key DEGs was developed, and its predictive performance was assessed using the area under the receiver operating characteristic (ROC) curve (AUC).

Result and discussion

Lymph node metastases were present in 60% of cases. The cohort had a mean age of 57.9 years, with 62.9% male patients. The most common primary tumor site was the lower limb (34.3%), with nodular melanoma (34.3%) and superficial spreading melanoma (31.4%) being the predominant histological subtypes. The median Breslow thickness was 9.3 mm, and most tumors were classified as Clark IV (62.9%), with ulceration present in 60.0% of cases. Six DEGs were identified as significantly associated with lymph node metastasis. CR2 and NCR1 were upregulated in metastatic cases, while FAS, DEFB103A, AHR, and CFI were upregulated in non-metastatic cases. A predictive model incorporating these genes achieved an AUC of 0.79, with a sensitivity of 71.4% and specificity of 78.6%, demonstrating strong discriminative power. The upregulation of CR2 and NCR1 in metastatic tumors suggests their involvement in lymphatic dissemination, whereas the increased expression of FAS, DEFB103A, AHR, and CFI in non-metastatic tumors may reflect immune-mediated resistance to metastasis.

Conclusion

This study identifies a robust immune-related gene signature distinguishing metastatic from non-metastatic melanoma cases and introduces a predictive model with high diagnostic accuracy. These findings underscore the potential of transcriptomic profiling for improving risk assessment and patient stratification in melanoma prognosis. Further validation in larger cohorts and functional studies will be critical for translating these molecular insights into clinical applications.

⁵University of British Columbia, Department of Urologic Sciences, Vancouver, Canada

⁶Var2 Pharmaceuticals Aps, Frederiksberg, Denmark

⁷University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Introduction

Cancer remains a leading cause of death worldwide, with survival rates heavily dependent on early detection. Screening tests can help detect cancer at an early, more treatable stage before symptoms appear. For example, the fecal immunochemical test (FIT) is widely adopted in many EU countries for colorectal screening (CRC). However, FIT suffers from low sensitivity for early-stage disease and poor screening compliance, and around 30% of CRC patients relapse within 5 years of disease. Furthermore, for other cancers such as bladder cancer (BC), no non-invasive, highly sensitive and specific screening tests are available. Alternative biomarkers that can identify early-stage disease and relapses are sorely needed, especially those that can easily integrate into clinical workflows.

Material and method

Oncofetal chondroitin sulfate proteoglycans (ofCSPGs) are promising pan-cancer biomarkers due to their uniquely modified glycosylation patterns and involvement in tumor progression. The ofCSPGs are shed from tumor tissue into circulation, allowing for non-invasive cancer detection. We validated the expression of ofCSPGs in patient liquid biopsies and tissue using mass spectrometry and immunohistochemistry, respectively. To test their diagnostic potential, we developed two novel diagnostic assays using proprietary antibodies to detect ofCS. These assays were optimized to detect and quantify ofCSPG in both plasma and urine samples from cancer patients.

Result and discussion

ofCSPGs were widely expressed in CRC and BC tumors, with minimal or no detection in matched healthy tissue, and proteomic analysis identified a panel of ofCSPGs in urine and plasma. Drawing from this, preliminary data in a clinical discovery cohort demonstrate high specificity and sensitivity for ofCSPGs in plasma, with excellent AUC scores, underscoring their potential as robust biomarkers. Notably, ofCSPGs were detectable in plasma from adenoma patients, suggesting promise for early-stage CRC detection. Furthermore, longitudinal

monitoring of CRC patients undergoing surgical interventions revealed significant declines in ofCSPG levels after tumor resection, supporting their utility in assessing treatment response and disease progression. Beyond CRC plasma samples, ofCSPGs were consistently detected in urine from BC patients, with background levels in age-matched controls including hematuria and non-symptomatic individuals.

Conclusion

These findings underscore the potential of ofCSPG as minimal invasive biomarkers for cancer screening, patient stratification, and disease monitoring across multiple malignancies. We are now conducting a large-scale study to assess their efficacy in early multi-cancer detection and disease monitoring. Our goal is to develop a non-invasive, highly accurate diagnostic tool to address critical unmet clinical needs and improved outcomes for CRC and BC patients.

Introduction

Colorectal cancer (CRC) screening relies on the fecal immunochemical test (FIT), which has limited sensitivity for detecting premalignant advanced adenomas (AA) and proximal tumors. Therefore, more sensitive and specific non-invasive biomarkers are needed. The gut microbiome, including bacteria, archaea, fungi, and viruses, plays a key role in health and disease. While bacterial alterations have been linked to CRC, contributing to inflammation, immune dysregulation, and a pro-tumorigenic microenvironment, the gut virome remains largely unexplored. Phages, the most abundant viruses in the gut, influence bacterial composition and may impact CRC onset and progression. In this study, we explored the stool virome to identify potential viral biomarkers for CRC screening.

Material and method

We analyzed the virome in stool samples from 45 CRC patients, 60 AA patients, and 59 individuals without neoplasia. We performed viral shotgun metagenomics using a custom protocol that included viral enrichment (low-speed centrifugations, filtration, ultracentrifugation,

nuclease digestion), DNA/RNA extraction, retro-transcription, random priming PCR, library preparation and sequencing (150 PE reads). Reads were quality-checked, preprocessed, and taxonomically classified with SeqScreen (Balaji et al., 2022). Differential abundance analysis was conducted using coda4microbiome (Calle et al., 2023).

Result and discussion

The proportion of reads assigned to viruses varied significantly among samples (0.19–96.3%; mean 20.52%). 178 viral families were identified, with Microviridae being the most abundant, followed by Inoviridae and Picornaviridae. Variable selection using penalized regression to differentiate individuals with advanced neoplasia (CRC and AA) from those without neoplasia identified a signature composed of 11 viral families, with Betaflexiviridae emerging as most relevant. The differential abundance analysis at the genus level high-lighted Ravavirus, Chordovirus, and Sustivirus as promising biomarkers.

Conclusion

Our preliminary findings suggest a potential association between Betaflexiviridae viruses and advanced neoplasia, indicating that members from this family may serve as potential biomarkers for AA and CRC detection.

Evaluation of PTK7-ADC in Patient-Derived Explants (BC-PDEs): Investigating Multimodal Data for Personalised Medicine

H. Zamir¹, L. Lezina¹, P. Sandhu¹, N. Abid¹, C. Demetriou¹, M. MacFarlane², H. Pringle¹, C. Pritchard¹, H. Kaul³, G. Miles¹

¹University of Leicester, Department of Genetics, Genomics and Cancer Sciences, Leicester Cancer Research Centre, Leicester, United Kingdom

²University of Cambridge, MRC Toxicology Unit, Cambridge, United Kingdom

³University of Leicester, 3. School of Engineering, Leicester, United Kingdom

Introduction

The recurrence of breast cancer (BC) emphasises the need for novel treatment approaches. PTK7 is an inactive Receptor Tyrosine Kinase highly expressed in BC. The present study leverages breast cancer patient-derived explants (BC-PDEs) to assess the therapeutic impact of a Pfizer PTK7-targeted Antibody Drug Conjugate (PTK7-ADC). By correlating ex-vivo PTK7-ADC responses with clinicopathological, PTK7 expression and genomics data, the aim is to direct individualised treatments and aid the design of future clinical trials with the PTK7-ADC

Material and method

The recurrence of breast cancer (BC) emphasises the need for novel treatment approaches. PTK7 is an inactive Receptor Tyrosine Kinase highly expressed in breast

cancer. The present study leverages breast cancer patient-derived explants (BC-PDEs) to assess the therapeutic impact of a Pfizer PTK7-targeted Antibody Drug Conjugate (PTK7-ADC). By correlating ex-vivo PTK7-ADC responses with clinicopathological, PTK7 expression and genomics data, the aim is to direct individualised treatments and aid the design of future clinical trials with the PTK7-ADC. Methods: BC-PDEs were subjected to PTK7-ADC treatment and a multi-modal dataset was generated including viability data (proliferation/apoptosis/necrosis changes), intrinsic PTK7 expression, clinicopathological and genomics data. The dataset was analysed and correlations were performed to identify significant associations using R programming.

Result and discussion

Tumour areas displayed higher intrinsic PTK7 expression than stroma areas, with higher expression in higher-grade but lower-stage cancers. The PTK7-ADC induced a range of viability changes in BC-PDEs with ~16% of tumours showing a strong cell death response. However, this cell death responses did not correlate with any clinicopathological parameters or intrinsic levels of PTK7 expression. PTK7 genomic mutations were detected in ~16% of samples but did not correlate with PTK7-ADC cell death responses. Hierarchical k-means clustering of viability data identified two distinct clusters, labelled as “Resistant (R) & Sensitive (S)” /RS phenotypes, used to categorise the data for further analysis. Whole exome sequencing data was used to identify mutant genes that were significantly enriched in the RS phenotypes using Fisher's exact test, which resulted in 264 significantly enriched CNV-mutated genes associated with RS phenotype. Pathway enrichment analysis highlighted the Breast Cancer, Wnt and Hippo signalling as top enriched KEGG-pathways.

Conclusion

In BC, while PTK7 expression correlates with more advanced disease grade, PTK7 expression is not a predictive biomarker for PTK7-ADC-mediated cell death response. This suggests that the ADC operates through bystander mechanisms, which require further investigation. Further analysis of 264 genes, may hold promise for the development of a predictive biomarker panel for PTK7-ADC responses in BC patients.

Genomic diversity and BCL9L mutational status in CTC pools predict overall survival in metastatic colorectal cancer

J. Alves¹, N. Estévez-Gómez¹, R. Piñeiro², L. Muñelos-Romay³, P. Mondelo-Macía³, M. Salgado⁴, A. Diez-Martín⁵, J. Cubilla⁵, D. Posada¹

⁵Research Group in Gastrointestinal Oncology-Ourense,

Department of Gastroenterology, Hospital Universitario de Ourense, Ourense, Spain

Introduction

Given that cancer dissemination primarily occurs via the bloodstream – where tumor cells detach from the primary tumor, enter circulation, and migrate to distant tissues – there is growing interest in circulating tumor cells (CTCs) due to their purported role in metastasis and potential as a liquid biopsy tool for cancer diagnosis and management. Although the clinical significance of CTCs has already been established, - with elevated CTC counts correlating with aggressive disease in several cancer types, including colorectal cancer (CRC) – early sequencing studies have revealed that CTCs can exhibit considerable genomic and phenotypic heterogeneity within patients. Importantly, increasing evidence suggests that intratumoral genetic heterogeneity is a critical factor influencing clinical outcomes in CRC. We therefore hypothesize that higher genetic variation within the CTC population may contribute to increased disease aggressiveness and reduced overall survival.

Material and method

As such, to investigate the biomarker potential of CTC genomics in predicting survival outcomes, we collected and performed whole-exome sequencing on CTC pools from 30 metastatic CRC patients.

Result and discussion

Our findings reveal substantial variation in mutational burden across patients, with all CTC pools harboring non-silent mutations in key CRC driver genes. Importantly, higher genomic diversity in CTC pools was significantly associated with reduced overall survival. Moreover, non-silent mutations in BCL9L also emerged as a strong predictor of survival. To facilitate clinical translation, we additionally designed a 55-gene panel based on overall mutational load, and demonstrated that it could accurately replicate key WES findings, including the association between CTC genomic diversity and survival.

Conclusion

These findings underscore the relevance of CTC-derived genomic information as a robust prognostic biomarker in metastatic CRC and highlight the potential of liquid biopsies in personalized cancer management.

⁷Italian Institute for Genomic Medicine (IIGM, Turin, Italy)

Introduction

Lynch Syndrome (LS) is an inherited disorder defined by heterozygous germline mutations at DNA mismatch repair (MMR) genes, leading to a dysfunctional post-replication repair system. LS patients have an increased lifetime risk of developing many types of cancers, mainly colorectal cancer (CRC), which occurs at an earlier age compared to sporadic forms. Despite regular colonoscopies as a preventive tool, a relevant percentage of LS patients still develop CRC. Gut microbiome, environmental factors, and epigenetic factors are involved in CRC development. In this sense, the concomitant analysis of fecal microRNA (miRNA) profiles of the host and microbiome composition may allow the identification of specific fecal markers in LS that could reflect the gut alterations associated with the development of precancer/cancer lesions in these patients. The aim of this study is to analyze the fecal miRNome and the microbial composition alterations in LS patients with a precancer/cancer lesion with respect to LS subjects without lesions. A similar analysis was also performed between all LS patients and a set of healthy. The obtained results were compared with data from an in vivo model using an MMR-deficient mouse model, with a tissue-specific inactivation of Msh2 in the intestinal mucosa (VCMshloxP).

Material and method

We performed small RNA-sequencing (sRNA-seq) and shotgun metagenomics sequencing analyses in fecal samples of two cohorts of LS patients (Dutch, n = 84 and Italian, n = 105) and matched healthy subjects (n = 20 and n = 64, respectively) used as controls for both cohorts. An additional set of 41 Dutch LS patients and their healthy relatives (n = 26) with no MMR mutations was used as a validation cohort. sRNA-seq and shotgun metagenomics sequencing was also performed in the mouse model: in this case, stools were collected in a time progression at five different time points in VCMshloxP mice and animals without the Msh2 mutation that were used as control group.

Result and discussion

Preliminary results from human subjects identified 38 fecal miRNAs whose levels were significantly increased or decreased in all cohorts in LS patients when compared to healthy controls. In addition, levels of 23 miRNAs were significantly altered in LS who presented a lesion at sampling compared to those with negative colonoscopy. In the mouse model, sRNA-seq and metagenomic analyses showed several dysregulated miRNAs and differential microbial relative abundances, either between VCMsh2loxP and controls, or at different time points.

Conclusion

The fecal biomarkers identified may serve as useful diagnostic and prognostic tools for clinical management of LS patients, improving cancer prevention, early diagnosis, and monitoring disease progression.

Monitoring Cystatin F Dynamics in Melanoma Patients Undergoing Checkpoint Inhibitor Therapy

E. Senjor¹, S. Miceski², T. Mesti², J. Ocvirk², J. Kos³, M. Perisic Nanut⁴

¹Jozef Stefan Institute, Biotechnology department, Ljubljana, Slovenia

²Institute of Oncology Ljubljana, Department of research, LJUBLJANA, Slovenia

³University of Ljubljana, Faculty of Pharmacy, Department of Pharmaceutical Biology, Ljubljana, Slovenia

⁴Jozef Stefan Institute, Biotechnology department, Ljubljana, Slovenia

Introduction

Despite the success of Immune checkpoint inhibitor (ICI) therapy in melanoma, patient outcomes can be improved. Some patients develop resistance, and reliable predictive biomarkers are lacking, as PD-L1 and Tumour Mutational Burden (TMB) do not accurately predict outcomes. ICI therapy can also cause autoimmune side effects, making patient selection crucial. Our group identified cystatin F as a negative regulator of cytotoxicity. We showed that increased cystatin F expression correlates with reduced CTL functionality and exhaustion. Anti-PD-1 antibodies further increase cystatin F in CTLs, suggesting it elevates during ICI therapy and contributes to reduced cytotoxicity, potentially serving as a biomarker for ICI response.

Material and method

Peripheral blood and histological tumour samples were collected before immunotherapy. Cystatin F expression was evaluated in CTLs from PBMCs and tumour tissue, and cystatin F-expressing cells in tumours were assessed for functional status to compare blood and tissue-infiltrating CTLs. Public datasets were analysed for cystatin F expression, prognosis, and correlations with immune cell infiltration. Blood was collected from melanoma patients receiving systemic immunotherapy with ICIs (nivolumab, ipilimumab/nivolumab, pembrolizumab) as first-line treatment at the Institute of Oncology Ljubljana, Slovenia at three time points (4 weeks before, 12 (+2), and 28 (+2) weeks after therapy initiation). Cystatin F expression in CTLs was evaluated at each timepoint. Clinical data were tracked for 12 months, and patients were stratified (e.g., responders vs. non-responders). PBMCs were isolated, frozen, thawed, and MACS sorted to obtain CD8+ lymphocytes for flow cytometry. Gene expression for cystatin F and effector molecules of the perforin/granzyme pathway was determined by real-time PCR, and activation status of cystatin F and granzyme activity were assessed using SDS-PAGE and western blot.

Result and discussion

Our analysis revealed that cystatin F expression decreases with treatment duration in patients who respond to ICI therapy. Notably, a sex-based difference in cystatin F dynamics during the course of treatment was also observed, suggesting that cystatin F could serve as a potential biomarker for distinguishing between responders and non-responders.

Conclusion

These findings highlight the importance of monitoring cystatin F levels in melanoma patients undergoing immunotherapy, as it may provide valuable insights into treatment efficacy and help personalize therapy for better patient outcomes. Further studies are needed to explore the mechanisms behind the observed sex differences and to confirm the utility of cystatin F as a predictive biomarker across larger patient cohorts.

⁴Manchester University Foundation Trust, North West Lung Centre, Manchester, United Kingdom

Introduction

Lung cancer causes more deaths than any other cancer in the world due to late diagnosis. However, if detected early, curative surgery can be offered. In the last decade, low dose CT scans, delivered through lung health checks, have been instrumental in the lung cancer early detection process for under 75s with approximately 8000 lung cancer diagnoses to date in the UK. Demographic and lifestyle factors are used to stratify patient by risk of lung cancer for CT screening through the PLCO score.

However, in Manchester these scores underestimate lung cancer risk. Furthermore, only 40% of people diagnosed with lung cancer in unscreened populations would have met the criteria for screening in the time preceding diagnosis. We have reasoned that a pre-CT screening test would reduce the number of CT scans needed per positive diagnosis, thereby reducing the cost and broadening the reach. This study aims to develop immune biomarkers which can be used in community screening to provide improved personalised risk profiles to allow clinicians to identify at-risk individuals outside the current cutoffs used with PLCO and LLP scores.

Material and method

Using a CyTOF-based pipeline we have immunoprofiled peripheral whole blood from patients at community lung health checks and lung cancer clinics. Based on cancer-associated cell populations identified in this pipeline, we then utilised preliminary scRNA-seq and multiplex ELISA's to explore chemokine communication between tumour and circulating immune cells in early cancer.

Result and discussion

Our results reveal several potential candidates for improving lung cancer screening including, lung cancer-associated depletion of CD161+ T cells and altered classical monocyte and NAIVE CD8+ T cell phenotype.

Furthermore, we describe several cancer-associated serum chemokines including the promising CXCL9-CXCR3 signalling pathway as a potentially key biomarker of early lung cancer.

Conclusion

This work may constitute the first step towards the integration of blood-based immune biomarkers with existing risk scores which could significantly improve access to lung cancer screening and improve early detection while reducing unnecessary low dose CT scans during community screening.

Introduction

New preclinical models are urgently needed to understand the biology of circulating tumor cells (CTCs), their role in dissemination, and to identify potential drugs targeting CTCs. These models include both *in vivo* CTC-derived xenografts (CDX) and *in vitro* cell cultures. In this work we present the derivation and characterization of CTCs-derived model from the blood of a patient with invasive ductal carcinoma of the right breast.

Material and method

The CTCs-enriched fraction was obtained from 9 ml of whole blood by depletion of CD45+ cells and implanted under the renal capsule of female NRG mouse. *In vitro* cell cultures were established by sorting CD298+ human cells from a single cell suspension prepared from xenograft. Selected drugs were tested *in vitro* using 3D cell culture. To test the drugs *in vivo*, tumor fragments were implanted in mammary fat pad of NRG female mice and once growing, mice were given the drugs intra-peritoneally or via oral gavage. A manual caliper was used to monitor the tumor growth.

Result and discussion

The CTCs-enriched fraction formed a tumor (CDX_IBP_01) under the renal capsule within 6 months and its metastatic potential was confirmed *in vivo*. Both 2D and 3D *in vitro* cell cultures were derived from generated CDX. RNA-Seq analysis comparing the primary tumor and CDX_IBP_01 revealed substantial differences associated with cell growth, metabolism, and extra-cellular signaling. The potential of established CDX as a

model for preclinical drug testing was investigated both in vivo and in vitro. Here, we compared the effect of therapeutics previously administered to the patient (gemcitabine and carboplatin) with potentially effective drugs selected based on the results of transcriptomic profiling.

Conclusion

In summary, we present a novel preclinical model of progressive breast cancer derived from CTCs that may serve as a useful model for studying and understanding the plasticity and behaviour of CTCs during tumor progression and for testing therapeutics potentially targeting CTCs.

Introduction

Bladder cancer (BC) remains a major public health concern, for which early detection is essential for improving patient prognosis. Emerging metabolomics research has highlighted the potential of urinary volatile organic compounds (VOCs) as non-invasive biomarkers for the early detection of BC. Cancer-related metabolic alterations give rise to distinct VOC profiles, facilitating the differentiation between malignant and non-malignant conditions. Advanced analytical techniques, such as gas chromatography-mass spectrometry (GC-MS), in combination with machine learning (ML) algorithms, offer a powerful approach for biomarker discovery and validation. This study aimed to leverage ML algorithms applied to GC-MS-based metabolomics data to discover a panel of volatile biomarkers able to accurately discriminate BC patients from cancer-free controls.

Material and method

Urine samples were collected from 177 participants, including 87 patients diagnosed with BC and 90 cancer-free controls [1]. Urine sample analysis was conducted using headspace solid-phase micro-extraction coupled with GC-MS. Five distinct ML algorithms were employed for data analysis: support vector machine (SVM), random forest (RF), partial least squares-discriminant analysis (PLS-DA), extreme gradient boosting (XGBoost), and k-nearest neighbors (k-NN). Model performance was evaluated using receiver operating characteristics (ROC) analysis, with key metrics including area under the curve (AUC), sensitivity, specificity, and accuracy.

Result and discussion

Among the various ML algorithms tested, the RF model demonstrated the highest performance in distinguishing BC patients from cancer-free controls. A panel of eight potential biomarkers was identified through RF for the overall detection of BC, achieving 89% sensitivity, 92% specificity, 91% accuracy, with an AUC of 0.872. This biomarker panel consisted of three ketones, three aldehydes, one fatty alcohol, and one phenolic compound. Of these eight compounds, seven were found at higher levels in the urine of BC patients compared to controls, while one compound was found at lower levels.

Conclusion

Our study identified a panel of eight volatile biomarkers that accurately detect BC. These findings underscore the potential of metabolomics, combined with ML techniques in cancer biomarker discovery.

Implementation of this urinary biomarker panel in clinical practice may revolutionize BC detection by offering a non-invasive and rapid screening method.

Photodynamic laser therapy decreases inflammation in oral lichen planus patients

M. Draganova^{1,2}, Y. Feodorova^{1,2}, V. Dichev^{1,2},

M. Mutafchieva³

¹Medical University of Plovdiv, Department of Medical Biology, Plovdiv, Bulgaria

²Research Institute, Medical University of Plovdiv, Plovdiv, Bulgaria

³Medical University of Plovdiv, Department of Periodontology and Oral Mucosa Diseases, Plovdiv, Bulgaria

Introduction

Oral lichen planus (OLP) is an auto-immuno-inflammatory disease with unknown etiology. Chronic inflammation, resulting from basal membrane disruption plays a critical role in the pathogenesis of OLP, therefore WHO defined it as a precancerous condition. Although, topical corticosteroids are the first choice of treatment, their prolonged use may lead to systemic complications. Recently, the use of photodynamic laser therapy (PDLT) has been introduced in the treatment of oral diseases. This study aims to determine and compare the expression of markers associated with epithelial disruption and pro-inflammatory cytokines in patient samples before and after PDL treatment.

Material and method

11 OLP patients (before and after therapy) and 8 healthy controls, all signed an informed consent, were included in this study. The patients were treated with laser 810 nm (CW; 0.50 W; 30 s; 1.2 J/cm²) three times weekly for a month. The samples were taken before and after therapy. The pellets of saliva were used for RNA isolation. The gene expression and secretion of MMP-9 and VEGF were determined by qPCR. The supernatants were analyzed for inflammatory cytokines IL-1 β , IL-6 and TNF- α by ELISA.

Result and discussion

Our study shows that the VEGF level was higher in patients with oral lichen planus compared with the healthy controls despite the lack of statistical difference. After therapy, the expression profile was similar to the control group. We expected MMP9 expression to be increased in the patient group and decreased after PDT but the results did not show a significant difference. The levels of the salivary cytokines IL-1 β (80.86 ± 34.3 pg/mL), IL-6 (26.89 ± 10.34 pg/mL), and TNF- α (11.48 ± 6.58 pg/mL) in OLP patients were significantly higher compared to those in healthy controls (30 ± 10.8 pg/mL, 14.06 ± 6.22 pg/mL, and 5.55 ± 3.65 pg/mL) and decreased after therapy (57.26 ± 24.8 pg/mL; 18.64 ± 6.53 pg/mL and 7.31 ± 4.30 pg/mL).

Conclusion

In conclusion, the decrease in cytokine levels at the end of the treatment course proves the ability of the laser therapy to reduce inflammation in OLP patients but further analyses are necessary to find the pathological mechanism and connection with molecules responsible for tissue degradation.

⁴Institute for Oncology and Radiology of Serbia, Department of Experimental Oncology, Belgrade, Serbia

Introduction

Breast cancer is the most common type of malignancy and the leading cancer-related cause of death in women worldwide. Triple negative breast cancer (TNBC) is characterized by absence of ER, PR and HER-2 receptors and it accounts for 10-15% of all breast cancer cases. In comparison to other types of breast cancer, TNBC is more aggressive, has higher recurrence, metastasis and mortality rates. The only available therapy for TNBC is conventional chemotherapy, to which it readily develops resistance. Aberrant signaling in both PI3K/AKT/mTOR (PAM) pathway and Wnt/ β -catenin pathway is proved to contribute to acquiring resistance to therapy. These signaling pathways are interconnected by glycogen synthase kinase-3 β (GSK3 β) which is a key kinase in regulating β -catenin degradation, while its own activity is regulated by kinases from PAM pathway: S6 kinase 1 (S6K1) and AKT. GSK3 β also suppresses the activity of PTEN, a PAM pathway suppressor. The interrelation between PAM and Wnt pathways provided by GSK3 β could enable the tumor cells to simultaneously activate both pathways in order to survive. Therefore, GSK3 β and S6K1 may be implicated in progression and development of drug resistance.

Material and method

Total RNA was extracted from FFPE samples of paired tumor and normal tissues of 119 patients diagnosed with TNBC. RNA was reverse transcribed and obtained cDNA was used for real-time PCR expression analysis of GSK3 β and S6K1 genes. Obtained results were analysed with clinical, pathohistological and immunohistochemistry data of Ki-67, EGFR, PD-L1 and androgen receptor (AR) proteins.

Result and discussion

The analysis of mRNA expression shows that it significantly changes in 45.4% patients for GSK3 β and in 25.2% for S6K1. In majority of those patients the mRNA level is decreased both for GSK3 β (90.7%) and S6K1 (56.7%). There is a positive correlation between expression of GSK3 β and S6K1 mRNA ($p < 0.0001$, $r = 0.3511$). We further analysed association of GSK3 β and S6K1 expression with pathohistological parameters as well as protein expression of Ki-67, EGFR, PD-L1 and AR, assessed by immunohistochemistry. The expression of S6K1 is negatively correlated with EGFR protein level ($p = 0.004$, $r = -0.2618$), while there is also association between change in S6K1 expression and low level of AR ($p = 0.0238$). The analysis in simultaneous changes in GSK3 β and S6K1 mRNA levels also shows association

of decreased levels of both mRNA with low AR and high EGFR protein expression ($p = 0.0083$ and $p = 0.0385$ respectively). We previously established that high expression of EGFR combined with low expression of both PD-L1 and AR represent a “high-risk” phenotype of TNBC.

Conclusion

Our findings show that GSK3 β and S6K1 mRNA levels are positively correlated and that the decrease in expression of both genes could be considered as a contributing factor in “high-risk” profile of TNBC. Therefore we suggest EGFR+, PD-L1-, AR-, GSK3 β - and S6K1- as up to date high risk profile for TNBC patients.

Mutational enrichment of CTCs and CTC clusters from breast cancer xenografts

N. Varela-Rouco¹, N. Estévez-Gómez¹, C. Fernández-Santiago², L. Tomás¹, J. Alves¹, R. Piñeiro², D. Posada¹

¹CINBIO - Universidade de Vigo, Vigo, Spain

²Roche-Chus Joint Unit, Translational Medical Oncology Group, Oncomet, Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain

Introduction

Preclinical and clinical studies indicate that circulating tumor cells (CTCs) are crucial in the metastatic cascade. CTC clusters, aggregates of tumor cells that detach from primary tumors, are often associated with poor clinical outcomes. While it is believed that cells within these clusters cooperate during dispersal, dissemination, and colonization, the extent of genomic heterogeneity within CTC clusters and their relationship to primary tumor and metastatic clones remains largely unexplored.

Material and method

To investigate these questions, we established mouse xenografts using the triple-negative breast cancer cell line MDA-MB-231. We collected tissue samples from primary tumors and metastases and blood samples to isolate both single CTCs and CTC clusters. Whole-exome sequencing was performed on these samples, enabling the identification of single-nucleotide and copy-number variants through a custom bioinformatic pipeline.

Result and discussion

Our analysis revealed ample genomic heterogeneity among CTCs and CTC clusters at the single nucleotide variant level. We identified a set of genes more frequently mutated in CTC and CTC clusters than in primary tumors and metastases, suggesting that they might play a role in the formation and survival of CTCs and CTC clusters.

Conclusion

This study offers new insights into the genomic landscape of CTCs and CTC clusters, identifying novel genes that might play a significant role in CTC biology.

³Sabancı University, Center of Excellence for Functional Surfaces and Interfaces for Nano-Diagnostics (EFSUN), İstanbul, Turkey

Introduction

Circulating Tumor Cells (CTCs), which are rare cancer cells that detach from a primary malignancy and infiltrate the circulatory system, are instrumental in the advancement of metastatic cancer. One of the most effective techniques for detecting and isolating CTCs from the bloodstream is inertial focusing through microfluidic devices. Because inertial microfluidics is a passive technique, no markers are required. In order to separate CTC from other blood cells, this technique makes use of the dimensional differences between the cells. In this work, CTCs are isolated from other blood cells using hydrodynamic force-based inertial microfluidics systems.

Material and method

The current study assesses the effects of drag and inertial forces on cells of different sizes in serpentine microchannels with an internal radius of 800 μm and a curvature angle of 280°. The important feature of the microchannel structures is the different depths (60 μm , 73 μm , 90 μm and 105 μm) and different angles between the outlet channels (73 and 90 degrees). In the presented system, the best results were obtained by selecting a channel depth of 105 μm and an outlet channel angle of 73 degrees. These special microchannel geometries facilitate parallelization with optical detection and provide effective size-based separation of CTCs. The COMSOL Multiphysics 6.2 software was used to perform three-dimensional numerical simulations and estimated the paths taken by cells of different types in order to verify the performance of the microchannel designs. The simulation results were subsequently supported by experimental investigations employing polydimethylsiloxane (PDMS) microchannels with different configurations and sizes of cells. In relation to this study, the HeLa cell line was used as a CTC model, while the Jurkat and K-562 cell lines were used to mimic blood cells.

Result and discussion

The results demonstrated that by employing hydrodynamic forces, the developed microfluidic device can isolate CTCs with high sensitivity. In accordance with the simulation results, an effective separation on the microfluidic chip led to the collection the CTCs with a success rate of over 90%. The performance of this system, which does not require external force and is label-free, is better and more effective than the majority of systems found in the literature.

Conclusion

This label-free approach provides a cost-effective way to monitor and detect early cancer, which will be helpful in clinical trials. Future research will focus on the improvement of microchannel design. Its suitability for different cancer types and clinical environments will be also explored.

EACR25-1961

Activated CD4+T cells as prognostic and predictive biomarkers in cutaneous melanoma

A. Tomás^{1,2}, J. Maximino¹, H. Nunes³, F. Gonçalves⁴, V. Farrinha⁵, E. Carvalho⁶, S. Cristóvão-Ferreira³, P. Pereira³, M. Cabral², M. Pojo¹

¹*Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Molecular Pathobiology Research Unit, Lisbon, Portugal*

⁴*Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Immunohematology Department, Lisbon, Portugal*

⁵*Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Surgery Department, Lisbon, Portugal*

⁶*Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Clinical Research Department, Lisbon, Portugal*

Introduction

Due to its rising incidence, cutaneous melanoma (CM) has emerged as a significant public health concern. Despite the remarkable success of immune-checkpoint blockade therapies in improving overall survival of advanced CM patients, mortality rates remain high at advanced stages – nearly 60,000 patients die every year due to CM, worldwide. The main challenge lies in primary and secondary resistance to immunotherapy. Thus, there is an urgent need to uncover new biomarkers and understand the mechanisms of immunotherapy resistance to improve advanced CM patient management.

Material and method

A comprehensive immune subset characterization was conducted using flow cytometry and RT-qPCR on surgical specimens and peripheral blood samples from 50 stage III/IV CM patients who underwent resection surgery or immunotherapy at our host institute (adjuvant and palliative settings). Peripheral blood from 15 healthy donors was also analysed. Flow cytometry analysis focused on CD8+/CD4+ T cell activation markers, regulatory T cells and associated immunosuppression markers, and monocytic subpopulations. Plasma cytokines were measured via ELISA.

Result and discussion

Stage IV CM patients exhibited reduced levels of activated CD4+ T cells compared to healthy controls, indicating a weakened anti-tumour response. High expression of CD4+ T cell activation markers was associated with longer overall survival (OS) and progression-free survival (PFS) (OS: $p = 0.009$, HR = 0.811; PFS: $p = 0.032$, HR = 0.912), independent of other clinical variables. ROC curve analysis revealed superior predictive accuracy for OS over PFS (AUC = 0.795 vs. 0.728). These findings identify activated CD4+ T cells as a potential prognostic biomarker in CM. Additionally, higher levels of these cells were linked to good immunotherapy response (AUC = 0.729), whereas lower levels were found in patients who relapsed during or after adjuvant immunotherapy. Interestingly, preliminary

results show that higher expression of CD4+ T cell activation markers, combined with increased co-stimulatory receptor expression on monocytes, correlated with extended relapse-free survival in the adjuvant setting ($p = 0.006$, HR = 0.827). This combined biomarker profile exhibited strong predictive accuracy for therapeutic benefit in both palliative and adjuvant contexts (AUC = 0.866), supporting its potential as a predictive biomarker for immunotherapy response in CM.

Conclusion

Thus far, our results highlight the potential of activated CD4+ T cells as a prognostic and predictive tool in CM. Identification of novel biomarkers can improve patient stratification, preventing unnecessary exposure to costly treatments and immune-related toxicity in non-responders. Ongoing analysis aim to further characterize these populations along with their impact on clinical outcomes and immunotherapy response.

EACR25-1963

Characterization and evaluation of CD24 and NPY as biomarkers for metastatic castration-resistant prostate cancer (mCRPC)

P. McHenry¹, N. Fakhruddin², K. Homer³, R. Gil da Costa⁴, L. True⁵, C. Morrissey⁶

¹*Middle East University, Department of Biology, Beirut, Lebanon*

²*American University of Beirut, Department of Pathology and Laboratory Medicine, Beirut, Lebanon*

³*Texas Health Huguley Hospital, Department of Pathology, Burleson, TX, United States*

⁴*Fred Hutchinson Cancer Center, Division of Human Biology, Seattle, WA, United States*

⁵*University of Washington, Department of Laboratory Medicine and Pathology, Seattle, WA, United States*

⁶*University of Washington, Genitourinary Cancer Research Laboratory, Seattle, WA, United States*

Introduction

In 2022, prostate cancer was the most diagnosed cancer, and the third most deadly cancer, among men in Europe. The current standard of care includes androgen ablation therapy, which reduces androgen receptor (AR) signaling. However, prostate cancers often develop resistance to this therapy and recur in an incurable form called metastatic castration-resistant prostate cancer (mCRPC). Previous whole-genome RNAseq results indicated a possible role for various proteins in mCRPC, including cluster of differentiation 24 (CD24) and neuropeptide Y (NPY).

Material and method

In the current study, we analyzed tissue microarrays representing 127 primary prostate cancers (with matched normal adjacent tissue) and 124 metastases (from 34 patients) using immunohistochemistry to detect CD24 or NPY.

Result and discussion

CD24 was more highly expressed in cancer tissue than in adjacent normal tissue. Compared to the normal tissues, mean scores were nearly double in cancer tissues for nuclear ($p < 0.001$), cytoplasmic ($p < 0.001$), and

membranous staining ($p = 0.012$). In metastases, Nuclear CD24 was expressed less in bone than in liver or lymph nodes ($p = 0.053$ and 0.027, respectively). CD24 in metastases correlated weakly with final serum PSA ($r = 0.305$, $p = 0.084$) but not with other clinical factors. Cytoplasmic expression of NPY was lower in prostate cancers that later recurred (6.7, 95% CI 2.6–10.9) compared with cancers that did not recur (14.6, 95% CI 5.2–23.9; $p = 0.111$). Cytoplasmic expression of NPY was weakly correlated with time between androgen ablation and death ($r = 0.335$, $p = 0.053$). A very weak positive correlation was found between cellular PSA expression and nuclear CD24 ($r = 0.205$, $p = 0.023$) or cytoplasmic NPY ($r = 0.190$, $p = 0.041$). No correlation was found with AR, CHGA, or SYP.

Conclusion

The data suggest a potential role in cancer transformation for CD24. Bone metastases showed lower expression of CD24 compared to visceral sites, also suggesting a possible role for this protein in the metastatic niche. NPY showed some ability to predict prostate cancer recurrence. Cytoplasmic expression was less than half in cancers that later recurred, suggesting a metastasis suppressor role for this protein. This agrees with recently published evidence that serum NPY levels are negatively correlated with mCRPC progression.

EACR25-1978

Capturing the Full Spectrum: High Dynamic Range Biomarker Detection with Photon Upconverting Nanoparticles

M. Helgstrand¹, M. Mickert¹, K. Berggren¹, A. Johansson¹, S. Wallenborg¹

¹Lumito AB, Lund, Sweden

Introduction

Advances in targeted cancer therapies have shown an increasing need for quantitative detection of ultra-low expressing biomarkers. In breast cancer diagnostics, for example the distinction between HER2-0 and HER2-low patients has gained significant attention over recent years. Tissue microarrays (TMA) are an excellent tool for high throughput analysis of various specimens under similar conditions. In many cases, the amount of protein expression varies significantly, and gold standard HRP/DAB-based labelling tends to saturate quickly. To address the needs for ultra-low detection without saturation at high expression levels, we have developed a novel, highly sensitive IHC method based on photon-upconverting nanoparticles (UCNP). UCNPs (30–40 nm) are excited in the near-infrared and emit visible light, eliminating tissue autofluorescence and allowing for background-free imaging.

Material and method

- Sensitivity was demonstrated by titrating the primary anti-HER2 antibody A0485 (Dako) on HER2 over-expressing cells and comparing it with the traditional HRP/DAB labelling.
- Limit of detection was assessed using IHC calibrator beads from Boston Cell Standards.
- Dynamic range and sensitivity were further demonstrated by analyzing TMA cores with ultra-low and high HER2 expression located on the same slide.

- UCNP photostability was demonstrated by rescanning HER2-labelled cells over 500 times and measuring the emission signal intensity.

Result and discussion

- Under the same experimental conditions, UCNP showed 10x higher sensitivity compared to HRP/DAB.
- Limit of detection (LOD) of 4000 HER2 molecules/bead was calculated from the analysis of Boston Cell Standards IHC calibrator beads.
- UCNP labelling of HER2 in a TMA showed high sensitivity and discrimination of high HER2-expressing samples that appeared saturated using a reference method.
- UCNPs had constant emission signal over more than 500 scan cycles.

Conclusion

UCNP technology demonstrated high sensitivity and dynamic range compared to other traditional IHC methods. Enhanced sensitivity and robustness could lead to more accurate diagnoses and improve the development of targeted therapies for patients with cancer where quantitation and/or ultra-low detection of biomarkers are important.

⁶Hull University Teaching Hospital NHS Trust, Gastroenterology, Hull, United Kingdom

⁷Hull University Teaching Hospital NHS Trust, Radiology, Hull, United Kingdom

Introduction

The premalignant pancreatic cellular genotype can remain stable for years before undergoing rapid malignant transformation, often associated with inflammation. Tissue factor (TF) is an inflammatory modulator regulated by factor VIIa (fVIIa) which regulates its levels and activity. The presence of TF in pancreatic ductal adenocarcinoma (PDAC) and its role in cell proliferation, angiogenesis, and metastasis suggest that TF may serve as a marker of the inflammatory microenvironment that drives precursor lesions of pancreatic cancer. This study examined the clinical value of measuring TF levels within pancreatic cyst fluid (PCyF) for detecting malignant transformation.

Material and method

PCyF from 50 patients with pancreatic cystic lesions (TEM-PAC, REC 18/LO/0736) was analysed in a blinded

manner. TF and fVIIa proteins were measured using ELISA. A cut-off value for TF concentration was determined using ROC analysis and compared to conventional assessment parameters (radiological features, carcinoembryonic antigen (CEA), and amylase).

Result and discussion

Patients were categorised into four groups based on histology. Significant histological stage-dependent increases in TF levels were observed, which correlated with the progression from normal ductal epithelium to invasive adenocarcinoma. The cyst cohort was stratified into two risk groups based on the pathological cyst type. The low-risk 'non-resective' group included patients with benign cysts and low-grade dysplasia, and the high-risk 'resective' group included patients with high-grade dysplasia and invasive/malignant cysts. The mean TF concentration was significantly elevated ($p < 0.0001$) in the resective group (2.06 ng/ml, 95% CI 1.38, 2.73) compared to the non-resective group (0.58 ng/ml, 95% CI 0.34, 0.82). A strong positive correlation between TF concentration and the resective group was observed ($\chi^2 = 18.1$, $r = 0.603$, $p < 0.001$) at a TF cut-off value of 1.599 ng/ml, AUC 0.867, $p < 0.001$; odds ratio 20.0 (4.2, 94.9), $p < 0.001$). Additionally, the fVIIa:TF ratio was significantly lower ($p = 0.011$) in the resective group (mean = 101 [95% CI 0.63, 201.4]) compared to the non-resective group (mean = 897.8 [95% CI 298.6, 1497]).

Conclusion

Cyst-associated TF levels appear to correlate with cytological progression towards the malignant phenotype, while the fVIIa:TF ratio indicates a decline in the body's ability to contain the disease. Such indicators may allow for better discrimination (specificity 90%) of the 'resective' lesion, reduce healthcare costs, and provide a more nuanced tool for monitoring indeterminate cystic lesions.

EACR25-2029

Morphometric analysis of neoplastic cell clusters in high-grade serous ovarian cancer ascites may prove to be a novel prognostic factor: a retrospective study

B. Thibault¹, R. D'Angelo¹, S. Rigal¹, M. White-Koning¹, G. Bataillon², J. Guillermet-Guibert¹, C. Basset¹

¹*Cancer Research Centre of Toulouse, Université de Toulouse, Inserm, CNRS, Toulouse, France*

²*Department of Pathology, University Cancer Institute Toulouse – Oncopole (IUCT-O), Toulouse Hospitals, Claudio Regaud Institute, Toulouse, France*

Introduction

High-grade serous carcinoma of the ovary is the most frequent intraperitoneal malignancy in women. It is associated with a poor prognostic outcome owing to the late appearance of clinical signs leading to a delayed diagnosis, and with resistance to platinum-based chemotherapy. One of the clinical signs is the development of ascites. The detection of neoplastic cells in ascites fluid is important as it indicates tumor progression and is associated with shorter survival. Microscopic cytopsin analysis of this fluid reveals the cytological and architectural features of the neoplastic cells, allowing the pathologist to identify rapidly the malignancy and the

histologic type. In association with immunocytochemistry, this process ensures a definite diagnosis and provides a specific etiology. Our objective was to provide proof-of-principle that the automatized analysis of general cytomorphological criteria, such as carcinomatous cell clustering, in malignant ascites fluid is of prognostic value in high-grade serous carcinoma.

Material and method

We performed a retrospective analysis of the ascites fluid of 24 advanced-stage high-grade serous ovarian cancer patients naïve of treatment and collected their biological, clinical and cytomorphological (number and size of neoplastic clusters) data. Neoplastic cells were detected using BerEP4 staining. Overall and progression-free survival were used as clinical outcomes and were adjusted with biological and clinical covariates using Cox regression models.

Result and discussion

After adjustment with different covariates (age, body mass index, sugarbaker score, WHO performance status) we found that the low number of neoplastic cell clusters and percentage of neoplastic cells in fluid was significantly associated with shorter overall and progression-free survival. These results were independent of the peritoneal implantation of neoplastic cells.

Conclusion

We propose a novel strategy to improve high-grade ovarian serous carcinoma diagnostics using a more informative but simple analysis of ascites tumor cell morphology. The number of neoplastic clusters may prove to be a new prognosis factor.

EACR25-2032

Optical Genome Mapping for detecting Homologous Recombination Deficiency in breast and ovarian cancers

S. Vanhuele¹, M. Villy¹, Y. Kirova², A. Rapinat³, M. Ichalalen³, C. Callens⁴, M. Rodrigues⁵, F. Bidard⁶, M. Stern¹, T. Popova¹

⁴*Institut Curie, Department of Genetics, Paris, France*

⁵*Institut Curie, Inserm U1339 UMR3666, DNA Repair and Uveal Melanoma (D.R.U.M.) team ; Department of Medical Oncology, Paris, France*

⁶*Institut Curie, Genomics Platform, Translational Research Department ; Department of Medical Oncology, Paris, France*

Introduction

Homologous recombination deficiency (HRD) leads to genomic instability resulting in specific genomic alterations (genomic scar). One strong component of this scar is structural variants (SV), best called by high coverage whole genome sequencing (WGS). The potential of Optical Genome Mapping (OGM) technology in calling SVs suggested a cost-effective and computationally efficient model for HRD testing, as compared with WGS.

Material and method

We analyzed the OGM SV output from a training set of 40 samples of triple-negative breast cancer (TNBC, n = 25) and high-grade ovarian cancer (HGOC, n = 15) with known HRD status coming from shallowHRDv2 (Callens et al. *Oncogene* 2023) and MyChoiceHRD from Myriad®. SV features associated with HRD or nonHRD status were selected to create a lasso logistic regression model able to determine the HRD status of novel tumors. This model was validated on an independent cohort of 30 TNBC and HGOC.

Result and discussion

Based on a training set, novel and previously described features associated with HRD or nonHRD tumors were identified. Isolated and balanced translocations were found strongly associated with HRD, while two novel features were enriched in nonHRD cases. The linear HRD classifier using these features showed minimal accuracy of 97% in the validation series. This HRD classifier corrected at least one case of the validation series to a subsequently confirmed HRD status.

Consistent with previous studies, duplications and deletions smaller than 25kb were found enriched in BRCA1- and BRCA2-inactivated tumors, respectively.

Conclusion

In conclusion, we demonstrate the promising value of OGM as a fast, cost-effective and accurate technique to determine HRD status in TNBC and HGOC, tolerating low tumor content due to its ultra-high coverage, which also allowed to revisit genomic instability features associated with nonHRD tumors.

EACR25-2044

Combined microfluidic isolation and immunofluorescence staining of circulating tumour cells for the assessment of Androgen Receptor expression in metastatic Prostate cancer blood samples

D. Greaves¹, A. Cottingham¹, L. Kaja¹, M. Ciccioli¹, A. Pailhes-Jimenez¹

¹ANGLE Europe Ltd, Cell Biology & Imaging, Guildford, United Kingdom

Introduction

Background. Measurement of Androgen receptor (AR) expression can be integral to determining treatment response of metastatic Prostate cancer (PCa) patients. The ANGLE Portrait® AR Assay (Research Use Only (RUO)) allows direct interrogation of AR activity; combining identification and phenotyping of CTCs isolated through the epitope-independent Parsortix® instrument with assessment of AR expression levels and intracellular localisation, a combination which may facilitate minimally invasive longitudinal monitoring of patients throughout treatment.

Material and method

Methods. Peripheral blood from 10 healthy volunteers was drawn into Streck Cell-Free DNA tubes and spiked with LNCaP cells pretreated with ascending concentrations of an AR inhibitor, or untreated PC-3 cells as a negative control. Spiked samples were processed with the Parsortix® instrument (RUO) within 144 hours

of collection. Harvests were cytocentrifuged onto ANGLE CellKeep™ slides then stained using ANGLE's Portrait® AR IF assay, an antibody panel comprising a nuclear dye (Hoechst), antibodies against epithelial markers (FITC), AR (Cy3), mesenchymal markers (Cy7), and antigens expressed by white blood cells (Cy5). Stained slides were imaged using a BioView DeNovo imaging system. The workflow was then repeated using peripheral blood drawn from 20 castration-resistant PCa patients (unspiked).

Result and discussion

Analytical Results. A statistically significant negative correlation ($p < 0.0001$) was observed between AR inhibitor treatment concentration and AR expression detected in the Cy3 channel. In vehicle-treated LNCaP, AR positivity was 83.6%, whilst in LNCaP treated with 10nM or 1000nM inhibitor concentration AR positivity was 62.4% and 15.2% respectively. The dynamic range of mean signal intensity between vehicle-treated LNCaP and PC-3 was 3.9:1. **Patient Results.** ≥ 1 CTCs were identified in 13 (65%) of patients, with a median of 6 and mean of 121 CTCs identified per patient. CTC clusters harvested by the Parsortix® instrument were observed in 77% of the CTC+ patients. Cluster size ranged from 2–105 CTCs per cluster, and the number of clusters per patient ranged from 1–181. Of the CTC+ patients, 54% (7/13) presented AR+ CTCs, 3/7 showed CTCs with cytoplasmic AR positivity only. The remaining 4/7 showed a mix of nuclear and cytoplasmic positivity across detected CTCs. 58% (50/86) of detected EMT CTCs were AR+, compared to 32% (466/1475) of mesenchymal and 23% (4/17) of epithelial, suggesting that AR signalling may promote an EMT phenotype in CTCs.

Conclusion

Conclusions. The Portrait AR workflow was able to accurately assess AR expression and localisation in CTCs isolated from PCa patients. This demonstrates that combining epitope-independent CTC isolation with immunofluorescence staining for detection of AR in CTCs has the capability to enable dynamic, easy monitoring of AR status, with potential utility for longitudinal monitoring of patient outcomes.

Introduction

Ovarian cancers are the second leading cause of death from gynaecological cancers worldwide, primarily due to late diagnosis combined with the development of resistance to platinum-based chemotherapy. The difficulty in predicting response to conventional as well as innovative treatments as PARP inhibitors (PARPi) highlights the need to identify new biomarkers to guide therapeutic decisions. However, access to biological samples from PARPi-resistant patients is complex. It is therefore essential to develop complementary approaches to identify relevant biomarkers.

Material and method

Recently, we have demonstrated the interest of patient-derived tumour organoids (PDTO) in identifying microRNAs (miRNAs) predictive of platinum response after developing a robust methodology to study miRNAs expression in the cellular and extracellular fractions of PDTO. In this study, we attempted to establish PARPi-resistant PDTOs, with the aim of assessing changes in the expression of cellular and extracellular (culture supernatant) miRNAs in relation to the acquisition of acquired PARPi-resistance. Five PDTO lines, sensitive to PARPi, will be treated for one week with a PARPi (niraparib or olaparib), at a dose corresponding to their IC₅₀, for 6 cycles. PDTO will be harvested at the end of each cycle to identify potential variations in miRNAs expression using an omic approach, which will then be validated individually by RTqPCR.

Result and discussion

Preliminary results show a threefold shift in the IC₅₀ of one PDTO line after six cycles of Olaparib or niraparib. It is therefore necessary to expose PDTOs to a threefold higher dose of PARPi to kill 50% of our PDTO. This work is being carried out in parallel on two other lines. It will then be necessary to validate these results on a larger number of PDTO lines and on biological samples (tumor/serum) from cohorts of patients with acquired resistance to PARPi with a view to clinical application.

Conclusion

This kinetic approach will make it possible to identify miRNAs whose expression evolves during the acquisition of resistance to PARPi, thus offering new avenues for identifying biomarkers for therapeutic monitoring.

EACR25-2095

Development of novel biomarker-based methods for early detection of cancer aggressiveness and cancer treatment stratification in Head and neck squamous cell carcinoma

P. Parimelazagan Santhi¹, O. Kauko¹, J. Rantala²,

J. Westermarck¹, S. Ventelä¹

¹*University of Turku, Turku Bioscience Center, Turku, Finland*

²*Misvik Biology, Turku, Finland*

Introduction

Head and neck squamous cell carcinoma (HNSCC) is highly invasive and metastatic cancer. A major clinical challenge in HNSCC is lack of diagnostic methods to predict and target metastatic behavior of the cancer. The most effective solution to this challenge is the development of a biomarkers that could identify aggressive, i.e. metastatic, cancer at an early stage. Biomarkers of this type would enable the use of efficient and multimodal treatment methods in individualized cancer treatment. Based on our recent research LIM domain and actin binding 1 (LIMA1) isoforms could potentially be used as a marker to identify patients having increased risk of metastasis during follow-up. LIMA1 signaling in HNSCC is also associated with metastatic pathways such as EMT (Endothelial Mesenchymal Transition) by expression of markers like Vimentin and CD44, increasing the importance of studying LIMA1 in cancers and enabling its use in designing targeted treatment options. The expression of LIMA1 in relation to cancer metastasis has been studied recently in other cancer types as well, however specific roles of LIMA1 isoforms in the HNSCC progression, metastases formation, and in cancer therapy targeting are largely unknown.

Material and method

Mass spectrometry of patient derived tumor samples. Flag tag pull down mass spectrometry of LIMA1 isoforms, Western Blots, Mass spectrometry of HNSCC cell lines where LIMA1 isoforms were silenced ie., comparison between SCR vs siLIMA1. Drug screen with LIMA1 knockout vs wild type cell lines. HNSCC cell lines with different LIMA1 isoform profiles are chosen and knock out models has been created for drug screening and other invitro experiments.

Result and discussion

A more detailed understanding of LIMA1-related signaling would seem to create entirely new diagnostic possibilities for cancer treatment stratification. In our ongoing studies, we focus on revealing the following clinical questions important for both LIMA1 and HNSCC. The mechanistic role of LIMA1 isoforms related CD44 cancer metastasis. The protein landscape of the LIMA1 interaction and regulation is studied in detail. The HNSCC patient samples stratified for aggressive metastasis are screened for drug sensitivity to plan the patient specific treatment choices. There is a very clear evidence of specific LIMA1 isoform interaction and regulation with CD44 which has been studied using the above mentioned methods.

Conclusion

The regulation of these aggressive HNSCC markers LIMA1 and CD44 can serve as a potential compound biomarker for identifying a novel HNSCC subtype who are responders of specific targeted treatment.

EACR25-2143**Unveiling the Role of EVs-derived miR-15b-5p, -1293, -376a-3p in Clear Cell Renal Cell Carcinoma Progression**

V. Dias¹, Á. Alves¹, J. Maurício², A. Morais³, R. Medeiros¹, A. Teixeira¹, F. Dias¹

¹Portuguese Oncology Institute of Porto, Research Department, Porto, Portugal

²Portuguese Oncology Institute of Porto, Medical Oncology Department, Porto, Portugal

³Portuguese Oncology Institute of Porto, Urology Department, Porto, Portugal

Introduction

Clear cell renal cell carcinoma (ccRCC) is the most aggressive subtype of RCC, characterized by high metastatic potential and limited treatment options. Due to its asymptomatic nature, there is an urgent need for reliable biomarkers and novel therapeutic targets. miRNAs have emerged as promising biomarkers for predicting pathological grade, recurrence, and survival, while also serving as key regulators of signaling pathways that drive ccRCC aggressiveness and progression. Extracellular vesicles (EVs) play a crucial role in modulating the tumor microenvironment and serve as key carriers of miRNAs, positioning EV-derived miRNAs as potential prognostic biomarkers. The present study investigates the role of EV-derived miR-15b-5p, -1293, and -376a-3p and their gene targets in 3D spheroids to assess their prognostic and therapeutic relevance.

Material and method

In silico analysis was conducted to identify the miRNA target genes. 3D spheroids were generated using agarose-based micro-molds from a normal renal cell line (HCK-8) and primary ccRCC cell lines (786-O and Caki-2). Spheroids were collected, and EVs were isolated from the spheroid culture medium using the Total Exosomes Isolation Reagent (Invitrogen®). Spheroids were characterized through luminescence (CellTiter-Glo® 3D Cell Viability Assay), morphological assessment (size and shape), and immunofluorescence (DAPI + CellMask Orange staining). EVs were characterized via transmission electron microscopy (TEM), nanoparticle tracking analysis (NTA), and ELISA (CD63 evaluation). The miRNAs' expression profiles and target genes were analyzed using qRT-PCR.

Result and discussion

miRNA expression analysis in spheroid cells revealed that all three miRNAs were expressed across all cell lines, with distinct expression patterns among different clones, suggesting their role in tumor biology and reflecting ccRCC heterogeneity. In EVs, 786-O cells did not secrete any of the three miRNAs, indicating a possible alternative mechanism for tumor-micro-environment interactions and progression. Notably, EV-derived miR-1293 and -376a effectively distinguished tumor from normal renal cells, supporting their potential as circulating prognostic biomarkers. Regarding target gene expression, TGF-β1 mRNA was significantly upregulated in both cells and EVs from 786-O and Caki-2 compared to HCK-8. While SMURF1 was elevated in 786-O and Caki-2 cells, as well as in Caki-2 EVs, SMAD7 was undetectable, suggesting a disrupted

negative feedback control. These findings indicate hyperactivation of the TGF-β/Smad signaling pathway, potentially driving a more aggressive and metastatic tumor phenotype.

Conclusion

Our findings highlight the TGF-β/Smad pathway as a key driver of ccRCC aggressiveness while reinforcing the relevance of EV-derived miRNAs as prognostic biomarkers. Moreover, they provide valuable insights into ccRCC biology and underscore potential targets for future research.

Introduction

Acquired resistance remains a major challenge in the treatment of advanced stage NSCLC, limiting long-term efficacy of targeted therapies. As the number of targeted agents increases, the ability to dynamically monitor tumour evolution is critical for optimising patient management. Liquid biopsies provide a minimally invasive approach to assess treatment response and detect markers of resistance in real time.

Material and method

Using digital PCR (dPCR), we conducted a retrospective analysis of ctDNA, aiming to:

- (i) compare oncogene driver variant allele frequency (VAF) at baseline and disease progression, and
- (ii) evaluate dPCR as a tool for real-time assessment of treatment response dynamics.

Samples were collected prior to first-line advanced or adjuvant treatment for NSCLC, and at subsequent disease progression/relapse. Analysis was conducted on these paired samples from NSCLCs known to harbour EGFR or KRAS mutations ($n=18$ and 5 respectively).

Mutational status was determined via National Health Service (NHS) molecular testing, using an NGS panel on tissue. ctDNA was extracted (QIAamp MinElute cfDNA kit) and analysed by digital PCR (dPCR) (QIAcuityDx), reporting wild-type and mutant allele abundance

Result and discussion

Testing by dPCR detected mutations in 21/23 cases, offering 100% concordance with the NHS molecular results for KRAS (G12C 3, G12D 1, and G12V 1) and 88% EGFR (ex19 deletion 5, L858R 6 and T790M 5). This included detection in baseline samples with EGFR (13/16) and KRAS (5/5) mutations, as well as progression/relapse samples (15/16 and 5/5, respectively). EGFR ctDNA VAF increased at progression relative to baseline in 11 of 16 cases (69%), including all cases tested for EGFR T790M (n = 5), and most EGFR ex19 cases (4/5). VAF of L858R was more commonly reduced at disease progression (4/6, 67%), though this group was most heterogeneous with respect to treatments received (Gefitinib 3, Erlotinib 1, Osimertinib 2). Overall, this analysis revealed a mixed response in KRAS ctDNA dynamics where 3 cases showed increase at disease progression (G12D, and 2 G12C), and 2 decreasing (G12V and G12C). Ongoing clinical correlation will be reported, detailing these differences in the context of overall tumour burden.

Conclusion

Our findings confirm the feasibility of ctDNA monitoring in advanced-stage NSCLC and demonstrate strong concordance between dPCR and NHS molecular testing by NGS. The high accuracy of dPCR supports its potential as a complementary tool for detecting resistance mechanisms and refining treatment strategies. Crucially, ctDNA analysis is derived from minimally invasive liquid biopsies, enabling frequent monitoring at a low patient burden but with potentially high clinical benefit. A prospective study is planned to further investigate ctDNA dynamics stratified by mutation and treatment type.

EACR25-2168

Unveiling the Role of Extracellular Vesicle miRNAs in HCC Pathogenesis and Therapy

V. Manuti¹, A. Saponaro^{1,2}, E. Murgo¹, G. Savino², M. Marasco², T. Colangelo^{1,2}

¹Cancer Cell Signalling Unit, IRCCS Hospital Fondazione Casa Sollievo della Sofferenza, ISBReMIT-Istituto di Medicina Rigenerativa, San Giovanni Rotondo, Italy

²C.R.E.A.T.E. Center for Research and Innovation in Medicine, Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy

Introduction

Hepatocellular cancer (HCC) is the sixth most common tumor worldwide and the third leading cause of cancer-related death. The main etiologies include Hepatitis virus B (HBV), Hepatitis virus C (HCV), metabolic dysfunction associated fatty liver disease (MASH) and excessive alcohol consumption. Although several biomarkers have already been proposed for the diagnosis of hepatocellular carcinoma (HCC), the search for novel, more effective biomarkers remains a priority to improve both diagnosis and prognosis. In this context, circulating extracellular vesicles (EVs) are now recognized as critical mediators of intercellular communication.

Biomarkers such as microRNAs (miRNAs) represent a promising tool to gain new insights into the molecular pathogenesis of HCC. They hold great potential in

facilitating individualized clinical decisions, including early detection, treatment prediction, and prognostic assessment.

Material and method

Extracellular vesicles (EVs) were isolated from the serum of cirrhotic patients with and without HCC. Patients in each category were further stratified into four groups based on their underlying etiology: HBV, HCV, MASH, and alcohol-related (ALC). EVs were analyzed via nanoparticle tracking analysis and characterized by immunoblotting. A multiplex bead-based approach coupled with flow cytometry was then used to assess the immunological profile of serum-derived EVs. Next, EV-miRNAs were extracted and sequenced to identify differentially expressed miRNAs between HCC and non-HCC samples. Bioinformatic analyses were performed to identify key dysregulated miRNAs. Candidate EV-miRNAs were validated by digital PCR (dPCR).

Result and discussion

Our results revealed a distinct EV-miRNA signature differentiating HCC patients from non-HCC individuals. Functional studies demonstrated that altered miRNAs influence key oncogenic pathways, including proliferation, invasion, and inflammatory response, highlighting their active role in tumor progression. Notably, specific EV-miRNAs were associated with critical molecular mechanisms underlying HCC pathogenesis, reinforcing their potential as both diagnostic biomarkers and therapeutic targets.

Conclusion

This study highlights the potential of EV-derived miRNAs as non-invasive biomarkers for HCC diagnosis and monitoring, as well as promising therapeutic targets. Given their stability in circulation and detectability in biological fluids, these miRNAs may play a crucial role in modulating key pathways involved in hepatocarcinogenesis. Further validation and functional study will be essential to establish their clinical utility, paving the way for more precise and personalized approaches in HCC prevention and treatment.

EACR25-2198

Comparative molecular analysis of CTCs and cfDNA Detection using Parsortix® System

F. Mahbubinejad¹, M. Coates¹, M. Geraldizo¹, M. Giunta¹, A. Papadimitropoulos¹, A. Pailhes-Jimenez¹, ANGLE plc, Guildford, United Kingdom

Introduction

Liquid biopsies offer a minimally invasive approach for cancer monitoring through the analysis of circulating tumour cells (CTCs) and circulating tumor DNA (ctDNA). The ability to detect tumor mutations in liquid biopsies may provide a powerful, non-invasive tool for real-time monitoring of tumor dynamics, which may enable rapid adjustments to clinical strategies. This study investigates the detection of seven clinically relevant oncogenic mutations in spike-in experiments as well as the concordance of genomic alterations between CTC and ctDNA in cancer patient samples.

Material and method

Blood from three healthy volunteers was collected in K2EDTA tubes and processed using the Parsortix®

system (ANGLE plc). Cancer cell lines (H1975 and SK-MEL-28) were added to background cells harvested with the Parsortix® system at five different levels (0, 2, 5, 10, and 20 cells) to evaluate detection sensitivity across seven clinically relevant mutations (BRAF V600E, CDK4 R24C, PTEN T167A, EGFR L858R, EGFR T790M, PIK3CA G118D, and TP53 R273H).

Additionally, blood samples from 27 lung cancer patients were collected in K2EDTA tubes and processed using the Parsortix® system. gDNA and ctDNA was then isolated from CTCs and blood plasma. Multiple blood draws were processed for some patients: five patients had multiple blood samples collected and analysed (between 2 and 4 draws, with few months delay between blood collection). Genomic analysis was performed using Illumina Cell-Free DNA prep with enrichment combined with a 79-gene custom panel targeting Lung Cancer and sequenced on Illumina NextSeq2000.

Result and discussion

In contrived experiments with varying cell numbers, BRAF V600E, EGFR mutations (L858R and T790M), and TP53 R273H were consistently detected (100%) at both 10 and 20 cells. In contrast, other mutations, including CDK4 R24C, PTEN T167A, and PIK3CA G118D, exhibited inconsistent detection at 10 cells but showed significant improvement at 20 cells. Analysis of clinical samples revealed that the majority of clinical samples (30/39) displayed unique variants between CTC gDNA and ctDNA from the same patient at the same timepoint. Specifically, 971 variants were detected in CTCs gDNA only, 661 variants were detected in ctDNA only and 204 variants were detected in both analytes.

Conclusion

This study demonstrates that CTCs and ctDNA provide complementary insights in liquid biopsy analysis. The observed variation in concordance suggests that analyzing both CTCs and ctDNA offers a more comprehensive assessment of tumor heterogeneity than either analyte alone. Integrating Parsortix® CTC isolation with Illumina-based ctDNA analysis has the potential to improve the detection of clinically relevant mutations, thereby enhancing patient monitoring and informing treatment selection.

⁴*Slovak Center of Scientific and Technical Information, Bratislava, Slovakia*

⁵*Comenius University, Department of Molecular Biology, Faculty of Natural Sciences, Bratislava, Slovakia*

Introduction

Prostate cancer is a prevalent health concern in Slovakia, with incidence rates exceeding the EU average. Therefore, the development of robust tools, particularly for early detection, is essential for improving patient outcomes and reducing mortality rates. Emerging diagnostic tools based on detection of aberrant fragmentation patterns in circulating tumor DNA (ctDNA) hold considerable promise to detect and characterize cancer. However, analyzing ctDNA within typical whole genome sequencing set-up with ultra-low genome coverage around 1x presents significant challenges for reliable anomaly detection. We propose a fragmentomics-based model utilizing various characteristics of ctDNA fragments. We also analyzed the impact of emerging end-motif patterns as a biomarker to evaluate the association of fragment sizes and 4-mer end-motifs in cancer and healthy samples.

Material and method

We obtained blood plasma samples of 71 prostate cancer patients with presence of primary tumor and 366 cancer-free control samples. We performed ultra low-coverage whole genome sequencing (WGS) and divided samples into training, validation and testing sets considering the age balance of the subgroups to minimize the potential confounding effects of age-related variations. We utilize a combination of state-of-the-art tools in the domain, public databases and own designed tools for extraction of a variety of fragmentomic metrics from short sequenced reads, incorporating them into an in-house pipeline. Then we employed advanced statistical and machine learning models for classification of samples into categories of healthy or oncological patients. The proportion of specific motifs was then evaluated against the characteristics of the studied oncological disease, individually for each motif, as well as for possibly biologically relevant groups of motifs.

Result and discussion

We propose a ctDNA extraction workflow along with a machine learning model to classify blood samples sequenced by ultra low-coverage WGS data, which demonstrates a high prediction rate to distinguish between prostate cancer patients and healthy individuals. We demonstrate that combining various fragmentomics-based characteristics with other genomic variabilities improves the prediction accuracy of cancer screening approaches.

Conclusion

Thorough analysis of ctDNA fragments presents a promising screening method for the detection of prostate cancer. Combining a wide range of measured ctDNA characteristics leads to incremental improvements in predictions. Due to the predominant representation of patients with early-stage cancer, its potential lies in early diagnosis and its application in preventive settings.

Introduction

Colorectal cancer (CRC) is the most prevalent gastrointestinal malignancy and the second leading cause of cancer-related deaths. Symptoms of CRC often manifest only in the advanced stages. Circulating tumor DNA (ctDNA), tumor-released DNA in the bloodstream, may display cancer-related mutations originating from all metastatic lesions of the patient. Liquid biopsy in forms of ctDNA analysis provides a non-invasive method for monitoring treatment response, detecting minimal residual disease (MRD), and identifying resistance-associated mutations. In this study, we used serial plasma samples from metastatic colorectal cancer (mCRC) patients to assess a novel next generation sequencing (NGS)-based Bridge Capture technology for mutation profiling and MRD detection. We also evaluated the scalability of the technology using synthetic DNA targets.

Material and method

This study included 80 plasma samples collected from ten mCRC patients participating in the AXOAXI phase II trial. Written informed consent was obtained from all patients. Each patient had a codon 12 or 13 KRAS mutation in the primary tumor specimen, enabling a tumor-informed approach to ctDNA analysis. Cell-free DNA (cfDNA) was extracted from 2 ml plasma using QiaSymphony DSP Circulating DNA Kit (QIAGEN). The performance of a novel Bridge Capture™ technology was compared to those of droplet digital PCR (ddPCR; Bio-Rad) and Ion AmpliSeq™ Cancer Hotspot Panel v2 (Thermo Fisher Scientific).

Result and discussion

Bridge Capture 282-probe panel and ddPCR detected KRAS mutation in 35 of the 80 ctDNA samples (44%), while 33 samples (41%) were negative with both methods. Twelve samples showed discrepant results, with

eight samples being positive with Bridge Capture but negative with ddPCR and four samples being positive with ddPCR but negative with Bridge Capture. The KRAS variant allele frequency (VAF) values showed a very strong correlation (Spearman $\rho = 0.86$). In a subset of ten samples analyzed with NGS-based AmpliSeq, both Bridge Capture and AmpliSeq identified 15 CRC driver mutations with strong correlation in VAF values ($\rho = 0.74$). Bridge Capture further detected several additional oncogenic mutations. Scalability of Bridge Capture was confirmed using an expanded 851-probe panel and synthetic DNA targets, with dilutions from 0.03% to 1% VAF showing a very strong linear correlation between the observed and expected total VAF signals for all probes (Pearson $r = 0.99$).

Conclusion

This study demonstrates the potential of Bridge Capture to improve mutation profiling and MRD detection in mCRC plasma samples. It shows substantial agreement with other technologies in clinical sample validation, and the VAF values strongly correlate with those from ddPCR and the NGS-based Ion AmpliSeq. The high scalability of the probe panel enables comprehensive ctDNA analysis. Further validation in larger and diverse cohorts is necessary to establish its clinical utility.

EACR25-2216

MicroRNAs for the Detection of Basal Breast Tumor Subtype

K. Bruce¹, V. Richard¹, M. Kerin¹

¹*Lambe Institute for Translational Research, Surgery, Galway, Ireland*

Introduction

Breast cancer (BC) is currently the most common cancer affecting females worldwide [1]. The heterogeneous nature of breast tumors is addressed histologically to encompass multiple subtypes based on the expression of hormone receptors [2]. Advanced screening techniques fail to detect the most aggressive form, the basal tumor subtype, due to an early incidence, tissue density, and lack of specific receptor biomarkers [3]. Molecular markers such as microRNAs (miRNAs) known to regulate post-transcriptional gene expression are reported to be aberrantly expressed in a tumor tissue-specific manner and are detectable in biofluids [4]. Aim:

Identification of microRNAs correlating with the presence of basal tumors in patient-matched plasma as liquid biopsy biomarkers of basal subtype of breast cancer.

Material and method

In silico screening of miRNA-sequencing datasets from The Cancer Genome Atlas (TCGA) and SCAN-B led to the selection of a panel of significantly deregulated miRNAs [$p\text{-value} < 0.05$; fold change > 2.0]. Candidate miRNAs were screened across clinically classified basal tumors [$n = 6$] and matched plasma [$n = 6$] retrospectively, stored at the Cancer Biobank of Lambe Institute for Translational Research, Galway. Ethical approval was obtained from the CREC at University Hospital Galway (Galway C.A. 2073). RNA extraction from tissues and plasma was completed using specific Qiagen kits, reverse transcribed with TaqMan™ cDNA synthesis kit, and expression quantitated by real-time

PCR using TaqMan probes. Data normalization using the 2- $\Delta\Delta CT$ method [5] and expression significance were analysed using XLSTAT (version 2023.3.1).

Result and discussion

miRNAs hsa-miR-125b-5p, hsa-miR-135b-5p, hsa-miR-195-5p, hsa-miR-21-3p, and hsa-miR-31-3p showed significant expression difference between basal tumors and matched plasma [p -value < 0.05], and in basal tumors when compared to normal plasma, indicating the disease-specific expression status. The expression significance of these miRNAs needs to be confirmed in a large sample cohort to validate its diagnostic potential.

Conclusion

Liquid biopsy-based testing for basal breast cancer will enable the development of a specific diagnostic test to conduct multiple minimally invasive screenings to detect an early onset or relapse of breast cancer post-therapy.

⁶Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Unit of Molecular and Genetics Diagnostics, Rome, Italy
⁷Italian Institute for Genomic Medicine, Cancer Genomics and Bioinformatics Laboratory, Milan, Italy

Introduction

Despite advances in molecular profiling, the prognosis for many high-grade serous tubo-ovarian cancer (HGSC) patients remains poor, with conventional biomarkers failing to clarify disease progression fully. We leverage machine learning to uncover transcriptomic signatures that enable early risk stratification of unresectable HGSC patients by integrating bulk and spatial sequencing data.

Material and method

An unselected cohort of 67 HGSC patients enrolled in an institutional genomic program (NCT06020625) at Fondazione Policlinico Gemelli IRCCS Rome was analysed. All patients underwent platinum-based neo-adjuvant chemotherapy (NACT), followed by interval

debulking surgery (IDS), if feasible. DNA and RNA from chemo-naïve tissue blocks were subjected to targeted and transcriptome sequencing. Transcriptomic signatures were identified using unsupervised k-means clustering and were integrated with somatic alterations. Random forest models (RFM) were trained on differentially expressed genes. The intra-tumoral distribution of these signatures and markers was assessed using Visium spatial transcriptomics on publicly available HGSC samples collected at IDS. The prognostic relevance was evaluated by event-free survival (EFS).

Result and discussion

We identified four transcriptomic profiles: energetic, proliferative, mesenchymal, and immunoreactive; partially refining the clusters proposed by The Cancer Genome Atlas. The energetic-related profile's cumulative gene expression correlated with low chemotherapy response score (CRS1, $p \leq 0.001$), IDS' failure ($p < 0.05$), short platinum-free interval (PFI < 12 months, $p < 0.01$), and high genomic instability (copy number alterations counts > 30 , $p < 0.05$). We integrated those profiles using a generalised linear model (GLM) to classify chemosensitivity (CRS3 vs. non-CRS3) and survival (PFI $> = 12$ vs. < 12 months). The energetic and proliferative profiles emerged as key drivers of poor response and early relapse. We applied RFM within each profile, identifying molecular markers critical for patients' stratification. At a spatial level, the energetic profile remained dominant after NACT; CRS2 samples exhibited divergent spatial patterns, either resembling CRS1 or CRS3, underscoring the intratumoral heterogeneity of chemosensitivity.

Conclusion

The energetic and proliferative profiles emerged as key determinants of poor platinum response and early relapse. The RFM identified markers which might represent the basis for an innovative, time- and cost-effective multi-gene panel for early risk stratification. Spatial analysis revealed the persistence of the energetic profile after NACT. The heterogeneity within CRS2 samples, rather than being considered a challenging 'gray zone', may represent a group that requires better stratification to distinguish patients who truly respond to platinum-based chemotherapy.

EACR25-2234

Systemic dissemination in glioblastoma multiforme patients

P. Stejskal¹, J. Srovnal¹, O. Kalita², M. Slachta², A. Rehulkova¹, M. Hajduch¹

¹Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Czech Advanced Technology and Research Institute, Palacky University and University Hospital in Olomouc, Olomouc, Czech Republic

²Department of Neurosurgery, University Hospital in Olomouc, Olomouc, Czech Republic

Introduction

Glioblastoma multiforme (GBM) is a highly invasive subtype of the central nervous system malignant tumors. Circulating tumor cells (CTCs) are tumor cells released into the peripheral blood and migrating to distant organs.

CTC presence is related to tumor spread and recurrence. In GBM, factors like short patient survival, the blood-brain barrier, and lack of lymphatic drainage in brain tissue make systemic dissemination rare but possible. The liquid biopsy (LB) concept has gained significant attention in the last decade and has the potential to revolutionize cancer care. Thus, noninvasive CTC detection can hold potential for diagnostic, predictive, and prognostic applications.

Material and method

After validating the CTC detection procedure by spiking experiments of the U87-MG cell line, the peripheral blood samples from curatively resected GBM patients were collected preoperatively in Cell-Free DNA BCT® tubes (Streck, Inc.). CTC presence was analyzed by CytoTrack CT11TM (2/C), a semi-automated immunofluorescence microscopy using glial fibrillary acidic protein, vimentin, and CD45 immunostaining, and DAPI counterstaining. The preliminary Kaplan-Maier survival analysis based on CTC positivity was performed in 39 patients with a follow-up longer than two years.

Result and discussion

We analyzed the CTC presence in 58 peripheral blood samples of GBM patients who underwent their first surgery. The CTCs or cancer cell clusters were found in 35% of cases. We also analyzed 19 blood samples of relapsing patients with a positivity rate of 57.9%. The Kaplan-Maier survival analysis did not show a correlation between CTC presence and survival. This phenomenon may be associated with the generally short survival of these patients, which is expected to increase with advances in oncology and palliative care and/or a possible suppression of tumor cell growth outside the CNS. The patient enrolment and clinical data recording are still ongoing.

Conclusion

We have observed the CTCs in the peripheral blood of GBM patients. The patient enrolment and clinical data recording are still ongoing.

Detection of Aggressive Prostate Cancer in Urine by Fragment-Level DNA

Methylation

T. Bedekovics¹, W. Taylor¹, Z. Sun², S. Baheti², K. Burger², P. Foote¹, B. Gochanour², D. Mahoney², M. Getman³, J. Kisiel¹

¹Mayo Clinic, Division of Gastroenterology and Hepatology, Rochester, United States

²Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States

³Mayo Clinic, Department of Urology, Rochester, United States

Introduction

Prostate cancer (PCa) is the second most commonly diagnosed cancer in men representing 1.46 million new cases and 396,000 deaths worldwide in 2022. By 2040 these numbers are projected to double. An earlier diagnosis of less advanced disease provides most men the best chance of curative treatment. However, screening with PSA may lead to the diagnosis of more indolent, low risk tumors and subsequent overtreatment. We've previously shown that methylated DNA markers

(MDMs) for PCa can be detected in urine using next generation sequencing (NGS) and fragment-level analysis. Here, we address the specific detection of aggressive PCa (Gleason 7-9) using targeted NGS on urine cfDNA samples.

Material and method

Buffered urines were collected from 15 patients with biopsy confirmed PCa (Gleason score 7-9). The control arm consisted of 8 G-6 PCa patients and 22 otherwise healthy age matched cancer-free men. cfDNA was isolated and enzymatic methyl-seq libraries were prepared and enriched by hybrid capture using synthetic probes mapping to 190 differentially methylated regions (DMRs) selected from an earlier PCa/normal tissue marker discovery study in our lab. These tissue DMRs were tested against a methylome-wide dataset of 36 clean and disease control urines to ensure low non-cancer background signal (<1%). Indexed libraries were sequenced at 560X deduplicated coverage and fragment-level CpG methylation information was extracted from individual sample .bam files. Mapped sequencing reads exhibiting concordant methylation were used to derive a quantitative α -score. Reads had to contain at minimum 5 CpGs and have an α -value (% 5mC per read) > 60%. Positivity for any of the 190 markers required an α -score greater than 4 sigma (σ) above the mean of the control arm score. At least two tumor-derived fragments for a given DMR had to be present for a positive call. Values were variance-adjusted to ensure equal weighting.

Result and discussion

Of the 190 markers, 30 were positive for 4 or more aggressive PCa patients. Marker positivity per sample ranged from 1 to 98. At 90% specificity, tumor-derived fragments were detected in 13 of 15 cases (87%), which included 10 G-7, 2 G-8, and 3 G-9 patients. As was expected, the number of tumor-derived fragments was proportional to the grading of the cancers. Two G-7s were missed, though the sequencing coverage for one of the missed samples was significantly lower than the others due to poor library enrichment. At 100% specificity, the sensitivity dropped to 60%. 4 of the 8 G-6 and 17 of the 22 cancer-free controls were not positive for any of the 190 markers.

Conclusion

By employing DNA fragment-level methylation analysis of well-vetted PCa marker candidates, we were able to detect the presence of intermediate and high-grade cancers in the urine of patients in this retrospective case-control study. These observational results are encouraging and warrant further studies.

EACR25-2266

Elevated miR-21-5p Expression as a Prognostic Biomarker in Cervical Cancer: Insights from the Indian Patient Cohort

K. Siwach¹, M. Vashist¹

¹Maharshi Dayanand University, Department of Genetics, Rohtak, India

Introduction

MicroRNAs (miRNAs) are small, non-coding RNA molecules that play a pivotal role in the regulation of gene expression. MiR-21-5p is a well-characterized

oncogenic miRNA implicated in the pathogenesis of various cancers, including cervical cancer.

Material and method

The purpose of this study was to determine the expression levels of miR-21-5p in Indian cervical cancer patients and to estimate the potential of this biomarker as a blood-based diagnostic tool. Total RNA was extracted from blood sample of 50 cervical cancer patients and 35 age-matched healthy individuals. Real-time quantitative PCR is done using the kit Mir-X miRNA First-Strand Synthesis and TB Green qRT-PCR (Takara Bio USA, Inc.), miR-21-5p expression was quantified in blood samples and U6 as the internal reference gene.

Result and discussion

The results demonstrated a significant upregulation of miR-21-5p in cervical cancer patients compared to healthy controls, with an average fold change of 1.877 ± 0.174 ($p < 0.001$) relative to the control sample of 0.905 ± 0.173 . This significant rise in miR-21-5p expression suggests that it may play a part in the development of cervical cancer. MiR-21-5p levels and cervical cancer stages were found to be significantly correlated by statistical analysis ($p < 0.05$).

Conclusion

These findings highlight the diagnostic and prognostic potential of miR-21-5p as a blood-based biomarker in cervical cancer. The consistent upregulation of miR-21-5p in blood samples from cervical cancer patients shows its potential for early detection of cervical carcinoma. This study contributes to a better understanding of circulating miRNA biomarkers and emphasizes the importance of population-specific validation.

EACR25-2273

A Novel Multimodal Liquid Biopsy workflow for the characterization of Circulating Tumor Cells in Metastatic Breast Cancer

L. Bascetta¹, F. Senic Matuglia¹, C. Luise¹, M. De Marn¹, L. Gole¹, G. Viale², M. Morgante³, G. Bianchini², O. Gentilini³, R. Carbone¹

¹Tethis S.p.A, Milan, Italy

²IRCCS San Raffaele Hospital, Medical Oncology Department, Milan, Italy

³IRCCS San Raffaele Hospital, Breast Surgery, Milan, Italy

Introduction

Circulating Tumor Cells (CTCs) enumeration provides valuable prognostic and treatment-response information, but its clinical utility remains limited due to the lack of comprehensive biological characterization. Despite technological advancements, confirming the tumoral nature of CTCs and assessing their genetic alterations remain challenging. In this study, we present a novel multimodal approach to address these limitations in the context of Metastatic Breast Cancer (MBC). The method employs Tethis' SmartBioSurface® slides, which enable efficient adhesion of CTCs without prior selection, preserving their integrity and allowing direct biomarkers analysis.

Material and method

Blood samples were collected in EDTA tubes from 27 MBC patients enrolled at San Raffaele Hospital (Milan, Italy) and processed within 6 hours of collection. After red blood cell lysis, the entire white blood cell fraction, including rare cells, was adhered on nanostructured titanium dioxide-coated slides (SmartBioSurface® slides). CTCs identification was performed through immunofluorescence staining targeting epithelial (pan-cytokeratins, EpCAM) and tumor-specific markers (ER, HER2), followed by AI-driven detection and imaging analysis. When indicated, CTCs were subsequently analyzed by Hematoxylin/Eosin stain and FISH for ERBB2 amplification.

Result and discussion

The Tethis approach defines CTCs based on the co-expression of epithelial and tumor markers, employing a 0.3 CTCs/ml threshold. Among 20 MBC patients with ER-positive histology, Epithelial+/ER+ CTCs were detected in 10 cases (50%). Similarly, among 9 MBC patients with HER2-positive tumors, 4 (44.4%) showed Epithelial+/HER2+ CTCs. In addition to single CTCs, clusters of CTCs were detected and characterized in 5 MBC patients (18.5%). Furthermore, we demonstrated the feasibility of a multimodal analysis on SmartBio-Surface® slides, with no cell detachment or sample degradation. In a HER2+ MBC case, HER2 status was first assessed in CTCs via immunofluorescence, subsequently confirmed by cytological evaluation in brightfield, and further validated by FISH for ERBB2 amplification.

Conclusion

The liquid biopsy workflow using SmartBioSurface® slides – combining immunofluorescence, cytological staining, and FISH – proves to be a powerful tool for single-cell characterization of ER and HER2 expression, as well as genetic alterations, in CTCs from MBC patients. These promising findings highlight its potential for tracking metastatic cancer progression and detecting biomarker-related changes, paving the way for improved disease monitoring and personalized treatment strategies.

Transcriptional profiling of patients with metastatic hormone-sensitive prostate cancer to uncover specific signatures linked to the transition from androgen-dependent to androgen-independent phenotypes

D. Esposito¹, G. Pecoraro¹, S. Belli¹, F. Messina¹, F. Pepe¹, A. Servetto¹, R. Bianco¹, L. Formisano¹

¹University of Naples Federico II, Naples, Italy

Introduction

Metastatic hormone-sensitive prostate cancers (mHSPC) initially respond to androgen deprivation therapy (ADT), but resistance often develops, leading to disease progression and poor outcomes. Understanding the transcriptomic changes that facilitate the shift from androgen dependence to independence is crucial for developing targeted therapies.

Material and method

Sixty patients with mHSPC undergoing ADT plus androgen receptor pathway inhibitors (ARPI) were enrolled. We defined responder patients (R) as those who achieved complete/partial response or stable disease within 6 months of the first treatment, while non-responder (NR) patients were those with biochemical or radiological progression within 6 months of treatment. Total RNA was extracted from Formalin-Fixed Paraffin-Embedded (FFPE) tissue samples using Maxwell® RSC RNA FFPE Kit, and RNA was profiled using NanoString® Tumor Signaling 360 Panel.

Result and discussion

To identify gene signatures associated with response to ADT + ARPI, we analyzed differentially expressed genes between NR and R patients. Notably, NR patients exhibited significant upregulation of genes linked to cell cycle progression and DNA replication. The mitotic kinases AURKB and PLK1 were the most markedly upregulated genes in NR patients, indicating unchecked cell proliferation. The hyper-expression of KIF23 and CDC20 in NR vs R further highlighted aberrant regulation of cell cycle progression. Importantly, NR patients' biopsies were characterised also by increased expression of metastasis-promoting genes, such as HGF, which may influence therapy response. Collectively, these findings delineate deregulated genes that may sustain the transition to androgen independence inducing ADT+ARPI unresponsiveness. Kaplan-Meier survival analysis reinforced the clinical significance of these findings, revealing that patients with hyper-expression of AURKB, KIF23, and CDC20 had significantly shorter progression-free survival (PFS) compared to those with lower expression levels (p-values of 0.0037, 0.0007, and 0.0289, respectively). These results underscore the potential of these molecular markers as predictive tools for resistance to ADT + ARPI and as potential targets for future therapeutic interventions.

Conclusion

This study offers novel insights into the transcriptomic profile of mHSPC and uncovers key gene signatures associated with the shift from androgen dependence to independence, which contributes to resistance against standard-of-care therapies. Validation in larger cohorts is crucial to establish the predictive value of these genes and to identify patients who could benefit from new combinatory treatments designed to delay this critical transition.

EACR25-2281

Identification of outcome-associated tumor perivascular features in renal cell carcinoma

A. Martín-Bernabé¹, V. Sánchez-Miñarro¹, P. Schmucker¹, M. Lindskog¹, U. Harmenberg¹, M. Johansson², L. Egevad¹, A. Östman¹

¹Karolinska Institutet, Dept. Oncology-Pathology, Stockholm, Sweden

Introduction

One third of patients with clear cell renal cell carcinoma (CCRCC) eventually develop metastasis. The introduction of anti-angiogenic therapy and immuno-therapy

in metastatic CCRCC (mCCRCC) has significantly improved outcomes for many patients. Among vascular endothelial growth factor tyrosine kinase inhibitors (TKIs), sunitinib is the most commonly used first-line drug. However, treatment is administered without specific patient selection criteria and relapse occurs in approximately 40% of cases. Given the lack of clinical stratification of these patients, predictive and prognostic biomarkers are needed to improve their clinical outcome.

Material and method

This work explored the clinical impact of perivascular (PV) characteristics in RCC by performing multiplex-based tissue profiling in a population-based cohort (N = 70) and a sunitinib-treated mCCRCC cohort (N = 61). Vessel features and tumor PV cell subsets were characterized based on multimarker (CD34, PDGFRα, PDGFRβ, αSMA and pSMAD2) expression combinations. In both cohorts, patients were categorized using a tertile-based dichotomization of the variables, with the upper tertile compared against the combined lower and middle tertiles to explore associations.

Result and discussion

Two PV cell subsets, PER4 (PDGFRB+/ASMA+/PDGFRα-/pSMASD2-) and PER5 (PDGFRB+/ASMA-/PDGFRα-/pSMASD2-), showed statistically significant survival associations using multiple endpoints in both cohorts. In the sunitinib-treated cohort (OS from treatment), PER4 (log-rank p < 0.001) and PER5 (log-rank p = 0.002) were associated with poor survival. Similarly, in the population-based cohort (OS), PER4 (log-rank p = 0.043) and PER5 (log-rank p = 0.001) were also linked to worse survival. Univariate and multivariate analyses confirmed robust survival associations for the identified PV cell subsets PER4 and PER5.

Conclusion

Collectively, this study identified candidate prognostic or TKI predictive response markers in RCC. These data provided in-depth characterization of PV cell subsets associated with clinical outcome in RCC. These data could be further explored to find clinically useful patient selection to improve the accuracy of anti-angiogenic therapy administration in RCC.

Introduction

Cholangiocarcinoma (CCA) is a highly aggressive form of bile duct cancer accounting for approximately 15% of liver tumors. Although considered a rare cancer in Europe, its incidence has been rising over the past 20 years. The lack of reliable biomarkers for the early diagnosis of CCA significantly limits effective treatments and worsens patient survival. In this context, extracellular vesicles (EVs) have emerged as promising sources of biomarkers for disease, as their molecular cargo reflects the pathological state of their cells of origin. In this study, miRNA contained in EVs isolated from CCA patients were analyzed to explore potential biomarkers for this disease.

Material and method

EVs were isolated from biliary aspirates of CCA patients and control patients (with lithiasis or benign stenosis) through ultracentrifugation and characterized by nanoparticle tracking analysis, transmission electron microscopy and atomic force microscopy, as well as by the detection of CD9 and CD63. RNA was isolated by TRI Reagent® LS and analyzed with the Affymetrix miRNA 4.0 array. DEmiRNA were identified considering a fold change of 1.5 and p-value < 0.05. Functional analysis of differentially expressed miRNAs (DEmiRNA) was performed using the TAM 2.0 tool. Additionally, the targets of the DEmiRNA were predicted, and an over-representation analysis was conducted with the validated targets to identify the enriched Reactome pathways.

Result and discussion

A total of 53 DEmiRNA were identified, all of which were upregulated in CCA patients compared to controls. Functional analysis revealed that the DEmiRNA were involved in processes such as Cell differentiation, Cell division, Cholesterol Metabolism, Epithelial-to-Mesenchymal Transition, and Glucose Metabolism. The transcription factors identified involved in the expression of these DEmiRNA were LIN28, MYC, and ZEB1, among others. Finally, the functional analysis of the downregulated targets by the DEmiRNA showed the most affected Reactome pathways were the RHO GTPase cycle, Transcriptional regulation by TP53, DNA repair, and Cell cycle checkpoints.

Conclusion

These findings suggest that miRNA contained in EVs from biliary aspirates could be evaluated as potential biomarkers to improve CCA diagnosis. Furthermore, the identified DEmiRNA may provide key insights into the underlying mechanisms of disease progression, contributing to a better understanding of CCA.

²Milan,

Introduction

Platinum-based neoadjuvant chemotherapy (pb-NACT) is the primary approach for locally advanced non-small cell lung cancer (LA-NSCLC). In preclinical models, cisplatin-induced damage activates CXCL12/CXCR4 axis, paradoxically leading to the dissemination of CD133+/CXCR4+ metastasis-initiating cells (MICs). Our aim was to assess the prognostic significance of CTCs number/phenotype in LA-NSCLC patients undergoing pb-NACT

Material and method

A total of 72 patients were enrolled and blood samples were collected at baseline (T1), post-pb-NACT (T2), and post-surgery (T3). CTC analyses have been completed for 65 patients at T1 and T2 and for n=22 at T3, exploiting cryopreserved PBMCs and a marker-independent strategy combining Parsortix® pre-enrichment step and DEPArrayTM technology. Single CTCs were identified as cells negative for a cocktail of immune cells markers and characterized for CXCR4, CD133 and PDL-1 expression. Isolated single cells were subjected to LowPass sequencing, and the CNA profiles of different CTC subsets were obtained.

Result and discussion

At T1, a higher number of CTCs and in particular of CXCR4+CTCs (>5/10 ml blood) was associated with a lower Disease Control Rate (DCR) ($p < 0.0001$; AUC adjusted [CI 95%]: 0.945 (0.766 - 0.992)), shorter EFS (HR = 6.8, $p = 0.0001$) and OS (HR = 3.6, $p = 0.001$). At T2, we observed that subset of the circulating MIC (CD133+CXCR4+) (>1/10 ml blood) was associated with an inferior overall response rate (ORR) ($p = 0.007$, AUC adjusted [CI 95%]: 0.836 [0.699 - 0.912]) and represented a negative prognostic biomarker for OS (HR = 8.2, $p < 0.0001$), whereas total number of CTC was not associated with patients outcome. Finally, detection of more than one MIC post-surgery showed a trend toward reduced DFS ($n = 20$ patients, 8.15 vs 29.8 months, $p = 0.000$). No correlation in PD-L1 expression was found between tissue biopsies and CTCs, but interestingly an higher frequency of PD-L1+CTCs at T1 was associated with inferior DCR ($p < 0.0001$) and could potentially identify a subgroup of patients who could benefit most from neo-adjuvant immunotherapy. Class comparison analysis of CNA profile of CTC isolated from chemotherapy responder and non-responder patients, identified specific chromosomal regions linked to treatment response. Moreover, CTCs expressing CXCR4 and CD133 markers showed distinctive CNA patterns and higher genomic instability, suggestive of a greater metastatic potential.

Conclusion

Specific subsets of CTCs could serve as novel biomarkers for assessing the effectiveness of pb-NACT and outcome in LA-NSCLC. Specifically, elevated levels of CXCR4+CTC at baseline along with increased MIC post-pb-NACT and post-surgery indicate a suboptimal

response to treatment and unfavorable prognostic factors for survival, suggesting the potential need for alternative treatment/therapy intensification.

UHRF1 role in the repression of Embryonic Morphogenesis genes predicts better prognosis and improves clinical and molecular classification in gastric cancer

J. Biotti¹, M. Spadarotto¹, L. Muccillo², C. Gino¹, C. Migliore³, S. Corso³, S. Giordano³, L. Bonapace¹

¹University of Insubria, Department of Biotechnology and Life Sciences, Busto Arsizio (VA), Italy

²Laboratory of Genomics and Epigenomics, Research Institute for Technological Innovation, Trieste, Italy

³University of Torino, Candiolo Cancer Institute - FPO, IRCCS, Dept. of Oncology, Candiolo (TO), Italy

Introduction

The key epigenetic regulator UHRF1 recruits DNA methyltransferases and chromatin modifiers to maintain genome stability, DNA methylation, chromatin structure, gene expression, and stem cell homeostasis. In cancer, UHRF1 overexpression can drive tumorigenesis by disrupting epigenetic stability, causing dysregulation of DNA methylation, altered histone marks, and onco-suppressor silencing. To further investigate the UHRF1 oncogenic mechanisms, we analysed its role in clinicopathological and molecular features using The Cancer Genome Atlas (TCGA) and the Asian Cancer Research Group (ACRG) datasets.

Material and method

Omics and clinical data were retrieved from TCGA and GEO portals and were analysed using R packages. Chromatin immunoprecipitation (ChIP) was performed on published patient-derived xenografts (PDX).

Result and discussion

Stratifying patients based on UHRF1 expression (UH/UL) and analysing survival data and clinicopathological parameters revealed that high UHRF1 expression defines better prognosis in gastric cancer (GC) (UH-BP, pVal = 0.0049), but poorer prognosis in renal and adrenocortical (ACC) cancers (UH-WP). UHRF1 acts as an independent prognostic marker (pVal=8.69e-03). Gene ontology analysis identified Embryonic Morphogenesis (EM) as the only category that classifies better and poorer prognoses based on UHRF1 expression. As predicted, UH-EML and UL-EMH categories in GC and UL-EML and UH-EMH in renal and ACC cancers showed the lowest and highest EM gene expression, respectively (pVal < 0.0001), with a >35% difference in 5- and 10-year survival rates.

Promoter DNA methylation of EM genes in GC was higher in UH-EML (pVal < 0.0001), inversely correlated with gene expression ($r = -0.52$; pVal = 3.09e-12), and linked to better prognosis (pVal = 0.009). ChIP showed that selected EM gene promoters in GC PDX cells exhibit closed and open chromatin patterns in UH-EML and UL-EMH. In GC, the expression patterns and clinical outcome of oncofoetal genes largely overlapped (>85%) with UHRF1-EM-based patient stratification. UHRF1 interacting epigenetic regulators (EZH2, SUV39H1/2,

DNMT1) negatively correlated with EM and oncofoetal gene expression, defining a favourable prognosis UL-EMH GC patients relapse twice as much as UH-EML ones (58% vs 27%, pVal = 0.003). UH-EML category showed an immune and stromal infiltration correlating with better prognosis in GC, whereas UL-EMH with poorer prognosis (pVal ≤ 0.001) Receiver Operating Characteristic curves revealed that UHRF1-EM stratification outperformed the current molecular classifications (AUC = 0.56 and 0.64 compared to 0.46 and 0.48, for TCGA and ACRG), but was slightly lower than pathological stage (AUC = 0.62 and 0.74).

Conclusion

These findings underscore the diagnostic and prognostic value of the combined UHRF1-EM-oncofoetal categorisation in GC, providing an enhanced molecular classification that could improve patient-specific treatment strategies.

EACR25-2389

Pre-cancer MicroRNA Profile of Normal Tissues Adjacent to Tumor (NAT) in HER2-positive Subtype of Breast Cancer

V. Richard¹, K. Bruce¹, M. Kerin¹

¹Lambe Institute for Translational Research, Discipline of Surgery, Galway, Ireland

Introduction

The Human Epidermal Growth Factor Receptor 2 (HER2) is an important predictive and prognostic marker of the aggressive HER2-enriched subtype of breast cancer [1, 2]. With HER2-targeted therapy, pathological complete response (pCR) is achievable and the precise surgical excision of tumor cells creates a ‘clear’ margin of ‘normal’ cells ensuring loco-regional disease control [3]. Recurrence post treatments are primarily due to residual infiltration of tumor cells in normal tissues beyond the assessed surgical margin [3] or the early onset of carcinogenesis events in normal tissues adjacent to the tumor (NATs) driven by field cancerization [4]. MicroRNAs are regulatory transcripts produced early on during gene expression and may provide insights into the malignant transformation in the tumor microenvironment. Aim: Comparative profiling of microRNAs as traceable molecular markers of field cancerization in normal adjacent to tumor (NAT) tissues in HER2+ Breast Cancer.

Material and method

A panel of miRNAs chosen from RNA-seq dataset [GSE131599] were screened in HER2+ tumors [n = 14], and matched NATs [n = 14]. Normal mammary tissues were used as healthy controls [n = 10]. The study received ethical approval from CREC (Galway C.A. 2073) and samples from the Biobank of Lambe Institute for Translational Research, Galway were used. Wet lab experiments included RNA extraction from tissues, cDNA synthesis, real-time PCR on Quant Studio 6, data normalization in the 2-ΔΔCT method, and statistical analysis [Mann Whitney t-test] using XLSTAT (version 2023.3.1).

Result and discussion

A distinct panel of miRNAs from the discovery panel was found upregulated specifically in HER2+ tumor tissue and a second set in Normal controls [p-value <

0.05; fold change > 2.0]. A shared expression profile of miRNAs across NATs and healthy tissues highlighted tissues of a common origin and were predominantly tumor suppressor miRNAs. A loss of expression of these miRNAs may correspond to malignant transformation.

Conclusion

MicroRNAs upregulated in NATs are potential traceable biomarkers of relapse and field cancerization in the HER2+ breast cancer subtype.

Introduction

Non-small-cell lung cancer (NSCLC) remains a leading cause of cancer-related deaths, due to late diagnosis and therapy resistance. Immune checkpoint inhibitors (ICIs), either alone or in combinations with chemotherapy (CT), achieve durable responses in approximately 10–15% of patients with advanced disease. However, many patients do not respond and remain at risk for adverse effects. PD-L1 expression, the only FDA-approved biomarker for ICI selection, has limitations due to technical discrepancies and incomplete knowledge about its regulation.

Emerging evidence suggests that microRNAs (miRNAs) influence PD-L1 expression, either by direct binding or through the modulation of regulatory genes. This study aims to elucidate miRNA-mediated PD-L1 regulation in NSCLC.

Material and method

To identify miRNAs involved in PD-L1 regulation in lung cancer cells, we utilized a pooled lentiviral library to overexpress the entire human miRNome ($N = 2,580$). Transduced cells were sorted based on PD-L1 expression (PD-L1High & PD-L1Low), followed by next-generation sequencing (NGS) of genomic DNA to identify miRNAs enriched or depleted in each population. To explore the association between miRNA expression and PD-L1 abundance in patient tumor cells, we analyzed miRNA and PD-L1 expression (mRNA & protein) from the TCGA-LUAD dataset ($N = 507$). Additionally, we performed whole miRNome profiling (miRNA-seq) on a cohort of stage IV NSCLC patients ($N = 35$) treated with ICIs or ICI+CT as first-line therapy, categorized by PD-L1 expression levels (TPS: <1%, 1–49%, and >50%).

Result and discussion

The in vitro screening identified 550 candidate miRNAs significantly associated with PD-L1 expression ($p \leq 0.05$), with 458 miRNAs enriched/depleted in PD-L1High cells and 92 miRNAs enriched/depleted in PD-

L1Low cells. Of these, 21 miRNAs exhibited differential expression in the TCGA-LUAD dataset when comparing PD-L1High and PD-L1Low patient tumors (based on either PD-L1 mRNA or protein levels). These candidates were further validated in an independent NSCLC cohort receiving ICI-based therapy. More importantly, computational target prediction using the TargetScan algorithm identified 7 miRNAs with putative binding sites in the PD-L1 3'UTR, suggesting direct regulatory interactions. These findings highlight a subset of miRNAs as key regulators of PD-L1, with potential implications for refining patient selection for ICIs. Ongoing functional studies aim to validate their impact on PD-L1 expression and assess their predictive value for immunotherapy response.

Conclusion

This study aims to identify miRNA-based biomarkers which are superior in terms of their stability in FFPE samples, capable of predicting ICI response in NSCLC patients; while unveiling novel mechanisms involved in immunotherapy response in order to enhance patient stratification and guide the development of more effective immunotherapy strategies.

Introduction

Early detection of oral cancer (OC) remains to be a critical challenge due to the lack of reliable and accessible tools for early detection and screening. Unfortunately, 60% of patients are diagnosed at advanced stages which are associated with a poor prognosis, highlighting the urgent need to develop non-invasive and effective molecular strategies to improve early diagnosis and survival rates. Herein, we performed a global DNA methylation profiling to identify novel DNA methylation markers for early and non-invasive detection of OC.

Material and method

To discover novel DNA methylation markers for the diagnosis of OC, genome-wide analysis using the Infinium HumanMethylationEPIC array was carried out in 19 OC patients including matched tumor tissue, adjacent non-tumor tissue and saliva samples. Differentially methylated CpGs (DMCs) were selected for validation in an independent cohort of saliva samples from 123 OC patients and 79 healthy controls by quantitative-methylation specific PCR. Receiver operating characteristic (ROC) curves were constructed to evaluate the diagnostic performance of individual CpG sites and models.

Result and discussion

DNA methylome analysis revealed 2752 and 17612 DMCs in tumor and saliva, respectively. Focusing on shared DMCs at gene promoter region, we identified a set of shared hypermethylated DMCs in tumor and saliva that could effectively discriminate OC. Of these, five selected CpGs were further confirmed hypermethylated in OC in the saliva independent validation cohort, yielding to AUC values >0.80. A three-CpG methylation signature showed the best diagnostic performance for discriminating OC and controls: sensitivity: 91.9%, specificity: 89.9%, positive predictive value: 93.4%, negative predictive value: 87.7% and accuracy: 0.911.

Conclusion

Our study identifies a DNA methylation signature with high diagnostic accuracy for OC detection, offering a non-invasive and efficient tool for developing a molecular screening program through a saliva-based epigenetic test.

Introduction

Pancreatic cancer (PDAC) is one of the most common causes of cancer-related death in the world. PDAC patients are often treated with opioid analgesia after surgery. These drugs act through opioid and cannabinoid receptors, which pathways are involved in tumor progression and metastases and can negatively affect the survival of patients. In a previous study, we determined the effect of morphine analgesia and gene expression of cannabinoid receptor 2, opioid growth factor receptor and cannabinoid receptor delta on survival of pancreatic cancer patients. In this study, we associate our gene expression results with protein expression in selected patients.

Material and method

Protein expression of opioid receptors mu, delta, nociceptin and cannabinoid receptor 2 was analyzed immuno-histochemically in FFPE tissue samples in 30 pancreatic cancer patients. Statistical analysis was performed using R software. Relationship between opioid/cannabinoid receptors expression in tumor tissue and patients survival was analysed using COX regression, Kruskal-Wallis/ANOVA test and Kaplan-Meier method.

Result and discussion

Using immunohistochemistry, we analyzed the protein expression of opioid receptor mu, delta, nociceptin and cannabinoid receptor 2 in tissues of 30 patients with pancreatic cancer. One patient was excluded from the analysis. Membrane, nuclear, and cytoplasmic positivity and positivity in the stroma of tumor tissue were assessed. And membrane, nuclear and cytoplasmic positivity in ductal and acinar cells was also assessed. We detected no or only weak positivity of mu, delta and nociceptin receptor expression in tumor, ductal or acinar cells at the protein level. Conversely, at the gene level, high positivity of expression of the opioid receptor delta was detected in approximately 50% of patients and was associated with shorter overall survival. High positivity of protein expression was detected in the case of cannabinoid receptor 2 in the cytoplasm of tumor and ductal cells. High CB2 protein positivity was observed in approximately 50% of patients as well as high gene expression positivity. High expression of CB2 receptor in tumor tissue was associated with significantly longer overall survival in patients with pancreatic cancer.

Conclusion

Cannabinoid receptor 2 is highly expressed at the gene and protein level in pancreatic cancer tissue and its high expression improves OS.

Introduction

Breast cancer is the most frequent cancer type among women worldwide and cancer metastasis is still the major cause of cancer related death. Predicting the risk of metastasis and therapy resistance remains an obstacle to improved treatment. Extracellular vesicles (EVs) are known to mediate cell-to-cell interaction within the tumour microenvironment (TME), influencing therapeutic resistance, and metastasis formation.

Tumour-derived EVs (tEVs) comprise a mixture of EVs secreted from malignant and non-malignant cells of the tumour, which are released into biological fluids such as blood. Hence, (tEV)-associated cargo proteins could serve as valuable biomarkers in liquid biopsies. This study aims to identify EV-based molecular signatures that could be used in liquid biopsies to predict the tumour microenvironment composition and response to treatment.

Material and method

Using the MMTV-PyMT transgenic mouse model of breast cancer, we isolated tEVs secreted from distinct TME cells using an immunoprecipitation-based approach following ultracentrifugation of total tEVs. The tEVs were then analyzed for their proteomic content using nano-liquid chromatography-mass spectrometry/mass spectrometry (Nano LC-MS/MS). Total EVs isolated from the plasma of non-tumour bearing and tumour bearing mice were also included in our analyses. EVs isolated from in vitro cultures of corresponding distinct cell lines were used as control. All EV samples were further characterized using transmission electron microscopy (TEM), scanning electron microscopy (SEM) and western blotting for EV-specific markers. Proteomic analysis was performed to identify unique protein signatures within the EV subsets.

Result and discussion

We isolated CD31+ endothelial cell-derived EVs, CD140a+ cancer-associated fibroblast EVs, CD11b+ myeloid cell-derived EVs and enriched cancer cell derived EVs (negative selection). By investigating their physical properties, we confirmed that the purified particles are small EVs. Proteomic analysis revealed distinct protein signatures in tEVs across the different tEV subpopulations. In plasma samples, specific proteins were uniquely detected while others were significantly enriched in tumour-bearing mice compared to tumour-free animals. Similarly, immunoprecipitated EVs (IP-EVs) contained uniquely abundant proteins in each subpopulation. These results were compared to cell line-derived EVs thus validating cell-specific proteomic signatures.

Conclusion

Our findings suggest that different tEV subpopulations carry unique molecular signatures, highlighting their potential to be used as predictive biomarkers for treatment response in liquid biopsies. Exploiting the heterogeneity of circulating tEVs to predict response to therapy could be an exciting route towards improved patient stratification and treatment of choice.

Introduction

Head and neck squamous cell carcinoma (HNSCC), particularly the human papillomavirus (HPV)-negative subtype, represents a significant clinical challenge due to late diagnoses, limited biomarkers, and poor survival outcomes. This study investigates the potential of circulating cell-free DNA (ccfDNA) as a minimally invasive biomarker for diagnosis, prognosis, and disease monitoring in HNSCC, aiming to improve early detection and personalized treatment strategies.

Material and method

A multicenter, prospective case-control study was conducted, enrolling 85 treatment-naïve and recurrent HPV-negative HNSCC patients and 28 healthy controls. Blood samples were collected at baseline and multiple follow-up timepoints. Plasma ccfDNA was isolated and quantified using two methods: fluorometry (Qubit) and quantitative real-time polymerase chain reaction (qPCR). Diagnostic accuracy was assessed using receiver operating characteristic (ROC) curve analysis, while prognostic value was evaluated through Kaplan-Meier survival analysis. Longitudinal ccfDNA kinetics were analyzed to monitor disease progression and treatment response.

Result and discussion

Baseline ccfDNA levels were significantly elevated in HNSCC patients compared to healthy controls (2147 ± 1617 GE/mL vs. 1235 ± 345.1 GE/mL, $p < 0.001$), with a diagnostic accuracy of 70.5% (AUC = 0.705). Notably, higher ccfDNA levels were observed even in early-stage HNSCC patients, suggesting its potential for early detection. While ccfDNA levels correlated with patient age ($p = 0.024$), no significant associations were found with tumor stage, size, or location. In locally advanced HNSCC (LA-HNSCC), patients with lower post-treatment ccfDNA levels at the 10-week follow-up demonstrated significantly longer progression-free survival (PFS) compared to those with higher levels (16.37 months vs. 9.63 months, $p < 0.05$). Longitudinal analysis revealed dynamic ccfDNA changes during treatment, with inter-patient variability in ccfDNA kinetics. However, no significant correlation was observed between ccfDNA levels and imaging-based treatment response. Strong agreement was found between Qubit and qPCR quantification methods ($r = 0.8987$, $p < 0.001$), though Qubit consistently yielded higher ccfDNA concentrations.

Conclusion

This study highlights the potential of ccfDNA as a diagnostic, prognostic, and monitoring biomarker in HNSCC, particularly for early detection and risk stratification. Fluorometric quantification offers a practical, cost-effective, and minimally invasive

approach for integration into clinical practice. However, further well-designed studies with larger cohorts are needed to validate these findings, optimize ccfDNA-based strategies, and explore its combined use with other biomarkers to enhance diagnostic and prognostic accuracy in HNSCC management.

³National and Kapodistrian University of Athens, Hepatogastroenterology Unit, Second Department of Internal Medicine- Propaedeutic, Medical School, Attikon University General Hospital, Athens, Greece

Introduction

Colorectal cancer (CRC) is the second-leading cause of cancer-related mortality in Europe and the United States, but early detection boosts the 5-year relative survival rate to 91%. While colonoscopy remains the gold standard for screening, its invasiveness reduces adherence. Although less invasive stool-based and blood-based biomarker tests have advanced screening efforts, additional strategies are needed to enhance accuracy, particularly for early-stage CRC and advanced adenomas (AA). In this study, part of the Horizon-funded DIOPTRA project for Mission Cancer, a blood-based protein biomarker approach to improve early detection was investigated.

Material and method

A prospective clinical study was conducted to collect blood samples from individuals undergoing colonoscopy (N=260). Participants were categorized into four groups: Healthy, Non-AA (NAA), AA, and CRC based on the colonoscopy findings and subsequent histopathological diagnosis. Each sample was analyzed using Olink's next-generation proteomics platform, based on the proximity extension assay technology, measuring 3,072 proteins in blood. Bioinformatic analysis, utilizing machine learning algorithms and differential expression methods, identified a 22-protein signature capable of distinguishing the four study groups.

Result and discussion

In a 5-fold cross-validation scheme, the linear combination of these proteins achieved a sensitivity of 90.7% (95% CI: [79.7%, 96.9%]) for CRC detection and a specificity of 90.0% (95% CI: [73.5%, 97.9%]) for advanced neoplasia (calculated by combining the Healthy and NAA groups). Notably, the model's sensitivity for stage I/II CRC was 95.8% (95% CI: [78.9%, 99.9%]) and for AA was 53.7% (95% CI: [47.8%, 59.4%]), demonstrating the potential of protein signatures in blood to detect early stage cancer and advanced precancerous lesions.

Conclusion

Future work is focused on developing multiplex immunoassays for these biomarkers to orthogonally

validate the findings and assess the signature's analytical and clinical performance in a large participant cohort from the DIOPTRA validation studies ($N = 1600$ participants). This protein biomarker signature could pave the way for more accurate, patient-friendly CRC screening methods that detect both cancer and its precursors at earlier, more treatable stages.

Unraveling Extracellular Vesicle MicroRNA Signatures as Novel Biomarkers and Therapeutic Targets in Sarcopenic Hepatocellular Carcinoma

G. Savino¹, E. Murgo², A. Saponaro^{1,2}, V. Manuti², M. Marasco¹, T. Colangelo^{1,2}

¹*University of Foggia, Department of Medical and Surgical Sciences, Foggia, Italy*

²*IRCCS Fondazione Casa Sollievo della Sofferenza, ISBReMIT, Cancer Cell Signaling Unit, San Giovanni Rotondo, Italy*

Introduction

Hepatocellular carcinoma (HCC) is the predominant form of liver cancer, with a high mortality rate often exacerbated by sarcopenia, a condition characterized by severe muscle wasting. Sarcopenia significantly worsens patient prognosis and quality of life, yet its underlying molecular mechanisms remain poorly understood. Emerging evidence suggests that extracellular vesicle (EV)-derived microRNAs (miRNAs) play a critical role in cancer progression and intercellular communication. This study aims to identify and validate novel EV-miRNA signatures specifically associated with sarcopenic HCC, thereby advancing diagnostic, prognostic, and therapeutic strategies for affected patients.

Material and method

The study involves a multi-tiered approach integrating molecular biology techniques, high-throughput sequencing, and bioinformatics analysis. Serum samples from patients with HCC (both sarcopenic and non-sarcopenic) and healthy controls will be collected and processed for EV isolation. EVs will be characterized using nanoparticle tracking analysis (NTA), western blotting, and transmission electron microscopy. High-throughput sequencing will be employed to profile miRNA content, followed by bioinformatics analysis to identify differentially expressed miRNAs linked to sarcopenic HCC. The identified miRNA candidates will be validated using droplet digital PCR (ddPCR) in an independent patient cohort. Additionally, functional assays using HCC-derived EVs will be conducted on muscle cells to evaluate their role in metabolic dysregulation and muscle wasting.

Result and discussion

Preliminary data suggest that a subset of EV-miRNAs exhibits distinct expression patterns in sarcopenic HCC patients compared to non-sarcopenic counterparts and healthy controls. These miRNAs appear to be involved in pathways regulating muscle metabolism, inflammation, and cancer progression. Functional consequences of EV-mediated miRNA transfer to skeletal muscle cells will be further explored, revealing potential molecular

mechanisms contributing to sarcopenia. Artificial intelligence-assisted meta-analysis will enhance the prognostic accuracy of these biomarkers. The integration of these findings could pave the way for novel RNA-based therapeutic interventions aimed at mitigating muscle loss in HCC patients.

Conclusion

This study represents a groundbreaking step in understanding the role of EV-miRNAs in sarcopenic HCC. By identifying specific miRNA signatures, this project seeks to improve early diagnosis, refine prognostic models, and develop innovative therapeutic strategies. The findings have the potential to revolutionize HCC management by offering a non-invasive, liquid biopsy-based approach for monitoring disease progression and response to therapy. Ultimately, the project applies precision medicine to improve therapies for liver cancer and metabolic dysfunctions.

Introduction

Colorectal cancer (CRC) is the fourth most common cancer worldwide, with a higher incidence in developed countries. Despite the implementation of screening programs based on fecal occult blood (FOB) tests, which have contributed to a reduction in mortality rates, CRC remains a significant public health concern. Extracellular vesicles (EVs) are lipid-based vesicles released by cells that carry various macromolecules, making them a promising source for discovering new biomarkers. Since FOB testing has a high rate of false positives, often leading to unnecessary exploratory colonoscopies, this study aims to identify more specific CRC biomarkers within fecal EVs from patients.

Material and method

20 stool samples from healthy individuals ($N = 5$) and patients with different grades of colonic lesions (including cancer) ($N = 15$) were analyzed. EVs were isolated using size-exclusion chromatography, followed by characterization through nanoparticle tracking analysis, transmission electron and atomic force microscopy, and the detection of tetraspanins CD9 and CD63. The protein content of the EVs was then analyzed through proteomics using Liquid Chromatography - Mass Spectrometry to identify differential expressed proteins (DEP) between healthy individuals and patients with

colonic lesions. Also, an Over Representation Analysis (ORA) was conducted on the DEP using the WebGestalt tool. Finally, a study of the Protein-Protein Interaction Networks (PPIN) of the DEP was performed using the STRING database.

Result and discussion

EVs isolation method was successfully optimized, ensuring effective separation of EVs from free proteins in stool samples. A total of 65 upregulated and 142 downregulated DEP (out of 484 detected) were identified in the fecal EVs of patients with premalignant lesions or CRC (with a Fold Change > 2 and p-value < 0.05), highlighting potential biomarkers for disease detection. Moreover, the ORA revealed significant enrichment ratios in multiple pathways for both upregulated (mainly related to immune response and antioxidant activity) and downregulated (principally linked to metabolic reprogramming, cell-cell interactions and cell death) proteins in patient with colonic lesions-derived EVs. Lastly, PPIN analysis revealed connections between the DEP found in the stool EVs.

Conclusion

This study underscores the feasibility of using fecal EVs as a non-invasive approach for early CRC detection, including the detection of colonic lesions that are highly likely to develop into CRC in the short to medium term. This method could enhance diagnostic accuracy while reducing the need for unnecessary colonoscopies. Future research should focus on validating the identified biomarkers in larger and independent patient cohorts.

Comparative Analysis of Technologies for Circulating Tumor Cell Capture, Purity, and Survival: A Comprehensive Evaluation

C. von Zuben de Valega Negrao¹, H. Hendrick², F. Ammar², R. Klotz², S. Dias¹, M. Yu²

¹Brazilian Center for Research in Energy & Materials (CNPEM), Brazilian Biosciences National Laboratory (LNBio), Campinas, Brazil

²University of Maryland School of Medicine, Department of Pharmacology and Physiology, Baltimore, United States

Introduction

Circulating tumor cells (CTCs) are crucial for understanding cancer metastasis and prognosis, offering valuable insights into tumor dissemination and therapeutic resistance. However, their detection remains a significant challenge due to their low abundance in blood and considerable heterogeneity across different tumor types. To address these challenges, reliable and sensitive CTC capture and analysis technologies are essential. Despite many existing CTC technologies, the cross comparison among multiple platforms is rarely done. This study aims to compare various CTC isolation methods and evaluate capture efficiency, purity score, and culture viability.

Material and method

Luminal breast cancer patient-derived CTC lines were spiked into human blood (100 CTCs/ml) and mouse

blood (400 CTCs/animal). The technologies tested included the TellDx CTC System, the Genesis System with Celselect Slides, and non-equipment-based methods, such as the RosetteSep™ Human CD45 Depletion Cocktail and the EasySep™ Mouse/Human Chimera Isolation Kit. Flow cytometry (FC) was also used for comparison. Capture efficiency, purity score, and survival in culture were evaluated. Capture efficiency was calculated as the percentage of recovered CTCs from the total spiked cells. Purity score was determined as $\log[(\text{CTC}_\text{out}/\text{PBMC}_\text{out}) / (\text{CTC}_\text{in}/\text{PBMC}_\text{in})]$. Survival was assessed by measuring viable cells via fluorescence, normalized to day 1.

Result and discussion

TellDx demonstrated the highest capture efficiency for human CTCs ($88.1 \pm 3.7\%$), followed by Genesis ($40.6 \pm 12.1\%$), RosetteSep™ ($36.5 \pm 9.0\%$), and FC ($7.6 \pm 4.5\%$). In the mouse model, Genesis exhibited the highest efficiency ($62.2 \pm 4.6\%$), followed by EasySep™ Chimera ($13.7 \pm 5.0\%$). The TellDx system achieved the highest purity score (3.8 ± 0.2), with no significant differences between Genesis and RosetteSep for human samples ($p > 0.05$, Tukey). Ongoing experiments have assessed the impact of each method on cell viability and heterogeneity over extended periods.

Conclusion

This study provides the first comprehensive evaluation of both equipment-based and non-equipment-based technologies for CTC isolation, considering capture efficiency, purity score, and post-capture survival. These findings are critical for advancing reliable and versatile CTC detection methods with potential applications in cancer diagnostics and therapy.

⁴Merck KGaA, Translational Quantitative Pharmacology, BioPharma, R&D Global Early Development, Darmstadt, Germany

⁵The University of Manchester, Division of Pharmacy and Optometry, Faculty of Biology Medicine and Health, School of Health Sciences, Manchester, United Kingdom

Introduction

Alterations in the abundance and activity of receptor tyrosine kinases (RTKs) are associated with cancer progression, which makes them important disease biomarkers and pharmacological targets for cancer treatment. Appendix tumors are rare entities that usually

metastasize to the peritoneum, for which there is no targeted treatment. Small intestine (SI) cancer is also rare but rising in the last decades. Colorectal cancer is a leading cause of death. Although RTKs are promising targets in oncology, their abundance has not been studied thoroughly in the above cancer types. This study aimed to quantify, for the first time, RTKs in patients with these cancer types, as well as healthy subjects for comparison.

Material and method

Tissues were homogenized, and epithelial cells were extracted from small intestine (5 healthy, 7 non-tumor peri-carcinomatous, 8 tumor), colon (5 healthy, 2 non-tumor peri-carcinomatous, 3 tumor), appendix (5 healthy, 16 non-tumor peri-carcinomatous, 15 tumor) and peritoneum (44 non-tumor peri-carcinomatous, 63 tumor) tissues. Exosomes from plasma (6 healthy subjects, 19 patients with appendix tumors) were prepared (liquid biopsy). Filter-aided sample preparation was used for protein digestion, and global liquid chromatography–mass spectrometry for quantification of all the identified proteins, including RTKs.

Result and discussion

RTKs had low abundance in SI and colon tissues, with only 3 of them being quantifiable. Similar trends were observed in both cancer types. EGFR was 7-fold lower in non-tumor compared with healthy SI and not detected in SI tumors. ERBB2 and INSR were 4- and 2-fold lower, respectively, in SI tumors compared with healthy SI. Similarly, EGFR, ERBB2 and INSR were 10-, 13- and 5-fold lower in colon tumors compared with healthy colons. Higher number of RTKs were quantifiable in appendix and peritoneum tissues with several of them being impacted in tumors. More profound differences were observed in appendix cancer. Interestingly, CSF1R, EPHA2, and IGF1R were only identified in tumor appendix. UFO and KIT were only identified in non-tumor and tumor appendix, at similar levels, but not in healthy appendix. INSR was 2-fold lower in non-tumor and tumor compared with healthy appendix, while ERBB2 was not detected in tumor appendix. In peritoneum tumors, PGFRA was 2-fold higher compared with non-tumor peritoneum. Additionally, NTRK2 and MET were not detected in tumor in contrast to non-tumor peritoneum. Lastly, in exosomes isolated from plasma of AT patients, only PGFRA and VGFR3 were identifiable and quantifiable, with VGFR3 being exclusively identifiable in tumor.

Conclusion

Overall, our study provides, for the first time, absolute quantification of RTKs in SI, colon, appendix and peritoneum cancer, reflecting significant perturbations of several RTKs in tumors. Our findings could be used as potential markers for diagnosis, prognosis and treatment, after further investigation and validation.

Introduction

The incidence of Colorectal Cancer (CRC) in young patients is increasing each year and near half of these cases are diagnosed at advanced stages. We have previously identified a copy-number variant (CNV) molecular signature in primary CRCs (some at an early age of onset) significantly associated with synchronous distant metastases. Mimicking the identified CNV signature in a 3D CRC cell model led to the acquisition of a Circulating Tumor Cells-like molecular profile with a gene expression signature associated with hybrid Epithelial-to-Mesenchymal Transition and increased stemness/chemoresistance. Phenotypically, it promoted the acquisition of a pro-metastatic phenotype in vitro, facilitating early budding of small cell clusters from the tumor aggregate, thus mimicking synchronous distant metastasis in vitro.

Material and method

To evaluate if these CNVs could be detected in circulation and to mitigate the need for new biomarkers for longitudinal disease monitoring and predictive of therapy response, we conducted a non-interventive trial by following 19 CRC patients (<65 years) collecting >200 liquid biopsies of peripheral blood collected at different treatment stages. Cell-free DNA (cfDNA) was isolated from plasma and CNV analysis was performed by ddPCR.

Result and discussion

Three CNVs were detected in cfDNA and shown to be candidate circulating biomarkers (B1, B2 and B4). Loss of B2 was identified in all patients along treatment and associated with disease progression especially when maintained over time (either metastases dimension/number and/or spread to distant organs), being indicative of disease progression up to 6 months before radiological methods. Similarly, loss of B1 was also associated with disease progression in 13/19 cases 1-3 months before radiological progression. Gain of B4 and persistence of this profile was also associated with disease progression 1-5 months before radiological progression. These circulating biomarkers have demonstrated predictive potential for local or distant disease recurrence in response to treatments and in the postoperative context. CNVs normalization often coincided with post-surgery moments and/or response to therapy with disease regression by radiological methods. These CNVs were

not detected on genomic DNA of lymphocytes from the respective blood samples. These markers anticipated disease progression earlier and appeared to be more specific than conventional biochemical markers, sometimes dissociated from the radiological response. The persistence of this profile over several liquid biopsy collections has been shown to anticipate periods of disease escalation, particularly in M1 stages.

Conclusion

The modulation of these biomarkers demonstrated predictive potential for therapeutic response and disease progression, and could potentially be used as circulating biomarkers for disease monitoring and personalized clinical management throughout patient follow-up.

The role of SLC7A9 in inducing ferroptosis resistance in colorectal cancer

Z. Guo¹, W. Jia¹, F. Zheng¹, Z. Li¹, X. Cheng¹, Z. Xu¹, H. Feng¹, R. Zhao¹

¹Ruijin Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Department of General Surgery, Shanghai, China

Introduction

Ferroptosis is a ferro-dependent programmed cell death characterized by lethally accumulation of lipid hydroperoxides, closely related to extensive cystine transport and glutathione (GSH) metabolism. Solute Carrier Family 7 Member 9 (SLC7A9), a functional subunit of the cystine transporter System Xc-, belongs to the same family as the classical ferroptosis inhibitor SLC7A11 which has been deeply investigated. However, SLC7A9 expression in colorectal cancer (CRC) and mechanism in regulating ferroptosis remain elusive.

Material and method

The clinical implications of SLC7A9 were explored with TCGA CRC cohort. Effects of SLC7A9 expression on proliferation and death of CRC cell lines were investigated with SLC7A9 shRNA and overexpression system. Transcriptome and non-target metabolome sequencing were introduced to screen the related pathways and metabolites. Lipid and iron metabolism were characterized with western blot and total iron content assay. LDH cytotoxicity assay, GSH/GSSG assay, MDA and C11 BODIPY assays were used to explore cell ferroptosis and oxidation-reduction (REDOX) state. Cystine tracer experiments (FITC-L-cystine and 13C2-L-cystine), flow cytometry and LC-MS assay were introduced to examine the cystine transportation via SLC7A9.

Result and discussion

The expression of SLC7A9 in CRC was significantly higher compared to adjacent normal tissues. Moreover, CRC patients with higher SLC7A9 expression depicted worse survival outcomes. We validated that over-expression of SLC7A9 promotes CRC proliferation. Further transcriptomic and non-target metabolomics analyses indicated that higher expression of SLC7A9 was

related to upregulated GSH metabolism, amino acid metabolism, and cystine metabolism. Western blotting and total iron content assay revealed similar iron state and identical phospholipid metabolism as well as ALOX and NOX family. Exploration of intracellular REDOX state showed that higher expression of SLC7A9 depicted reduced state, lower level of MDA and oxidized lipid peroxides, and a more potent resistance to ferroptosis. Cystine tracer experiments confirmed that CRC with higher level of SLC7A9 can efficiently transport cystine intracellularly and participate in GSH synthesis to counteract ferroptosis.

Conclusion

Accordingly, our study has unveiled the role of SLC7A9 in CRC ferroptosis resistance by transporting cystine intracellularly, promoting the synthesis of GSH and eliminating oxidized lipid peroxides.

EACR25-0023

Innovation and Optimization of Surgical Treatment Strategies for Gliomas

R. Zhao¹

¹Chongqing University Three Gorges Hospital, Neurosurgery, Chongqing, China

Introduction

Gliomas, the most common primary brain tumors, present a significant therapeutic challenge due to their infiltrative nature and proximity to critical brain structures. Surgical resection remains the cornerstone of treatment for these tumors, aiming for maximal safe resection while minimizing neurological deficits.

Material and method

This review explores the innovative and optimized surgical strategies for glioma management, focusing on recent advancements in intraoperative imaging, neuro-navigation, and minimally invasive techniques. Advanced intraoperative imaging techniques like 5-ALA fluorescence-guided surgery and intraoperative MRI have greatly enhanced tumor resection and patient outcomes. These technologies offer real-time visualization of tumor margins, enabling more precise and aggressive removal while protecting critical brain areas. Neuronavigation systems have evolved to offer high precision in glioma surgery, with the incorporation of diffusion tensor imaging (DTI) and functional MRI (fMRI) data. These systems enable surgeons to navigate around critical brain structures and plan resection paths that minimize post-operative neurological deficits. Minimally invasive surgical techniques, such as endoscopic procedures and laser interstitial thermal therapy (LITT), have emerged as promising strategies to mitigate surgical morbidity and enhance the quality of life in glioma patients. These methodologies facilitate the precise ablation of tumor tissue while minimizing disruption to the adjacent normal brain tissue.

Result and discussion

Furthermore, the role of awake craniotomy in glioma surgery has been redefined, providing a unique opportunity for intraoperative neurological assessment and functional mapping, thus ensuring maximal tumor resection with preservation of neurological function. In conclusion, the innovation and optimization of surgical strategies for gliomas involve a multidisciplinary

approach, incorporating cutting-edge technology and refined surgical techniques. These advancements not only enhance the extent of tumor resection but also improve patient safety and long-term outcomes.

Conclusion

Future directions in glioma surgery will likely focus on further personalizing treatment strategies, integrating molecular and genetic tumor characteristics, and exploring the synergistic effects of surgery with adjuvant therapies.

Downregulation of MicroRNA-497-5p Promotes Tumor Cell Malignancy and Contributes to Hepatitis B Virus-Related Hepatocellular Carcinoma Recurrence

C. Teng¹, F. Shih², L. Jeng³

¹*China Medical University, Graduate Institute of Biomedical Sciences, Taichung, Taiwan*

²*China Medical University, Ph.D. Program for Biotech Pharmaceutical Industry, Taichung, Taiwan*

³*China Medical University Hospital, Organ Transplantation Center, Taichung, Taiwan*

Introduction

High hepatocellular carcinoma (HCC) recurrence after curative surgical resection leads to poor patient prognosis, highlighting an urgent need for valuable prognostic biomarkers and potential therapeutic targets.

Material and method

This study evaluated the clinical association of microRNAs (miRNAs) with post-resection hepatitis B virus (HBV)-related HCC recurrence and explored their tumorigenic functions in human HCC cell lines.

Result and discussion

The results showed that miR-497-5p had a decreased tumor-to-non-tumor (T/NT) expression ratio in patients with HCC recurrence compared with patients without HCC recurrence after curative surgical resection. The decreased T/NT expression ratio of miR-497-5p independently predicted a higher risk of post-resection HCC recurrence. Moreover, overexpression of miR-497-5p exhibited inhibitory effects on proliferation, anchorage-independent growth, migration, and invasion abilities of human HCC cell lines.

Conclusion

Collectively, this study suggested miR-497-5p as a promising prognostic biomarker and therapeutic target for HBV-related HCC recurrence after curative surgical resection.

EACR25-0063

Comprehensive bioinformatics analysis DNA damage repair gene with prognosis and immune response in Lung adenocarcinoma

D. Zou¹

¹*Chongqing Hechuan People's Hospital, cardiothoracic surgery, Chongqing, China*

Introduction

Abnormal expression of DNA damage repair (DDR) genes is observed in Lung adenocarcinoma (LUAD). However, there are few studies exploring the correlation between DDR gene expression levels and prognosis, as well as immune responses in patients with LUAD.

Material and method

All data obtained from The Cancer Genome Atlas (TCGA) database. Differentially expressed genes (DEGs) were identified using the Wilcoxon rank-sum test. Univariate and multivariate Cox regression analyses were performed for DEGs, and after optimization based on AIC values, six DDR genes were sorted as prognostic genes for patients with LUAD to calculate the risk score. Simultaneously, a nomogram was conducted and validated by calibration curve and C-index. Single-sample gene set enrichment analysis (ssGSEA), CIBERSORT algorithms, and ESTIMATE scores were applied to evaluate the immune filtration of tumor samples. Subsequently, anticarcinogen sensitivity analysis and unsupervised clustering was used to excavate the correlation between the prognostic-significant DDR genes and clinical features.

Result and discussion

Six DDR genes (RPA 3, ENDOV, DDB 2, CCNO, FAAP20 and BLM) were preserved as prognostic genes to estimate risk scores, which was applied to establish the prognostic model and stratified LUAD patients into high or low risk groups. Immune filtration analysis, anticarcinogen sensitivity analysis, and unsupervised clustering were applied to reveal the character of prognosis-significant DDR genes between low- and high-risk groups.

Conclusion

We identified 6 prognosis-significant DNA repair genes to establish prediction models and immune responses in LUAD patients, which may could serve as a novel prognostic biomarker and therapeutic target for LUAD.

EACR25-0112

The integrated stress response drives MET oncogene overexpression in cancers

M. Cerqua¹, M. Foiani¹, C. Boccaccio², P. Comoglio³, D. Altintas¹

¹*IFOM ETS, IFOM ETS, Milan, Italy*

²*Candiolo Cancer Institute, Candiolo Cancer Institute, Candiolo, Italy*

³*IFOM, IFOM, Milan, Italy*

Introduction

Cancer cells rely on invasive growth to survive in a hostile tumour microenvironment; this growth is characterised by interconnected processes such as epithelial-to-mesenchymal transition and migration. A master regulator of these events is the MET oncogene, which is overexpressed in the vast majority of cancers. However, since genetic alterations in the MET oncogene are relatively infrequent, the mechanisms that drive this pervasive MET overexpression remain obscure. Here, we demonstrate that the 5' untranslated region (5'UTR) of MET mRNA harbours two functional stress-responsive elements, conferring translational regulation by the integrated stress response (ISR), which is mediated by

phosphorylation of eukaryotic translation initiation factor 2 alpha (eIF2 α) at serine 52.

Material and method

To investigate MET regulation under stress, we exposed cancer cell models to stressors mimicking the tumour microenvironment: serum starvation, leucine deprivation, hypoxia, irradiation, and chemotherapeutic agents. Functional reporter assays were used to analyze the MET 5'UTR, focusing on the role of its upstream open reading frames (uORFs). We applied CRISPR/Cas9 and Prime Editing to introduce uORF or eIF2 α (S52A) mutations and used ISR pathway inhibitors to evaluate their effects on MET translation. Western blotting was performed to assess MET protein expression, and migration and invasion assays were used to evaluate MET-dependent invasive growth after ISR activation.

Result and discussion

We identified two stress-responsive elements in the MET 5'UTR that regulate translation via ISR activation. Stress conditions induced MET protein overexpression through eIF2 α phosphorylation. Disruption of this pathway – either by mutating the uORFs, generating eIF2 α (S52A) mutations, or applying ISR inhibitors – markedly reduced stress-induced MET translation. Functionally, this reduction blunted MET-driven invasive growth, highlighting the essential role of ISR in facilitating MET-mediated invasive growth.

Conclusion

These findings indicate that upregulation of the MET oncogene is a functional requirement linking the integrated stress response to cancer progression. Moreover, they highlight the concept of adaptive translational control of an oncogene as a critical player in invasive growth, providing a new perspective on the role of stress-responsive mechanisms in driving tumor progression.

Introduction

Cancer stem cells (CSCs) are a small but critical subpopulation within tumors that drive progression, metastasis, and resistance to conventional therapies. The purpose of this study was to develop a reliable and cost-effective method to isolate and characterize CSCs from metastasized tissues, overcoming the limitations of traditional cell culture methods that fail to sustain CSCs while promoting the growth of non-cancerous cells such as tumor-associated fibroblasts and macrophages.

Material and method

We utilized a selective culture system designed to deplete benign stromal cells while supporting the growth of CSCs in a defined environment.

Result and discussion

Using this approach, CSCs were successfully isolated from a gastrointestinal stromal tumor (GIST) liver metastasis. The CSCs exhibited distinct stem cell properties, confirmed by fluorescence-activated cell sorting (FACS) analysis of stem cell markers SOX2 and OCT4. These cells were maintained in culture for up to 49 days, enabling extended studies of their biological properties. Next-generation sequencing (NGS) of the isolated CSCs further validated the retention of proto-oncogene KIT mutations, characteristic of the patient's tumor.

Conclusion

In conclusion, this method offers a cost-effective and resource-sensitive platform for isolating and cultivating CSCs from patient-derived tumor samples, facilitating advanced studies of their biology and therapeutic vulnerabilities.

EACR25-0122

Effects of the anti-diabetic dipeptidyl-peptidase 4 inhibitor on radiation response in breast carcinoma cells with different metastatic potential

M. Eling¹, D. Savic¹, S. Skvortsov², U. Ganswindt², I. Skvortsova¹

¹Medical University of Innsbruck, EXTRO-Lab, Tyrolean Cancer Research Institute, Department of Therapeutic Radiology and Oncology, Medical University of Innsbruck, Innsbruck, Austria

²Medical University of Innsbruck, Department of Therapeutic Radiology and Oncology, Medical University of Innsbruck, Innsbruck, Austria

Introduction

Diabetes mellitus and cancer are two of the leading causes of illness and death globally. Patients diagnosed with both breast cancer and diabetes often face poorer clinical outcomes compared to those without diabetes. This may be due to the complex interactions between diabetes, its treatments, and cancer therapies. In recent years, incretin-based therapies, particularly dipeptidyl-peptidase 4 (DPP4) inhibitors, have become a mainstay in diabetes treatment. However, it remains unclear how these drugs may influence the effects of radiation therapy, which is a key treatment for breast cancer. The primary aim of this study was to investigate how the DPP4 inhibitor sitagliptin might affect the radiation response of breast carcinoma cells with differing metastatic capacities. The study focused on both triple-negative breast cancer (TNBC) and hormone-dependent breast cancer cells.

Material and method

Invasive (INV) breast cancer cells were derived from the parental TNBC (MDA-MB-231) and hormone-dependent (T47D) cell lines. Both parental and INV cells were treated with sitagliptin (4 μ M), radiation (2 or 8 Gy), and their combination. The study assessed changes in cell cycle, cell death, and molecular mechanisms triggered by these treatments. In order to determine whether sitagliptin

can change the survival of the irradiated cells, the clonogenic assay was additionally performed.

Result and discussion

The results demonstrated that INV breast carcinoma cells exhibited elevated DPP4/CD26 expression, though sitagliptin treatment did not induce apoptosis or cell cycle arrest in either parental or INV cells. In parental MDA-MB-231 cells, radiation primarily induced cellular senescence, whereas in INV MDA-MB-231 cells, autophagy was the predominant response. Although sitagliptin did not significantly reduce these radiation-induced effects, a slight decrease was noticed. In contrast, T47D cells did not display senescence following any treatment, although a marked downregulation was noted in INV T47D cells. Parental T47D cells exhibited increased expression of autophagy markers in response to higher radiation doses, an effect further enhanced by sitagliptin. INV T47D cells showed significantly increased autophagy marker expression following combined treatment with sitagliptin and radiation.

Conclusion

The findings indicate that sitagliptin does not substantially alter radiation-induced cell cycle arrest or cell death in breast carcinoma cells. Nevertheless, radiation triggers senescence and autophagy in TNBC cells, with sitagliptin potentially modulating these responses, thereby conferring some protection against radiation-induced cellular damage. Hormone-dependent breast carcinoma cells appear less responsive to these protective mechanisms, instead undergoing autophagy-mediated cell death. Future studies will focus on characterizing the molecular and metabolic differences.

EACR25-0124

Unique lipidomic signature in colorectal adenocarcinoma

Y. Agarwala¹, B. Das¹, P. Leung¹, G. Hanna¹

¹Imperial College London, Department of Surgery and Cancer, London, United Kingdom

Introduction

Colorectal cancer (CRC) has a poor prognosis when diagnosed at the advanced stage, but early diagnosis is difficult due to non-specific symptoms. The situation strongly calls for novel non-invasive biomarkers for early diagnosis. Many cancers present with lipid dysbiosis profiles, but studies on lipidomic changes in CRC are lacking. Hypoxia stabilizes the hypoxia-inducible factor (HIF-1) protein which alters the expression of genes involved in lipid metabolism. Here, we investigated the lipidome of CRC in hypoxia to deduce potential biomarkers.

Material and method

The colorectal adenocarcinoma (COAD) cell lines, HCT116, HT29, SW480, were cultured in normoxia (21% O₂) or hypoxia (0.1% O₂) for 72 h. A western blot was performed to quantify HIF-1 expression. Lipids were extracted using a modified Bligh and Dyer method, with water/ice-cold methanol/chloroform (2:2:1, v/v/v).

Untargeted lipidome analysis was performed using positive and negative ion mode liquid chromatography-mass spectrometry. Peaks were annotated based on the NIST17 library, and were analyzed by principal

component analysis and orthogonal projections to latent structures discriminant analysis, with species with a variable importance projection score >1.0 being considered relevant to group separation.

Result and discussion

HIF-1α was constitutively expressed in hypoxia in all cell lines, with limited expression in normoxia. In hypoxia, relative abundance of saturated fatty acid (SFA) levels increased ($p < 0.05$) and polyunsaturated fatty acids (PUFA) decreased ($p < 0.05$) compared to normoxia in all cell lines, with monounsaturated fatty acids (MUFA) not showing any trends. This is consistent with the literature. Specifically, the SFA stearic acid (18:0), the MUFAAs phosphatidylcholine (18:0/18:1) and hexosylceramide (d18:1/16:0) were increased in hypoxia ($p < 0.001$). Interestingly, stearic acid is known to increase in hypoxia, but some studies have suggested it as an anti-tumorigenesis agent by inhibiting tumor proliferation. Elevated levels of phosphatidylcholine (18:0/18:1) and hexosylceramide (d18:1/16:0) have been reported in tissues from prostate cancer, breast cancer, and in the plasma of CRC patients. Our results provide further evidence for these as biomarkers in COAD and highlight the potential underlying mechanism for the increased levels of these lipids.

Conclusion

This study identified 3 key lipidomic changes in COAD due to hypoxia. These targets have been reported in COAD or other cancers, and here we evidence the role of hypoxia in this dysbiosis. Further mechanistic studies are required to target these lipids as biomarkers as well as delineate their potential in therapeutics.

EACR25-0136

Characterizing Bladder Cancer Cells: Morphological and Biophysical Signatures for Advanced Label-Free Detection

R. Leão Monteiro¹, A. Correia Azevedo², C. Nogueira Fernandes³, L. Vale³, C. Martins Silva³, F. Cruz⁴, I. Calejo⁴, R. Canadas⁴

¹Faculdade de Medicina da Universidade do Porto, Biomedicina, Paços de Ferreira, Portugal

²Politécnico do Porto, Escola Superior de Saúde E2S, Bioquímica em Saúde, Porto, Portugal

³Centro Hospitalar Universitário do São João, Urologia, Porto, Portugal

⁴Faculdade de Medicina da Universidade do Porto, Biomedicina, Porto, Portugal

Introduction

Bladder cancer (BC) is a highly heterogeneous disease, marked by considerable variation in cellular morphology and biophysical signatures. As BC progresses, cells transition from epithelial to mesenchymal (EMT) phenotypes, complicating diagnosis and treatment. Traditional diagnostic methods, such as urine cytology, fail to detect low-grade tumors due to their low sensitivity, particularly in the face of sparse cellular content (<5 cells/mL), further diminishing their diagnostic reliability. While molecular techniques have advanced, there is an urgent need for non-invasive, label-

free methods that can address these limitations. This gap in clinical practice leaves us without a reliable tool for accurately detecting BC, especially in its early stages when intervention is most critical. New research frontiers in cell biophysics offer new ways for label-free BC detection, addressing these challenges. Aiming to identify key biophysical biomarkers and improve clinical outcomes, we profiled morphological, light-metrics and clustering features of BC cell lines and clinical samples using imaging flow cytometry.

Material and method

BC cell lines ($n = 15$), controls ($n = 6$) and clinical samples ($n = 2$) were cultured and subsequently fixed for ImageStream analysis. Morphological criteria such as diameter, area, perimeter, elongation, compactness, and circularity and light-based metrics, e.g., brightfield and light-side scatter contrast were quantified. Self-clustering frequency was also evaluated. Data analysed using two-way ANOVA and multiple comparisons with significance set at $p < 0.001$.

Result and discussion

Significant morphological and light-based differences were observed between BC cells and controls, including clinical cases, and these differences correlated with the EMT scale. Cells with a high EMT score (more mesenchymal) exhibited increased elongation and reduced compactness and circularity, traits linked to higher metastatic potential. Light-based metrics revealed greater contrast and side-scattering intensity in cells with a low EMT score (more epithelial), suggesting a potential marker for early-stage diagnosis. Additionally, self-clustering frequency was inversely correlated with EMT score, highlighting its potential as a diagnostic risk stratification tool.

Conclusion

The study shows that biophysical parameters can serve as effective, label-free biomarkers for BC diagnosis and risk, while offering a non-invasive method for early detection. Ultimately, the findings are crucial for clinicians and researchers aiming to establish a foundation for validating biophysical signatures as cancer biomarkers, with the potential to transform clinical practice and enhance survival rates.

EACR25-0138

Studying Stem Cell Fate & Plasticity in Pre-cancerous Gastric Organoids

C. Oddy¹, L. McKenzie¹, L. Conde¹, A. Farswan¹, W. Waddingham², D. Graham³, M. Jansen¹

¹*UCL Cancer Institute, UCL, London, United Kingdom*

²*Royal Free London NHS Foundation Trust, Barnet & Chase Farm Hospitals, London, United Kingdom*

³*University College London Hospitals NHS Foundation Trust, Gastroenterology Medicine, London, United Kingdom*

Introduction

Gastric stem cells (GSCs) sustain the gastric epithelium, ensuring its health and function. A single GSC will proliferate and differentiate to form a clonal gland. However, aberrations in genetic and epigenetic landscapes can derail this process, setting the stage for the pre-malignant phenotype, gastric intestinal metaplasia (GIM), to take over. Through staining of gastric gland

serial sections, we demonstrated the sudden moment that an individual GSC deviates from their native gastric lineage to assume an intestinal-like identity, before then taking over the whole gland. Now, the question remains: How does that GSC become set up to fall to an intestinal lineage?

Material and method

Leveraging a robust translational pipeline, we have cultivated patient-matched normal, GIM and duodenal organoids from clinical biopsies, culminating in a repertoire of 22 organoid lines from 6 patients. Through interrogation of these organoid lines, we aim to understand the processes pushing GSC to develop into GIM.

Result and discussion

Utilising rt-PCR and confocal microscopy, we have demonstrated the nuanced expression patterns of gastric and intestinal markers within these organoids. Furthermore, our ongoing methylation analyses has demonstrated the epigenetic forces governing the transition from normalcy to pathology. We have shown distinct methylation signatures associated with each phenotype. Next, we hope to uncover specific differentially methylated gene sets that demonstrate the processes altered as GIM takes hold. Alongside the methylome work, sc-RNA sequencing stands to be as a powerful tool to decode the transcriptional dynamics orchestrating GSC lineage decisions hinted at in earlier analyses. Additionally, this sequencing will allow us to interrogate how the transcriptional dynamics within GSC affect the transcriptional activities of the whole cellular population. Moreover, employing novel techniques such as thiol-reactive organoid barcoding *in situ* (TOBis) and cytometry by time-of-flight (CyTOF), we aim to decipher the intricate post-translational signalling cascades underlying the acquisition of a cancerous phenotype in GIM.

Conclusion

In summation, our comprehensive investigation should underscore the transformative potential of GIM organoids in unravelling the intricacies of metaplastic evolution. These multidimensional analyses will not only illuminate the pathophysiological underpinnings of GIM but also intimate pivotal evidence for the development of prognostic models in gastric cancer risk stratification.

EACR25-0150

Increasing autophagy activity suppresses *Helicobacter pylori* related gastric cancer tumorigenesis

H. Liu¹

¹*Kaohsiung Medical University Hospital, Medical Research Center, Kaohsiung, Taiwan*

Introduction

Helicobacter pylori (*H. pylori*) infection induces autophagy in human gastric cancer (GC) cells. *H. pylori* infection of GC cells increase the secretion of hepatocyte derived growth factor (HDGF). HDGF, a heparin-binding protein, plays a crucial role in gastric carcinogenesis. We speculate that secretory autophagy participates in *H. pylori* infection-induced HDGF secretion to affect GC tumorigenesis. *H. pylori* alters mesenchymal stem cells to differentiate into tumor-associated fibroblasts and affects mitochondrial metabolism of the cancer cells and the surrounding cells in the microenvironment. This study

explored the role of autophagy in GC under *H. pylori* infection conditions.

Material and method

GES-1, AGS, and MKN45 GC cells were used for immunoblotting, immunofluorescent staining, lentiviral shRNA, CRISP-Cas9 system, MTT, focus formation, wound healing, and Transwell™ assays. Clinical GC specimens were analyzed using tissue microarray (IR) and TCGA database. Xenograft GC nude mouse with *H. pylori* infection was established.

Result and discussion

Clinical GC specimens and TCGA STAD data analysis reveal that the level of the autophagy marker protein LC3 is high in tumor tissues compared to non-tumor parts, which is correlated with low overall survival rates of GC patients. *H. pylori* 49503 strain infection of GC cells robustly increased autophagy activity accompanied by decreased cell proliferation, focus and tumor-sphere formation, as well as cell migration. Notably, increasing autophagy by inducers further promotes the suppression of cell proliferation, motility as well as focus and tumor-sphere formation. Investigation of *H. pylori* infected AGS cells under TEM reveals that *H. pylori* is detected in autophagic like vesicles and the outer membrane of the cell. In contrast, fewer *H. pylori* was detected in the Atg5 gene knockout cells, indicating the importance of autophagy. RNA-Seq and pathway analysis disclosed that autophagy participates in diverse GC-relevant pathways, including PI3K-Akt, MAPK, and JAK-STAT pathways. To validate the in vitro findings, the xenograft GC mouse model demonstrated that increasing autophagy activity by the inducer [amiodarone] significantly reduces GC cell proliferation and tumor growth.

Conclusion

This study provides evidence that increasing autophagy activity may suppress *H. pylori*-related GC tumor development. Competing interests The authors declare that they have no competing interests.

EACR25-0159

Novel applications of senolytics to prevent treatment resistance in cervical cancer

M. Meyer¹, A. Engelbrecht¹, C. Eksteen¹

¹Stellenbosch University, Physiological Sciences, Stellenbosch, South Africa

Introduction

Cervical cancer remains a significant global health concern, ranking as the fourth most common malignancy among women. Over 90% of cases are linked to high-risk subtypes of the human papillomavirus (HPV). Despite advancements in prevention, treatment resistance continues to hinder improved patient outcomes. One major contributor to this resistance is senescence induction, particularly the senescence-associated secretory phenotype (SASP), which promotes the tumour microenvironment. Targeting senescent cells with senolytic agents presents a promising therapeutic approach to overcome these challenges. Navitoclax, a senolytic under investigation, has shown considerable potential in inducing apoptosis in senescent cells. However, its synergistic effects with carboplatin and its

influence on treatment resistance in cervical cancer remain unexplored. This study investigates the mechanisms underlying the combination treatment of navitoclax and carboplatin, evaluating its impact on treatment resistance through a personalized medicine approach, with comparisons between 2D and 3D models using immortalized cervical cancer cell lines. Improve treatment effectiveness, reduce side effects and healthcare expenses, and lower the risk of recurrence.

Material and method

Ethical approval was granted by Stellenbosch University. Following patient consent, cervical tumor biopsies were collected, dissociated, and cultured to confluence before being treated with low-dose chemotherapies. A retrospective analysis examined correlations between senescence markers and treatment responses. Cytotoxicity was assessed via MTT assays, while senescence was evaluated using SA-β-gal staining and western blot analyses for markers such as p16, p21, p53, and Rb. Further, treatment resistance markers including ABC and MDR1 were measured. Select biopsies were cultured in 3D using Clinostar bioreactors. Experiments on HeLa, SiHa, and CaSki cell lines in 2D and 3D employed assays such as MTT, Annexin V, and confocal microscopy

Result and discussion

Patient-derived data revealed an increase in senescence and treatment resistance markers post-chemotherapy, though individual responses varied. Variations between 2D and 3D cultures further highlighted the need for advanced models to study drug responses. Co-treatment with carboplatin and navitoclax in both 2D and 3D cell lines led to enhanced apoptosis and reduced resistance marker expression, confirmed by western blot and confocal microscopy analyses.

Conclusion

These findings demonstrate a clear link between chemotherapy-induced senescence and treatment resistance, supporting the therapeutic potential of senolytics in overcoming drug resistance. This study underscores the importance of integrating senolytics into conventional treatment regimens, advancing personalized therapeutic strategies to improve outcomes for cervical cancer patients.

EACR25-0161

Carboplatin-induced transcriptional landscape and growth morphology of ovarian cancer cell models growing in 3D stem-cells supporting environment

J. Baranašić¹, V. Tadić¹, K. Vukušić¹, L. Gudlin¹, I. Tolić¹, A. Brozović¹

¹Ruder Bošković Institute, Division of Molecular Biology, Zagreb, Croatia

Introduction

Ovarian cancer is the most lethal cancer of the female reproductive system with a significantly increasing incidence and mortality rate. Three-dimensional (3D) cancer models are changing the way research is conducted as they allow replication in a more complex and physiologically accurate in vitro system compared to the traditional two-dimensional (2D) model.

Material and method

In this study, three ovarian cancer cell lines (MES-OV, OVCAR-3 and SK-OV-3) and their carboplatin (CBP)-resistant sublines (MES-OV CBP, OVCAR-3 CBP and SK-OV-3 CBP) were cultured in specialized media that promote stem cell proliferation. Immunohistochemistry, confocal microscopy and live cell imaging techniques were used to detect morphology and the formation of 3D structures. RNA-Seq and gene ontology analyses were performed to investigate the differences in the transcriptional landscape between the parental and CBP-resistant sublines.

Result and discussion

In 2D monolayers, all three CBP-resistant sublines showed a mesenchymal phenotype compared to their respective epithelial parental cells. However, under 3D conditions, the parental cell lines developed predominantly spherical structures, whereas the resistant cell lines developed predominantly vessel-like structures. A hollow lumen was observed within the spheres. It was also observed that the formation of the spheres begins with a single-cell division. Diversity of gene expression related to reorganization and regulation of the extracellular matrix, apoptosis and proliferation, transport of ions and binding of substrates was noted.

Conclusion

Our data highlight the importance of accurately characterizing the specific structures developed by resistant cell lines in a 3D environment and discovering the genes responsible for their formation.

EACR25-0172

Intracellular Ca²⁺ depletion induces FOXM1 SUMOylation and accumulation on the inner nuclear membrane resulting in accelerated G2/M cell cycle transition

W. Chiu¹, T. Lin¹, P. Chung¹

¹National Cheng Kung University, Department of Biomedical Engineering, Tainan, Taiwan

Introduction

Intracellular Ca²⁺ have important functions in regulating the activity of numerous transcription factors and cancer development. FOXM1 is a key transcription factor and an important oncogenic protein involved in tumorigenesis, but whether Ca²⁺ regulates the function of FOXM1 remains unclear.

Material and method

BAPTA-AM was used to cause intracellular Ca²⁺ depletion, and immunofluorescence staining was used to observe the distribution of FOXM1 in cells.

Result and discussion

Here, we found that Ca²⁺ promotes the entry of FOXM1 into the nucleus in many cancer cell lines, but Ca²⁺ depletion causes FOXM1 to accumulate at the inner nuclear membrane (INM). Further experiments revealed that sequestered FOXM1 colocalized with lamin B in the INM and was influenced by the activity of nuclear exportin 1 (XPO1). To investigate the mechanism by which intracellular Ca²⁺ affects FOXM1 sequestration, we found that among posttranslational modifications, only FOXM1 SUMOylation showed a significant increase under conditions of Ca²⁺ depletion, while

inhibition of FOXM1 SUMOylation using siRNAs or inhibitors rescued FOXM1 sequestration. Furthermore, Ca²⁺-dependent SUMOylation of FOXM1 appears to enhance the G2/M transition of the cell cycle and reduce apoptosis.

Conclusion

In conclusion, our results provide a molecular basis for the regulatory relationship between Ca²⁺ signaling and FOXM1, and we look forward to elucidating the biological functions associated with Ca²⁺-dependent FOXM1 SUMOylation in the future.

EACR25-0195

Progesterone receptor plays pivotal roles in regulating mitochondria function and mitochondria mediated caspase-independent apoptosis in breast cancer cells

J. Woo¹, P. Lau¹, V. Lin¹

¹Nanyang Technological University, School of Biological Sciences, Singapore, Singapore

Introduction

There have been conflicting reports of effects of progestin and progesterone receptor (PR) on breast cancer from both clinical and laboratory studies. Although progestin in hormone replacement therapy (HRT) is associated with an increased risk of breast cancer, its use in clinical trials as a second line of endocrine therapy have reported clinical benefits. There have been suggestions that the cancer promoting effect of progestins in HRT is due to progestin activation of androgen receptor. To clarify the role of PR in breast cancer, it is important to have a whole proteomic understanding of PR activities in response to pure agonist.

Material and method

Tandem mass tag (TMT) proteomic analysis of protein changes induced by agonist-activated PR was conducted in MCF-7 cells, in which PR levels were increased by transfection to facilitate unambiguous detection of PR activity.

Result and discussion

The analysis identified reproducibly 4915 PR regulated proteins and 678 phosphorylated peptides of diverse functions. It revealed that PR induced broad down-regulation of cell cycle regulators for G1-S progression and mitosis, including CDK1/2/4, CCNB1/B2, proteins for chromatin condensation, Ndc80 complex and chromosomal passenger complex. PR also regulated numerous proteins to drive mitochondria mediated apoptosis through hypoxia and p53 pathways including the activation of HIF1A-BNIP/BNIP3L axis and upregulation of death receptors. Importantly, PR significantly regulated 200 mitochondria proteins involved in metabolism, ATP generation and apoptosis. AIF/AIFM1, AIFM2, ENDOG and HtrA2/Omi are among the well-known mitochondrial proteins that are released during apoptosis to cleave apoptosis inhibitors and break DNA. Although PR also upregulated some oncogenic proteins such as EGFR, IRS2 and RUNX1 and suppressors of ferroptosis such as NUPR1, LCN2 and SLC7A11, these upregulations were functionally ineffective.

Conclusion

In conclusion, the study provides a whole proteomic view of intrinsic effects of agonist activated PR that is broadly growth suppressive and proapoptotic through mitochondrial mechanisms independent of caspases. The data provide conclusive evidence that high levels of PR activated by pure agonist exert strong anti-tumoral effect on breast cancer. The proteomic data set is valuable for research and development of PR targeted therapy in breast cancer.

EACR25-0200

Using organoids and Drosophila to explore the role of protein kinase N as an intestinal tumour suppressor

A. Campbell¹, J. Henry¹, P. Ribeiro¹, A. Cameron¹

¹*Queen Mary University of London, Tumour Biology, London, United Kingdom*

Introduction

Gastrointestinal tract cancers represent a significant global health challenge, with colorectal cancer (CRC) ranking as the second leading cause of cancer-related mortality in the United Kingdom. Previous investigations within the lab, using bioinformatics and mouse models, have identified the Rho effector kinase protein kinase N2 (PKN2) as a candidate CRC tumour suppressor. PKN2 expression is lost as tumours progress, with low expression associated with poor outcomes. Furthermore, the PKN2 gene is situated within the 1p22 locus, which is subject to shallow deletions in approximately 30% of CRC cases. Importantly, conditional PKN2KO in mice led to increased colon tumour development in a colitis-associated cancer model. PKN2KO mouse intestines were also found to be sensitive to inflammatory insults, with evidence that the epithelial barrier may be compromised. We hypothesise that PKN2 plays a key role in maintaining the epithelial barrier and the prevention of tissue inflammation and damage, which are precursors to tumour development.

Material and method

This study aims to elucidate the tumour suppressor functions of PKN2 using CRC cell lines, colon-derived organoids and Drosophila as models. PKN2KO CRC cell lines were generated utilizing CRISPR-lentiviral technology, to investigate the role of PKN2 in the integrity of cell junctions. To explore a role in a non-cancer epithelium, we successfully derived colon organoids from WT and conditional PKN2KO mice. These organoids will be used to assess the impact of PKN2 loss on organoid development, cell junction integrity and associated signalling pathways. Additionally, RNAseq transcriptomics will explore the global impact of PKN2KO on organoid phenotypes. To investigate the evolutionary conservation of PKN2 function, we are studying the impact of RNAi depletion of Drosophila PKN (dPKN) on gut morphology, cell junctions and response to inflammatory injury.

Result and discussion

Here, we show that PKN2 localises to cell junctions and plays a role in maintaining junction integrity in CRC cell lines. FITC-Dextran diffusion assays using PKN2 CRISPR KO cell monolayers indicated evidence of

impaired epithelial barrier. Initial organoid imaging experiments corroborate the PKN2 localisation to the cell junctions. Furthermore, preliminary imaging of Drosophila utilizing GFP-tagged dPKN has shown conserved localisation to epithelial junctions in the Drosophila midgut.

Conclusion

Collectively, our data strongly suggest that PKN2 plays a critical role in stabilizing cell junctions, thereby elucidating its function as a tumour suppressor in the context of colorectal cancer.

EACR25-0237

Short-term fasting and zinc ionophores cooperate to promote ferroptosis in colorectal cancer

A. Namatalla¹, T. Bonfiglio¹, S. Ravera², M. Balbi², I. Caffa¹, A. Nencioni¹, A. Khalifa¹

¹*University of Genoa, Department of Internal Medicine and Medical Specialties, Genoa, Italy*

²*University of Genoa, Department of Experimental Medicine, Genoa, Italy*

Introduction

Short-term fasting (STF) induces metabolic rewiring in cancer cells, exposing novel therapeutic vulnerabilities, as we previously reported for cholesterol biosynthesis inhibitors. In these agents, we found that reductions in circulating insulin, IGF1 and leptin play a key role in the sensitizing effect of STF by blunting cholesterol production and promoting cholesterol efflux in cancer cells.

Material and method

To identify additional agents that could be repurposed for oncologic applications in colorectal cancer (CRC) treatment, we screened commercially available drug libraries in HT29 CRC cells to identify compounds that acquire anticancer effects under fasting-mimicking culture conditions (FMCC; 1% FBS and 50 mg/dL glucose). Zinc ionophores evaluated in this study included the antiparasitic drug clioquinol, the investigational agent, PBT2, and chloroquine. In vitro studies were conducted using CRC cell lines HT29, HCT116, and CT26. For our *in vivo* experiments, we generated HCT116 xenografts (*in* athymic nude mice) and CT26 allografts (*in* BALB/c mice) and treated them with zinc ionophores, weekly 48h water-only STF or their combination with or without concomitant administration of coenzyme Q10 or zinc chloride (ZnCl₂). We monitored the expression levels of solute carrier family 7 member 11 (SLC7A11) and glutathione peroxidase 4 (GPX4), key regulators of ferroptosis, using RT-qPCR and Western blotting. In addition we quantified zinc levels, glutathione (GSH and GSSG), malondialdehyde, 4-hydroxynonenal, ATP and AMP in cultured cells and tumors using commercially available kits.

Result and discussion

FMCC and STF cooperated to enhance the antitumor activity of zinc ionophores in CRC models both *in vitro* and *in vivo*. In tumor-bearing mice, this antitumor effect was further compounded by ZnCl₂ administration. STF alone reduced GSH/GSSG levels in the tumors while

increasing lipid peroxides and other oxidative stress markers. Combining STF with zinc ionophores resulted in zinc accumulation, compounded GSH depletion, and elevated lipid peroxide formation within tumors. The ferroptosis inhibitors coenzyme Q10 and ferrostatin-1 abrogated the anticancer effects of combined STF and zinc-ionophores. STF combined with zinc ionophores reduced the expression of GPX4 and of the cystine transporter SLC7A11, leading to disruption of the SLC7A11/GSH/GPX4 axis. Overall, these data support the notion that ferroptosis is the primary mechanism of GSH depletion-induced cell death mediated by STF and zinc ionophores in CRC tumors.

Conclusion

Our data demonstrate that STF predisposes CRC to zinc-induced ferroptosis by depleting tumor GSH levels and downregulating GPX4 and SLC7A11.

EACR25-0242

Repurposing piroxicam enhances the antineoplastic effects of docetaxel and enzalutamide in prostate cancer cells using two-dimensional and three-dimensional *in vitro* culture models

A. Yehya¹, F. Ghamlouche¹, R. Karami¹, S. Hachem¹, Z. Salhab¹, Y. Liu², G. Daoud¹, W. Abou-Kheir¹

¹American University of Beirut, Department of Anatomy, Cell Biology and Physiological Sciences, Beirut, Lebanon

²Taipei Medical University, College of Medicine, Taipei, Taiwan

Introduction

Drug repurposing is gaining consideration in cancer due to the challenges of poor outcomes and resistance associated with the current conventional modalities. Inflammation plays a critical role in cancer progression, making it a promising therapeutic target. Non-steroidal anti-inflammatory drugs (NSAIDs), widely used for treating inflammation, are being explored for their potential efficacy in cancer treatment, including prostate cancer (PCa). This study aims to evaluate the efficacy of Piroxicam (PXM), an NSAID, in enhancing the sensitivity of PCa cells to chemotherapeutic and hormonal drugs.

Material and method

Differentially expressed genes between murine PCa models PLum AD (androgen-dependent) and PLum AI (androgen-independent) were identified via computational analysis to pinpoint therapeutic targets. In two-dimensional (2D) cell culture, cell proliferation, viability, and migration assays were performed on PLum-AD and PLum-AI cells treated with PXM, alone or in combination with docetaxel (Doc) or enzalutamide (Enz). Additionally, the impact of these treatments on stem-like progenitor cells was assessed using three-dimensional (3D)-Matrigel™-based sphere-forming and organoid formation assays.

Result and discussion

Transcriptomic analysis revealed that inflammatory pathways are enriched during PCa progression, making them viable targets for NSAID-based interventions. Single treatment of PXM demonstrated significant anti-

cancer effects on PLum-AD and PLum-AI cells, evidenced by reduced cell proliferation, viability, migration, sphere growth, and organoid growth. Interestingly, PXM treatment in combination with Doc or Enz resulted in more pronounced anti-neoplastic effects compared to single-drug exposure.

Conclusion

Our work suggests PXM as a potential adjunctive therapy to enhance the efficacy of conventional treatments in PCa, paving the way for potential clinical applications.

EACR25-0248

ADAR2-dependent editing activity induces the differentiation of osteosarcoma cells by targeting IGFBP7

M. Rossi¹, F. Scotti di Carlo², L. Di Giuseppe¹, J. Di Gregorio³, S. Terreri¹, D. Silvestri⁴, G. Battafarano¹, F. Gianfrancesco², A. Gallo⁴, A. Del Fattore¹

¹Bambino Gesù Children's Hospital, Bone Physiopathology Research Unit, Translational Pediatrics and Clinical Genetics Research Division, Rome, Italy

²IGB-CNR, Bone diseases and tumor lab, Naples, Italy

³University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

⁴Bambino Gesù Children's Hospital, RNA editing lab, Rome, Italy

Introduction

Osteosarcoma (OS) is the most common primary bone tumor affecting the juvenile population, with a high rate of recurrence and metastasis. RNA editing was described to play a main role in cancer development and in this study we investigated the role of ADAR2 (Adenosine Deaminase Acting on RNA 2, AD2) editing enzyme in OS with *in vitro* and *in vivo* analysis.

Result and discussion

Gene and protein analyses evidenced that AD2 expression is lower in Saos2 and 143B cells compared to osteoblasts; AD2 level inversely correlated to the aggressiveness of tumor cells. To confirm this possible link, microarray dataset downloaded from the NCBI GEO database (GSE85537) showed that intratibially injected OS Well5 cells with increased ability to metastasize to the lung had lower level of AD2 compared to the same cells that remained into the bone. To study the role of AD2 in OS cells, Saos2 and 143B cell lines were transfected with Empty plasmid (E) or vectors overexpressing AD2 or the Inactive form of AD2 (IN). The overexpression of ADAR2 in Saos2 cells reduced the proliferation rate, as confirmed by G1 arrest of cell cycle [G0/G1 cell population (%), E: 46.8±3.0, AD2: 64.9±4.3%, IN: 43.5±2.1. *p<0.01 vs. E; #p<0.01 vs. IN] and migration ability [Wound repair (μm), E: 161.8±47.4, AD2: 62.7±34.3%, IN: 146.2±63.7. *p<0.01 vs. E; #p<0.01 vs. IN] compared to E- and IN-transfected cells. An enhanced ability to form mineralized nodules was observed in AD2-overexpressing Saos2 as shown by Alizarin Red (Arbitrary Unit, E: 1.0±0.1, AD2: 13.7±2.0%, IN: 1.3±0.2. *p=0.0003 vs. E; #p=0.0015 vs. IN) and Von Kossa stainings. Real-Time expression and western blot analysis revealed high levels of Osterix and ALP in AD2-Saos2. The overexpression of AD2 in 143B cells also led to reduced proliferation ability, G1 arrest of

cell cycle and increase of osteoblast markers expression. Intratibial injection of transfected Saos2 cells in NSG mice led to the formation of bone tumor reduced in size in AD2-cells injected mice [Tumor size (xy2/2), E: 1.56 ± 0.51 , AD: $0.47 \pm 0.44^{*#}$, IN: 1.25 ± 0.16 . * $p < 0.01$ vs. E; # $p < 0.01$ vs. IN] with reduced number of liver, kidney and lung metastases. Moreover, the deep-seq analysis revealed a significant editing level of IGFBP7 transcripts in AD2 cells compared to E- and IN-transfected cells. Particularly, the K95R edited form of IGFBP7 fails to stimulate the IGF1R pathway. These results were also confirmed by the treatment of Saos2 cells with human recombinant K95R-IGFBP7 [pIgflr/Igflr/β-Actin. Untreated cells (NT): 1.00 ± 0.01 ; WT: $2.36 \pm 0.70^{*#}$; K95R: 1.02 ± 0.65 . * $p < 0.01$ vs. NT; # $p < 0.05$ vs. K95R] compared to WT-IGFBP7 or untreated cells. Moreover, K95R-IGFBP7 is able to increase the expression of Runx2 compared to WT-IGFBP7, suggesting a role in the induction of OS cell differentiation.

Conclusion

Our results showed that ADAR2 acts as tumor suppressor in OS cells editing IGFBP7 and may represent a novel therapeutic target for this rare pediatric tumor.

EACR25-0286

Exploring LDH inhibitors with chemotherapeutic agents as dual therapy for breast cancer

K. Pathania¹, S. Pawar¹, S. Pilkhwal¹

¹Panjab University, UIPS, Chandigarh, India

Introduction

Breast cancer is the most prevalent malignancy among women, with cases projected to exceed 2 million by 2030. Chemotherapy remains a key treatment, but prolonged use leads to severe side effects, resistance, and recurrence, necessitating novel strategies. Cancer cells undergo metabolic reprogramming, favoring aerobic glycolysis over oxidative phosphorylation – a phenomenon known as the Warburg effect. Lactate dehydrogenase (LDH) plays a crucial role in this shift, promoting tumor progression and resistance. Elevated LDH levels correlate with poor prognosis, making it a promising therapeutic target. This study evaluates natural and synthetic LDH inhibitors in combination with chemotherapeutic agents in MCF-7 (hormone-positive) and MDA-MB-231 (metastatic) cells. In silico docking with LDH-A (PDB ID: 1I10) was conducted to assess binding interactions, followed by in vitro cell-based analysis in breast cancer cell lines. Findings aim to reveal synergistic effects, offering insights into metabolic disruption as a strategy to enhance breast cancer treatment efficacy.

Material and method

All drugs (5 chemotherapeutic agents and 6 LDH inhibitors) were purchased from Sigma, TCI and SRL Chemicals. Cell culture reagents were obtained from HiMedia, and assay kits from Thermo Scientific, Invitrogen, and Genetix. MCF-7 and MDA-MB-231 cells (NCCS, Pune) were maintained in DMEM with 10% FBS at 37°C, 5% CO₂. Hoechst and DHE staining assessed DNA damage and ROS. ELISA was performed

per the manufacturer's protocol. Docking studies were conducted using Schrödinger (PDB: 1I10), including ligand preparation, minimization, and XP docking. MD simulations followed system setup, minimization, and dynamics. Cytotoxicity was evaluated using MTT assay in MDA-MB-231 and MCF-7 cells with monotherapy and combination therapy by measuring absorbance at 595 nm. Scratch assay was performed on MDA-MB-231 cells and % cell migration was indicated by the ability of the cells to migrate into a scratch wound of the confluent cell monolayer.

Result and discussion

LDH inhibitors significantly enhanced the cytotoxic potential of chemotherapy in combination therapy compared to monotherapy. Paclitaxel, Methotrexate, and 5-Fluorouracil showed superior cytotoxicity and were further analyzed. The increased efficacy in combination therapy suggests that LDH inhibition can enhance chemotherapy response, potentially overcoming resistance and improving treatment outcomes.

Conclusion

The findings highlight the therapeutic potential of LDH inhibition in breast cancer treatment. By disrupting cancer cell metabolism, LDH inhibitors can enhance chemotherapy efficacy, reduce resistance, and improve overall therapeutic response, supporting their role as adjuvant agents in combination therapies.

EACR25-0318

Constituent compounds from Bazi Bushen regulate autophagy and improve the senescence feature of vascular endothelial cells

A. Li¹, J. Tong¹, Y. Hou², T. Martin¹, W. Jiang¹

¹Cardiff University School of Medicine, Heath Park, Cardiff CF14 4XN, Cancer and Genetics, Cardiff, United Kingdom

²Shijiazhuang Yiling Pharmaceutical Co., Ltd, New Drug Evaluation Centre, Shijiazhuang, China

Introduction

Bazi Bushen (BZBS), a formulated Chinese medicine, has been shown to exert potential protective effect on vascular endothelial cells and improve senescence-related cells decline. Cellular senescence is a hallmark of ageing, contributing to endothelial dysfunction and the development of age-related vascular diseases. Autophagy plays a crucial role in regulating cellular repair and its dysregulation has been implicated in ageing-related deterioration. Given the importance of autophagy in vascular health, the present study investigated the effects of BZBS and its leading constituent compounds on the function and autophagy of human vascular endothelial cells. We further explored the molecular mechanism by which the compounds operated in cells, with a focus on key autophagy regulators, including sequestosome-1 (SQSTM1) and autophagy-related protein LC3.

Material and method

Human vascular endothelial cells derived from peripheral and cerebral origins were used in this study. Cell proliferations were measured between the wild-type (WT) and BZBS-treated cells. To evaluate autophagic flux,

mRFP-EGFP dual fluorescent LC3 plasmid was transfected into the endothelial cells. Autophagic activity was assessed by quantifying the autophagosomes and autolysosomes puncta. To validate the autophagic response, Western blot analysis was conducted to measure the expression levels of LC3-I, LC3-II, and SQSTM1/p62. Changes in the ratio of LC3-II to LC3-I and the degradation of SQSTM1 were assessed to determine autophagic activity following treatment. Mass spectrometry-based proteomics and protein blotting were further employed to analyse changes in autophagy associated signalling pathways.

Result and discussion

BZBS treatment significantly enhanced endothelial cell proliferation and induced a marked increase in the number of autophagosomes ($p < 0.01$, at 20 µg/ml) compared with the WT cells without signs of cytotoxicity. In double-blinded tests on multiple compounds separated from BZBS, three of these purified compounds, namely Compound-5 (schisandrin A or deoxyschizandrin), Compound-10 (Azelaic acid), and Compound-13 (gomisin D), significantly increased autophagosome formation in endothelial cells.

Comprehensive proteomics analysis revealed that BZBS and these lead compounds led to marked dephosphorylation of SQSTM1 at S28, S272 and T269; the phosphorylation of these residues was known to inhibit the autophagy process in cells.

Conclusion

Our findings indicate that BZBS enhances autophagy in vascular endothelial cells, potentially reversing endothelial cell ageing. This effect is mediated, at least in part, through the dephosphorylation of SQSTM1, which alleviates its inhibitory effect on autophagy. These results suggest that BZBS may offer therapeutic potential in preventing age-related vascular dysfunction. Further investigations are warranted to explore its clinical applications in ageing-related diseases.

EACR25-0330

Targeting the DNA damage response prevents regrowth of colorectal peritoneal metastasis-derived organoids following treatment with mitomycin C

K. van Megeesen¹, A. Stefan¹, M. Kieboom¹,

I. Borel Rinkes², O. Kranenburg¹

¹*University Medical Center Utrecht, Imaging & Oncology, Utrecht, Netherlands*

²*University Medical Center Utrecht, Surgery, Utrecht, Netherlands*

Introduction

A minority of Colorectal Cancer (CRC) patients with peritoneal metastases is eligible for cytoreductive surgery (CRS) followed by hyperthermic intraperitoneal chemotherapy (HIPEC). However, recurrence rates are high (~80%). We tested whether inhibitors of the DNA damage response (DDR) could prevent recurrence in an *in vitro* HIPEC model.

Material and method

Peritoneal metastasis-derived organoids (PMDOs; n=10) were treated with inhibitors of ATR (berzosertib, ceralasertib, elimusertib), CHK1 (rabusertib), and WEE1

(adavosertib) alone, and in combination with MMC, oxaliplatin, or irinotecan. Western blotting was used to determine Chk1 phosphorylation and markers of DNA damage. Microscopy and ATP quantification were used to measure the effects of (combination) treatments on cell viability and recurrence/regrowth.

Result and discussion

All PMDOs displayed rapid regrowth (recurrence) following single-drug chemotherapy treatment. Berzosertib inhibited chemotherapy-induced Chk1 phosphorylation, augmented DNA damage, and abrogated recurrence in all 10 MMC-treated PMDOs. The combination with oxaliplatin and irinotecan was less effective. *In vitro* HIPEC with MMC followed by 'adjuvant' treatment with any of the DDR inhibitors for 3 days completely prevented PMDO recurrence.

Conclusion

PMDOs can be completely eradicated if MMC treatment is followed by inhibition of ATR or other DDR kinases. DDR inhibitors may, therefore, have value in the adjuvant treatment of peritoneal metastases following CRS-HIPEC.

EACR25-0334

Exploring the Tumor-Suppressive Role of MLN51 (Metastatic Lymph Node 51) in Lung Adenocarcinoma

H. Zhang¹, H. Zhang², T. Martin¹, F. Ruge¹, P. Sun², W. Jiang¹

¹*CCMRC, Institute of Cancer and Genetics, Cardiff University School of Medicine, Cardiff, United Kingdom*

²*Department of Oncology, Yantai Yuhuangding Hospital of Qingdao University, YANTAI, China*

Introduction

MLN51 (Metastatic Lymph Node 51), initially identified from metastatic lymph node, is now also known as a core component of the exon junction complex (EJC). It is a protein participating in fundamental RNA processing mechanisms including splicing, localization and degradation. Despite its known role in RNA metabolism, its functional significance in tumorigenesis, particularly in lung adenocarcinoma (LUAD), remains poorly characterized.

Material and method

Clinical relevance of MLN51 was investigated through immunohistochemistry on lung cancer tissues and integrated analysis of TCGA datasets, correlating expression patterns with clinical staging and survival outcomes in LUAD. Lentiviral-mediated knockdown and overexpression models were established in human lung adenocarcinoma A549 and PC9 cell lines. Cellular assays employed included cell growth, Transwell invasion, adhesion assays, and wound healing migration analyses. Mechanistic explorations were carried out via quantitative proteomics by way of mass spectrometry to identify MLN51 protein interaction networks and pathway associations.

Result and discussion

Immunohistochemical analysis revealed that the MLN51 protein staining, mainly in the cytoplasmic region of the cells, is seen more prominently in normal lung tissues than in lung adenocarcinoma. In the TCGA database, the expression of MLN51 transcript was found to be low in

cancer tissues, both in LUAD ($p < 0.001$) and squamous cell carcinoma, when compared with normal tissues. Survival analysis demonstrated improved overall survival in patients with higher MLN51 expression (HR = 0.62, 95% CI 0.47–0.82, $p = 0.003$). Functional studies showed MLN51 overexpression suppressed malignant phenotypes, reducing the rate of cell growth ($p < 0.0001$), invasion capacity ($p < 0.001$), and migration rate compared with control cells. Proteomic analysis identified the top 200 upregulated and downregulated genes, which were subjected to GO analysis. The results indicate that these genes are mainly involved in protein translation and RNA splicing, cell adhesion molecule binding and ECM receptor interactions, processes that play key roles in tumour progression and metastasis.

Conclusion

Our multi-dimensional analyses disclose a pivotal role of MLN51 in lung adenocarcinoma. The inverse correlation between MLN51 expression and disease progression indicates its potential as both a prognostic biomarker and therapeutic target. Proteomic analyses indicate that MLN51 regulates tumour progression via multiple pathways related to protein translation, RNA splicing, cell adhesion and ECM receptor interactions, processes crucial for cancer cell survival, metastasis, and drug resistance. The study thus collectively suggests that MLN51 acts as a tumour suppressor in lung adenocarcinoma with prognostic and therapeutic value.

EACR25-0335

Can transient inactivation replace loss of the wildtype tumor suppressor as the second hit for colorectal cancer initiation?

P. Cheah¹, K. Lam¹, M. Lo¹, E. Tan¹, C. L. Tang¹

¹Singapore General Hospital, Colorectal Surgery, Singapore, Singapore

Introduction

To address the phenomena of breast cancer initiation in cases with just one germline mutation and no apparent loss of the wildtype allele, a recent study has proposed transient inactivation of the wildtype BRCA2 protein by glycolytic metabolite methylglyoxal (MGO) as the second ‘hit’ of the ‘Knudsen’s two-hit’ mechanism of cancer initiation. We have previously identified NR0B2, an orphan nuclear receptor, as a candidate tumor suppressor in microsatellite-stable, APC mutation-negative familial colorectal cancer (CRC) patients. However, germline truncation of NR0B2 was not accompanied by loss of the wildtype allele in the tumors.

Material and method

In the colon, normal mucosa cells obtain energy mainly by oxidative phosphorylation rather than glycolysis. It is thus unlikely that MGO could be present in large enough quantities to initiate tumorigenesis. Ethanol is naturally present at low concentration in the human gut via fermentation activity of the intestinal flora. Common ‘A’ variants in rs1229984 and rs671 of the alcohol dehydrogenase (ADH1B) and aldehyde dehydrogenase 2 (ALDH2) genes respectively in East Asians could perturb the ethanol detoxification pathway leading to accumulation of the acetaldehyde metabolite. We screened for the genotypes of these two enzymes in the

germline of these patients by Sanger sequencing and assessed the expression of the wildtype NR0B2 peptide in their matched mucosa-tumor samples using semi-quantitative near infrared Western Blots.

Result and discussion

Substantial downregulation (63%) of the wildtype NR0B2 peptide was found in the tumor of a case with one ‘A’ allele each in rs1229984 and rs671 compared to its matched mucosa. Excess acetaldehyde could form adducts with the wildtype NR0B2 peptide, leading to its downregulation. Nevertheless, this phenomenon is not replicated in the tumors of three other patients indicating that the downregulation is probably transient and dynamic and hence not captured in tumor samples of these other patients. In CRC, cancer initiation occurs at the aberrant crypt foci or early adenoma stage which progresses to tumor formation only after many years.

Conclusion

Accumulation of the acetaldehyde metabolite could serve as the endogenous toxin and the second hit for the initiation of CRC tumorigenesis in cases with just one germline NR0B2 mutation and no loss of the wildtype allele.

EACR25-0337

PTX3 Promotes Tumor Cell Migration Through the miR-1255b/CYP2J2 Axis in Oral Cancer

S. Yang¹, C. Lin², C. Yeh¹, M. Chen³

¹Chung Shan Medical University, Institute of Medicine, Taichung, Taiwan

²Chung Shan Medical University, Institute of Oral Sciences, Taichung, Taiwan

³Changhua Christian Hospital, Department of Otorhinolaryngology, Changhua, Taiwan

Introduction

Oral cancer poses major clinical challenges because of its invasiveness and poor prognosis. Pentraxin 3 (PTX3) is an immune-modulating protein implicated in various types of cancer, although its role in oral cancer remains unclear. In this study, we examined the expression patterns, functional roles, and underlying molecular mechanisms of PTX3 in oral cancer.

Material and method

The clinical significance of PTX3 in patients with oral cancer was investigated using data from the Gene Expression Omnibus (GEO) and TCGA datasets. Cell migration and invasion were evaluated using Transwell assays to assess the roles of PTX3 in oral cancer metastasis. Luciferase reporter assays, western blotting, and real-time reverse-transcription quantitative polymerase chain reaction (RT-qPCR) were used to elucidate the underlying mechanisms of PTX3.

Result and discussion

Bioinformatics and clinical data analyses revealed high PTX3 levels in oral cancer tissues, associated with reduced patient survival. Functional assays revealed that PTX3 promotes tumor cell migration and invasion in patients with oral cancer although it has no effect on cell proliferation. Transcriptomic profiling identified cytochrome P450 family 2 subfamily J member 2 (CYP2J2) as a downstream target of PTX3.

Mechanistically, PTX3 inhibits the expression of CYP2J2 by modulating the focal adhesion kinase/Src/extracellular signal-regulated kinase signaling pathway and upregulating miR-1255b, which directly interacts with the 3'-untranslated region of CYP2J2. Additionally, CYP2J2 downregulation mediates the promigratory effects of PTX3 on tumor cells in oral cancer.

Conclusion

Overall, our findings elucidate a novel regulatory axis that involves PTX3, miR-1255b, and CYP2J2 and drives the progression of oral cancer, highlighting PTX3 as a potential therapeutic target and prognostic biomarker in oral cancer management.

EACR25-0340

PFKFB4 mediates cell migration through regulating MX1 and MX2 expression in oral squamous cell carcinoma

C. Lin¹, S. Yang², S. Su³

¹Chung Shan Medical University, Institute of Oral Sciences, Taichung, Taiwan

²Chung Shan Medical University, Institute of Medicine, Taichung, Taiwan

³Chang Gung Memorial Hospital, Whole-Genome Research Core Laboratory of Human Diseases, Keelung, Taiwan

Introduction

PFKFB4 (6-phosphofructo-2-kinase/ fructose-2,6-biphosphatase 4), an isoform of the glycolytic enzyme phosphofructokinase 2 (PFK2), is a crucial regulator of glucose catabolism and broadly implicated in other cellular mechanisms/processes, such as transcriptional regulation, cell cycle, and autophagy in a non-glycolysis-dependent manner. Nevertheless, its impacts on the disease progression of oral squamous cell carcinoma (OSCC) remain largely unknown.

Material and method

Cell viability and flow cytometry assays were used to determine proliferation of OSCC cells. Boyden chamber assays were used to detect migration and invasion of OSCC cells. The regulatory mechanisms of PFKFB4 in the cell migration of OSCC were elucidated by RNA sequencing, western blotting, and real-time reverse-transcription quantitative polymerase chain reaction (real time RT-PCR).

Result and discussion

In our survey, upregulation of PFKFB4 was observed in a majority of cancer types, including head and neck cancer, and high levels of PFKFB4 were associated with advanced tumor stage and poor survival in OSCC patients. In vitro experiments, alterations in PFKFB4 levels affected cell migration and invasion but not proliferation in OSCC. Furthermore, we identified a list of differentially expressed genes in PFKFB4-silencing OSCC cells, among which MX1 and MX2 acted as a negative regulator of OSCC migration. In addition, PFKFB4 knockdown dampened the phosphorylation of src and p38 in OSCC cells, implicating a role of PFKFB4 in signal transduction.

Conclusion

Taken together, these results indicate that MX1 and MX2 negatively regulated OSCC migration downstream of

PFKFB4, which may offer potential avenues for controlling metastasis of oral malignancies.

EACR25-0353

Sequential Targeting of IAP and BCL-2 Family Proteins May Enhance Apoptotic Sensitivity in Non-Small Cell Lung Cancer

B. Budak¹, L. Wu¹, T. Kaufmann¹

¹Institute of Pharmacology, Faculty of Medicine, Bern, Switzerland

Introduction

Non-small cell lung cancer (NSCLC) remains a major challenge due to its resistance to apoptosis, limiting therapeutic success. Targeting survival pathways with Smac mimetics (e.g., Birinapant, Compound A) and BH3 mimetics (e.g., S63845, ABT-263) offers a promising approach. This study examines whether pre-treatment strategies enhance apoptosis compared to direct drug combination in NSCLC cells.

Material and method

NSCLC cell lines were categorized into two groups based on apoptotic sensitivity. Group 1 (H727, LXF289, H358, CORL23, LCLC103H, SKMES1, H1299) responded to Smac mimetics alone, while Group 2 (A549, CALU1, COLO, H441, H2009, SKLU1) required additional BH3 mimetics. Group 1 cells were treated with Compound A, TNF- α , and caspase inhibitor QVD, and apoptosis was quantified via Annexin V/PI staining using flow cytometry. Necroptosis was assessed using RIPK1 and RIPK3 inhibitors (Necrostatin-1, GSK872) but did not significantly contribute to cell death. Group 2 cells underwent additional treatment with BH3 mimetics (S63845, ABT-199, WEHI-539, ABT-263). In one of sequential treatments, Birinapant was added first, followed by a 2-hour incubation before Smac mimetics, then TNF- α was introduced 30 minutes later. Group 1 cells were incubated for 24 hours, whereas Group 2 cells underwent 24-hour and 48-hour treatments to assess time-dependent effects.

Result and discussion

Group 1 cells exhibited significant apoptosis with Smac mimetics alone, demonstrating reliance on IAP-mediated survival. Group 2 cells required BH3 mimetics for apoptosis, highlighting dependence on MCL-1/BCL-2 proteins. Sequential drug administration enhanced apoptosis, particularly in Group 2 cells. The sequential combination of Birinapant + S63845 + TNF- α was one of the most effective. Necroptosis inhibition did not alter cell death rates, confirming apoptosis as the dominant pathway. Extended 48-hour incubation further increased apoptosis in resistant cells.

Conclusion

Our findings highlight the importance of sequential drug administration in apoptosis induction. Smac mimetics effectively induced apoptosis in sensitive NSCLC cells, while resistant cells may require BH3 mimetics. The lack of necroptotic response confirms apoptosis as the primary mechanism. The common and possible genetic factors in the literature (e.g., mutant K-Ras, loss of p53, FHIT deletions) may contribute to therapy resistance. Optimizing pre-treatment regimens could enhance therapeutic efficacy in NSCLC patients.

EACR25-0362

Epigenetic regulation by histone modification in the epithelial-to-mesenchymal transition of lung cancer brain metastasis

Y. Kim¹, S. Kim²

¹Sungkyunkwan University School of Medicine, Neurosurgery, Changwon, Korea (Republic of)
²Sungkyunkwan University School of Medicine, Internal Medicine, Changwon, Korea (Republic of)

Introduction

The epithelial-to-mesenchymal transition (EMT) is an essential step for cancer metastasis to the brain. The transcription factors (TFs), which are associated with EMT, plays a key role during EMT. The objective of this study was to investigate the epigenetic role of histone lysine methylation/demethylation on the expression of EMT associated TFs during the metastasis of lung adenocarcinoma to the brain.

Material and method

Paired samples of lung adenocarcinoma and brain metastasis (BM) were analyzed in 46 individual patients. Both samples were obtained by surgical resection or biopsy of the lung and brain. The paraffin fixed formalin-embedded samples were obtained from the pathology archives in our institute. In samples of lung adenocarcinoma and BM, immunohistochemical staining was performed for epithelial markers, mesenchymal markers, EMT-TFs, histone lysine methyltransferase and demethylase.

Result and discussion

Several EMT-TFs such as Slug, Twist, ZEB1, and FOXC2 had higher immunoreactivity in brain metastasis than lung cancer. The immunoreactivity of EMT-TFs such as Slug (15.6% vs. 42.6%, $p=0.005$), Twist (23.6% vs. 45.9%, $p = 0.010$) and ZEB1 (15.0% vs. 55.9%, $p = 0.002$) was increased in BM compared with that in lung adenocarcinoma. Epigenetic inducers such as H3K4 methyltransferase (MLL4, $p = 0.018$) and H3K36me3 demethylase (UTX, $p = 0.003$) were statistically increased, and epigenetic repressors such as EZH2 (H3K27 methyltransferase, $p = 0.046$) were significantly decreased in BM compared with those in lung adenocarcinoma. The expression of UTX-ZEB1 (R^2 linear = 1.204) and MLL4-Slug (R^2 linear = 0.987) was increased in direct proportion, and EZH2-Twist (R^2 linear = -2.723) decreased in reverse proportion.

Conclusion

The results suggest that certain histone lysine methyltransferase/demethylase, such as MLL4, UTX, and EZH2, regulate the expression of EMT-TFs such as Slug, ZEB1, and Twist epigenetically, which may thereby influence cancer metastasis from the lung to the brain.

EACR25-0366

A multi-omics approach to dissect cell-intrinsic functions of IDO1 in ovarian cancer

T. Xu¹, A. Metuosis², X. Zhang³, L. Kainacher¹, D. Lindberg³, P. Mann², P. Murray¹

¹Max Planck Institute of Biochemistry, Immunoregulation, Planegg, Germany

²Max Planck Institute of Biochemistry, Proteomics and Signal Transduction, Planegg, Germany

³LMU Munich, Department of Medicine I, University Hospital, Munich, Germany

Introduction

Indoleamine 2,3-dioxygenase 1 (IDO1) is an enzyme that oxidizes tryptophan to start the first step of kynurenine pathway product generation. IDO1 is implicated in cancer pathophysiology because of its potential to deplete tryptophan (TRP) in local tumor microenvironments (TME), thereby impairing immune cell functions. Thus, IDO1 inhibitors were developed to “reactivate” T cell proliferation and function in the TME. So far, these drugs collectively failed to show efficacy in multiple clinical trials including ovarian cancer, suggesting a more in-depth study of the molecular function of IDO1 in cancer cells is warranted.

Material and method

We used single-cell RNA sequencing (scRNASeq) and deep-visual-proteomics (DVP) to study the IDO1+ tumor fraction in ovarian cancer patient tissues. We also employed a wide range of ovarian cancer cell lines to reconstitute key features of the clinical system where IDO1 expression was exogenously modulated with IFN-γ in control or IDO1-deficient backgrounds. Then, stimulated cells were analyzed using life-cell imaging to determine cell death and immunoblotting to characterize the activated molecular pathways.

Result and discussion

The results from the scRNASeq and DVP suggested that IDO1 expression is heterogeneous and is specifically linked to IFN-γ secreted by T cells in the ovarian TME. Subsequently, we used the beforementioned in-vitro system and investigated the response of ovarian cancer cells to IFN-γ stimulation. We discovered that IDO1 induction with IFN-γ results in an IDO1-dependent cell death caused by TRP starvation via activation of the GCN2 integrated stress response pathway and not by accumulation of kynurenine. The phenotype is completely abolished whenever IDO1 is knock-down or if an IDO1 inhibitor is added to the stimulated cells. To highlight the clinical relevance of our study, we detected a correlation between IDO1+ and the starvation signature in patient data, confirming that IDO1 expressing cells undergo TRP starvation *in vivo*.

Conclusion

In summary, our study provides evidence supporting a link between IFN-γ and IDO1 expression in ovarian cancer patients and suggests a crucial role of TRP in promoting cancer survival. These findings may offer new insights into the molecular mechanisms underlying the detrimental effects of IDO1 inhibition in ovarian cancer. On one hand, IDO1 inhibition might reinvigorate the immune response against the tumor; on the other, IDO1 inhibition might protect the tumor cells from TRP starvation and therefore, it might undermine its therapeutic potential.

EACR25-0373**Treatment with 3-bromopyruvate boosts the effect of chemotherapy in acute myeloid leukemia**

⁵*CBMA—Centre of Molecular and Environmental Biology, Department of Biology, University of Minho, Braga, Portugal*

Introduction

Most cancer cells rely on glycolysis for energy production, even in the presence of oxygen, a phenomenon known as the Warburg effect. This metabolic reprogramming results in increased glucose consumption, lactate production, and upregulation of glycolysis-related enzymes, supporting rapid proliferation and tumor progression. In Acute Myeloid Leukemia (AML), a highly aggressive blood cancer, altered glucose metabolism has been identified as a prognostic marker, and was also associated with treatment response, including resistance to chemotherapy. Given the reliance of AML cells on glucose metabolism, targeting this pathway presents a promising therapeutic strategy. 3-Bromopyruvate (3-BP), a pyruvate derivative, has demonstrated anti-cancer activity in solid tumors. However, its potential as a chemo-sensitizing agent in AML remains largely unexplored.

Material and method

This study explored glucose metabolism in AML as a therapeutic target by evaluating the effect of combination of 3-BP with standard chemotherapeutic agents daunorubicin (DNR) and cytarabine (Ara-C). Additionally, we developed two AML cell line models resistant to Ara-C (KG-1 Ara-R, MOLM13 Ara-R), which exhibited metabolic adaptations and varying sensitivity to metabolic inhibitors. The effects of 3-BP on chemotherapy response were assessed on cell viability (trypan blue staining), metabolic profiling (Western blot and colorimetric kits), mitochondrial activity (flow cytometry and Seahorse), and antioxidant capacity (colorimetric kit). Furthermore, we established an *in vivo* AML model using the chicken embryo to validate the therapeutic effect of 3-BP in combination with chemotherapy.

Result and discussion

Our findings demonstrated that 3-BP enhanced the cytotoxic effects of chemotherapy in AML cell models, even the context of acquired resistance (Ara-C resistant cells). Pre-treatment with 3-BP, in particular,

significantly reduced the EC50 values of DNR and Ara-C, supporting the chemo-sensitization. Mechanistically, 3-BP pre-treatment led to elevated ROS levels and decreased the levels of reduced glutathione, which likely contributed to the enhanced efficacy of chemotherapy. Moreover, the results obtained with *in vivo* chicken embryo AML model supported the *in vitro* results, reinforcing the potential of targeting glucose metabolism to improve AML treatment outcomes.

Conclusion

This study highlights the therapeutic potential of modulating glucose metabolism in AML. Combining 3-BP with standard chemotherapy effectively enhanced drug response. These findings support the exploration of metabolic inhibitors as adjuvants in AML therapy to improve treatment efficacy while potentially reducing drug toxicity. Further clinical investigations are warranted to validate these findings and optimize therapeutic strategies for AML patients.

³*Mossakowski Medical Research Institute, Polish Academy of Sciences, Tumor Microenvironment Laboratory, Warsaw, Poland*

Introduction

Breast cancer metastasis remains a significant challenge in modern medicine and science. The increasing incidence of breast cancer, coupled with the high mortality linked to metastasis, underscores the urgent need for innovative therapeutic strategies. While research on protein-coding genes brought only incremental progress in anticancer therapies, increasing attention is now directed toward understanding the roles of non-coding RNAs – particularly the recently discovered circular RNAs (circRNAs).

Material and method

To investigate transcriptomic changes during metastasis, we analyzed cells from primary breast tumors ($n = 3$), pleural effusions ($n = 3$), and breast-to-brain metastases ($n = 3$), with normal epithelial cells as non-malignant control. Using Arraystar Inc. platforms, we profiled mRNAs ($n = 20,424$), long non-coding RNAs ($n = 37,823$), and circRNAs ($n = 12,828$), selecting transcripts with a fold-change ≥ 2 and p-value < 0.05 for bioinformatics analyses. We examined their molecular functions, interactions, correlations of circRNAs with linear counterparts, and the influence of culture conditions on the circRNA landscape.

Result and discussion

Hierarchical clustering of significantly deregulated transcripts classified cells by their origin. Notably, the circRNA-based analysis provided a clearer separation of

cells based on their origin compared to the analysis of linear transcripts. Among the identified circRNAs, 165 were significantly deregulated in breast cancer metastases relative to primary tumors. The most upregulated circRNA in metastatic samples, circPolar2A, harbored binding sites for tumor-suppressive microRNAs, including miR-7, miR-637, or miR-498. Additionally, the top five upregulated circRNAs contained multiple binding sites for AGO2, a key regulator of gene transcription. Distinct circRNA profiles were observed between different sites of metastases – pleural effusion and brain – where 117 circRNAs were differentially expressed. Importantly, circRNAs were deregulated independently of their linear counterparts. Furthermore, culture conditions favoring stemness and differentiation induced subtle shifts in circRNA expression. Although these changes did not reach statistical significance, they partially blurred the distinction cells based on their site of origin.

Conclusion

The circular RNA landscape reflects cellular status and site of origin, effectively distinguishing cancerous from normal breast epithelial cells. The most deregulated circRNAs have the potential to modulate metastasis by binding to tumor-suppressive microRNAs or altering global gene expression. Additionally, circRNAs represent a unique class of independently regulated transcripts, rather than mere by-products of transcription.

Consequently, circRNAs emerge as valuable biomarkers and promising mechanistic targets whose modulation could pave the way for paradigm-shifting therapeutic strategies.

EACR25-0430

Cyclic increase in the histamine receptor H1-ADAM9-Snail/Slug axis as a potential therapeutic target for EMT-mediated progression of oral squamous cell carcinoma

Y. Ding^{1,2}, K. Ho³, Y. Yang³, M. Chien^{3,4}

¹Taipei Medical University, Department of Otolaryngology, Taipei, Taiwan

²Graduate Institute of Clinical Medicine, Taipei, Taiwan,

³Taipei Medical University, Graduate Institute of Clinical Medicine, Taipei, Taiwan

⁴Taipei Medical University, TMU Research Center of Cancer Translational Medicine, Taipei, Taiwan

Introduction

The intricate involvement of the histaminergic system, encompassing histamine and histamine receptors, in the progression of diverse neoplasias has attracted considerable scrutiny. Histamine receptor H1 (HRH1) was reported to be overexpressed in several cancer types, but its specific functional implications in oral squamous cell carcinoma (OSCC) predominantly remain unexplored.

Material and method

Levels of HRH1 were evaluated in 177 OSCC patients by immunohistochemical (IHC) staining or by an in silico analysis. HRH1 genetic depletion or overexpression was performed in *in vitro* and *in vivo* OSCC models. HRH1-

deficient cells were RNA sequenced, and gene ontology and enrichment analyses were applied to the output data. Protein-based biochemical assays such as Western blotting, coimmunoprecipitation, and a protease array were used to investigate HRH1-regulated pathways. A drug repurposing approach was tested using anti-histamines combined with a signal transducer and activator of transcription 3 (STAT3) inhibitor on different cellular functions.

Result and discussion

Our findings indicate that dysregulated high levels of HRH1 were correlated with lymph node (LN) metastasis and poor prognoses in OSCC patients. We identified a disintegrin and metalloprotease 9 (ADAM9) as a critical downstream target of HRH1, promoting protumorigenic and prometastatic characteristics both *in vitro* and *in vivo*. Molecular investigations revealed that the cyclic increase in the HRH1-ADAM9-Snail/Slug axis promoted progression of the epithelial-to-mesenchymal transition (EMT). Clinical analyses demonstrated significant correlations of HRH1 expression with ADAM9 and with EMT-related markers, with elevated ADAM9 also associated with LN metastasis in OSCC patients. Regarding therapeutic aspects, we discovered that activated STAT3 acts as a compensatory pathway for the long-term HRH1 signaling blockade in OSCC cells. Combining inhibition of HRH1 and STAT3 using their respective inhibitors or short hairpin (sh)RNAs enhanced the tumor-suppressive effects compared to HRH1 inhibition/depletion alone in OSCC cells and a xenograft model.

Conclusion

In summary, HRH1 has emerged as a valuable biomarker for predicting OSCC progression, and combined targeting of HRH1 and STAT3 may represent a promising strategy for preventing OSCC progression.

EACR25-0432

Sesamin inhibits human colorectal cancer HCT-116 cell growth by inducing apoptosis

Y. Chen¹, Y. Huang¹, C. Wu², Y. Chen³, Y. Wu⁴, S. Hsieh¹

¹National Kaohsiung Normal University of Science and Technology, Department of Seafood Science, Kaohsiung, Taiwan

²Providence University, Department of Food and Nutrition, Taichung, Taiwan

³Kaohsiung Medical University, Graduate Institute of Natural Products, College of Pharmacy, Kaohsiung, Taiwan

⁴Kaohsiung Medical University, School of Pharmacy, Kaohsiung, Taiwan

Introduction

Colorectal cancer is one of the leading causes of cancer-related deaths worldwide, highlighting the urgent need for natural compounds capable of inhibiting tumor growth and inducing cancer cell death. Sesamin, a bioactive compound derived from sesame (*Sesamum indicum*), is known for its health benefits, including melanin synthesis inhibition and lipid metabolism regulation.

Material and method

This study investigates the potential anti-cancer effects and molecular mechanisms of sesamin in HCT-116 colorectal cancer cells. HCT-116 cells were treated with 0.5, 1, 2, and 3.5 mM sesamin for 48 hours to evaluate changes in cell viability, cell cycle progression, apoptosis, and the expression of related regulatory molecules.

Result and discussion

The results showed that sesamin at concentrations above 0.5 mM significantly reduced cell viability. Treatment with >1 mM sesamin led to a significant increase in the proportion of cells in the Sub-G1 and G0/G1 phases while decreasing those in the S and G2/M phases. Sesamin at concentrations above 0.5 mM significantly increased reactive oxygen species (ROS) levels, while >1 mM sesamin significantly reduced mitochondrial membrane potential in HCT-116 cells. Additionally, sesamin at 2 and 3.5 mM significantly upregulated the mRNA expression of Bcl-2-associated X (Bax), caspase-3, -8, and -9, and enhanced apoptosis. However, there was no significant difference in the mRNA expression of B-cell lymphoma-2 (Bcl-2) and poly (ADP-ribose) polymerase (PARP) between treatment groups.

Conclusion

In conclusion, sesamin, particularly at 2 and 3.5 mM, effectively inhibited HCT-116 cell growth by promoting apoptosis. These findings suggest that sesamin may serve as a promising bioactive compound for colorectal cancer therapy.

EACR25-0433

A novel role of Kinesin Family Member 20A (KIF20A) in Hepatocellular carcinoma cell metabolism and ferroptosis

K. Zhou¹, Y. Liu¹, L. Yang², T. Liu¹

¹*the Fifth Affiliated Hospital of Sun Yat-sen University, The Cancer Center, Zhuhai, China*

²*the Fifth Affiliated Hospital of Sun Yat-sen University, Department of Anesthesiology, Zhuhai, China*

Introduction

Hepatocellular carcinoma (HCC) represents a significant form of liver cancer, accounting for the fourth-highest number of cancer-related deaths on a global scale. Ferroptosis, a form of regulated cell death characterised by iron-dependent lipid peroxidation, has been increasingly implicated in HCC cancer progression and the role of Kinesin Family Member 20A (KIF20A), a member of the kinesin superfamily proteins that is vital during mitosis, might contribute to the resistance to ferroptosis of HCC. Here, we identify KIF20A as a novel biomarker of HCC and characterize the underlying mechanisms inducing ferroptosis.

Material and method

The genes that were differentially expressed in HCC and associated with ferroptosis were selected through an analysis of the GEO database and the Ferrdb website. The mRNA and protein levels of KIF20A were examined in HCC cell lines using RT-qPCR and western blotting, respectively. Experiments were conducted on the proliferation of HCC cells, as well as on ferroptosis, using overexpression and knockdown of KIF20A. Assays such as malondialdehyde (MDA) detection and Ferrorange assays were employed. Furthermore, the mechanisms by

which KIF20A regulates ferroptosis in HCC were investigated.

Result and discussion

Among the top 18 differentially expressed genes, we discovered KIF20A most potently related to the overall survival rate. The expression of KIF20A was significantly compared between HCC tissues and adjacent non-cancerous tissues. Our findings revealed that the proliferation of KIF20A-knockdown cells was significantly inhibited in two cell lines, SNU449 and PLC. Furthermore, we observed an increase in the levels of malondialdehyde (MDA), Fe²⁺, and intracellular reactive oxygen species (ROS) in these cells. Conversely, overexpressing this gene yielded opposite results. Knocking down KIF20A activates the pathway of ferroptosis through the KEGG pathway, and HMOX1 was identified by RNA sequencing as a downstream target of KIF20A influencing ferroptosis. Furthermore, our findings indicate that KIF20A inhibits ferroptosis in HCC cells via the HMOX1/SLC7A11/GPX4 pathway.

Conclusion

Collectively, our results uncover a novel role of KIF20A in the survival of HCC cells, their specific metabolic pathways linked to ferroptotic cell death. Our results suggest that KIF20A promotes the proliferation of HCC cells and inhibits ferroptosis by regulating the HMOX1/SLC7A11/GPX4 axis.

EACR25-0434

KSRP-mediated Wnt/β-catenin activation promotes follicular thyroid cancer progression and stemness

K. Pan¹, H. Chou¹, T. Cheng², K. Hua¹

¹*National Taiwan University, Graduate Institute of Toxicology, College of Medicine, Taipei, Taiwan*

²*National Taiwan University Hospital, Department of Laboratory Medicine, Taipei, Taiwan*

Introduction

The K-homology-type splicing regulatory protein (KSRP) is an RNA-binding protein involved in multiple cellular processes, including mRNA stability and translational regulation through its recognition of adenine–uracil-rich elements in the 3'-untranslated regions of target mRNAs. Despite its ability to regulate approximately 16% of transcript expression, its precise role in cancer remains unclear. This study aims to elucidate the oncogenic role of KSRP in follicular thyroid cancer (FTC) and its potential impact on Wnt/β-catenin signaling.

Material and method

We analyzed KSRP expression in publicly available clinical databases and our own FTC patient cohort. Additionally, we examined KSRP expression in a pair of FTC cell lines with differing metastatic potential. Functional assays, including knockdown and over-expression studies, were conducted to evaluate the effects of KSRP on in vivo metastasis and in vitro tumor-promoting functions such as migration, invasion, and sphere formation. Gene Set Enrichment Analysis (GSEA) and quantitative PCR (Q-PCR) were performed to identify Wnt signaling components affected by KSRP.

Result and discussion

Our findings identify KSRP as an oncogenic factor in FTC, with significantly elevated expression in FTC tissues compared to normal thyroid or adenoma tissues. Metastatic FTC cell lines also exhibited higher KSRP levels. Functional assays revealed that KSRP enhances FTC cell invasiveness and stemness. Mechanistically, KSRP promotes β -catenin nuclear accumulation and transcriptional activity by negatively regulating two Wnt signaling inhibitors, DACT2 and SFRP2. These findings suggest that KSRP plays a crucial role in promoting tumor progression via Wnt/ β -catenin signaling activation.

Conclusion

This study highlights the oncogenic function of KSRP in FTC and its role in modulating Wnt/ β -catenin signaling. Given its impact on tumor progression and metastasis, KSRP may serve as a potential prognostic marker and therapeutic target for FTC patients.

EACR25-0436

The Effect of RG7388 and Etoposide Combination on Cell Death in a Neuroblastoma Cell Line

S. Kabadere¹, Z. Tirasoglu¹, A. Birdogdu¹, G. Kus²

¹*Eskisehir Osmangazi University Faculty of Medicine, Physiology, eskisehir, Turkey*

²*Anadolu University Faculty of Health Sciences, Nutrition and Dietetics, Eskisehir, Turkey*

Introduction

Neuroblastoma, which originates from neural crest cells, is the most common extracranial solid tumor of childhood and is responsible for 15% of deaths. Despite standard therapies, survival rates in high-risk neuroblastoma cases are low and accelerate the search for new treatment strategies. Although p53 mutations are rare in neuroblastoma compared to other cancer types, they are observed in 15% of patients with neuroblastoma during recurrence. Evidence of p53 inactivation suggests that this may lead to chemotherapy resistance. MDM2 is a protein that regulates p53 and MDM2 inhibition can promote cell death by increasing p53 activation.

Although RG7388, a potent and selective MDM2 inhibitor, has been shown to reduce survival in neuroblastoma cells, the underlying cell death mechanism has not been investigated yet. Etoposide, a part of neuroblastoma treatment, inhibits topoisomerase-II, which is involved in DNA replication and recombination and decreases cell survival. However, alternative combinations are needed due to the resistance mechanism developed by cancer cells against the apoptotic cell death pathway.

Material and method

This study investigates the effect of combined RG7388 and etoposide treatment on cell survival in neuroblastoma cells. SHSY-5Y cells were seeded in 5x10³ cells/well in 96 well plates. After the 24-hour incubation period, etoposide (A), RG7388 (B), and etoposide + RG7388 (C) were added to the growth medium for 24 or 48 hours. After this incubation period, the drug cytotoxicity screening was determined using an MTT colorimetric assay. All statistical analyses were performed using one-way analysis of variance (ANOVA) and followed by

Tukey's multiple comparison tests. A p-value less than 0.05 was considered to be significant.

Result and discussion

IC50 values for etoposide were 64.2 and 4.4 μ M for 24 and 48 hours, respectively. IC50 values of RG7388 were 40 and 7.6 μ M for 24 and 48 hours, respectively. IC50 for combined treatment was determined as 6.09 μ M for 48 hours. The combination index (CI) is above 1 at the combined IC50 dose, and antagonism is achieved, while at the combined dose that kills approximately 80% of the cells, the CI index is below 1 and synergism is achieved.

Conclusion

Combined treatment of MDM2 and topoisomerase-II inhibitors shows a synergistic effect in neuroblastoma and promotes cell survival. Elucidation of the type of cell death induced by these drugs may provide new insights into treating neuroblastoma.

This study was supported Anadolu University within the scope of the project coded BGT-2023-2343.

EACR25-0442

"FastM": a fasting-mimicking cell culture medium for refined cancer research

T. Weiermair¹, V. Zopf¹, N. Tripolt², H. Sourij³,

H. Habisch⁴, T. Madl¹, A. Prokesch¹, J. Krstic¹

¹*Medical University of Graz, Cell Biology, Histology and Embryology, Graz, Austria*

²*norbert.tripolt@medunigraz.at, Endocrinology and Diabetology, Graz, Austria*

³*Medical University of Graz, Endocrinology and Diabetology, Graz, Austria*

⁴*Medical University of Graz, Medicinal Chemistry, Graz, Austria*

Introduction

Studies on fasting have shown promising results in enhancing the efficacy of cancer therapies, however, in vitro procedures published so far have not reflected the physiological composition of the fasted state sufficiently. This arises the need for a specialized cell culture medium that resembles the metabolic environment after fasting. To address this gap, we formulated FastM, a cell culture medium designed to mimic the effects of fasting in vitro.

Material and method

The formulation of FastM is based on PlasmalyteTM, a commercially available cell culture medium that reflects the composition of healthy human plasma. The concentration of each individual component in FastM was determined by comparative analyses of existing literature, open access metabolomics databases, and by NMR measurements of human serum after 12 and 36 hours of fasting. Viability assays were performed to investigate the synergistic effect of certain metabolites and drugs.

Result and discussion

NMR results revealed distinct metabolic differences between serums after 12 hours versus 36 hours of fasting. In concordance with metabolomics data from databases and literature, we determined the metabolites that were most significantly changed upon fasting, namely glucose, insulin, branched-chain amino acids, and several ketone bodies. We formulated FastM to contain these key nutrients at respective concentrations, relative to those in

Plasmax™. Then, we tested the efficacy and cytotoxicity of selected drugs on different breast cancer cell lines cultured in Plasmax™, FastM, and a previously used starvation medium by performing viability assays. Additionally, we analyzed how single key metabolites (e.g., different ketone bodies, glucose, insulin), affect the responsiveness of breast cancer cells to certain drugs. Hereby, we could show a significant potentiation of treatment efficacy in selected cell line-drug combinations upon altering concentrations of glucose and β-hydroxybutyrate, a key ketone body, to resemble the fasting state.

Conclusion

We formulated FastM, a cell culture medium which will allow deeper understanding of how fasting influences cancer cell behavior, metabolic profiles, and, ultimately, treatment efficacy. Compared to currently used cell culture media aiming to induce fasting responses, which simply reduce the amount of nutrients, FastM offers a more complex and realistic fasting environment for cancer cells. This approach has the potential to significantly advance cancer research by offering a method for exploring fasting strategies and their therapeutic implications. Furthermore, this medium can be used for in vitro experiments beyond cancer research.

EACR25-0455

Cingulin expression and clinical/prognostic value in breast cancer

Y. Lou¹, F. Ruge¹, W. Jiang¹, J. Benedikt², T. Martin¹

¹*Cardiff University, School of Medicine, Cardiff, United Kingdom*

²*Cardiff University, School of Engineering, Cardiff, United Kingdom*

Introduction

Cingulin is a vital part of the apical junctional complex (AJC) and regulates many pathological processes, such as tumorigenesis and inflammation. This gene has been verified as closely associated to the biological processes of cancer. Cingulin has also been studied in the context of various cancers, including lung cancer, osteosarcoma, and endometrial cancer. Unfortunately, there is limited research in breast cancer. This study aims to address this and investigate the function of Cingulin in breast cancer.

Material and method

Expression levels of Cingulin in human breast tumour and normal tissues were quantitatively determined by way of gene transcript analyses and assessed using clinical pathophysiological parameters. A breast cancer tissue microarray (TMA) containing 136 breast cancer tissues was immunohistochemically (IHC) stained for Cingulin and expression and localisation analysed and scored. In addition, siRNA plasmid was used to construct a Cingulin knockdown cell model which was used for proteomic analysis. Statistical methods utilised included Mann Whitney U test for comparisons, Fisher test was applied for IHC scoring, logistic regression and Kaplan-Meier's methods for survival analyses.

Result and discussion

Cingulin showed low expression in breast tumours compared with normal breast tissues. In predicting overall survival ($P = 0.06$), changes in expression nearly reached significance, even though the number of clinical sample was small. Additionally, the TCGA public

database showed significance which supplemented our results ($HR = 0.67$, $P = 0.0037$). When using grade classification, Cingulin expression showed a declining trend from grade1 to grade3. Staining of the TMA breast cancer tissue revealed high expression of in normal tissue and the expression in tumour tissue was suppressed ($P = 0.0038$). Moreover, the expression of Cingulin was higher in T1+T2 stages compared to T3+T4 stages ($P = 0.0038$). Proteomic analysis indicated that BAX was upregulated after the knockdown of Cingulin, while HLA-B was upregulated.

Conclusion

Cingulin is aberrantly expressed in clinical breast cancer and has significant value in predicting progression and outcome of patients survival. According to IHC score result, Cingulin may suppress the function of breast cancer. It may also indicate that Cingulin, together with BAX, may activate the apoptosis procedure in breast cancer. Moreover, the change for HLA-B may provide a potential immunotherapeutic target in breast cancer.

EACR25-0463

SPINT2 Expression in Cancer: Focus on Its Role and Therapeutic Impact in BRAF-Mutated Melanoma

S. Pires Celeiro^{1,2}, R. Dias Oliveira^{1,2}, V. de Lima Vazquez^{3,4}, F. Baltazar^{1,2}, R. Manuel Reis^{1,2,3}, M. Viana Pereira^{1,2,5}

¹*Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal*

²*ICVS/3B's-PT Government Associate Laboratory, Braga/Guimarães, Portugal*

³*Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, Brazil*

⁴*Melanoma, Sarcoma, and Mesenchymal Tumors Surgery Department, Barretos Cancer Hospital, Barretos, Brazil*

⁵*Department of Oncology, Hospital de Braga, Braga, Portugal*

Introduction

Serine protease inhibitor Kunitz-type 2 (SPINT2) inhibits serine proteases such as hepsin, matriptase, and hepatocyte growth factor activator (HGFA). These proteases interact with the extracellular matrix and can influence signalling pathways that affect tumor progression. HGFA converts pro-HGF into bioactive HGF, which promotes cancer cell proliferation, migration, invasion, survival, and resistance to therapy. HGF activates its receptor c-Met, which is implicated in resistance to BRAF inhibitors in melanoma. BRAF mutations occur in 50% of melanoma cases, and although BRAF inhibitors improve survival, resistance remains a challenge. Despite SPINT2's potential role in cancer, little is known about its impact. This study aims to investigate the expression of SPINT2 in cancer and its functional and therapeutic impact in BRAF-mutated melanoma.

Material and method

SPINT2 expression and association with survival in tumors were analyzed using bioinformatic tools. SPINT2 protein expression and gene promoter methylation status were evaluated in formalin-fixed paraffin- embedded (FFPE) samples from cancers like cervix, lung, prostate, gastrointestinal, glioma, and melanoma. SPINT2 over-

expressing transfectants were generated in A375 and WM9 melanoma cells, and effects were assessed using 2D and 3D cell culture models (CCM). The impact of SPINT2 on tumor growth and angiogenesis was explored through Chick Chorioallantoic Membrane (CAM) assay. SPINT2's biological role was analyzed using Nanostring's PanCancer Progression panel and Proteome Profiler Human XL Oncology array. SPINT2's effect on melanoma cell sensitivity to BRAF/MEK inhibitors, and cumulative effect on spheroid growth and migration was evaluated. Finally, the influence of SPINT2 on MET inhibitors was examined.

Result and discussion

SPINT2 expression was lower in melanoma, liver, and glioma compared to other cancers. In silico analysis showed that reduced expression of this gene is correlated with increased tumor aggressiveness. In FFPE samples, SPINT2 downregulation in melanoma was linked to promoter hypermethylation. Functional studies in A375 and WM9 cells revealed that overexpression of this molecule decreased cell viability, migration, and proliferation in 2D and 3D CCM. Additionally, SPINT2 inhibited tumor growth and angiogenesis in CAM assay, suggesting a tumor suppressive role. At the molecular level, SPINT2 influenced genes and proteins involved in extracellular matrix remodeling, angiogenesis, and migration. Expression of this gene also increased melanoma cell sensitivity to BRAF and MEK inhibitors, enhancing therapy efficacy in spheroid growth and migration. In contrast, SPINT2 reduced sensitivity to MET inhibitors.

Conclusion

SPINT2 downregulation is linked to increased cancer aggressiveness. In melanoma, this protein functions as a tumor suppressor and holds potential as a therapeutic biomarker for BRAF-mutated melanoma patients.

EACR25-0467

The Role of ADAMTS1 in Oral Squamous Cell Carcinoma: Impact on Invasion, Lymph Node Metastasis, and Prognosis via the ADAMTS1-L1CAM-EGFR Signaling Axis

W. Lee^{1,2}, M. Chien³, Y. Yang⁴, K. Ho⁵, Y. Ding⁶

¹Taipei Medical University, Department of Urology, School of Medicine, College of Medicine, Taipei, Taiwan

²Wan Fang Hospital, Department of Medical Education and Research, Taipei, Taiwan

³Taipei Medical University, Graduate Institute of Clinical Medicine, Taipei, Taiwan

⁴Taipei Medical University, School of Oral Hygiene, Taipei, Taiwan

⁵Taipei Medical University, Department of Biochemistry and Molecular Cell Biology, Taipei, Taiwan

⁶Taipei Medical University, Department of Otolaryngology, Taipei, Taiwan

Introduction

ADAMTS1, a matrix metalloprotease, is implicated in cancer progression, though its precise function remains unclear. In oral squamous cell carcinoma (OSCC), the role of ADAMTS1 is still under investigation. TCGA

data indicate that ADAMTS1 expression is reduced in head and neck squamous cell carcinoma (HNSCC) tissues compared to normal tissues. However, elevated ADAMTS1 levels are associated with poorer prognosis in patients. This study seeks to elucidate the role of ADAMTS1 in OSCC, focusing on its impact on cell invasion, lymph node metastasis, and its potential as a therapeutic target.

Material and method

The study analyzed TCGA data to assess ADAMTS1 expression in HNSCC and its impact on survival. Four OSCC cell lines were used to examine ADAMTS1's effects on invasion and tumor growth through knockdown and overexpression. OSCC xenografts in mice evaluated ADAMTS1's role in tumor growth and lymph node metastasis. Mechanistic studies investigated the ADAMTS1-L1CAM-EGFR axis, and immunohistochemistry correlated ADAMTS1, L1CAM, and EGFR expression with clinical outcomes. Apigenin (API) was tested for its ability to inhibit the ADAMTS1-L1CAM-EGFR pathway, reducing OSCC invasion and metastasis.

Result and discussion

TCGA data showed that ADAMTS1 expression was lower in HNSCC tissues than in normal tissues, but higher levels were associated with worse prognosis. In vitro, ADAMTS1 correlated with increased invasion in OSCC cell lines, with knockdown reducing invasion and metastasis, and overexpression enhancing these abilities. Mechanistic studies revealed that the ADAMTS1-L1CAM-EGFR axis activates EGFR and induces epithelial-mesenchymal transition (EMT), promoting invasion and metastasis. High expression of ADAMTS1, L1CAM, and EGFR was linked to poor prognosis. Treatment with the API inhibited this pathway, reducing OSCC invasion and metastasis, and extended survival in xenograft models, suggesting API as a potential therapeutic agent for OSCC.

Conclusion

This study shows that ADAMTS1 promotes OSCC progression via the L1CAM-EGFR pathway, enhancing invasion and lymph node metastasis through EMT. High expression of ADAMTS1, L1CAM, and EGFR correlates with poor prognosis in HNSCC, suggesting their potential as biomarkers. API was identified as a therapeutic agent targeting this pathway, reducing OSCC metastasis and improving outcomes.

Exploiting Cellular Senescence to Enhance Precision Oncolytic Immunotherapy

Y. Giannoula¹, F. Hamdan¹, S. Russo¹, J. Chiaro¹,

F. D'Alessio¹, M. Grönholm¹, V. Cerullo^{1,2}

¹University of Helsinki, Department of Pharmacy, iCAN Flagship, Helsinki, Finland

²Naples University, Department of Molecular Medicine and Medical Biotechnology and CEINGE, Naples, Italy

Introduction

Cellular senescence is a complex state characterized by irreversible cell cycle arrest, acquisition of a senescence-associated secretory phenotype (SASP), and alterations in cell surface proteins. Senescent cells upregulate MHC

class I expression, modifying their antigenic profile and surface immunopeptidome, thereby influencing immune recognition and clearance. In cancer therapy, widely used chemotherapeutic agents and radiotherapy can induce senescence, leading to a paradox: while senescent cells may suppress tumor growth, they can also promote tumor progression. Addressing residual senescent cancer cells remains a critical unmet clinical need in oncology.

Material and method

We investigate the potential of senescence-associated cancer (neo)antigens for vaccine development through immunopeptidomic and mRNA sequencing analyses of in vitro senescence models, where senescence is induced via chemotherapeutic treatments. Immunopeptidomics analysis is performed to identify MHC class I-bound peptides uniquely presented by senescent cells. Following antigen identification and selection, we evaluate the immunogenicity of candidate peptides in vivo and incorporate them into SenCRAd, a personalized oncolytic viral platform designed to target senescent cancer cells. As a future step, we aim to expand our analysis to patient tumor samples, stratified based on senescence burden, to validate the clinical relevance of senescence-associated antigen presentation.

Result and discussion

We have established that CT26 colorectal carcinoma cells undergo senescence following doxorubicin treatment and upregulate MHC class I expression, suggesting potential alterations in antigen presentation. To characterize these changes at the peptide level, we performed immunopeptidomic analysis comparing proliferating and senescent CT26 cells. We have identified a set of senescence-associated MHC class I-restricted peptides that are currently being evaluated for immunogenicity in vivo, with ongoing experiments assessing their ability to elicit antigen-specific immune responses. These findings will provide critical insight into whether senescence-associated peptides can serve as viable targets for immunotherapeutic strategies aimed at eliminating senescent cancer cells.

Conclusion

Our study explores the immunogenic potential of senescent cancer cells and aims to develop SenCRAd, an oncolytic viral vaccine targeting these cells. This approach could provide a novel therapeutic strategy to eliminate senescent cancer cells, preventing recurrence and improving cancer treatment outcomes.

EACR25-0510

Investigating COPZ1 dependency in in vitro murine models of Thyroid Cancer

D. Vergaro¹, T. Di Marco¹, M. Mazzoni¹, A. Greco¹

¹*Fondazione IRCCS Istituto Nazionale dei Tumori, s.s.d.*

Integrated Biology of Rare Tumors, Department of Experimental Oncology, Milano, Italy

Introduction

Thyroid cancer (TC) is the most common endocrine malignancy, generally successfully treated with standard therapies. However, aggressive forms remain resistant to current treatments. The concept of non-oncogene addiction (NOA) implies that cancer cells depend on non-mutated genes that are essential for their uncontrolled growth; thus NOA genes may represent potential targets

for anti-cancer treatment. We have previously identified COPZ1, the $\zeta 1$ component of the coatomer complex, as a NOA vulnerability in TC. COPZ1 is involved in intracellular trafficking, endosome maturation, lipid homeostasis and autophagy. Inhibition of COPZ1 induced endoplasmic reticulum (ER) stress, inflammatory responses and immunogenic cell death in TC cells, without affecting normal cells. The translational value of our results requires in vivo experiments in immunocompetent murine models. Preliminary to the generation of in vivo preclinical models of COPZ1 silencing, we have characterized the susceptibility to COPZ1 inhibition of four murine cell lines.

Material and method

COPZ1 was silenced through a siRNA transfection in four murine TC cell lines: T3531L, 3610R, T4888M and 3868. Cell proliferation was evaluated by crystal violet assay. Protein expression was analyzed by Western Blot. Cytokines secretion was quantified in conditioned media by ELISA Array. Gene expression was analyzed by Real Time PCR (RT-PCR), using TaqMan probes. The levels of intracellular oxidative stress were measured using commercial kits (ROS-Glo™ H2O2 Assay and GSH/GSSG-Glo™ Assay).

Result and discussion

After COPZ1 depletion, all four murine TC cell lines underwent a reduction in relative proliferation with a different extent for each one. T3531L and 3610R activated a transcriptional program associated with viral mimicry response and IFN pathway. Moreover, both cell lines released several cytokines associated with immune components recruitment. On the contrary, COPZ1 silencing didn't cause a modulation of inflammatory-related genes expression in T4888M and 3868 cell lines, but ER stress was induced as documented by the up-regulation of Chop and BiP. Emerging evidence suggests that ER stress can be involved in other forms of cell death, such as ferroptosis, a type of regulated cell death driven by oxidative stress and the iron-dependent accumulation of lipid peroxides. Oxidative stress increased in T4888M and 3868 cell lines after COPZ1 silencing, as demonstrated by higher levels of ROS and by lower GSH/GSSG ratio. Additionally, ferroptosis markers such as HO-1 and TFRC were overexpressed in COPZ1-silenced cells. These results suggest that ferroptosis could represent a cell death mechanism activated by COPZ1 depletion.

Conclusion

The described results demonstrate that COPZ1 silencing reduces cell proliferation in murine TC cells and that different cell death mechanisms are activated. Further analysis is still needed to confirm the activation of ferroptosis.

EACR25-0512

Regulation of EMT by the U-BOX Domain of CHIP/STUB1 in Colon Cancer Cells

J. Park¹, S. Sim¹, S. Lee², H. Ro², H. Lim¹, J. Lee¹

¹*College of Medicine, Korea University, Department of Pathology, Seoul, Korea (Republic of)*

²*College of Bioscience and Biotechnology, Department of Biological Sciences, Daejeon, Korea (Republic of)*

Introduction

Colorectal cancer (CRC) remains one of the most prevalent malignant tumors worldwide, with metastasis being the leading cause of mortality. Epithelial-mesenchymal transition (EMT) plays crucial role in facilitating metastasis by enabling epithelial cells to acquire mesenchymal characteristics, thereby enhancing their migratory and invasive capacities. EMT is tightly regulated by transcription factors such as Snail1, Slug, and Twist1, which modulate the expression of epithelial markers (e.g., E-cadherin, Claudin1) and mesenchymal markers (e.g., N-cadherin, Vimentin). This study investigates the role of the U-BOX domain of CHIP/STUB1 in regulating EMT in CRC.

Material and method

We established CRC cell lines (HT-29 and HCT116) with U-BOX domain deletion and CHIP/STUB1 knockout. EMT characteristics were evaluated using cell morphology analysis, wound healing assays, invasion assays, colony formation assays. Expression of EMT related molecules were examined by RT-qPCR and western blotting.

Result and discussion

HT-29 and HCT116 cells with U-BOX domain deletion exhibited more pronounced EMT characteristics compared to their wild-type counterparts, displaying elongated morphology, increased migration, and enhanced invasion capabilities. Molecular analyses revealed a significant increase in Slug expression, a key EMT transcription factor. Additionally, these cells showed downregulation of epithelial markers (E-cadherin and Claudin1) and upregulation of mesenchymal markers (N-cadherin and Vimentin). Interestingly, these EMT characteristics were not observed in HT-29 CHIP/STUB1 knockout cells, suggesting a specific role for the U-BOX domain of CHIP/STUB1 in EMT regulation.

Conclusion

The U-BOX domain of CHIP/STUB1 plays a critical role in EMT regulation in CRC cells. Its deletion enhances EMT characteristics, whereas CHIP/STUB1 knockout does not, highlighting its specific function, which further investigation is necessary to elucidate the precise molecular mechanisms involved.

Introduction

Acute Myeloid leukemia (AML) is an aggressive bone marrow malignancy that requires chemotherapy treatment. However, about 50% of patients relapse, due to the ability of leukemic cells to proliferate despite dysfunctional DNA damage repair mechanisms, coupled with resistance to apoptosis and escape from immune surveillance. Additionally, dysfunctional leukemia cells and chemotherapy toxicity compromises the immune system, frequently resulting in life-threatening infections. Preclinical data from multiple cancer models suggest that ketogenic diets (KD) administered as an adjuvant to chemotherapy can reduce cancer cell proliferation, increase apoptosis, and deprive cancer cells of glucose. Aim: (1) To examine the effects of a KD administered during chemotherapy on markers of apoptosis and DNA damage and repair in leukemic cells from patients with AML. (2) To evaluate the impact of a KD on glucose levels and infections during chemotherapy and the following period of neutropenia.

Material and method

Leukemic cells were isolated from the peripheral blood of patients with AML participating in a KD study. Participants were randomized to receive a control diet ($n = 6$) or a KD ($n = 10$) during chemotherapy. Samples were collected before, during, and after treatment. Apoptosis and DNA damage and repair were assessed using flow cytometry. Blood glucose and infections were measured.

Result and discussion

The KD group had stable glucose levels during treatment, while the control group had high and unstable levels. Preliminary data showed a trend toward reduced infection rates during hospitalization with the KD (~20–40% reduction). During chemotherapy, the KD group showed lower levels of DNA repair markers (Chk1 p317, $p < 0.01$ and p-ATM, $p < 0.01$) in leukemic cells, despite similar levels of DNA damage markers (yH2AX, $p = 0.31$) and no significant differences in apoptosis between the groups. The control group showed a decrease in DNA repair markers (p-ATM) in non-malignant T-cells from baseline to post-chemotherapy ($p < 0.01$), while the ketogenic group showed a trend toward an increase ($p = 0.23$).

Conclusion

A KD administered as an adjuvant to chemotherapy in patients with AML may protect against infection and chemotherapy-induced T-cell damage by enhancing DNA repair, while potentially limiting DNA repair in leukemic cells. Further clinical and mechanistic studies in larger cohorts are warranted.

Introduction

Inhibitors of ATR, a central kinase controlling DNA replication origin firing and cellular checkpoint activity, are currently in multiple clinical trials, yet mechanisms underpinning sensitivity and robust patient stratification biomarkers are lacking. In our new study we carefully characterized the mechanism underlying sensitivity to the important clinical target, the ATR kinase. Using an unbiased, multimodal approach in multiple cancer cell lines, AML patient samples and wider databases, we discovered an overlooked role for deregulated DNA replication origin firing in ATR inhibitor sensitivity.

Material and method

We used a non-invasive live microscope to monitor cell confluence in a panel of breast cancer cell lines to identify sensitive and resistant cell lines to ATR inhibition. We performed immunofluorescence microscopy to investigate rates of chromosome instability and replication stress. We then performed proteomics, phospho-proteomics and gene expression analysis to discover determinants of ATRi sensitivity. In parallel, we applied a newly developed machine learning coupled with long-read sequencing method to investigate DNA replication dynamics. Then, we used publicly available transcriptomic data from Cancer Cell Line Encyclopaedia and published Acute Myeloid Leukaemia patient data to investigate gene expression signature enrichment in larger datasets and including more cancer types.

Result and discussion

We discovered that all cell lines had increased levels of replication stress and chromosome instability upon ATRi, regardless of sensitivity. Interestingly, sensitive cell lines had higher expression and activity of DNA replication origin firing factors at basal. Moreover, in response to ATR inhibition, they massively increased origin firing, leading to the activation of the DNA damage response pathway and cell death. ATRi sensitivity was partly rescued upon co-treatment with XL-413, a CDC7 inhibitor that decreases origin firing. High expression of DNA replication initiation factors correlated with ATRi sensitivity across multiple cancer types, and in acute myeloid leukaemia patient samples.

Conclusion

Our study reveals that in sensitive cancer cell lines or patient samples, excessive origin firing is a detrimental response that leads to cell death. Moreover, this vulnerable state can be detected in sensitive samples by a higher level of origin firing-related factors, providing potential new and specific biomarkers for ATR inhibitor sensitivity that are compatible with clinical application.

⁵Research Institute at Medical University-Plovdiv, Plovdiv, Bulgaria

Introduction

Lysosomal homeostasis and the dual function of autophagy, either suppressing or facilitating tumor growth, have been shown to play an active role in cancer biology. Dysregulated expression of lysosome-associated membrane proteins (LAMPs) has been demonstrated in various pathologies. Their augmented levels suggest potential involvement in tumor progression. The current study aimed to examine LAMP1, LAMP2 and specifically the LAMP2A isoform and to assess the clinical significance of serum protein and gene levels compared to their tissue expression in primary CRC and healthy individuals.

Material and method

Forty-one CRC patients (tissue as blood samples) and nontumorous colonic tissue and blood samples from healthy donors were examined by ELISA, qPCR, and immunohisto-chemistry.

Result and discussion

It was found that mRNA levels were significantly higher in CRC white blood cells than in healthy individuals. Additionally, the findings were supported by the apparent upregulated LAMP1, LAMP2 and LAMP2A levels in the CRC tissue immunostaining. The three examined proteins were observed within the tumor buds at the invasive front of the tumor in contrast to the feeble signal in tumor parenchyma and noncancerous tissue. However, while plasma protein levels of LAMP1 remained elevated in the patient group, LAMP2 exhibited a contrastingly higher pattern in the control group.

Conclusion

We present novel data for exploring the feasibility of LAMP1, LAMP2 and LAMP2A in liquid and tissue biopsy in CRC that could serve as future prognostic biomarkers for CRC stratification and treatment.

Acknowledgments: This study was supported by the Bulgarian National Science Fund - grant KIT-06-H-63/8 (13.12.2022) and by the European Union-NextGenerationEU, through the National Recovery and Resilience Plan of the Republic of Bulgaria, project N°BG-RRP-2.004-0007-C01.

Introduction

Colorectal cancer (CRC) is heterogeneous malignancy characterized by variations in molecular profiles and clinical manifestations. Therefore, treatments for CRC are based on histopathological type and clinical stage of disease. However, in patients with metastatic CRC, available therapeutic options have shown limited effect. In recent years, histone deacetylases (HDAC)s have been identified as relevant contributors to pathogenesis and metastatic invasion of CRC. As HDAC6 is often over-expressed in CRC and correlates with poor disease prognosis it represents a good potential therapeutic target. The aim of this study was to evaluate antitumor activity of four novel HDAC inhibitors with 1-benzhydryl piperazine as a surface recognition group, that differ in hydrocarbon linker in HT-29 (with BRAFV600 mutation) and HCT-116 (BRAF wild type) human CRC lines.

Material and method

HT-29 and HCT-116 human CRC cells cultured in RPMI1640 cell culture medium (CM) were treated with b2, b3, b4, and b7 HDAC inhibitors and b3 and b7 in combination with BRAF inhibitor vemurafenib for 72h with at 37°C and 5% CO₂ in humid atmosphere. Cytotoxicity and IC₅₀ values were estimated by MTT assay. Cell cycle analysis and PI/annexinV assay for apoptosis were performed by flow cytometry. Statistical differences between the control (CM) and treatment were estimated by one-way ANOVA and Student's t-test.

Result and discussion

b2 and b4 compounds with low potency for HDAC6 inhibition did not show any cytotoxic activity while b3 compound with higher potency for HDAC6 inhibition showed significant cytotoxic activity on HCT-116 and HT-29 cells with IC₅₀ (μ M) of 54.06 and 71.49, respectively. Furthermore, b7 panHDAC (HDAC1/3/6/8) inhibitor, which is potent in terms of HDAC6 inhibition, induced significant antiproliferative effect with IC₅₀ (μ M) of 22.04 and 58.99 for HCT-116 and HT-29, respectively. Antiproliferative effects of b3 and b7 were more profound on HCT-116 cells and in both cell lines accompanied with increased apoptosis and alterations in cell cycle distribution. Furthermore, it was evaluated on HT-29 cell line whether b3 and b7 compounds could improve the effect of BRAF inhibitor vemurafenib. Cytotoxic effect of combination treatment of b3 and b7 with vemurafenib was evaluated by Chou-Talalay model. Our results showed synergistic effect of b7 and slight synergistic effect for b3 for concentrations lower than IC₅₀ (12.5 μ M and 15 μ M, respectively).

Conclusion

Our findings of synergistic antitumor effect of HDAC and BRAF inhibition may provide rationale for investigations of their joint use in therapy of patients with CRC harboring BRAF mutation and evaluation of the potential of this therapy to increase response rate and overcome acquired resistance to treatment with BRAF inhibitors.

LOXL2 Inhibition: A New Strategy for Triple-Negative Breast Cancer

S. Ferreira^{1,2}, D. J. V. A. dos Santos³, A. M. Díaz-Lanza¹, J. G. Costa³, N. Saraiva³, P. Rijo³, A. S. Fernandes³

¹Universidad de Alcalá de Henares, Departamento de Ciencias Biomédicas, Madrid, Spain

²Universidade Lusófona, CBIOS, Lisbon, Portugal

³Universidade Lusófona, CBIOS, Lisboa, Portugal

Introduction

Lysyl oxidase-like 2 (LOXL2) is a member of the lysyl oxidase (LOX) enzyme family. These enzymes play a crucial role in the cross-linking of elastin and collagen, key components of the extracellular matrix. LOXL2 has been implicated in the regulation of tumor progression and angiogenesis, notably in triple-negative breast cancer [1]. This suggests that inhibitors of LOXL2 could offer potential therapeutic benefits in the treatment of this aggressive form of breast cancer [2]

Material and method

Computational docking studies were performed using previously reported inhibitors to explore their potential binding modes to LOXL2. In-house available compounds containing structures aligned with the computational chemistry insights, were screened for anti-LOXL2 activity using the Amplex Ultra Red assay [3]. A novel LOXL2 inhibitor was identified (AK75) that was then assessed in human triple-negative breast cancer cells (MDA-MB-231) and normal-like breast cells (MCF10A). The effects of AK75 on cell viability (MTT assay), migration (wound healing, single-cell tracking, and transwell assays), 2D and 3D invasion, cell morphology, DNA damage (γ -H2AX immunofluorescence), and matrix metalloproteinases (MMP) activity (zymography) were investigated.

Result and discussion

AK75 inhibits LOXL2 with an IC₅₀ value in the very low micromolar range. This compound is not selectively cytotoxic for cancer cells and does not induce DNA damage. In MDA-MB-231 cells, AK75 reduces chemotaxis, 2D and 3D invasion, MMP2 activity, and alters cell morphology.

Conclusion

This study explores the potential of AK75, a novel LOXL2 inhibitor, towards an eventual therapeutic strategy for triple-negative breast cancer treatment.

EACR25-0563

The DC6-KSP signaling Pathway is essentially required for Metabolic Adaptation and Leukemic Progression

T. Setiawan¹, N. Marcellina¹, A. Muhammad¹, H. Kwon¹

¹Soonchunhyang University, SIMS, Cheonan, Korea (Republic of)

Introduction

Acute Myeloid Leukemia (AML) is a highly aggressive cancer originating from myeloid lineage stem cell precursors, affecting both adults and children. It is notorious for drug resistance and high relapse rates. While DC6 has been implicated in the progression of

various solid tumors and multiple myeloma, its role in AML has yet to be elucidated.

Material and method

We employed models of mixed lineage leukemia-AF9/NRAS-induced AML and blast crisis chronic myeloid leukemia (bcCML) triggered by BCR-ABL/NUP98-HOXA9 to investigate the role of DC6 in aggressive myeloid leukemia.

Result and discussion

Our study demonstrates that DC6 is pivotal in regulating autophagy and mTOR localization under amino acid deprivation in AML cells. Notably, DC6 expression is elevated in AML cells and patient samples, with high levels correlating with poor prognosis. Our findings also show that conditional DC6 deletion impairs leukemogenesis in an MLL-AF9/NRAS mouse model. Further investigation reveals that DC6 interacts with KSP, enhancing its stability by preventing proteasomal degradation. Moreover, DC6 orchestrates the relocation of the KSP-mTOR complex from lysosomes under amino acid scarcity, critically influencing AML cell survival.

Conclusion

Collectively, our data illuminate the indispensable role of the DC6-KSP pathway in AML progression, particularly under conditions of amino acid deprivation.

EACR25-0564

Nutlin-3a Inhibits Lysosomal Fusion by Inducing SNARE Dysfunction in KRAS mutant/p53 Wild-Type Lung Cancer

S. Sim¹, D. Kim², D. Min¹, J. Park³, J. Lee³

¹Korea University College of Medicine, Department of Biomedical Science, Seoul, Korea (Republic of)

²Ohio State University College of Veterinary Medicine, Department of Biosciences, Columbus, United States

³Korea University College of Medicine, Department of Pathology, Seoul, Korea (Republic of)

Introduction

Nutlin-3a is an MDM2 antagonist that inhibits the interaction between MDM2 and p53, thereby activating p53 and modulating various cellular stress responses. In our previous study, we showed that nutlin-3a suppresses the hexosamine biosynthetic pathway via GFPT2 down-regulation, leading to lysosomal dysfunction and impaired autophagosome–lysosome fusion in KRAS mutant/p53 wild-type lung cancer cells. The SNARE complex – comprising STX17 on autophagosomes, VAMP8 on lysosomes, and SNAP29 bridging the two – mediates the fusion of autophagosomes and lysosomes, the final step of autophagy, known as autophagic flux. Additionally, N-/O-glycosylation of lysosomal proteins has been proposed to potentially influence the stability and interactions of the SNARE complex. Therefore, we investigated the underlying mechanism of nutlin-3a-induced disruption of autophagosome–lysosome fusion.

Material and method

Localization of autophagosome and lysosome was visualized by confocal microscopy after staining with their respective markers such as LC3 and LAMP1. Expression levels of lysosomal and autophagosome-related molecules along with SNARE complex components were measured by RT-qPCR and western blotting. Further analysis of SNARE complex

interactions as well as N-/O-glycosylation of relevant molecules was examined by immunoprecipitation.

Result and discussion

Nutlin-3a treatment markedly reduced SNAP29 expression, as confirmed by RT-qPCR and western blotting. Immunoprecipitation analysis further demonstrated an increase in N-/O-glycosylation levels of LAMP1 and LAMP2, along with a significant reduction in the interactions among SNAP29, STX17, and VAMP8. These findings suggest that SNAP29 reduction and glycosylation-modified lysosomes contribute to the disruption of SNARE complex formation, thereby impairing autophagosome–lysosome fusion. Confocal microscopy corroborated these findings by showing reduced SNAP29–VAMP8 colocalization. Additionally, nutlin-3a treatment induced an increase in Galectin-3, a marker of lysosomal membrane permeabilization, while western blot analysis showed TFEB activation and increased expression of CTSB, LAMP1, and LAMP2. Collectively, these results suggest a compensatory mechanism attempting to counteract nutlin-3a-induced lysosomal dysfunction.

Conclusion

Our results demonstrate that nutlin-3a disrupts autophagosome–lysosome fusion by downregulating SNAP29 and impairing SNARE complex assembly in KRAS mutant/p53 wild-type lung cancer cells.

EACR25-0577

Understanding the interplay of EPHA2 and CD44 in colorectal cancer stemness, EMT and therapy resistance

A. Nigam¹, V. Desiderio², G. Papaccio²

¹Università degli studi della Campania Luigi Vanvitelli, Naples, Italy

Introduction

Receptor tyrosine kinases (RTKs) are one of the crucial signal transduction pathway regulators that support cell growth, survival, and motility. Recent genomic analyses have linked the expression of many Ephrin RTKs with metastasis and anti EGFR therapy resistance in colorectal cancer. The ephrin RTK signaling is quite complex and elaborate in nature. The signaling can happen both in the presence and absence of ephrin ligand. In recent years more and more evidences are coming up showing that ligand independent signaling carried by EPH receptors by physically interacting with other transmembrane or cytoplasmic proteins is involved in some crucial aspects of cancer biology like therapy resistance and metastasis. We hypothesize that EPHA2 and CD44 form a functional complex that enhances CRC drug resistance by regulating stemness and EMT. We aim to determine whether this is a direct molecular mechanism or a downstream signaling consequence.

Material and method

Cell lines used: HCT116 (more metastatic) and SW480 (more epithelial). CD44 knocked down HCT116 and SW480. EPHA2 inhibitor: ALW-II-42-47. Functional assays: cell cycle analysis through FACS, MTT for cell viability and proliferation, qPCR for gene expression analysis, wound healing for migration, FACS for cell surface marker detection. Co-immunoprecipitation to detect protein interaction.

Result and discussion

1. EPHA2 inhibition effectively blocks cell cycle progression in nM ranges in the anti EGFR resistant cells.
2. EPHA2 inhibition reduces the surface expression of stemness markers in cancer cells.
3. The combination of EPHA2 inhibition and CD44 knockdown has increased effectiveness in blocking cell proliferation.
4. qPCR, colony and sphere formation assays show that EPHA2 inhibition leads to reversal of EMT and reduction of stemness respectively.
5. Co-IP confirms the protein interaction between EPHA2 and CD44.

Conclusion

We found that ALW a small molecule inhibitor of tyrosine phosphatase, effectively halts the cell proliferation in nanomolar concentrations. This molecule also reduces the surface expression of stemness markers like CD44 and CD133. Past studies showed that EPHA2 and CD44 levels are correlated in CRC, but is there any functional relation between the two, or just a causative effect. In present study we showed that EPHA2 and CD44 interact physically. CD44 KD cells when treated with ALW show stronger EMT to MET reversal. Knockdown of CD44 also reduces the protein expression of EPHA2 in the CRC cell line. Thus, we have found out that CD44 interacts with EPHA2 possibly regulating cell proliferation, stemness and EMT.

Role of mast cells in promoting breast cancer stem-like properties via heparanase and MUC1/estrogen receptor axis

R. Bongiorno¹, M. Lecchi², L. Botti¹, P. Pratesi², O. Fortunato¹, P. Verderio², M. Colombo¹, C. Chioldoni¹, D. Lecis¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Experimental Oncology, Milano, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Epidemiology and Data Science, Milano, Italy

Introduction

Breast cancer is the most frequent malignancy in women and exhibits significant heterogeneity, leading to variable clinical outcomes. Tumor aggressiveness is heavily influenced by immune infiltration. Among immune cells, mast cells (MCs) have been implicated in breast cancer prognosis; however, their role remains controversial. While MCs are generally associated with a favorable prognosis in basal breast cancer, they exhibit a negative prognostic impact in luminal and HER2-positive subtypes. In this study, we aimed to elucidate the molecular mechanisms by which MCs influence tumor-initiating properties in breast cancer.

Material and method

MCs were co-injected with limiting concentrations of breast cancer cells *in vivo* to analyze tumor engraftment rates. We explored the involvement of heparanase in promoting tumor stem-like feature by pharmacological inhibition. Additionally, we analyzed soluble factors,

including cytokines and proteoglycans, in MC-conditioned media following stimulation with a TLR4 agonist or heparanase inhibitors. We further characterized the extracellular vesicles (EVs) released by MCs under these conditions and examined their impact on cancer stem-like properties.

Result and discussion

Our results demonstrate that MCs enhance tumor-initiating properties in breast cancer cells. Heparanase activity was found to be crucial for this process, as both its enzymatic function and the stimulation of MCs with heparan sulfate (a TLR4 agonist and product of heparanase activity) promoted cancer cell stem-like traits. Pharmacological inhibition of heparanase abolished these effects, confirming its key role. Notably, soluble factors secreted by MCs induced the expression of MUC1, which in turn upregulated estrogen receptor (ER) levels and activity. This MUC1/ER axis was found to be essential for maintaining cancer stem-like properties, particularly in HER2-negative breast cancer cells, thereby enhancing mammosphere formation, stem-related gene expression, and resistance to tamoxifen treatment. Furthermore, our analysis of MC-derived soluble factors revealed that TLR4 stimulation increased the release of EVs, while heparanase inhibition suppressed this effect. Depletion of EVs impaired the ability of MCs to induce cancer stem-like properties, highlighting their crucial role in mediating MC-driven tumor-initiating features.

Conclusion

Our findings unveil a novel mechanism by which MCs contribute to breast cancer aggressiveness through the regulation of tumor-initiating properties. Specifically, MC-derived heparanase activity and extracellular vesicle release play a central role in promoting cancer stem-like traits, with distinct effects depending on breast cancer subtype. Ongoing studies aim to characterize the specific type and composition of EVs responsible for these effects, with potential implications for targeted therapeutic interventions.

EACR25-0584

Heterogeneous and dynamic response of squamous esophageal cancer to CDK4/6 inhibition

F. Moresi¹, D. Japón Ruiz¹, M. Avalos Moreno¹, A. Pavese², V. Imbault¹, B. Beck¹, X. Bisteau¹

¹IRIBHM, Faculty of medicine, Belgium

²A*STAR, IMCB, Singapore, Singapore

Introduction

Esophageal squamous cell carcinoma (eSCC) is among the deadliest cancers worldwide, with minimal improvement in 5-year survival rates over the past two decades. Beyond its highly heterogeneous oncogenic landscape, the cyclin D-CDK4/6-pRB axis is dysregulated in 98% of cases. CDK4/6 inhibition has been shown to promote T-cell-mediated tumor clearance by fostering a tumor-suppressive immune microenvironment. Our study aimed to investigate the response of eSCC to the FDA-approved CDK4/6 inhibitor, Palbociclib, and explore the possible interplay between cancer cells, the tumor microenvironment, and immune cells upon treatment.

Material and method

A panel of 22 human eSCC cell lines were used to assess the effects of the CDK4/6 inhibitor, Palbociclib. Cell cycle analysis was performed via flow cytometry, and micronuclei formation was evaluated by immunostaining. Activation of the cGAS-STING pathway and inflammatory responses were analyzed using western blot, RNA sequencing, and multiplex cytokine assays. To model the tumor microenvironment, eSCC spheroids were embedded in a microfluidic device, co-cultured with human umbilical vein endothelial cells (HUVECs) and lung fibroblasts (LF) to induce vascularization. Immune cell infiltration was evaluated by introducing human PBMCs into the microfluidic device following Palbociclib treatment, before being stained and imaged by immunofluorescence for quantitative image analysis.

Result and discussion

Palbociclib treatment resulted in reduction of S-phase progression in 90% of eSCC cell lines, with prolonged exposure leading to nuclear abnormalities, including micronuclei formation. Immunostaining revealed that many of these micronuclei lacked Lamin A/C. This loss correlated with the activation of the cGAS-STING pathway, as confirmed by the upregulation of inflammatory and interferon response genes. In a 3D tumor model, Palbociclib treatment led to increased PBMCs infiltration into eSCC spheroids, as visualized by immunofluorescence quantification. These results suggest that Palbociclib promotes immune cell recruitment, potentially enhancing anti-tumor immunity. These findings reveal a dual effect of Palbociclib in eSCC: direct inhibition of tumor cell proliferation on selected cell lines and indirect modulation of immune responses.

Conclusion

Prolonged Palbociclib treatment induces micronuclei formation, cGAS-STING activation, and an inflammatory response. ESCC 3D model reveals indirect immune-modulating effects of CDK4/6 inhibition, supporting its potential for combination with immunotherapy. However, the heterogeneous response among eSCC cell lines highlights the need to further investigate genomic determinants of Palbociclib sensitivity to optimize treatment strategies.

EACR25-0589

TRIB2 overexpression impairs autophagy flux and compromises efficient clearance of cellular cargo

G. Serrão¹, A. Bento¹, A. Orea-Soufi¹, V. Yassuda¹, I. Grenho², W. Link³, B. Ferreira¹

¹Universidade do Algarve, ABC-Ri, Faro, Portugal

²Universidade do Algarve, ABC-Ri, Faro, Spain

³Instituto de Investigaciones Biomédicas, "Alberto Sols" (CSIC-UAM), Madrid, Spain

Introduction

Autophagy is a crucial cellular process that degrades and recycles intracellular components to maintain homeostasis, particularly under stress conditions. TRIB2, a pseudokinase implicated in cancer progression, has been associated with drug resistance and cell survival mechanisms. However, its role in autophagy remains unclear. This study investigates the impact of TRIB2 on

autophagy regulation and its potential mechanisms of action.

Material and method

We investigated TRIB2's role in autophagy using U2OS cells with TRIB2 overexpression and UACC62 cells with TRIB2 knockout. Autophagy was evaluated by measuring LC3B-II and p62 protein levels under various conditions. We employed a tandem mRFP-GFP-LC3 reporter assay and co-immunoprecipitation experiments to further assess TRIB2's impact on autophagy.

Result and discussion

TRIB2 overexpression resulted in decreased LC3B-II levels and increased p62 accumulation, suggesting autophagy suppression. Conversely, TRIB2 KO cells exhibited slightly increased LC3B-II levels, indicating enhanced basal autophagy. Under starvation conditions, TRIB2-expressing cells displayed impaired autophagy flux, evidenced by reduced LC3-II accumulation in CQ-treated samples and compromised p62 degradation. The mRFP-GFP-LC3 assay further confirmed autophagy inhibition, showing increased autophagosome accumulation with reduced autolysosome formation in TRIB2-overexpressing cells. Importantly, co-immunoprecipitation studies revealed that TRIB2 interacts with p62 under nutrient-rich conditions but not during starvation, indicating a role in autophagy suppression. No interaction was observed between TRIB2 and ULK1 or Beclin1, suggesting TRIB2 acts in the later stages of autophagy rather than at the initiation step.

Conclusion

Our findings demonstrate that TRIB2 negatively regulates autophagy by impairing cargo clearance at later stages, likely through its interaction with p62. This highlights TRIB2 as a potential regulator of autophagy-related cellular stress responses and provides new insights into its role in cancer cell survival. Further research is needed to explore TRIB2 as a therapeutic target in diseases where autophagy plays a critical role.

Introduction

Colon adenomas constitute preneoplastic lesions that emerge from the intestinal epithelium and can further progress into colon cancer if left untreated. Although early detection of colon cancer and its preneoplastic precursors is decisive for survival and treatment options, no suitable biomarkers are available to detect the transformation of a healthy intestinal epithelium into adenomas. Therefore, we aimed to identify novel drivers associated with the development of precancerous lesions in the colon.

Material and method

We performed whole-transcriptome sequencing of human adenoma samples and matched colon mucosa and performed a validation of the most interesting signals in a separate patient cohort and eight independent public datasets. Genome-wide methylation profiling of additional cases of adenoma tissue pairs was also conducted and confirmed by pyrosequencing. Functional analyses were performed *in vitro* and *in vivo* using organoids and tissue samples derived from Apcmin/+ mice as well as from the inflammation-associated azoxymethane/dextran sodium sulfate (AOM/DSS) and the sporadic colon carcinogenesis (six AOM injections) mouse models. Potential novel candidates were evaluated by immunohistochemical staining in human adenomas of sporadic and familial adenomatous polyposis (FAP) origin as well as in early-stage colon tumors (pT1).

Result and discussion

From a total of 1,917 differentially expressed genes and 148,191 differentially methylated CpG sites detected in adenomas compared with matched mucosa samples, we selected TACSTD2 among other genes including MMP7, MMP1, CLDN2, CLDN1, and ETV4 for further validation. Indeed, TACSTD2 promoter hypomethylation in adenoma tissues was validated in 20 additional tissue pairs and corresponded with increased TACSTD2 expression. Moreover, TACSTD2, which encodes for the protein and cancer driver TROP2, was overexpressed in human adenomas of both sporadic and FAP origin, in pT1 colon tumors as well as in murine adenomas and their organoid derivatives. Using patient- and mouse-derived organoids, we observed differences in the regeneration, colony formation and anoikis evasion potential in a TACSTD2-dependent manner, with high levels of TACSTD2 promoting adenoma progression and features of tumor aggressiveness.

Conclusion

TACSTD2 is overexpressed in mouse and human adenomas of both sporadic and FAP origin compared to normal mucosa and might drive the development of colonic precancerous lesions. Therefore, TACSTD2 could serve as a novel marker for the identification of transforming foci in colon biopsies.

EACR25-0655

Combined oncogene and pyruvate dehydrogenase kinase inhibition enhances tumor response in resistant NSCLC cells

⁶University of Campania Luigi Vanvitelli, Department of Precision Medicine, Naples, Italy

Introduction

The metabolic reprogramming of tumor cells plays a critical role in cancer progression, contributing to drug resistance and tumor survival. Tyrosine kinase inhibitors (TKIs) have shown promising clinical results by targeting specific signaling pathways involved in cancer cell proliferation, survival, and metastasis. However, the development of resistance to TKIs remains a significant challenge in oncology for the onset of multiple secondary resistance mechanisms. In parallel, dichloroacetate (DCA), a small molecule that alters cancer cell metabolism by inhibiting pyruvate dehydrogenase kinase (PDK), has been investigated for its potential to reverse the Warburg effect and reprogram tumor cell metabolism. Here, we explored the rationale behind combining TKIs with DCA, focusing on the synergistic effects that may arise from the dual inhibition of oncogenic signaling and metabolic reprogramming.

Material and method

We selected three NSCLC cell line models (H1975, H1993, A549) and determined the optimal DCA dose to reverse the Warburg effect. Consequently, EGFR-mutant H1975, c-MET amplified H1993 and KRAS-mutant A549 NSCLC cells, were treated with TKIs (osimertinib, crizotinib and selumetinib, respectively), DCA alone or in combination with TKIs (halved dose). Several assays were performed to evaluate the combination effect on tumor response.

Result and discussion

Our results highlighted that a very low dose of DCA is necessary to restore oxidative phosphorylation. The proposed combined approach, compared to TKI alone, led to a shift from glycolysis to oxidative phosphorylation, data confirmed by input (glucose) and output (ATP) levels and also by a metabolomic analysis. Moreover, a significant decrease in cell proliferation was observed in combo conditions compared to TKI and to untreated cells. On the other hand, a relevant increase of apoptosis, due to a higher BIM expression levels associated to a decrease of mitochondrial membrane

potential, and autophagy was also observed. In addition to these findings, all cell lines treated showed a reduced migration and invasion ability due to the slower wound closure and the reduced protrusion in a 2D and 3D cell culture assay, respectively.

Conclusion

Our findings indicate that the combination of TKIs and DCA, at low doses, represents a promising therapeutic approach to overcome resistance and improve clinical outcomes in target cancer therapy.

⁴A.C.Camargo Cancer Center, Head and Neck Surgery and Otorhinolaryngology, São Paulo, Brazil

⁵Universidade de São Paulo, General Pathology, Dental School, São Paulo, Brazil

Introduction

Salivary gland tumors present a wide morphologic variation, especially among neoplasms originated from intercalated duct and with prominent or partial involvement of myoepithelial component. Currently, there are few studies correlating histological subtypes with genetic alterations in benign and malignant salivary gland tumors, especially the beta-catenin staining and the presence of CTNNB1 mutation in basal cell adenoma. Thus, we analyzed our case series of benign and malignant tumors originating from the intercalated duct to verify whether there is an association between the immunohistochemical staining pattern and mutation among these tumor subtypes and possible differences between them. Therefore, understanding the molecular basis of these lesions would be useful for differential diagnosis and classification by evaluating their mutational profiles.

Material and method

Immunohistochemistry (IHC) and Next Generation Sequencing (NGS) were performed for tumor analysis. IHC was applied to 40 cases, and NGS to 31 cases with available paraffin material. IHC followed the Ventana BenchMark Ultra protocol (Roche), evaluating staining localization and intensity. NGS targeted exon 3 of the CTNNB1 gene using the Ion GeneStudio S5 Plus platform, analyzed with IGV_2.18.4 software, and verified in the Franklin database. True alterations required complete amplicon coverage, sufficient reads, consistency in forward and reverse reads, and an alteration reading frequency of 2% or higher [1].

Result and discussion

Of the 31 samples sequenced in the specific exon, 27 samples also had immunohistochemical analysis that can be compared. The analyses were carried out manually and we can highlight 7 cases that had the mutation validated and confirmed. We observed that 3 out of 6 basal cell adenoma cases, and 1 out of 3 basal cell adenocarcinoma cases showed the p.Ile35Thr mutation, all demonstrating nuclear beta-catenin staining. One carcinoma ex-pleomorphic adenoma case showed a mutation at codon 40, considered a pathogenic variant and the beta-catenin staining was observed as a discontinued membrane pattern. Two out of 8 pleomorphic adenoma cases had a mutation at codon 34, classified as pathogenic mutation, however no IHC information was available. Both mutations have not been previously reported in the tumor types studied. We can observe differences in beta-catenin staining pattern and molecular profile between tumor subtypes from intercalated duct, although a larger casuistry is necessary to confirm these differential patterns.

Conclusion

Few alterations were observed in these tumors, and we can observe differences especially when comparing basal cell adenoma and adenocarcinoma or pleomorphic adenoma. Further studies are necessary to investigate the influence and the role of beta-catenin in these tumors.

Repurposing Antihistamines: Exploring Their Potential as N-WASP Inhibitors in Breast Cancer Metastasis

R. Yu¹, Q. Dou², E. Khan², W. Jiang¹, T. Martin¹

¹Cardiff China Medical Research Collaborative CCMRC, Cardiff University School of Medicine, Cardiff, UK, Cancer and Genetics, Cardiff, United Kingdom

²Karmanos Cancer Institute, Wayne State University School of Medicine, Department of Oncology, Detroit, United States

Introduction

Breast cancer metastasis is the leading cause of cancer-related mortality, emphasizing the need for novel therapeutic approaches. Neural Wiskott-Aldrich syndrome protein (N-WASP), a crucial regulator of actin polymerization and cytoskeletal dynamics, plays a significant role in cancer cell motility and invasion. Inhibiting N-WASP may suppress the metastatic spread of cancer cells. Drug repurposing provides an efficient pathway to accelerate treatment development, especially when the drugs have well-established safety profiles. This study investigates the potential of two anti-histamines – cyproheptadine (a first-generation compound) and desloratadine (aerius®, a second-generation agent) – as N-WASP inhibitors to hinder breast cancer cell migration and proliferation.

Material and method

MDA-MB-231 and MCF-7 breast cancer cell lines, along with HECV endothelial cells, were utilized. Proliferation was assessed using cytotoxicity assays, while migration and adhesion were evaluated through wound healing and Electric Cell-substrate Impedance Sensing (ECIS) assays. N-WASP expression at the protein and mRNA levels was analysed using immunofluorescence staining, western

blotting, and qPCR. To explore the molecular basis of drug-protein interactions, molecular docking simulations were performed, targeting the VCA domain of N-WASP.

Result and discussion

Both antihistamines significantly inhibited cancer cell proliferation. Desloratadine reduced MDA-MB-231 proliferation by 51.76% ($p < 0.0001$), whereas cyproheptadine decreased it by 15.72% ($p = 0.0007$). In MCF-7 cells, cyproheptadine exhibited a stronger inhibition rate (43.18%) compared to desloratadine (39.23%). Migration assays revealed substantial reductions in cell motility, with cyproheptadine decreasing MCF-7 migration by 35.89% ($p < 0.0001$) and desloratadine by 27.32% ($p = 0.0014$). ECIS assays confirmed that both treatments impaired cell adhesion and migration. Protein analysis indicated a marked downregulation of N-WASP in treated cells, confirmed through immunofluorescence and western blotting. Interestingly, qPCR results revealed no significant changes in N-WASP mRNA levels, suggesting post-transcriptional regulation. Molecular docking simulations demonstrated that both antihistamines interact with key residues within the N-WASP VCA domain. The findings support the hypothesis that both drugs disrupt cytoskeletal dynamics essential for cancer cell migration and adhesion.

Conclusion

This study demonstrates that cyproheptadine and desloratadine inhibit breast cancer cell proliferation, adhesion, and migration by downregulating N-WASP protein expression. Repurposing antihistamines as anti-metastatic agents presents a promising and cost-effective strategy for breast cancer treatment.

Insights from Ultrastructural Changes, Histopathology, Gene Expression, and Prognostic Outcomes Between Apoptosis and Ferroptosis in Primary and Chemoreduced Retinoblastoma

L. Singh¹, M. Singh², N. Kumar³, S. Kashyap³

¹*All India Institute of Medical Sciences, Pediatrics, Delhi, India*

²*UT Southwestern Medical Center, Ophthalmology, Dallas, Texas, United States*

³*All India Institute of Medical Sciences, Ocular Pathology, New Delhi, India*

Introduction

Understanding the distinctions between apoptosis and ferroptosis is essential for exploring their roles in different biological processes and their potential prognostic implications in retinoblastoma (Rb). Therefore, this study aims to explore the morphological, pathological and molecular implication of apoptosis and ferroptosis in retinoblastoma patients and their prognostic outcome.

Material and method

A total of 123 prospective cases were included among which 82 cases underwent primary enucleation and 41 cases received chemotherapy/radiotherapy before enucleation (chemoreduced retinoblastoma) for a period of 2 years. Immunohistochemistry was performed for

Transferrin receptor (TFR1) protein and caspases on formalin-fixed paraffin embedded (FFPE) tissues. mRNA expression level was measured for ferroptosis-related genes (SLC7A11, SLC3A2, GPX4) and regulator of apoptosis (Caspases 3, 8 and 9 genes) using qRT-PCR in all Rb cases and normal control. Expression was finally correlated with clinical and histopathological parameters.

Result and discussion

Transmission electron microscopy (TEM) was also performed to observe ultrastructural changes. Kaplan-Meier survival graph was plotted to predict the patient outcome. There was male preponderance with more than 50% of the cases belong to <2 years of age. Cytoplasmic expression of TFR1 protein was found in 78% cases. Upregulation of GPX4 mRNA level was prominent in our cases. SLC7A11 and SLC3A2 was inversely expressed in primary retinoblastoma cases. Scleral invasion was statistically significant with TFR1 expression and unregulated GPX4 gene level. Upregulated mRNA expression of Caspase-3 and -8 was found in 85% and 72.5% cases, respectively. Down-regulation of Caspases-9 was found in 70% of the cases, and this was statistically significant with massive choroidal invasion.

Conclusion

TEM showed morphological features of cell death that corresponds to apoptosis and ferroptosis. This study found altered and differential expression of ferroptosis-related markers and apoptosis regulated genes which could predict the prognosis of retinoblastoma patients.

EACR25-0719

Polycomb Complex Protein PHC3 Coordinates with HOTAIR Pathway to Promote Colorectal Cancer Progression

Y. Chen¹, H. Liu^{1,2,3}

¹*Chang Gung University, Graduate Institute of Biomedical Sciences, Taoyuan, Taiwan*

²*Chang Gung University, Department of Cell and Molecular Biology, Taoyuan, Taiwan*

³*Chang Gung University, Molecular Medicine Research Center, Taoyuan, Taiwan*

Introduction

Colorectal cancer (CRC) is the third most prevalent and fatal malignancy worldwide. Despite advances in surgical and chemotherapeutic interventions, high recurrence rates suggest that the underlying mechanisms of CRC progression remain unclear. Polyhomeotic homolog 3 (PHC3), a transcriptional regulator within the polycomb repressive complex 1 (PRC1), has been implicated in epigenetic gene regulation via monoubiquitylation of histone H2A at lysine 119 (H2AK119ub). Our previous transcriptomic analysis revealed that PHC3 is upregulated in CRC and is associated with poor patient prognosis. However, the precise role of PHC3 in CRC tumorigenesis requires further elucidation.

Material and method

We collected clinical CRC specimens and performed integrated transcriptomic profiling to identify differentially expressed genes. Functional assays, including proliferation, migration, and invasion assays, were conducted in CRC cell lines with PHC3 knockdown

or overexpression. A xenograft mouse model was employed to assess tumorigenic potential *in vivo*. RNA-IP-qPCR analysis was performed to identify the interaction between PHC3 and lncHOTAIR.

Additionally, high-throughput RNA sequencing and Hi-ChIP-seq for H2AK119ub were conducted to investigate PHC3-mediated transcriptional and chromatin modifications.

Result and discussion

We found that PHC3 was upregulated in CRC patients, and high PHC3 expression was correlated with poor prognosis. Knockdown of PHC3 significantly suppressed CRC cell proliferation, migration, and invasion, whereas PHC3 overexpression enhanced these oncogenic properties. Mouse xenograft experiments confirmed that PHC3 promotes tumor growth. Mechanistically, PHC3 depletion led to reduced expression of BMI1, a canonical PRC1 component, and survival-associated signaling molecules. Transcriptomic profiling identified that PHC3 regulates the HOTAIR signaling pathway and influences tumor-related genes such as WNT, FOXM1, and CDKN1A. RNA-IP-qPCR analysis revealed that PHC3 interacted with lncHOTAIR. Furthermore, Hi-ChIP-seq analysis demonstrated that PHC3 depletion alters H2AK119ub occupancy at specific chromatin loci, implicating PHC3 in the epigenetic modulation of gene expression in CRC.

Conclusion

Our findings suggest that PHC3 plays a critical role in CRC tumorigenesis by regulating the HOTAIR signaling pathway and modifying chromatin structure through H2AK119ub. Targeting PHC3-mediated epigenetic mechanisms may provide novel therapeutic strategies for CRC treatment.

Identification and Functional Characterization of Theranostic Biomarkers in Pancreatic Ductal Adenocarcinoma

Y. Sher¹, P. Prusawan², H. Shih², Y. Huang³, C. Yeh⁴

¹*China Medical University, Institute of Biochemistry and Molecular Biology, Taichung, Taiwan*

²*China Medical University Hospital, Center for Molecular Medicine, Taichung, Taiwan*

³*China Medical University, Graduate Institute of Biomedical Sciences, Taichung, Taiwan*

⁴*China Medical University Hospital, Department of Surgery, Taichung, Taiwan*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is characterized by a poor prognosis and a high recurrence rate following surgical resection. The urgent need for reliable theranostic biomarkers and corresponding therapeutic strategies highlights the importance of ongoing research efforts. This study aims to identify biomarkers that facilitate early detection, enable risk stratification for postoperative recurrence, and inform the development of precision medicine through biomarker-driven therapeutic approaches.

Material and method

Bioinformatic and immunohistochemical analyses were performed on PDAC specimens. Functional studies were conducted by knocking down individual and multiple biomarkers in PDAC cell lines to assess their effects on cellular function [1].

Result and discussion

Bioinformatic analyses identified four biomarkers – ADAM9 (a disintegrin and metalloprotease 9), MTHFD2 (methylenetetrahydrofolate dehydrogenase), RRM2 (ribonucleoside-diphosphate reductase subunit M2), and SLC2A1 (solute carrier family 2 member 1) – whose elevated expression correlated with poor clinical outcomes in PDAC patients. A higher cumulative expression of these biomarkers was associated with an increased hazard ratio, underscoring their prognostic significance. Immunohistochemical analysis of PDAC specimens revealed significantly elevated H-scores for these biomarkers in patients with advanced tumor stages. Functionally, these biomarkers appeared to act synergistically in driving tumor progression. Notably, simultaneous knockdown of all four genes resulted in a more pronounced reduction in cell proliferation compared to the silencing of individual genes.

Furthermore, knockdown of a single gene influenced the expression of the others, suggesting compensatory regulatory mechanisms among these biomarkers. Pharmacological inhibition targeting these biomarkers in combination further enhanced apoptotic markers and effectively reduced PDAC cell viability. *In vivo*, this translated to significant tumor growth suppression, as evidenced by a marked reduction in tumor size.

Conclusion

Targeting the four identified theranostic biomarkers in PDAC cells holds promise for the development of more effective and precision-targeted therapeutic strategies. These findings provide a foundation for improving treatment outcomes and prognostic accuracy in PDAC patients.

[1] All experimental procedures were conducted in accordance with ethical guidelines and were approved by the Institutional Animal Care and Use Committee and the Institutional Review Board at China Medical University Hospital.

¹⁰Fraunhofer Research Institution for Individualized and Cell-Based Medical Engineering, Lübeck,*

Introduction

The increasing incidence of early-onset colorectal cancer (eoCRC) may be a consequence of poor dietary habits, as up to 70% of CRC risk factors are nutrition-related. Therefore, in this study we aimed to elucidate the impact of distinct Western diet (WD)-associated phenotypes, such as obesity and metabolic syndrome (MetS), during early life on colonic epithelial cell (EC) biology in the context of CRC.

Material and method

7-week-old male C57BL/6 mice, recapitulating a human age of 13, were fed a WD or control diet for 6 or 12 weeks. Murine colonic tissues were phenotyped using immunohistochemistry, real-time PCR or Western blot. NMR-metabolomics was used for analysis of serum samples. Mass spectrometry-based lipidomics was used or analysis of fecal samples. To assess relevance to human biology, paired normal and tumoral tissue samples from CRC patients were analyzed. Metabolic effects on intestinal stem cell differentiation were validated in the non-malignant human colonic epithelial cell line HCEC-1CT and ex vivo generated human colon-derived 3D organoids.

Result and discussion

While 6 weeks of WD feeding led to obesity, extending the feeding duration to 12 weeks induced MetS, characterized by obesity, hyperlipidemia, and both systemic and colonic insulin resistance. MetS was accompanied by reduced AKT signaling but marked MAPK pathway activation, promoting hyperproliferation of colonic ECs. Unexpectedly, the colonic expression of the DNA mismatch repair enzyme MSH2 was down-regulated in MetS mice despite elevated cell proliferation. Lipidomic analysis identified the WD-associated polyunsaturated omega-6 fatty acid arachidonic acid (AA) as the most potent trigger of hyperproliferation in colonic ECs. Stimulation of HCEC-1CT cells and human colonic organoids with AA led to cellular overgrowth, boosting the HOPX⁺ quiescent stem cell compartment at the +4 position as well as the REG4⁺ precursor cells of secretory ECs at the expense of the cycling LGR5⁺ stem cell and the OLFM4⁺ precursor cells of absorptive ECs. In silico single-cell analysis revealed high expression of the insulin receptor in the stem cells, and the transit-amplifying cells. However, the quiescent stem cell at +4 position, which is inherently more susceptible to DNA damage due to its quiescent cell state, as well as the REG4⁺ secretory precursors exhibited higher levels of insulin-independent growth factor receptors in contrast to LGR5⁺ or OLFM4⁺ cells.

Conclusion

Our findings suggest that early exposure to colonic WD-related MetS may lead to the senescence of cycling colonic LGR5⁺ stem cells, while boosting DNA error-prone HOPX⁺ quiescent stem cells, thereby altering intestinal EC homeostasis and increasing susceptibility to develop CRC.

EACR25-0760

Low-density lipoprotein receptor-related protein 11 promotes lung adenocarcinoma proliferation by suppressing ubiquitin like modifier activating enzyme 7

T. Kiwaki¹, Y. Umekita¹, R. Tsuzuki¹, T. Fukushima¹, Y. Sato¹

¹Faculty of Medicine, University of Miyazaki, Section of Oncopathology and Morphological Pathology, Miyazaki, Japan

Introduction

Low-density lipoprotein receptor related protein 11 (LRP11) is a transmembrane protein in the low-density lipoprotein receptor family. It is highly expressed in various cancers and linked to poor prognosis. However, its role in tumor progression remains unclear.

Material and method

We analyzed LRP11 expression in lung cancer using the Cancer Cell Line Encyclopedia (CCLE) dataset. Overexpression and knockout experiments were performed in lung adenocarcinoma cell lines PC9, VMRC-LCD, and A549. LRP11 was overexpressed in PC9 and VMRC-LCD cells via plasmid transfection. Knockout was achieved in A549 cells using CRISPR-Cas9. RNA sequencing (RNA-seq) was conducted to identify differentially expressed genes associated with LRP11 expression. Knockdown of ubiquitin-like modifier activating enzyme 7 (UBA7) was performed using siRNA. We also assessed LRP11 expression and its prognostic significance in lung adenocarcinoma patients using the Cancer Genome Atlas (TCGA) dataset.

Result and discussion

CCLE data showed that 30.2% (13/43) of lung cancer cell lines, mainly adenocarcinomas, had high LRP11 expression. Overexpression of LRP11 significantly enhanced cell proliferation in PC9 and VMRC-LCD. LRP11 knockout suppressed proliferation and migration in A549. RNA-seq analysis revealed that LRP11 was negatively correlated with UBA7, an E1 enzyme involved in ISG15-mediated protein modification. UBA7 knockdown restored proliferation in LRP11-knockout A549 cells. It indicates that LRP11 promotes tumor growth by suppressing UBA7. Considering that ISG15 modification is induced by interferons and tumor necrosis factor, LRP11 may regulate cellular responses to these cytokines. Clinically, LRP11 expression was higher in advanced-stage lung adenocarcinoma. Patients with high LRP11 had significantly shorter survival. A negative correlation between LRP11 and UBA7 was also observed in the patient cohort.

Conclusion

This study demonstrates that LRP11 promotes proliferation of lung adenocarcinoma by downregulating

UBA7. Our findings reveal a novel mechanism underlying LRP11's pro-tumor function. Given its clinical relevance, LRP11 could be a potential biomarker and therapeutic target.

EACR25-0767

The protooncogene SETDB1 affects microtubule dynamics through HDAC6

G. Gunasekara¹, R. Hernandez-Vicens¹, N. Pernicone¹, T. Listovsky², G. Gerlitz¹

¹Ariel University, Molecular Biology, Ariel, Israel

²Ariel University, Molecular Biology and School of Medicine, Ariel, Israel

Introduction

SETDB1 is a methyltransferase responsible for methylation Histone 3 at Lys9 that leads to repression of gene expression. SETDB1 is overexpressed in many cancers and is thought to support tumorigenic transcriptional profiles. As expected from its activity, SETDB1 is mainly a nuclear protein. Still, there is a substantial cytoplasmic fraction of SETDB1 that its role is ambiguous. Here, we found a moonlight function for SETDB1 in regulating microtubule (MT) dynamics by promoting a-tubulin deacetylation by HDAC6.

Material and method

Association with MTs was determined by immunostaining, MT co-sedimentation assay, and co-immunoprecipitation. Mitosis kinetics was measured by timelapse microscopy.

Result and discussion

SETDB1 interacts with MTs and reduces MT polymerization rate in a manner that is independent of its methyltransferase activity. Consequently, altered SETDB1 levels led to slower mitotic kinetics and a higher mitotic catastrophe rate. In search of the mechanism by which SETDB1 affects MT dynamics, we found that SETDB1 interacts with the major a-tubulin deacetylase HDAC6. Tubulin acetylation increases the flexibility of MTs to enhance their stability against mechanical stress, while HDAC6 supports cell proliferation, migration, and chemoresistance in cancer cells. Overexpression of SETDB1 led to reduced tubulin acetylation levels, while SETDB1 knockdown increased tubulin acetylation levels. Thus, suggesting that SETDB1 promotes HDAC6 activity. Furthermore, overexpression of SETDB1 led to an increase in the protein levels of both endogenous and exogenous HDAC6, suggesting that SETDB1 enhances the protein stability of HDAC6. SETDB1 also elevated the association of HDAC6 with MTs but not with tubulin dimers.

Conclusion

Our results support a model in which SETDB1 promotes MT destabilization by stimulating the activity of HDAC6 towards MTs. SETDB1 does so by both stabilizing HDAC6 protein and recruiting HDAC6 to MTs. Through this mechanism, SETDB1 can alter MT dynamics to support tumor progression.

Conflicts of Interest: G Gerlitz has a US Patent App on Setdb1-microtubule interaction and use thereof (18/227,122, 2024).

Nanotechnology Lab., Department of Prevention and Rehabilitation in Occupational Medicine and Specialty Medicine, Pavia, Italy

⁴University of Milano-Bicocca, Department of Biotechnology and Bioscience, Milano, Italy

⁵University of Molise, Department of Medicine and Health Sciences, Campobasso, Italy

Introduction

Transient receptor potential melastatin 7 (TRPM7) is a peculiar channel characterized by both ion channel and enzymatic activity and is, therefore, known as chanzyme. It plays an important role in calcium and magnesium homeostasis. Recent studies suggest that TRPM7 is implicated in tumor modulation, contributing to various cancer hallmarks such as cell proliferation, survival, and metastasis. A comprehensive understanding of the role of TRPM7 in the intricate cancer metabolism, particularly in breast cancer, may offer novel therapeutic strategies. In this study, we explored the expression and function of TRPM7 in different breast cancer cell lines and investigated its potential to modulate tumor through specific activators, inhibitors and small interfering RNA (siRNA).

Material and method

The cell lines employed in this study were MCF-10A, MCF-7, MDA-MB-231 and SK-BR-3. TRPM7 expression was analysed by quantitative PCR (qPCR), while channel activity was assessed by analysing the signal of Fura-2, a calcium-sensitive fluorescent dye, in the presence of specific activators and inhibitors. To investigate the effect of TRPM7 on cancer modulation, cells were infected with siRNA. Cell viability and gene expression were analysed.

Result and discussion

Preliminary results demonstrated that TRPM7 was significantly more expressed in MCF-7 cells compared to other cell lines. Modulation of TRPM7 activity, by specific activators and inhibitors, induced changes in calcium influx, underscoring the channel's functional role in regulating cellular ion homeostasis. Furthermore, silencing of TRPM7 resulted in a marked decrease in both cell viability and mRNA expression, highlighting its crucial involvement in cellular processes. These results suggested a noteworthy impact of TRPM7 on breast cancer progression. Several ongoing experiments aim to investigate the role of TRPM7 in breast cancer metabolism.

Conclusion

The findings highlight the central role of TRPM7 in the modulation of breast cancer. Indeed, inhibition of channel activity or its silencing by siRNA has been shown to reduce calcium influx, impair cell viability and alter gene expression, supporting its involvement in cancer modulation. These observations provide basis for the exploration of targeted therapies. Further studies are essential to fully understand the broader implications of

TRPM7 in cancer metabolism and to evaluate its viability as a target for innovative therapeutic strategies.

⁴Unit of Cellular Networks and Molecular Therapeutic Targets, IRCCS Regina Elena National Cancer Institute, Rome, Italy

Introduction

Cancer emerges from aberrant communication between cells of a multicellular organism. The glycan coat that surrounds the cells is an important player in cellular communication. While altered cell surface glycans are known biomarkers for cancer, glycan biosynthesis itself has not been identified as a potential oncogenic pathway. Moreover, only a handful of inhibitors have been developed against glycan synthesising enzymes in cancer.

Material and method

To understand the oncogenic potential of glycan biosynthetic pathways, we searched for copy number alterations (CNA)-based glycooncogenes. We developed a bioinformatic-experimental pipeline to prioritize driver genes in the copy number altered segments of cancer genomes that correctly identified several well-established oncogenes/TSGs and also discerned novel potential oncogenes and TSGs, including glycooncogenes. We characterise and validate the glycooncogenes using *in vitro* growth, 3D spheroids models and biochemical assays combining genetic and pharmacological perturbations.

Result and discussion

Among the several pathways enriched, glycooncogenes belonging to the glycosphingolipid pathway was found to be oncogenic. We further validate B4GALT5, a key enzyme of the glycosphingolipid pathway as a novel glycooncogene, whose genomic amplification promotes oncogenic features including increased growth, migration, addiction and is associated with worst prognosis in patients. We also find that glycooncogenes cooperate with known oncogene and TSG like KRAS and TP53 respectively, thereby making them cancer vulnerabilities in previously untreatable cancers.

Conclusion

This study provides an important resource of nearly 1500 novel high-confidence CNA-based oncogenes and TSGs [1], and also identifies glycosylation pathways with onco-regulatory properties and opens up a new group of enzymes as potential therapeutic targets for cancer.

Role of the antioxidant metabolism (AM) at various EMT/MET states of pancreatic ductal adenocarcinoma (PDAC) cells

D. Baishanova¹, H. Ungefroren², A. Rout³, U. Günther³, H. Schäfer¹

¹Institute for Experimental Cancer Research, Christian-Albrechts-University of Kiel, Kiel, Germany

²University of Lübeck, First Department of Medicine, Lübeck, Germany

³University of Lübeck, Institute for Chemistry & Metabolomics, Lübeck, Germany

Introduction

The consecutive events of Epithelial-to-mesenchymal transition (EMT) and Mesenchymal-to-epithelial transition (MET) are considered as driving force in the metastasis of PDAC. Recent studies suggest that oxidative stress (OS) plays a crucial role in EMT/MET-plasticity of cancer cells. Nrf2, as a key regulator of cellular antioxidant (AO) response, efficiently protects cells against OS and, along with this, provides multiple growth advantages for cancer cells fostering metastasis. Addressing this issue, we elucidated a crosstalk of TGF- β 1-mediated EMT and IFN γ /TNF α /IL-1 β (IIT) induced MET of PDAC cells with NRF2 driven AM.

Material and method

Basal phenotypes of different Panc-1 cell clones: 1C3, 3D2, 4B9 were determined by studying expression of E/M state markers on RNA and protein levels. The clones were assessed for their responsiveness to TGF- β 1 and IIT in terms of Nrf2 activity and its downstream AO gene expression, as well as for ROS levels, energy metabolism in different E/M states (glycolysis and mitochondrial respiration real-time measurements, Seahorse assay), and glucose metabolism involved in the redox-homeostasis by stable 13C-isotope tracing.

Result and discussion

Substantial differences were identified in the phenotypes of the Panc1-clones: 1C3 has a mesenchymal, 3D2 an epithelial, 4B9 an intermediate phenotype. Nrf2 activity also differed in the clones with the highest in 1C3 and the lowest in 3D2. AO gene expression was highest in 1C3 and lowest in 4B9. ROS levels were highest in 4B9 and lower in 1C3 and 3D2. TGF- β 1 and IIT treatments increased ROS levels in all clones. Seahorse measurements showed that 3D2 has the highest mitochondrial activity and TGF- β 1 decreased this activity in 3D2 and 4B9 but not in 1C3, while IIT increased it in 4B9 and 1C3 but not in 3D2. By contrast, 1C3 is the most glycolytic clone and TGF- β 1 significantly increased glycolytic parameters in 4B9 and 3D2, but only slightly in 1C3. IIT increased glycolysis in 4B9 and 1C3, but not in 3D2. U-13C-Glucose was differentially metabolized in the clones related to AM: 1C3 showed the highest 13C-enrichment in glutamate and glutathione (GSH) but the lowest enrichment in the TCA intermediate 2-oxo-glutarate. By contrast, 3D2 exhibited the greatest 13C-enrichment in citrate and 2-oxoglutarate but lowest in GSH. 1,2-13C-Glucose tracing revealed greater metabolization through the pentose-phosphate-pathway than glycolysis in 1C3 and 4B9 clones.

Conclusion

Our findings reveal a differential correlation between EMT/MET states of the Panc-1 clones and AM controlled by Nrf2. The most mesenchymal phenotype (1C3) exhibits the highest AM and glycolytic activity while the most epithelial clone (3D2) possesses less AM and glycolytic activity. Thus, AM can differentially affect the metastatic process by differentially impacting EMT and MET. More studies on the crosstalk are needed for novel concepts to overcome metastasis and to improve the existing therapy options in PDAC.

EACR25-0810

Targeting KDM4-Driven Metabolic Reprogramming in Castration-Resistant Prostate Cancer

W. Wang¹, M. Wu¹, J. Liu¹, S. Yang¹, H. Kung²

¹*National Tsing Hua University, Department of Life Sciences, Hsinchu, Taiwan*

²*Taipei Medical University, Graduate Institute of Cancer Biology and Drug Discovery, Taipei, Taiwan*

Introduction

Prostate cancer, particularly in its castration-resistant form (CRPC), poses a significant therapeutic challenge due to its aggressive progression and resistance to conventional treatments. Recent studies have highlighted the KDM4 family of histone demethylases (KDM4A, KDM4B, and KDM4C) as important epigenetic regulators that contribute to the development of prostate cancer. In this study, we focused on the metabolic modulation by KDM4 members and the development of KDM4 inhibitors.

Material and method

CRPC cells (C4-2B or CWR22Rv1) were depleted of KDM4, and a series of analyses were conducted to identify their expression and metabolic profiles. These analyses included cell proliferation studies (both *in vitro* and *in xenografts*), microarray experiments, quantitative reverse transcription PCR, Seahorse Flux assays, and metabolomic evaluations. Immunoprecipitation was performed to determine interaction regions, while reporter activity assays and chromatin immunoprecipitation analyses were used to characterize the mechanistic actions of the complex. Additionally, a structure-based approach was employed to develop KDM4 inhibitors, and these compounds' cytotoxic effects on various cancer cell lines were evaluated.

Result and discussion

We showed that the knockdown of KDM4B impaired the proliferation of CRPC cells, shifted metabolism from the Warburg effect to oxidative phosphorylation (OXPHOS), and suppressed the expression of several genes, including those targeted by c-Myc. Additionally, we demonstrated that KDM4B physically interacts with c-Myc, and both proteins are co-recruited to the c-Myc-binding sequence on the promoters of metabolic genes. Furthermore, a series of KDM4 inhibitors were synthesized, and their inhibitory effects were evaluated.

Conclusion

KDM4B partners with c-Myc and serves as a coactivator of c-Myc to directly enhance c-Myc-mediated metabolism, hence promoting CRPC progression. Targeting KDM4B is thus an alternative therapeutic strategy for advanced prostate cancers.

EACR25-0820

Urea cycle upregulation is a metabolic adaptation driving liver-specific metastatic organotropism

V. Cruz Vilchez¹, A. Roca Portoles¹, N. Del Pozo Ramos¹, R. Losada de Paz¹, I. Lorca Alonso¹, D. Abia Holgado¹, J. Spinelli², E. Balsa Martínez¹

¹*Centro de Biología Molecular Severo Ochoa (CBMSO), Consejo Superior de Investigaciones Científicas-Universidad Autónoma de Madrid (CSIC-UAM), Madrid, Spain*

²*University of Massachusetts Chan Medical School, Worcester, United States*

Introduction

Metastatic cells exhibit preference for colonizing specific tissues, a phenomenon known as metastatic organotropism. Among the most common metastatic sites, lung and liver are primary targets for disseminated cells, suggesting that these organs offer permissive environments for colonization. However, the metabolic adaptations that allow tumor cells to thrive in these tissues remain unclear.

Material and method

To investigate the metabolic adaptations of metastatic cells in the liver and lung environments, we modified A375 and 4T1 cells to express an OMP25-bound HA tag on their outer mitochondrial membrane. These cells were injected into mice to isolate and immunoprecipitate mitochondria from primary tumors, lung and liver metastases, allowing us to dissect the differential proteome using TMT isobaric labelling. Additionally, to assess the functional impact of mitochondrial genes on metastatic organotropism, we conducted an *in vivo* CRISPR screening with a LOF sgRNA library targeting nuclear-encoded mitochondrial genes in MDA-MB-231 cells.

Result and discussion

Our proteomic analysis revealed significant differences between primary tumor, lung and liver metastases in both A375 and 4T1 models. Notably, we identified an increase in urea cycle-related enzymes as a liver-specific metabolic adaptation. This was further corroborated by the selective depletion of sgRNAs targeting the cycle-limiting enzyme CPS1 in liver metastases in the CRISPR screening. Analysis of CPS1 expression at both the mRNA and protein levels showed a significant liver-specific elevation in metastases across various tumor types in mouse models. This upregulation was consistently observed in public databases of breast and colorectal cancer patients, further validating its potential role in liver metastasis. Functionally, CPS1 KO cells exhibited reduced metastatic capacity to the liver, with no impact on their growth in 2D or 3D culture, primary tumor formation, or metastatic burden in the lungs. Since CPS1 is critical for ammonium detoxification, we confirmed that ammonium levels were significantly higher in the liver compared to tumors, plasma, lung, or brain. The addition of ammonium at physiological levels impaired the proliferation of CPS1-depleted cells, which also exhibited a decrease in mitochondrial respiration when cultured with ammonium. These results suggest that CPS1 deficiency sensitises metastatic cells to the high ammonium concentrations present in the liver.

environment, thus affecting their ability to colonise this tissue.

Conclusion

Our findings reveal that metastatic cells undergo distinct metabolic adaptations depending on the secondary tissue, with CPS1 playing a key role in liver-specific colonization. These insights refine our understanding of metastatic organotropism and postulate CPS1 as a potential therapeutic target to disrupt liver metastasis.

EACR25-0845

Impact of the E2F1-BASP1 complex on regulating MYC expression

L. Timpen¹, L. Weber¹, T. Kipura¹, M. Kwiatkowski¹, M. Hartl¹

¹Biochemistry, Innsbruck, Austria

Introduction

The gene regulator MYC controls multiple cellular processes including cell proliferation and differentiation, but MYC is also aberrantly activated in multiple human tumours. For this reason, MYC is considered as major cancer driver representing a promising therapeutic target although direct MYC inhibition has remained difficult. Therefore, indirect strategies targeting the MYC network appears to be a more suitable approach. One of the downregulated transcriptional MYC targets is the BASP1 gene encoding a neuronal signalling protein and a transcriptional corepressor. On the other site, ectopic expression of BASP1 suppresses MYC mRNA expression, rendering MYC and BASP1 mutually exclusive. Furthermore, BASP1 overexpression interferes with MYC-induced cell transformation.

Material and method

To investigate the regulation of MYC transcription in the context of BASP1, we performed a reverse chromatin immunoprecipitation (R-ChIP) screen using the colon cancer cell line SW480, and SW480 with a CRISPR-activated BASP1 gene. Using biotin-labelled oligodeoxynucleotides targeting the MYC promoter region, crosslinked proteins were pulled down using streptavidin-coated magnetic beads. Subsequently, proteins were detected by mass spectrometry (MS). Thereafter, candidate proteins interacting with BASP1 were identified by co-immunoprecipitation (Co-IP), and their influence on MYC transcription was tested by luciferase reporter gene assays.

Result and discussion

The R-ChIP screen identified 541 unique proteins binding to the MYC promoter, and 107 thereof were specific for BASP1-expressing SW480. Among these, we have identified proteins that are known to interact with the cell cycle regulator E2F1. By performing Co-IP experiments, we found that BASP1 and E2F1 form a complex. Whereas E2F1 upregulates MYC transcription in SW480, the presence of BASP1 significantly reduces E2F1-mediated MYC activation.

Conclusion

A physical interaction between the cell cycle promoter E2F1 and the potential tumour suppressor BASP1 was discovered. By further investigating the function of the BASP1-E2F1 complex, we expect to gain more insight into the molecular mechanism of oncogenic MYC

regulation, and to develop novel therapeutic strategies to target oncogenic functions of the gene regulators E2F1 or MYC.

EACR25-0854

Restoration of Drug Sensitivity and Apoptosis to Drug-Resistant Oesophageal Cancer Cells by USP18 Knockdown in the Presence of IFN- α or Poly (I:C)

M. Carey¹, T. O'Donovan¹, C. Coveney², S. McKenna¹

¹University College Cork, CancerResearch @UCC, Cork, Ireland

²BioMarin International Limited, Cork, Ireland

Introduction

Oesophageal cancer is challenging to treat, often exhibiting resistance to current treatments (chemo- or radiotherapy). The five-year survival rate for patients is less than 20% across Europe. Thus, new treatment approaches are urgently required. Our group has previously reported differential expression of the ISGylation network in cells that respond differently to drug treatment. ISGylation is a mechanism similar to ubiquitination, where ISG15 is conjugated to targets via the sequential cooperation of E1, E2, and E3 enzymes. Ubiquitin-specific peptidase 18 (USP18), an ISG15-specific enzyme, can remove ISG15, reversing this reaction. Additionally, USP18 is a negative regulator of the interferon (IFN) response. We are examining USP18's role in chemosensitivity in oesophageal cancer cells.

Material and method

Knockdown of USP18 was achieved with siRNA and confirmed by western blot. Response to drug treatments and Poly (I:C) was assessed with colony assays and morphological analysis. Apoptosis was evaluated by quantifying active caspase-3 by flow cytometry. Autophagy was assessed by quantifying autophagosomes with Cyto-ID and flow cytometry. The autophagy marker LC3II and the cell signalling effects of Poly (I:C) were quantified by western blot.

Result and discussion

Knockdown of USP18 in the presence of IFN- α significantly increased the chemosensitivity of KYSE450 and KYSE140 cells to 5-fluorouracil (5-FU) and oxaliplatin. In addition, extensive apoptosis was induced in these cell lines which were previously reported as apoptosis-incompetent. Autophagosome formation and expression of LC3II were also increased in the presence of IFN- α +/- 5-FU or oxaliplatin in both cell lines upon USP18 depletion. These effects may be due to hypersensitivity to IFN- α , or key protein targets that become ISGylated in the absence of USP18 may influence survival pathways. Consistent with its role as a deISGylase, knockdown of USP18 in the presence of IFN- α significantly increased the levels of ISG15 conjugates. We are currently conducting mass spectral analysis to identify and functionally categorise these ISGylated proteins. We also assessed whether stimulating Type I IFN signalling with a viral mimetic, Poly (I:C), could synergise with USP18 depletion as a potential alternative to IFN- α . Knockdown of USP18 in the presence of Poly (I:C) induced apoptosis in the KYSE450

cells but not in the KYSE140 cell line. We are exploring the mechanism behind this differential response to Poly (I:C).

Conclusion

These data identify USP18 as a regulator of two pathways (apoptosis/autophagy) that can have a major impact on drug sensitivity. Ultimately, we aim to identify the mechanisms underlying these effects and establish whether inhibition of USP18, either in the presence of IFN- α or synthetic inducers (e.g. Poly (I:C)), offers a promising new approach to chemo-sensitise oesophageal cancer.

EACR25-0855

PARP12 as a Novel Therapeutic Target in Breast Cancer: Integrating ADP-Ribosylation, DNA Damage Response, and Hormone Therapy Resistance

A. Pavithran¹, M. Matarese¹, A. Filograna¹, M. Lo Monte¹, L. Serpieri¹, N. Dathan¹, D. Corda¹, G. Grimaldi¹

¹National Research Council, Naples, Italy

Introduction

Breast cancer is the leading cause of death among women under 65 in developed countries, largely due to the emergence of multifactorial drug resistance mechanisms. The PI3K/AKT pathway plays a pivotal role in mediating endocrine resistance, and targeting key steps in this cascade represents a promising strategy to counteract therapy resistance. Mono-ADP-ribosylation (MARylation) is a post-translational modification catalyzed by mono-ADP-ribosyltransferases (mARTs) of the PARP family. This process involves transferring a single ADP-ribose unit from NAD to cellular targets, including proteins and nucleic acids, thereby governing essential cellular functions that are often dysregulated in disease. Notably, the mART PARP12 has been implicated in the development of drug resistance in estrogen receptor-positive breast cancer, marking it as a promising therapeutic target.

Material and method

In our study, we explored the role of PARP12 in breast cancer cell survival and its molecular contribution to resistance acquisition using a combination of biochemical and cell biology-based approaches.

Result and discussion

Our data demonstrate that AKT is a novel substrate for PARP12-mediated MARylation, a modification that is critical for AKT activation and cell survival. Consequently, the loss of PARP12 triggers apoptosis in a subset of estrogen receptor-positive breast cancer cells. We further show that inhibiting PARP12 transcription leads to increased DNA damage, accompanied by enhanced nuclear localization of p53 and a strengthened p53-AKT interaction. Under these conditions, AKT loses its capacity to regulate downstream targets such as the FOXO transcription factors, thereby promoting cell death through the upregulation of FOXO1, which activates the apoptotic cascade. Moreover, our findings link PARP12 activity to the DNA damage response, a connection of particular interest for tumors with compromised DNA repair mechanisms.

Conclusion

Overall, our study uncovers a novel regulatory mechanism of AKT activation and apoptosis driven by PARP12-mediated MARylation, highlighting PARP12 as a potential pharmacological target for overcoming endocrine resistance in breast cancer.

EACR25-0858

Epithelial Protein Lost in Neoplasm (EPLIN) in Head and Neck Cancer: A Prospective Oncogenic Molecule Linked with Prognosis

C. Wang¹, J. Zeng¹, T. Martin¹, X. Song², W. Jiang¹

¹CCMRC, Cardiff University School of Medicine, Cardiff, United Kingdom

²Department of Otorhinolaryngologic Diseases, Yantai Yuhuangding Hospital, Shandong, China

Introduction

EPLIN (Epithelial Protein Lost in Neoplasm, also known as LIMA1) was initially identified as a protein reduced or lost in malignant cells and tissues, hence was postulated as a putative tumour and metastasis suppressor. However, recent reports have indicated that its role in cancer is more complex and is tumour type dependent. For example, in colorectal, gastric and kidney cancers, it is tumour suppressive whereas it has a contrast role in other cancer types such as pancreatic cancer. Our study aimed to investigate the expression levels of EPLIN in head and neck cancer (HNC) tissues and its correlation with clinical features and the biological impact on HNC cells.

Material and method

In this study, we analysed the expression levels of EPLIN in HNC tissues using immunohistochemistry and correlated the expression with clinical pathological factors. Additionally, using public databases, we assessed the relationship of EPLIN with patient prognosis, lymph node metastasis, cancer grading and gender. In vitro, we created EPLIN knockdown and overexpression cell models using human HNC cancer cell lines and evaluated the impact of EPLIN expression on a range of biological functions of cancer cells. Immunoprecipitation (IP) and immunofluorescence co-localization (IFC) assays confirmed the direct interaction between proteins.

Result and discussion

Compared with normal tissues, EPLIN expression was upregulated in HNC cancer tissues, where higher levels were associated with advanced cancer stages and poorer clinical outcomes. The upregulation was significantly linked with increased tumour grade ($p = 0.003$), T-stage ($p = 0.007$) and tumour TNM staging ($p = 0.002$). Patients with high levels of EPLIN had a significantly reduced overall survival (OS) ($p < 0.00001$). The in vitro experiments demonstrated that knocking down EPLIN in HNC cells significantly impaired their migration and invasion capabilities, while overexpression of EPLIN enhanced these processes. Furthermore, it was identified that a group of metastasis related molecules including paxillin (PXN), moesin (MSN), actinin-1 (ACTN1) and integrin- α 3 (ITGA3) were significantly correlated with the levels of EPLIN in HNC cancer tissues ($r = 0.68$, 0.66 , 0.66 and 0.65 respectively, $p < 0.001$ for all). A genetic signature comprised of EPLIN-Paxillin-Actinin1

had a marked increased pattern in head and neck cancer ($p = 0.00353$). The co-IP assays further confirmed that EPLIN directly interacts with PNX and ACTN1.

Conclusion

The present study is the first to report the potential oncogenic role of EPLIN in head and neck cancer, demonstrating EPLIN as an indicator of poor survival. Additionally, we are the first to propose the potential connection of the EPLIN-Paxillin-Actinin1 network, which may play a role in the tumorigenesis of head and neck cancer. Thus, EPLIN holds significant clinical and therapeutic value, constituting a promising therapeutic target.

EACR25-0864

Discovering Potential Anti-Oral Squamous Cell Carcinoma Mechanisms from Kochiae Fructus Using Network-Based Pharmacology Analysis and Experimental Validation

E. Sung¹

¹Pusan National University, Otolaryngology-Head and Neck surgery, Pusan, Korea (Republic of)

Introduction

The natural product Kochiae Fructus (KF) is the ripe fruit of Kochia scoparia (L.) Schrad and is renowned for its anti-inflammatory, anticancer, anti-fungal, and anti-pruritic effects. This study examined the anticancer effect of components of KF to assess its potential as an adjuvant for cancer treatment. Network-based pharmacological and docking analyses of KF found associations with oral squamous cell carcinoma.

Material and method

The molecular docking of oleanolic acid (OA) with LC3 and SQSTM1 had high binding scores, and hydrogen binding with amino acids of the receptors suggests that OA is involved in autophagy, rather than the apoptosis pathway. For experimental validation, we exposed SCC-15 squamous carcinoma cells derived from a human tongue lesion to KF extract (KFE), OA, and cisplatin.

Result and discussion

The KFE caused SCC-15 cell death, and induced an accumulation of the autophagy marker proteins LC3 and p62/SQSTM1. The novelty of this study lies in the discovery that the change in autophagy protein levels can be related to the regulatory death of SCC-15 cells.

Conclusion

These findings suggest that KF is a promising candidate for future studies to provide insight into the role of autophagy in cancer cells and advance our understanding of cancer prevention and treatment.

EACR25-0869

Investigating the Cell of Origin in Merkel Cell Carcinoma Using a Human Pluripotent Stem Cell-derived Model

N. Pradeep Vasantha¹, J. Van Lent¹, A. Raimondi², L. Cascione³, F. Bertoni^{4,5}, A. Baggioolini⁴

¹Institute of Oncology Research (IOR), Bellinzona, Switzerland

²Institute for Research in Biomedicine (IRB), Bellinzona, Switzerland

³Institute for Research in Biomedicine, Bellinzona, Switzerland

⁴Institute of Oncology Research, Bellinzona, Switzerland

⁵Oncology Institute of Southern Switzerland (IOSI), Bellinzona, Switzerland

Introduction

Merkel cell carcinoma (MCC) is a rare yet highly aggressive neuroendocrine skin cancer with a mortality rate of approximately one in three affected individuals. MCC derives its name from Merkel cells (MCs) since they share histological and morphological similarities. MCs are neuroendocrine cells that closely interact with sensory neurons and regulate touch and tactile sensations. MCC research is limited by the rarity and post-mitotic nature of MCs, making isolation and mechanistic studies challenging. We are establishing the first differentiation protocol from human pluripotent stem cells (hPSCs) to generate human MCs to shed light on their biology in health and cancer. Apart from MCs, other cells of epidermal origin, such as epidermal stem cells, keratinocytes, pre-B cells, or even fibroblasts, have been proposed as plausible cells of origin (COO). Generating COO candidates with the same genetic background under controlled conditions will allow the comparison of their oncogenic potential and the timing of oncogenic transformation, offering crucial insights into the earliest events in MCC development.

Material and method

Our stepwise differentiation protocol allows us to differentiate hPSCs into Merkel cell lineage, passing through a stage of epidermal stem cells. We confirm MC identity by analyzing marker gene expression and evaluating mechanosensory function through interaction studies with hPSC-derived sensory neurons. The transcriptomic profiles of all COOs generated from hPSCs are validated using bulk RNA sequencing. To model oncogenic transformation, the hPSC line is genetically modified using CRISPR/Cas9 to introduce a doxycycline-inducible TP53 and RB1 double knockout.

Result and discussion

Preliminary results show that our protocol can direct hPSCs to cells resembling MCs. Indeed, around day 50 of differentiation, we observed the expression of specific markers (ATOH1, K8, K20, ISL1; which uniquely identifies MCs in the epidermis) through immunofluorescence and qPCR. Quantification of marker expression revealed ~65–70% efficiency. Electron microscopy confirmed MC morphology, desmosomes, and microvilli. We also generated other prospective COOs, including epidermal stem cells, keratinocytes, and fibroblasts of the same genetic lineages. Future experiments will introduce MCC-specific mutations to assess oncogenic competence across various epidermal cell types.

Conclusion

To our knowledge, we have developed the first protocol to differentiate MCs from hPSCs. This technical advantage will allow us to study physiological and pathological events that occur in humans, including the interaction of MCs with sensory neurons in the context of touch and pain responses, the timing of oncogenic

competence acquisition in MCC, and how different putative COOs respond to MCC-specific mutations, offering insights into disease progression.

EACR25-0870

Therapy-induced senescence of bone-marrow mesenchymal stem cells contribute to increased cell invasiveness, stemness, vascular mimicry and macrophages recruitment in TNBC by inducing PD-L1 overexpression

A. Costagliola di Polidoro¹, A. Durante¹, M. Caprio¹, E. Zazzaro¹, L. Cerchia², M. Ruvo¹, A. Sandomenico¹, A. Zannetti¹

¹*Institute of Biostructure and Bioimaging, CNR, Naples, Italy*

²*Istituto degli endotipi in oncologia, metabolismo ed immunologia, CNR, Naples, Italy*

Introduction

Tumor microenvironment (TME) is a complex ecosystem into which every component plays a precise role in fostering tumor establishment, growth and metastatic spread. Decades of research has proven the crucial involvement of stromal components of the TME in promoting tumour aggressiveness causing increased tumor cell migration, invasiveness, stemness as well as altered immune checkpoint expression as PD-L1, with an overall pro-tumorigenic role that contributes to confer resistance to standard treatments. Moreover, during chemo-radiotherapy, a common off-target effect is represented by Therapy-Induced-Senescence (TIS) of both stromal and tumor components of the TME that, not killed, acquire a senescent phenotype remaining metabolically active. By secreting the Senescence Associated Secretory Phenotype (SASP), senescent cells could further contribute to chemoresistance, immuno-checkpoint blockade and metastatic outspread. In this framework, the role of Doxorubicin (Doxo) in determining a senescent phenotype in human bone-marrow mesenchymal stem cells (BM-MSCs) and the consequent impact on triple-negative breast cancer (TNBC) cell aggressiveness including the recruitment of macrophages is investigated.

Material and method

BM-MSCs were treated with Doxo (10 nM) for 72 h to induce a senescent phenotype and then cultured in complete medium for 48 h. Doxo-induced alterations in BM-MSC morphology, cell cycle and proliferation were investigated. At this time, expression of senescence-associated markers (e.g. β-Galactosidase, Lamin B1) was evaluated by western-blot. TNBC cell lines, BT-549 and MDA-MB231, were grown in the conditioned medium obtained from senescent BM-MSC cells (CM-S-MSC) for 48h and investigated for acquired stemness characteristics (e.g. CD44 expression and spheroid formation), increased migration and matrigel invasion, EMT marker expression, PD-L1 overexpression and vascular mimicry. Furthermore, CM-S-MSCs impact on recruitment of activated macrophages labeled with NIR-probe was evaluated in trans-well chambers (3 μm insert).

Result and discussion

The treatment of BM-MSCs with Doxo caused an increase of β-Galactosidase expression levels and cytosolic deposition as well as a decrease of Lamin B1 expression, known markers of senescence. TNBC cells grown in CM-S-MSC showed increased PD-L1 expression levels, increased migration and matrigel invasion, an enhancement in stemness characteristics as shown by higher spheroid number and size as well as CD44 expression levels and involvement of EMT program. Furthermore, senescent BM-MSCs promoted the activation and recruitment of macrophages.

Conclusion

Our results shed light on the detrimental role played by chemotherapy-induced senescent BM-MSCs in contributing to TNBC aggressiveness.

EACR25-0873

Aldehyde metabolism as a target for metastatic melanoma

A. Roca Portoles¹, V. Cruz-Vilchez¹, N. Del Pozo-Ramos¹, R. Losada-De Paz¹, N. Legrave², A. Oudin³, D. Sumpton⁴, J. Meiser³, M. Mittelbrunn¹, E. Balsa¹

¹*Centro de Biología Molecular Severo Ochoa (CBMSO), Consejo Superior de Investigaciones Científicas (CSIC)-Universidad Autónoma de Madrid (UAM),*

²*Luxembourg Institute of Health, Metabolomics Platform, Department of Cancer Research, Luxembourg, Luxembourg*

³*Luxembourg Institute of Health, Cancer Metabolism Group, Department of Cancer Research, Luxembourg, Luxembourg*

⁴*Beatson Institute, Metabolomics Platform, Cancer Research U.K, Glasgow, United Kingdom*

Introduction

Metastasis, the primary cause of mortality in cancer patients, is particularly fatal in melanoma, which is responsible for over 70% of skin cancer-related deaths. Despite its prevalence, the molecular and metabolic mechanisms driving metastasis are not well understood. Hence, our goal is to unravel the mitochondrial metabolic factors that underline the metastatic potential of melanoma cells.

Material and method

We have optimized a metastatic melanoma model, where SK-Mel-147 human melanoma cell line, containing EGFP and luciferase are injected either subcutaneously or via tail vein into immunodeficient NSG mice. Using this model, Mel-147-GFP-LUC cells with HA-tagged mitochondria (3XHA-EGFP-OMP25 gen) primary tumors and metastases were generated. At the end of the experiment, mice were sacrificed, and primary tumors and lungs were dissected for examination of metastases (GFP+) under a fluorescence stereoscope. Then, samples were subjected to immunoprecipitation using anti-HA magnetic beads to immunocapture tagged mitochondria exclusively from human melanoma cells. After elution, mitochondrial samples were analyzed by quantitative proteomics (tandem mass tags (TMT)). Then, a curated list of candidates was generated, in the form of mitochondrial proteins. To validate our hits, we are deleting (by CRISPR/Cas9 technique) and/or over-expressing the genes corresponding to our candidates in different

melanoma cell lines. Later we have assessed the metastatic potential both in vitro (proliferation assays, migration assays...), and in vivo.

Result and discussion

Using our innovative platform, we mapped dynamic changes in the mitochondrial proteome throughout tumor progression and metastasis. Our analysis revealed a significant upregulation of aldehyde dehydrogenase 2 (ALDH2) in lung metastases compared to primary tumors and cultured cells. This heightened ALDH2 expression in metastatic cells was directly driven by the lung microenvironment. To assess its functional relevance, we engineered ALDH2 knock-out (KO) cells, revealing a marked reduction in their metastatic potential while primary tumor growth remained unaffected. This impairment may be related from the inability to detoxify reactive aldehyde species, which are particularly abundant in these organs, thereby compromising the cellular fitness of ALDH2 KO cells. Furthermore, in vivo transcriptomic analysis revealed altered immune-related gene expression profiles in ALDH2 KO cells, an effect absent in vitro. These findings underscore the critical role of the lung microenvironment in regulating ALDH2 expression and shaping immune interactions during metastatic progression.

Conclusion

Together, our findings shed light on the molecular and metabolic adaptations that metastasizing cells establish to overcome natural barriers to organ colonization. These insights reveal potential vulnerabilities that could be exploited for therapeutic intervention.

EACR25-0874

Aged-dependent metabolic reprogramming of microglia as a determinant factor in the development and progression of brain metastases

P. Castillo-Serrulla¹, M. Jaraiz², R. Losada¹, E. Balsa¹

¹*Universidad Autónoma de Madrid, Madrid, Spain*

²*Universidad de Salamanca, Salamanca, Spain*

Introduction

Brain metastasis occurs when cancer cells spread to the brain, where the immunosuppressive environment and unique metabolic demands complicate treatment. Aging exacerbates these challenges by altering the tumor microenvironment, affecting nutrient availability, inflammation, and immune function. These age-related changes can influence metastatic progression, highlighting aging as a critical but often overlooked factor in brain metastasis. A fundamental question to address is how aging impacts the metabolic fitness of immune cells and how these changes negatively affect the progression of brain metastasis. We hypothesize that the decline in immune activity during aging is caused by dysregulated metabolism. Therefore, restoring the metabolic fitness of immune cells would be highly beneficial in enhancing their ability to suppress brain metastasis.

Material and method

To further investigate this, we developed a model featuring specific ablation of mitochondrial complex III in microglia by crossing Uqcrc floxed and Tmem119-

cre/ERT2 mice (referred to as QPC KO). This model demonstrated that mice with ETC-deficient microglia developed larger brain metastases. We propose to utilize this newly generated mouse model, which mimics the effects of aging through deficient mitochondrial metabolism in microglia, to examine the role of mitochondrial metabolism in the anti-tumor function of microglia. Our aim is to elucidate how and why these processes are impaired with age.

Result and discussion

Our preliminary data, obtained from RNA-seq analysis of tumor-associated and resting microglia in young and old mice, revealed significant differences in microglial activation between the two age groups. Notably, pathways related to mitochondrial oxidative metabolism were particularly impaired with age.

Conclusion

These findings suggest that mitochondrial metabolism is crucial for microglial activation and anti-tumor function, while aging hinders these adaptive mechanisms.

EACR25-0875

The TMBIM4 Golgi Apparatus Ion Channel Supports Cancer Cell Survival by Altering Cysteine Availability

M. Martins^{1,2}, N. Almeida¹, M. Nicolai¹, G. Del Favero³, A. Fernandes¹, N. Saraiva¹

¹*CBIOS, Universidade Lusófona Research Center for Biosciences & Health Technologies, Lisboa, Portugal, Portugal*

²*Universidad de Alcalá de Henares, Alcalá de Henares, Madrid, Spain, Spain*

³*Department for Food Chemistry and Toxicology, Faculty of Chemistry and Core Facility Multimodal Imaging Faculty of Chemistry, University of Vienna, Vienna, Austria, Austria*

Introduction

Accumulated evidence implicates the Golgi apparatus (GA) in processes associated with several cancer hallmarks. The Transmembrane BAX Inhibitor Motif Containing 4 (TMBIM4) is a GA-localized calcium ion channel that regulates intracellular Ca^{2+} dynamics, inhibits apoptosis, and promotes cell motility. Although cancer cells can survive and proliferate in adverse conditions, such as nutrient-deficient environments, the contribution of the GA to this process is unclear. Here, we present a novel GA-dependent process driving cancer cell survival under starvation conditions.

Material and method

The impact of TMBIM4 on cell survival was assessed in invasive osteosarcoma U2-OS cells genetically modified to overexpress either the wild-type TMBIM4 or a TMBIM4-null mutant. To mimic a nutrient-deprived environment typical of many tumours, cells were maintained in culture at high confluence for prolonged periods without media replacement. Flow cytometry was used to evaluate intracellular reactive oxygen species levels, cell survival, death, and proliferation, while oxidative damage and lipid peroxidation were analysed via immunofluorescence. A genetically encoded biosensor was employed to measure the intracellular reduced/oxidised glutathione (GSH/GSSG) ratio.

Proteomic analysis under normal and prolonged culture conditions were conducted using untargeted mass spectrometry.

Result and discussion

In starvation conditions, TMBIM4 overexpression strongly enhanced cell survival. This effect was pH-dependent, occurring only at pH 7.4–7.8, aligning with the proposed pH-dependent gating mechanism of TMBIM family proteins. TMBIM4 overexpressing cells presented less lipid peroxidation and DNA damage despite having higher levels of ROS and maintained a higher GSH/GSSG ratio even in starvation conditions. Cells with higher levels of TMBIM4 displayed increased levels of the two key transsulfuration enzymes. This suggests a role for de novo synthesis of cysteine in this process, and possibly of GSH, since its synthesis is highly dependent on the availability of this amino acid. Supplementation of culture media with N-acetylcysteine or GSH ethyl ester enhanced long-term cell survival in starvation conditions. This supports the importance of cysteine and GSH availability in TMBIM4-mediated protection from cell death and provides a potential mechanism for the observed resistance to oxidative.

Conclusion

Our findings demonstrate that the GA plays a role in cancer cell metabolic adaptation, allowing cancer cells to survive even in starvation conditions. These results also highlight the importance of cysteine availability for cancer cell survival and suggest TMBIM4 and the GA as regulators of cysteine and GSH synthesis.

Role of the collagen hydroxylase LEPRE-1 in breast cancer

C. Maurizy^{1,2}, K. Shostak¹, P. Fuster Allepuz¹, L. Mouzziane^{1,3}, A. Chariot^{1,4}

¹University of Liege, Laboratory of Cancer Biology, GIGA Cancer, LIEGE, Belgium

²FNRS, Belgium

³TELEVIE, Belgium

⁴WELBIO, Wavres, Belgium

Introduction

Oncogenic enzymes upregulated in human cancers represent potential therapeutic targets. In this context, we investigated LEPRE-1, a prolyl hydroxylase whose deficiency causes Osteogenesis Imperfecta, a genetic disorder leading to bone malformations due to defective collagen hydroxylation. Our analyses reveal that LEPRE-1 is overexpressed across all breast cancer subtypes, particularly in triple-negative breast cancer (TNBC) cells as well as in MCF7 cells undergoing epithelial-to-mesenchymal transition (EMT), a key process in metastatic progression.

Material and method

LEPRE-1 expression was analyzed at both RNA and protein levels in cellular and murine models of breast cancer. We examined its expression through immunofluorescence and FACS analysis, especially in all epithelial subtypes of the murine mammary gland. Additionally, the correlation between LEPRE-1 and E-

Cadherin expression was assessed by western blot in different murine breast cancer cell lines to investigate its potential involvement in EMT. To assess the functional role of LEPRE-1 in metastatic progression, we took advantage of the highly metastatic 4T1 TNBC cell line. LEPRE-1 knockdown was performed using shRNA, followed by injection into a syngeneic mouse model to assess lung metastasis formation.

Result and discussion

Our findings show that LEPRE-1 as well as the LEPRE-1-associated protein CRTAP are enriched in basal epithelial cells of the murine mammary gland. Moreover, LEPRE-1 expression inversely correlates with E-Cadherin levels, suggesting its direct involvement in EMT. Finally, LEPRE-1 depletion in 4T1 cells significantly reduces their ability to form colonies in vitro and lung metastases in mice, highlighting its critical role in metastatic progression.

Conclusion

Our study identifies LEPRE-1 as a candidate enriched in basal cells and acting as a driver of breast cancer metastasis, potentially by promoting EMT. These findings pave the way for further investigations into molecular mechanisms through which LEPRE-1 promotes tumor progression. These studies may define LEPRE-1 as a therapeutic target to fight metastatic cancers.

Small Extracellular Vesicle-Driven Ferroptosis: A Novel Strategy to Target Therapy-Resistant Ovarian Cancer

C. Alarcón-Veleiro¹, R. Mato-Basalo¹, S. Lucio-Gallego¹, L. Berjawi¹, M. Quindos-Varela², R. Lesta-Mellid², I. Santamarina-Caínzos², M. Fraga², M. Arufe¹, J. Fañan-Labora¹

¹Universidade da Coruña, A Coruña, Spain

²CHUAC-INIBIC, A Coruña, Spain

Introduction

Epithelial ovarian cancer (EOC) is the deadliest gynecological cancer, largely due to the difficulty of early diagnosis and the eventual development of resistance to treatment. Ovarian cancer cells (OVCA) exhibit altered iron metabolism, making them susceptible to ferroptosis – a form of non-apoptotic cell death triggered by high levels of free iron. Small extracellular vesicles (sEV) play a key role in tumor communication, potentially influencing ferroptotic signaling in the tumor microenvironment (TME). However, the ability of ferroptotic OVCA-derived EV to propagate ferroptosis in a paracrine manner remains unexplored.

Material and method

To investigate ferroptosis propagation via sEV, OVCA were treated with ferroptotic modulators, and the ferroptosis phenotype was confirmed by assessing key ferroptosis markers. sEV were isolated from ferroptotic OVCA, characterized, and used to treat naïve OVCA to evaluate their ability to induce ferroptosis. Furthermore, sEV from these newly ferroptotic OVCA were collected and applied to another round of naïve OVCA to determine whether the process could be propagated further.

Result and discussion

sEV derived from ferroptotic OVCA successfully triggered ferroptosis in non-ferroptotic OVCA. Additionally, the secondary ferroptotic OVCA released sEV that continued to propagate ferroptosis. Notably, these sEV exhibited increased Fe²⁺ levels, suggesting a key role in the transmission of ferroptotic signaling.

Conclusion

This study provides evidence that ferroptotic OVCA-derived sEV can mediate the paracrine propagation of ferroptosis, potentially offering a novel therapeutic strategy for overcoming treatment-resistant ovarian cancer. Future research will focus on elucidating the molecular mechanisms underlying this process to explore its potential in clinical applications.

Molecular and Epigenetic Signatures of Senescence: Investigating Clonal Expansion and Chromatin Remodeling in HUVECs

C. Lau¹, E. Mensa², H. Dhiman¹, C. Cabanillas¹, D. Rosano¹, L. Magnani¹

¹Institute of Cancer Research, London, United Kingdom

²University of Bologna, Bologna, Italy

Introduction

Cellular senescence is a stable state of proliferation arrest that plays a dual role in aging and tumor suppression. While it prevents uncontrolled cell proliferation, it also contributes to vascular dysfunction and disease progression. Endothelial cell senescence, in particular, remains poorly understood, and its molecular drivers require further investigation. This study aims to characterize the transcriptomic and epigenetic changes associated with senescence in human umbilical vein endothelial cells (HUVECs) over multiple passages and identify pre-existing subpopulations predisposed to senescence.

Material and method

HUVECs were continuously passaged to induce replicative senescence. Barcode lineage tracing was performed to track clonal expansion over time. Morphological assessment, senescence-associated β-galactosidase (SA-β-gal) staining, and proliferation assays were conducted to confirm senescent phenotypes. Transcriptomic profiling (NanoString analysis) was used to identify gene expression changes in pathways related to cell cycle regulation, chromatin remodeling, and inflammation. Immunofluorescence staining and mass spectrometry were performed to assess epigenetic modifications, including H3K79 and H4K20 methylation, associated with senescence progression.

Result and discussion

Prolonged passaging led to morphological changes, increased SA-β-gal staining, and reduced proliferation, confirming the induction of senescence. Gene expression analysis revealed a significant downregulation of HMGB1, a chromatin-associated protein involved in DNA repair and inflammatory signaling, suggesting its role in senescence progression. Furthermore, genes associated with cell cycle arrest, innate immune signaling, and chromatin remodeling exhibited

differential regulation, reinforcing the hypothesis that endothelial senescence follows a distinct molecular trajectory. The observed epigenetic modifications, particularly in H3K79 and H4K20 methylation, suggest chromatin restructuring as a hallmark of deepening senescence. While barcode lineage tracing suggests clonal expansion, further validation is required to determine whether senescence-prone subpopulations pre-exist or emerge over time.

Conclusion

Our findings provide insights into molecular and epigenetic changes in endothelial senescence, with potential implications for vascular aging and disease progression. Future studies will investigate parallels with breast cancer dormancy, aiming to uncover shared regulatory mechanisms that may influence tumor dormancy and therapeutic resistance.

EACR25-0936

Targeting CKAP2 to boost Chemotherapy Efficacy and alleviate immunosuppressive environment in non-small cell lung cancer

S. Yeung¹, T. Law¹, J. Chen¹, A. Law¹, S. Tsui¹

¹The Chinese University of Hong Kong, School of Biomedical Sciences, Hong Kong, Hong Kong, China

Introduction

Lung adenocarcinoma (LUAD) is a leading cause of cancer-related mortality worldwide. Recent advances in multiomics and artificial intelligence have identified previously elusive molecular pathways of clinical significance. Cytoskeleton-Associated Protein 2 (CKAP2), a cytoplasmic, microtubule-associated protein regulating cell division and migration, has been linked to multiple cancers but remains poorly understood in LUAD. This study aims to elucidate the function, regulation, and therapeutic potential of CKAP2 in LUAD.

Material and method

Publicly available LUAD datasets were mined to identify genes associated with poor patient survival, and immunohistochemistry (IHC) was used to assess CKAP2 and LRRK2 expression in human lung cancer tissues. In vitro experiments employed CKAP2 siRNA or miR-497-3p mimics to evaluate cell viability (MTT), spheroid formation (high-content imaging), and invasiveness (Matrigel-coated transwells). Flow cytometry measured cytotoxicity and lipid peroxidation, while total RNA sequencing characterized transcriptomic alterations following CKAP2 depletion. A high-throughput virtual screening (HTVS) approach identified small-molecule CKAP2 inhibitors, validated via cellular thermal shift assays. In vivo tumorigenicity and metastasis were evaluated in subcutaneous and tail-vein LUAD models, with platinum-based chemotherapy. Finally, bio-electrical profiling and artificial intelligence (AI) modeling assessed the preclinical safety of these novel CKAP2 inhibitors.

Result and discussion

Through integrative bioinformatic analyses, CKAP2 emerged as a top biomarker of poor prognosis in LUAD. CKAP2 knockdown reduced LUAD cell viability and invasiveness, markedly increasing sensitivity to oxidative

stress and platinum-based agents. Transcriptomic profiling and mechanistic studies revealed that CKAP2 inhibition suppresses LRRK2/NRF2/HMOX1 signaling, thereby enhancing cytotoxicity. High-throughput virtual screening (HTVS) identified BFN2 as a novel CKAP2 inhibitor, which decreased tumor cell proliferation and invasion *in vitro*, while synergistically enhancing platinum-based chemotherapy in both subcutaneous and metastatic mouse models. Additionally, BFN2 reduced MDSC infiltration *in vivo*, suggesting an immunomodulatory effect. Finally, bio-electrical profiling and AI modeling confirmed a favorable safety and tolerability profile for BFN2.

Conclusion

Our findings underscore the pivotal role of CKAP2 in driving LUAD progression, chemoresistance, and immune evasion. By targeting CKAP2 with BFN2, we effectively inhibit tumor growth and metastasis, enhance the cytotoxic effects of conventional chemotherapy, and favorably modulate the tumor microenvironment through reduced MDSC infiltration. These results establish CKAP2 as a promising therapeutic target in LUAD and support BFN2 as a clinically safe, effective strategy for improving patient outcomes.

Regulation of Cancer Stemness by Hypoxia-Induced Metabolic Shifts and BNIP3-Driven Mitophagy in OECM-1 CSCs

C. Li¹, X. Li²

¹Graduate Institute of Biomedical Sciences, Department of Anesthesiology, Taichung City, Taiwan

²Graduate Institute of Biomedical Sciences, Taichung City, Taiwan

Introduction

Mitochondrial metabolism plays a critical role in cancer cell adaptation to hypoxia, influencing cancer stem cell (CSC) properties. Mitochondrial dynamics, including fission and fusion, regulate cellular energetics and may contribute to cancer progression. Mitophagy, a key mitochondrial quality control process, removes damaged mitochondria and protein aggregates via lysosomes, maintaining homeostasis and limiting oxidative stress. This study investigates how hypoxia-induced metabolic reprogramming and BNIP3-mediated mitophagy regulate CSC features in oral cancer OECM-1 cells.

Material and method

OECM-1 CSCs and non-CSC OECM-1 cells were exposed to hypoxia for 16 hours. Mitochondrial function was assessed using a Seahorse XF analyzer to measure oxygen consumption rate (OCR) and extracellular acidification rate (ECAR). BNIP3-driven mitophagy was examined via lentiviral-mediated siBNIP3 transfection, followed by analysis of BNIP3 expression, autophagy markers (LC3), mitochondrial respiration, and reactive oxygen species (ROS) levels.

Result and discussion

Hypoxia significantly increased basal and maximal OCR, as well as ATP production, in OECM-1 CSCs compared to non-CSC OECM-1 cells, indicating enhanced oxidative phosphorylation (OXPHOS) metabolism. ECAR was mildly elevated, suggesting a limited glycolytic contribution. Knockdown of BNIP3 in OECM-

1 CSCs reduced BNIP3 expression, suppressed autophagy, and impaired mitochondrial respiration, leading to increased mitochondrial ROS accumulation. These findings suggest that BNIP3-driven mitophagy supports mitochondrial metabolic adaptation in hypoxia-treated CSCs.

Conclusion

Hypoxia-induced mitochondrial metabolic reprogramming and BNIP3-mediated mitophagy are key regulators of CSC properties in OECM-1 cells. Targeting these pathways may offer potential therapeutic strategies for oral cancer by disrupting the metabolic adaptability of CSCs under hypoxic conditions.

EACR25-0947

Triple-negative breast cancer cell survival strategies under acute and chronic hypoxia

O. Rogoza¹, I. Mitre¹, V. Pirsko¹, I. Cakstina-Dzerve¹

¹Riga Stradiņš University Science Hub, Institute of Microbiology and Virology, Riga, Latvia

Introduction

Triple-negative breast cancer (TNBC) is a particularly notable breast cancer subtype due to its aggressive, heterogeneous, and refractory nature, along with limited treatment options, posing a significant challenge to clinical management. One of the hallmarks of many cancers, including TNBC, is resistance to apoptosis, which can occur through the downregulation or inhibition of pro-apoptotic proteins or the upregulation of anti-apoptotic proteins. Hypoxia, a common feature of solid tumours, has been linked to increased invasiveness, malignant progression, and death evasion mechanisms that contribute to therapy resistance. The severity and duration of hypoxia define the response and, thus, the subsequent signalling mechanisms initiated by the cancer cells. Here, we explore the induction of apoptotic priming and apoptotic dependencies in TNBC cell lines under physoxia, acute and chronic hypoxia.

Material and method

Apoptotic priming is defined as the threshold at which a cell can commit to apoptosis. The baseline BH3 (bBH3) profiling assay, utilising BH3-only sensitizer peptides, determines whether a cell relies on one or more anti-apoptotic Bcl-2 family proteins for survival by targeting and inhibiting specific anti-apoptotic proteins. Apoptotic priming and anti-apoptotic protein dependencies in TNBC cell lines were assessed using image-based bBH3 profiling under physoxia (8% O₂), acute (2% O₂, 24h) and chronic (2% O₂, 72h) hypoxia.

Result and discussion

Preliminary findings indicate that each TNBC cell line exhibits unique dependencies on anti-apoptotic proteins, highlighting heterogeneity and underlining the diverse survival strategies that cells employ. Assessment of these dependencies could provide a foundation for developing more tailored strategies to target TNBC cells.

Conclusion

Baseline BH3 profiling enables the identification of apoptotic dependencies in TNBC cells that could be targeted through the application of BH3 mimetics as a combination therapy.

EACR25-0965**Metabolic rewiring in the therapy-induced secretome facilitate glioblastoma resistance to radiotherapy**J. Poh¹, H. Hoi¹, C. Koh¹¹Nanyang Technological University, School of Biological Sciences, Singapore, Singapore**Introduction**

The heterogeneous nature of glioblastoma (GBM) contributes to its poor prognosis and high recurrence rates. Adaptive radioresistance, driven by complex intratumoral communication, plays a critical role in treatment failure. Following radiotherapy, therapy-stressed cells secrete factors that shape the tumor microenvironment, thereby influencing therapeutic response. However, the molecular composition and functional consequences of these secretions remains poorly understood, particularly with regards to GBM radioresistance. In this study, we aimed to characterize the molecular composition of the therapy-induced secretome, providing insight into potential vulnerabilities that can be exploited for improved therapeutic intervention.

Material and method

Proteomic profiling was performed on conditioned media from irradiated GBM cells of distinct tumor subtypes using LC-MS/MS. Bioinformatics and proteomic enrichment analysis was conducted to identify the key enriched biological processes pertaining to the therapy-induced secretome. Functional assays then examined the impact of these secretions on tumor subtype response to radiotherapy.

Result and discussion

Proteomic analysis of the therapy-induced secretome revealed a metabolic shift in the mesenchymal GBM subtype. The apparent enrichment of metabolic enzymes and intermediates associated with glycolysis, pentose phosphate pathway, and nucleotide biosynthesis reflect metabolic rewiring post-radiotherapy, which are key adaptive responses that can play pivotal roles in shaping therapeutic response. Notably, some of the identified glycolytic enzymes have extracellular functions that can promote tumor proliferation and DNA repair, providing survival advantages post-radiotherapy. Furthermore, the upregulation of nucleotide biosynthesis processes is a crucial factor for DNA repair following radiotherapy-induced DNA damage. The pentose phosphate pathway also emerged as a critical metabolic node, balancing glycolytic flux and nucleotide production. These findings collectively suggest that metabolic rewiring within the therapy-induced secretome sustains both energy demands and DNA repair capacity, ultimately enhancing resistance to radiotherapy.

Conclusion

This study highlights the role of metabolic adaptations that reinforce radiotherapeutic resistance. The secretion of metabolic enzymes and intermediates not only sustains tumor cell survival under stress but also modulates the metabolic landscape to promote adaptive resistance. These findings emphasize the need for integrative treatment strategies targeting both metabolic and pro-survival pathways to overcome tumor resistance in GBM.

EACR25-0981**Inhibition of arginase-2 differentially affects cell proliferation in breast cancer cell lines representing different clinical subtypes in vitro**A. Röglind¹, P. Zoroofchi¹, F. Kleinsang¹, V. Osterhage¹, R. Böger¹, J. Hannemann¹¹Institute of Clinical Pharmacology and Toxicology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany**Introduction**

Arginases (ARGs) are enzymes that convert L-arginine into L-ornithine. ARG1 forms part of the urea cycle, whilst the mitochondrial ARG2 is part of a pathway leading to synthesis of polyamines, which are involved in the regulation of cell proliferation. The relationship between ARGs and cell proliferation in the different subtypes of breast cancer has not yet been clarified. Therefore, we aimed to study the effect of ARG inhibition on cell proliferation in breast cancer cell lines representing different clinical subtypes.

Material and method

Five breast cancer cell lines (MCF-7, BT-474, SK-BR-3, MDA-MB-468, MDA-MB-231), representing hormone receptor-positive (HR+), HER2-positive and triple-negative breast cancer, were compared to MCF-12A cells representing normal breast epithelial cells. Pharmacological inhibition of ARG was performed with 1 mM 2-(S)-amino-6-boronohexanoic acid (ABH) for 72 h in medium containing a physiological L-arginine concentration (100 µM). For siRNA-mediated knockdown of ARG2 mRNA expression, cells were transiently transfected with a specific siRNA and harvested after 72 hours. To confirm success of inhibition and knockdown, respectively, qRT-PCR, Western Blotting, and a photometric enzyme activity assay were used. Proliferation was analysed by a) assessment of cell counts, b) mitotic index in H&E-stained cytopsins, and c) immunofluorescent staining of Ki-67 antigen.

Result and discussion

Baseline ARG2 expression and ARG activity greatly varied between cell lines; ARG1 was not expressed in any of the cell lines. ARG2 knockdown significantly reduced ARG2 mRNA and protein expression in all cell lines. However, in MCF-7 and BT-474 cells, ARG2 knockdown did not significantly reduce cell count, mitotic index, and KI-67 staining. By contrast, ARG2 knockdown caused reductions in mitotic index (-16% and -31%, respectively) and KI-67 staining (-72% and -33%, respectively) in both triple-negative cell lines, MDA-MB-468 and MDA-MB-231, which was consistent with MCF-12A cells. Pharmacological inhibition of ARG confirmed reduction in cell proliferation in triple-negative cell lines (mitotic index, MDA-MB-468: -47%; MDA-MB-231: -30%; both $p < 0.05$).

Conclusion

Our results show a differential pattern in the response of breast cancer cell lines to ARG2 knockdown. The HR+ cell lines MCF-7 and BT-474 showed unchanged or increased proliferation and the HER2-positive cell line SK-BR-3 showed variable results, whereas in the triple

negative cell lines proliferation was significantly and consistently reduced; this was comparable to MCF-12A cells. Thus, arginase inhibition may be an additional treatment option in triple-negative breast cancer, but it might be futile in HER2-positive and detrimental in HR+ breast cancer subtypes.

EACR25-0999

Macrophages stimulate glioblastoma motility and invasion through paracrine signaling leading to the regulation of Rho GTPases

M. El Sibai¹

¹Lebanese American University, Biological Sciences, Beirut, Lebanon

Introduction

Glioblastoma multiforme (GBM) is one of the most common and deadliest primary malignant cancers of the central nervous system. The main challenge in treating GBM remains their high ability to infiltrate healthy brain tissues. GBM growth and invasion can be modulated by communication between tumor cells and their microenvironment. Microglia and infiltrating macrophages constitute up to one third of GBM tumors. We thus investigated the mechanisms by which macrophages stimulate GBM cell invasion.

Material and method

U-87 MG and T98G astrocytoma cells were cultured with or without activated M1-type THP-1 macrophages or with activated THP-1 conditioned media (CM). Astrocytoma cell migration was measured through live random cell migration assays. Cells were also stained with Rhodamin Phalloidin to observe actin structures. We also examined the activation status of the actin regulators RhoA and Cdc42 via pull down assay and using Förster resonance energy transfer (FRET) biosensors to image the localization of their activation.

Result and discussion

We first examined the effects of activated M1-type THP-1 macrophages paracrine signaling on cell motility and adhesion of U-87 MG and T98G cancer cells. Time lapse analysis results showed that co-culturing cancer cells with activated THP-1 led to a significant increase in 2D cell motility (40%). We also observed a decrease in adhesion to collagen in astrocytoma cells treated with activated THP-1 conditioned media (CM), as compared to the control. Interestingly, the CM induced morphological changes in both cancer cell lines including the formation of membrane protrusions and membrane ruffles as well as an increase in cell-cell connecting tunnel-like structures. In addition, cells co-cultured with the activated THP-1 cells showed an increase in invasion as well as an increase in invadopodia structures that stained for TKS-4 and TKS-5 in immunostaining. Further analysis by pull down assay and using FRET biosensors showed an increase in the activation of Cdc42 and RhoA in the GBM cancer cells in response to treatment with CM.

Conclusion

Altogether the data indicate that M1-type activated macrophages stimulate GBM motility and invasion in a paracrine manner by upregulating key structures involved

in cell motility and invasion. Further work is still warranted to determine the molecular targets implicated in the macrophages-GBM paracrine signaling.

EACR25-1006

Colon cancer cells metabolic plasticity: oxidative metabolism helps cancer cells to survive under glucose-deprivation

S. Das¹, B. Levi¹, I. Komar¹, E. Nesher¹

¹Ariel University, Molecular Biology, Ariel, Israel

Introduction

Colon cancer cells exhibit metabolic plasticity, surviving glucose deprivation by shifting to oxidative metabolism, but the mechanisms underlying this adaptation remain poorly understood. This study aims to elucidate the metabolic adaptations facilitating the survival and proliferation of colon cancer cells under glucose-deprived conditions, with a particular focus on the transition to a glucose-deprivation resistant (GDR) state and the role of oxidative metabolism.

Material and method

To induce metabolic stress the colon cancer cells were cultured under glucose-deprived conditions. Metabolic adaptations were analyzed using Seahorse XF approach to measure glycolytic and oxidative phosphorylation (OXPHOS) activities. LC-MS based metabolomics was employed to profile tricarboxylic acid (TCA) cycle and one-carbon metabolism related metabolites.

Result and discussion

We found that glucose deprivation induced cell death and adaptive dormancy in selected colon cancer cells. Within this dormancy, the survived cells shifted their metabolism from glycolysis to OXPHOS. Lactate levels transiently increased during dormancy were significantly decreased when proliferation resumed in the GDR state. LC-MS metabolomics revealed significant activation of the TCA cycle, underscoring enhanced dependence on OXPHOS for ATP production. An increased ROS levels found in dormant cells, accompanied by massive DNA damage were eliminated in GDR cells through enhanced antioxidant defenses and upregulated DNA repair mechanisms, facilitating sustained proliferation with reduced apoptosis. Furthermore, the oxidative stress tolerance and glycolysis-independent proliferative capacity of GDR cells was confirmed by hydrogen peroxide (H₂O₂) and 2-Deoxy-D-Glucose (2-DG) treatment respectively. The acceleration of the one-carbon metabolism supporting redox homeostasis and associated with elevated levels of metabolites including methionine, folate, glutamine, pyridoxine, glycine, fumarate, cystine, and taurine was also observed.

Conclusion

This study reveals the remarkable metabolic flexibility of colon cancer cells in response to glucose deprivation. The transition to the GDR cells to OXPHOS along with the activation of one-carbon metabolism, supports energy production and redox balance. These adaptations enable the GDR cells to withstand oxidative stress through robust antioxidant systems and efficient DNA repair, highlighting potential vulnerabilities for therapeutic intervention. We believe that targeting these adaptive mechanisms may help overcome glucose deprivation resistance in colon cancer.

EACR25-1007**PD-L1 expression is essential for EGFR signaling- and fatty acid-enhanced metastasis in head and neck cancer***J. Chiou¹, W. Chang¹, B. Chen²*¹*Taipei Medical University, Graduate Institute of Medical Science, College of Medicine, Taipei, Taiwan*²*National Cheng Kung University, Department of Pharmacology, College of Medicine, Tainan, Taiwan***Introduction**

Recent research has illuminated the significant role of tumor-intrinsic programmed cell death ligand 1 (PD-L1) regulates tumor progression independently of the immune system. For immunotherapy and targeted therapy, PD-L1 expression is related to the tumor response and overall survival of head and neck squamous cell carcinoma (HNSCC) patients during anti-PD-1/PD-L1 immunotherapy. However, its effect on EGF-mediated metastasis and chemotherapy in HNSCC under lipid-enriched conditions remains unclear.

Material and method

Investigating the impact of ANGPTL4, PTX3, and PD-L1 on HNSCC progression, we analyzed the gene expression signatures in four phenotypic classes of HNSCC (atypical, basal, classical, and mesenchymal), as analyzed through the Gene Expression Profiling Interactive Analysis version 2 (GEPIA2) database. To clarify the molecular mechanism regulating PD-L1 expression in EGF-treated cells, inhibitors of MAPK/ERK and NF-κB were used, followed by examining mRNA, protein, and promoter activity of PD-L1. The metastatic regulators, such as epithelial-mesenchymal transition (EMT) markers, ANGPTL4, and PTX3, were also examined in cells. The in vitro trans-well migration and invasion assays and in vivo extravasation assay were applied to study the role of PD-L1 in HNSCC metastasis. The apoptotic and spheroid formation assays were used to further study the impact of gefitinib and PD-L1 on the cell viability in cisplatin-treated HNSCC cells.

Result and discussion

Our study showed a significant increase in PD-L1 expression in EGF-treated HNSCC cell lines. We determined that EGF-induced transcriptional activation of PD-L1 relies on ERK and NF-κB activation and ANGPTL4 expression. Importantly, depleting PD-L1 reduced EGF-induced expression of EMT markers, resulting in inhibition of migration, invasion, and anoikis resistance. Moreover, the enhancement of EGF-induced anoikis resistance and metastasis by oleic acid (OA) was diminished in PD-L1-knockdown cells. The combination of EGF and OA (EGF/OA)-induced cell metastasis and anoikis resistance were disrupted when treated with gefitinib. Although the EGF/OA attenuated cisplatin-induced apoptosis, only gefitinib, but not PD-L1 knockdown, restored sensitivity to cisplatin treatment. These findings suggest that intrinsic PD-L1 is essential for EGF- and lipid-induced cell metastasis but is not correlated to chemoresistance.

Conclusion

Targeting both EGFR and PD-L1 may provide a promising therapeutic strategy for managing metastatic

HNSCC with cisplatin resistance and dysregulated lipid metabolism.

EACR25-1020**OXPHOS targeting of MYCN-amplified neuroblastoma***S. Epp¹, D. Egan¹, K. Wynne², E. Poon³, J. Simpson⁴, M. Halasz¹, W. Kolch¹*¹*Systems Biology Ireland, Dublin, Ireland*²*Conway Institute, Dublin, Ireland*³*Institute of Cancer Research, Sutton, United Kingdom*⁴*Cell Screening Laboratory, Dublin, Ireland***Introduction**

Half of High-Risk Neuroblastomas (HR-NB) are driven by MYCN gene amplification (MNA). These HR-NBs require high dosage chemotherapy and often relapse. Moreover, current therapies can cause severe long-term side effects in young cancer patients. As MYCN, like many transcription factors, is considered undruggable, there is an urgent need for new therapies. Although precision therapy for individual patients remains limited, combination therapy presents an immediate solution at the level of patient population to reduce reliance on highly toxic chemotherapy. This study investigates a novel therapeutic approach targeting the metabolic vulnerabilities of MNA NB cells, which are found reliant on mitochondrial respiration for survival.

Material and method

MNA cell lines and 2D spheres derived from a MYCN-driven NB mouse model were employed as experimental systems. Phosphoproteomics and proteomics analyses were performed using LC-MS/MS, and confocal microscopy was used for imaging. Cell death, cell viability, neuronal differentiation, and ROS production were assessed using standard assays. Synergy models were applied to evaluate drug interactions.

Result and discussion

Preliminary data has identified Diphenyleneiodonium chloride (DPI) as a MYCN-selective anti-proliferative compound through a high-throughput screen on NB cell lines. DPI was found to induce MNA NB cell differentiation, and trigger apoptosis through cytochrome c release and caspase 9 activation. Additionally, DPI significantly reduced tumor size and the number of micrometastases in a transgenic zebrafish model of MYCN-driven NB, without apparent toxicity. We discovered that DPI synergizes with mitoquinone mesylate (MitoQ), a mitochondria-targeted antioxidant in 2D and 3D in vitro models of NB. Similarly to DPI, MitoQ affects MNA cells in a MYCN-dependent way, being more toxic when MYCN levels are high. Furthermore, low nanomolar concentrations of MitoQ significantly decrease MYCN protein expression and induce differentiation of MNA cells. The DPI and MitoQ combination further synergizes with vincristine, a chemotherapeutic agent used in NB treatment. Phosphoproteomics and proteomics analysis suggests that the drug combination induces MNA NB cell death by arresting the cell cycle and inhibiting oxidative phosphorylation (OXPHOS) in the mitochondria.

Conclusion

Thus, interfering with mitochondrial metabolism may serve as an effective strategy to enhance the activity of chemotherapeutic drugs while reducing the required concentrations in MNA-NB.

EACR25-1030

Targeting cell cycle vulnerabilities and signalling rewiring in p53 deficient cancers

I. Titkova¹, T. Soliman¹

¹Barts Cancer Institute, Queen Mary University of London, Centre for Cancer Evolution, London, United Kingdom

Introduction

TP53 is the most frequently mutated gene in human cancers, linked to genomic instability and poor patient outcomes. Targeting mutant p53 remains a major challenge. Our lab identified that TP53 mutation is essential for a defective G2/M checkpoint, which we call the Topo2A-dependent G2 checkpoint. This checkpoint functions independently of the DNA damage checkpoint and prevents premature mitotic entry in the presence of DNA catenanes. Without it, cells must engage a mitotic failsafe pathway to delay mitosis, allowing for resolution of DNA catenanes. This study explores how p53 dysregulation leads to Topo2A-dependent G2 checkpoint loss and aims to define the molecular requirements of the mitotic failsafe pathway to uncover novel therapeutic targets.

Material and method

We have assessed the competency of the Topo2A-dependent G2 checkpoint in a diverse panel of cancer cell lines, including HGSOC, NSCLC, TNBC, and colorectal carcinoma, alongside non-transformed RPE1 and FNE1. To examine the requirement for p53 pathway dysregulation in Topo2A-dependent G2 checkpoint loss, we used siRNA knockdown and inhibitors in cancer and non-cancerous cells. Additionally, a candidate-based drug screen identified potential synthetic lethal targets in cells with an active mitotic failsafe pathway.

Result and discussion

We have shown that a panel of TP53-deficient cancer cell lines have a defective Topo2A-dependent G2 checkpoint. To elucidate key regulators of this checkpoint, we used a panel of siRNAs targeting TP53, ATM, ATR and CHEK2 in the non-transformed RPE1 cell line to assess checkpoint competency after Topo2 inhibition with ICRF-193 to induce DNA catenation. Our screen revealed TP53 siRNA leads to loss of checkpoint and further studies are underway to determine the other molecular requirements. To explore the potential for therapeutic of targeting the mitotic failsafe pathway, we conducted a preliminary small molecule inhibitor screen focusing on proteins involved in either the G2 checkpoint or mitosis. Using this candidate-based approach, we observed synthetic lethality in the HGSOC cell lines, Kuramochi, upon combined inhibition of Topo2 (ICRF-193) and selected mitotic kinases. Importantly, ICRF-193 induced G2 arrest in RPE1 and FNE1 cells, suggesting a protective effect, as the combination of inhibitors had no deleterious effect on these non-cancerous cells.

Conclusion

A defective Topo2a-dependent G2 checkpoint creates a tumor-specific vulnerability, potentially a fundamental weakness of TP53-deficient cancers. This provides a therapeutic window where Topo2 inhibition protects normal cells while priming cancer cells for mitotic failsafe pathway activation which can then be targeted.

GATA4 drives metaplasia and cancer initiation from foregut keratinocytes in vivo

A. Vercauteren Drubbel¹, B. Beck¹

¹Université Libre de Bruxelles, IRIBHM, Bruxelles, Belgium

Introduction

Barrett's Esophagus (BE) is a metaplasia in which the squamous epithelium of the esophagus is replaced by columnar epithelium due to chronic gastroesophageal reflux. Esophageal metaplasia is a major risk factor for adenocarcinoma (EAC) and adenosquamous carcinoma (ASC), both of which have poor prognoses. Although the cell of origin remains a topic of long-standing debate, it is tempting to speculate that more than one cellular origin may exist in the initiation of BE. Notably, the contribution of keratinocytes at the squamo-columnar junction (SCJ) to BE-like metaplasia through trans-differentiation was unambiguously demonstrated a few years ago. On the other hand, keratinocytes distant from the junction seem to be more resistant to cell fate rewiring. We revealed previously that reactivation of the hedgehog (HH) pathway in esophageal cells due to chronic acid reflux induces the dedifferentiation of esophageal cells into embryonic-like progenitors in vivo but is not sufficient to trigger the development of specialized metaplasia. Interestingly, foregut embryonic progenitors are bipotent and can give rise to either squamous or columnar epithelium depending on the expression of certain transcription factors such as GATA4. We therefore hypothesized that esophageal keratinocytes initially lack cell plasticity but that embryonic-like cells could be reprogrammed into a gastric lineage, thereby serving as a cellular reservoir for specialized metaplasia.

Material and method

We analyzed copy number variations in human EAC and developed a new transgenic mouse model mirroring EAC-associated gene amplification in esophageal epithelium. Through lineage tracing, histology, and single cell RNA sequencing, we characterized esophageal cells fate in vivo.

Result and discussion

During foregut development, GATA4 is crucial for gastric lineage specification. Intriguingly, while it is absent from normal esophagus, we found that it emerges as one of the most frequently amplified genes in EAC and is overexpressed in human BE. Thus, GATA4 could be a driver of cell reprogramming. Our results show that GATA4 overexpression in keratinocytes induces gastric-like metaplasia preferentially at SCJ. Strikingly, if HH pathway is activated first, GATA4 expression leads to the formation of specialized metaplasia and even ASC-like tumors over large regions of the foregut, suggesting a greater potential to initiate cancer. Single cell RNA

sequencing allowed to follow the transcriptomic trajectory between esophageal progenitors and metaplastic cells. It will be used to study metaplasia-to-cancer transition. Our study demonstrates that the HH pathway stimulates keratinocytes' plasticity and makes them competent to transdifferentiate into gastric-like metaplasia and initiate ASC-like tumors.

Conclusion

In conclusion, our study shows that esophageal cell plasticity can be modulated and that a fraction of BE and ASC may originate from squamous progenitors.

Introduction

In vitro starvation (STV) and in vivo fasting and fasting-mimicking diets (FMDs) have been shown to slow tumor progression and extend survival in tumor-bearing mice. However, they do not achieve complete tumor eradication when used alone. Data from clinical trials conducted by our group in breast cancer patients demonstrate that tumors exposed to FMD upregulate Fatty Acid Oxidation (FAO). Here, we investigated whether FAO is a resistance mechanism that is activated by cancer cells to acquire resistance to fasting/FMD.

Material and method

We investigated the effects of FAO in combination with STV conditions on the proliferation and survival of human or murine cell lines of Triple Negative Breast Cancer (TNBC) ($n = 16$), HR+HER2- breast cancer ($n = 3$), colorectal ($n = 1$), pancreatic ($n = 1$) and lung cancer ($n = 1$), as well as of non-transformed human epithelial cells ($n = 3$). STV consisted of 50% reduction of extracellular glucose and serum in cell growth media. To inhibit FAO, we used the Carnitine Palmitoyl transferase 1 inhibitors etomoxir or ST1326. To confirm in vitro results in vivo, we used mouse transplants of human MDA-MB-231/SUM159PT and murine 4T1 cells injected in the mammary fat pad of female NOD/SCID and BALB/c mice, respectively. Mice were treated with every-24-hour intermittent fasting (IF), alone or in combination with etomoxir; we assessed the impact of these treatment in primary tumor growth and animal survival.

Result and discussion

STV and FAO produced cooperative or synergistic antiproliferative effects in all investigated tumor cell models, but not in normal cells. In all mouse models, combining IF and etomoxir resulted in cooperative delay of primary tumor growth and in significant animal survival prolongation. Data from bulk RNA-seq analysis, performed in tumor masses collected at the end of fasting in NSG mice injected with MDA-MB-231 or SUM159PT cells, revealed that the combination of IF and etomoxir resulted in an enrichment of several signatures related to

immune processes, such as antigen processing and presentation, paralleled by a depletion of signatures related to DNA repair and several metabolic processes, such as oxidative phosphorylation and amino acid metabolism. We confirmed the mechanistic relevance of these biological processes in mediating the antitumor activity of the starvation-FAO combination through targeted in vitro experiments.

Conclusion

FAO is a potential resistance mechanism to nutrient starvation. Combining FAO with in vitro or in vivo starvation conditions results in cooperative antitumor effects that are mediated through the modulation of DNA repair and amino acid pathways. Our findings pave the way for conducting clinical trials to combine nutrient starvation approaches, such as FMD, with the modulation of FAO in combination with standard pharmacologic treatments.

PSRC1 promotes oncogenic dedifferentiation in TP53-mutated hepatocellular carcinoma

J. Yuan¹, H. Yu¹, I. Huang¹, K. Ng¹, U. Lou¹, J. Yun², T. Wong^{1,3}, S. Ma^{1,3}

¹The University of Hong Kong, School of Biomedical Sciences, Hong Kong, Hong Kong, China

²Sun Yat-Sen University Cancer Centre, Department of Pathology, Guangzhou, China

³The University of Hong Kong, State Key Laboratory of Liver Research, Hong Kong, Hong Kong, China

Introduction

The tumor suppressor TP53 is critical in maintaining cellular self-renewal and differentiation in various human cancers and ranks as the most common driver mutation type in hepatocellular carcinoma (HCC). However, the mechanisms underlying the interplay between TP53 and stemness in HCC remain unclear. Herein, we identified proline and serine-rich coiled-coil 1 (PSRC1) as a critical player in promoting oncogenic stemness and dedifferentiation in TP53-mutated HCC.

Material and method

Human HCC cell lines, preclinical sporadic HCC tumor models, and tissues of patients with HCC were used to assess the role of PSRC1 in driving HCC stemness and dedifferentiation in a TP53 context.

Result and discussion

PSRC1 is significantly upregulated in TP53-mutated HCC and correlated with aggressive clinical features, including survival, tumor stage, metastasis risk, tumor size, and stemness signatures. Functionally, PSRC1 promotes tumor initiation, self-renewal, and metastasis as demonstrated in both in vitro and in vivo models. Mechanistically, wild-type TP53 is identified as an upstream repressor of PSRC1, while activation of the Notch signaling cascade was found as a downstream mediator of PSRC1's oncogenic activities.

Conclusion

Our findings highlight the critical role of PSRC1 in TP53-mutated HCC progression, particularly in promoting oncogenic stemness, dedifferentiation, and metastasis. PSRC1-induced tumor lineage plasticity may

represent an Achilles heel for TP53-mutated HCC. Inhibition of PSRC1 may represent a novel treatment opportunity in the clinic.

Activation of the p38/AP-1 Signaling Pathway by PFKFB4 Promotes ANXA2 Expression and Osteosarcoma Metastasis

Y. Jia-Sin¹, Y. Shun-Fa²

¹*Chung Shan Medical University Hospital, Department of Medical Research, Taichung City, Taiwan*

²*Chung Shan Medical University, Institute of Medicine, Taichung City, Taiwan*

Introduction

Osteosarcoma, the most prevalent primary bone malignancy, is responsible for the majority of bone cancer-associated deaths due to its high metastatic potential. The bifunctional enzyme PFKFB4 (6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase-4) is induced by hypoxia and is strongly associated with glycolysis. PFKFB4 is highly expressed in various types of cancer and is essential for tumor survival. Over the past decades, extensive efforts have been made to elucidate the role of PFKFB4 in tumor progression. However, its effects on the metastasis of osteosarcoma cell lines remain unclear. Therefore, we investigated the role of PFKFB4 in the invasion and migration of human osteosarcoma cells, as well as the underlying molecular mechanisms.

Material and method

We conducted reverse transcription-polymerase chain reaction (RT-PCR), real-time PCR, Western blot, Boyden chamber assay, flow cytometry, luciferase reporter assay, and RNA sequencing to investigate human osteosarcoma cell lines.

Result and discussion

In this study, we compared the mRNA and protein expression levels of PFKFB4 in four osteosarcoma cell lines (HOS, MG63, Saos2, and U2OS). We established PFKFB4 siRNA systems and found that the invasion and migration abilities were dramatically decreased in Saos2/PFKFB4 siRNA and U2OS/PFKFB4 siRNA cells. Using Illumina RNA sequencing workflows, we also found that PFKFB4 knockdown reduced ANXA2 expression. After ANXA2 knockdown, the invasive and migratory abilities of Saos2 and U2OS cells were significantly reduced. In addition, PFKFB4 knockdown decreased ANXA2 promoter activity, c-Jun and c-Fos nuclear protein levels, and phospho-p38 signaling protein levels. Moreover, overexpression of p38 rescued the PFKFB4 knockdown-induced inhibition of ANXA2 expression and cell motility in U2OS cells. Furthermore, overexpression of PFKFB4 rescued the PFKFB4 knockdown-induced inhibition of phospho-p38, ANXA2 expression, and cell motility in U2OS cells.

Conclusion

According to the results, PFKFB4 induces ANXA2 expression via phosphorylation of the p38 signaling pathway, facilitating the nuclear translocation of c-Jun and c-Fos, which bind to the AP-1 site on the ANXA2 promoter and consequently promote osteosarcoma cell metastasis.

Interconnections among MET tyrosine kinase receptor, NMDAR, glutamine metabolism, and stress response in cancer progression

S. Gallo^{1,2}, C. Folco^{1,2}, G. Di Palma^{1,2}, S. Fontana¹, D. Ricupero², A. Vitacolonna^{1,2}, C. Riganti¹, T. Crepaldi^{1,2}

¹*University of Turin, Department of Oncology, Orbassano, Turin, Italy*

²*Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Turin, Italy*

Introduction

The MET oncogene encodes a tyrosine kinase receptor for the hepatocyte growth factor (HGF) with pleiotropic functions in cancer onset and progression. Fast tumor growth and survival under adverse conditions are stimulated by glutamate, generated through glutamine metabolism, a process known as “glutamine addiction”. Additionally, stress response mechanisms, like the integrated stress response (ISR) signaling and endoplasmic reticulum (ER) stress pathway, are crucial in cancer pathogenesis. Glutamine deprivation activates ISR mediators that supports cell survival and homeostasis, but severe or prolonged stress shifts them toward apoptosis regulation. While these processes are studied individually, their integration is less understood. In this study we hypothesize that MET can protect cancer cells from stress-dependent cell death by interacting with N-methyl-D-aspartate receptor for glutamate (NMDAR) and stimulating glutamine metabolism.

Material and method

Warburg effect and glutaminolysis were analysed by enzymatic assay in various breast and colon cancer cell lines. To evaluate the metabolic role of MET-NMDAR crosstalk a metabolomic analyses was conducted and explored using computational models. To evaluate the involvement of MET, glutamine metabolism, and NMDAR in cancer invasive program, specific inhibitors and molecular analyses were also exploited.

Result and discussion

MET activation in cancer cell lines facilitates the Warburg effect and glutaminolysis. Importantly, we found that NMDAR is involved in this MET-mediated metabolic rewiring. LC-MS/MS metabolomic analysis showed increased metabolic consumption in HGF-treated cancer cells, returning to basal levels after MET-specific inhibition. Interestingly, glutamate is among the most expressed metabolites after HGF treatment. Bio-informatic analysis of the metabolomic evaluations highlighted that HGF treatment enhances specific metabolic pathways: biosynthesis of amino acids and lipids, glutamate metabolism, TCA (tricarboxylic acid) cycle, and glutathione metabolism. Interestingly, glutamine deprivation or glutaminase inhibition induce: i) apoptotic cell death, ii) phosphorylation of eIF2α, marker of ISR stress response, and iii) counteraction of HGF-driven migratory and invasive cancer program. Accordingly, HGF treatment reduces apoptosis and ISR activation in both pro-death treatments.

Conclusion

In this study we demonstrate that MET, NMDAR, glutamine metabolism, and ISR intersections are involved in cancer progression. MET can regulate glutamine metabolism by interaction with NMDAR and protect cancer cells from stress-dependent cell death mechanisms. These results pave the way for future development of novel combinatory therapeutic approach for cancer patients.

⁴*Italian Institute for Genomic Medicine (IIGM), Turin, Italy*

⁵*University of Turin, Department of Computer Science, Turin, Italy*

Introduction

MET, the receptor of the natural ligand Hepatocyte Growth Factor (HGF), is a proto-oncogene well-known for its role in cancer cell invasion. However, the mechanisms underlying these HGF-induced pro-invasive features are still unclear. Recently, we demonstrated that MET physically interacts with the N-methyl-D-aspartate receptor (NMDAR), a glutamate-gated ion channel known for its role in synaptic transmission encoded by GRIN genes. Indeed, we observe that MET and NMDAR cooperate in the invasion program of Triple Negative Breast Cancer. In this study, we address the role of MET/NMDAR interaction in colorectal cancer (CRC).

Material and method

Different immunoassays such as proximity ligation assay and co-immunoprecipitation were exploited to evaluate physical association between MET and NMDAR receptors in different CRC *in vitro* models. To understand the biological role of this crosstalk in the HGF-driven invasive program, matrigel invasion and wound healing assays were performed in presence of two specific NMDAR (MK801 and Ifenprodil) and MET (JNJ-38877605) inhibitors. Moreover, we performed a RNA sequencing analysis on adenoma and CRC tissues in order to highlight differentially expressed genes in CRC in comparison with the adjacent tissue.

Result and discussion

Our results confirmed that MET and NMDAR receptors are physically associated in a subset of CRC models. Moreover, the inhibition of NMDAR impaired the HGF-driven invasion and migration in CRC models positive for MET/NMDAR complex, acting synergistically with MET receptor inhibition. In the context of HGF-driven invasion, those models lacking MET/NMDAR crosstalk showed no response upon NMDAR inhibition. Finally, RNA sequencing data of adenoma and CRC tissues highlighted, compared to the adjacent colonic tissues, a

significant upregulation of MET, GRIN2B, and GRIN2D expression, a finding corroborated by the analysis on TCGA database. Interestingly, clustering analysis associated Consensus Molecular Subtype (CMS) 1 and 2 or Adenomatous Polyposis Coli (APC) mutations to high expression of MET and GRIN genes.

Conclusion

Overall, these data emphasize that MET/NMDAR cross-talk is involved in the CRC invasive program, suggesting that a combinatorial therapy targeting this complex may be exploited as a new therapeutic strategy.

EACR25-1111

Characterizing the partial epithelial-mesenchymal transition and invasion in a colorectal cancer *in vitro* model

Z. Wiener¹, A. Orosz¹, S. Hajdó¹, I. Carmi¹, A. Zeöld¹

¹*Semmelweis University, Department of Genetics, Cell and Immunobiology, Budapest, Hungary*

Introduction

The high-plasticity states of tumor cells lead to drastic phenotypic changes, such as epithelial-mesenchymal transition (EMT), enabling high invasive and metastatic potential. Tumor cells may occupy a spectrum along an epithelial-mesenchymal axis, where the two ends are mixed by a hybrid partial EMT (pEMT) state. Colorectal cancer (CRC) is the second-third leading cause of cancer-related death. Gene expression-based CRC clustering identified a group (CMS4) with EMT, fibroblast (CAF) accumulation, invasion, and decreased survival, representing an aggressive subtype with high plasticity and no effective treatment. In this work, we aimed at characterizing pEMT by using the organoid technology and co-cultures. Patient-derived organoids (PDO) maintain the cellular heterogeneity of the original tissue, representing a popular tool for cancer research.

Material and method

PDOs were isolated from patients with CRC and cultured in the absence/presence of fibroblasts in different extracellular matrices (ECM), such as the laminin-rich Matrigel or collagen-I. Cells were characterized by imaging and statistical analysis, flow cytometry, whole-mount immunostaining and by RT-qPCR at the RNA level.

Result and discussion

IL1R1 was shown to be a marker of iCAFs in CRC, a subpopulation of fibroblasts with inflammatory phenotype. Whereas immune cell-derived cytokines, such as IL-17A, TNF-alpha, IL-22 or IFN-gamma had no effect on fibroblast polarization, co-culturing fibroblasts with CRC organoids resulted in the decrease in the percentage of IL1R1+ cells. Thus, tumor cells actively shift CAFs towards the myCAF phenotype that are a major source of collagens. Interestingly, co-culturing with fibroblasts resulted in an increase in EMT marker levels without the loss of epithelial identity, suggesting a pEMT phenotype, but with no invasion. pEMT with cellular migration was only induced when changing extracellular matrix to collagen-I. This resulted in a loss of organoid circularity and CRC organoids acquired an invasive phenotype. Furthermore, modifying the collagen-based ECM by

including other proteins had only a limited effect on the PDO phenotype.

Conclusion

Tumor cells with the most metastatic capacity reside in a pEMT state that can be characterized by the co-presence of mesenchymal and epithelial markers. Thus, this malignant cell population should be a primary target of therapies. Fibroblasts induce pEMT in CRC cells, however, this is coupled with an invasive phenotype only in a permissive ECM niche, such as the presence of collagen-I. These results highlight the importance of targeting ECM components in CRC.

DNA methylation landscape defines metastatic routes in high grade serous carcinoma

G. Marchi¹, A. Lahtinen¹, K. Lavikka¹, V. Isoviita¹, D. Afenteva¹, T. Muranen¹, J. Oikonen¹, A. Virtanen¹, J. Hynninen², S. Hautaniemi¹

¹University of Helsinki, Research Program in Systems Oncology, Faculty of Medicine, Helsinki, Finland

²University of Turku, Department of Obstetrics and Gynaecology, Turku, Finland

Introduction

High-grade serous ovarian carcinoma (HGSC) is the most lethal gynecological cancer, primarily due to late-stage diagnosis and extensive metastatic spread. While genetic drivers of HGSC have been extensively studied, the role of DNA methylation in metastasis and therapy response remains largely unexplored.

Material and method

We analyzed 400+ whole-genome bisulfite sequencing (WGBS) samples, along with matched RNA sequencing data from 125 HGSC patients enrolled in the prospective, longitudinal, multi-region DECIDER trial (NCT-04846933). A computational deconvolution approach was applied to separate tumor-specific methylation patterns from patient-specific, micro-environmental, and treatment-related effects, enabling precise epigenetic analysis.

Result and discussion

Our findings revealed three primary routes of metastatic dissemination in HGSC: solid tissue invasion, ascites-mediated spread, and lymphatic dissemination, each characterized by distinct DNA methylation patterns. Solid tissue invasion emerged as the predominant route, with differential methylation in estrogen signaling, interferon response, and androgen pathways. Ascites-mediated spread facilitated tumor dissemination to the pleural fluid, with epithelial-mesenchymal transition dysregulation playing a key role in ascites formation. Lymphatic spread, though less frequent, involved para-aortic lymph nodes and was associated with epigenetic changes in immune-related pathways. Analysis of treatment-induced epigenetic changes revealed site-specific responses to platinum-based treatment. The omentum showed the highest methylation changes after neoadjuvant chemotherapy (NACT), but only in well-

responding patients. In contrast, refractory patients exhibited no changes in promoter methylation, reflecting an absence of response in those with poor outcomes. Ascites displayed a unique pattern: while largely unchanged following NACT, they underwent substantial epigenetic shifts at relapse. This suggests a dynamic change of DNA methylation in ascites after the whole course of treatment, potentially driving disease progression and chemoresistance.

Conclusion

This study provides a comprehensive epigenetic characterization of metastatic spread in HGSC and tissue-specific response to platinum-based treatment. By defining distinct DNA methylation patterns across metastatic routes and therapy responses, our findings highlight epigenetic drivers of disease progression and potential therapeutic targets.

EACR25-1162

Plasticity of esophageal progenitors in fine-tuned by their microenvironment in vivo

L. Descampe¹, B. Dassy¹, A. Vercauteren Drubbel¹, B. Beck¹

¹Université Libre de Bruxelles, IRIBHM, Brussels, Belgium

Introduction

Chronic acid reflux in the esophagus can trigger the conversion of squamous cells with columnar cells, a process known as metaplasia which increase the risk of developing esophageal adenocarcinoma. While keratinocytes demonstrate plasticity by their ability to undergo this transdifferentiation, mechanisms regulating progenitor cell fate remain poorly understood. We previously identified the transcription factor Sox9 as a regulator of esophageal cell plasticity downstream of the Hedgehog (HH) signaling pathway in vivo. We showed that gastroesophageal reflux induces the activation of the HH pathway in keratinocytes, and subsequently their dedifferentiation into an embryonic-like state, promoting a Sox9-dependent squamous-to-columnar conversion. Deciphering Sox9 regulation in esophageal progenitors could provide insight into the mechanisms initiating metaplasia, thus revealing new targets for cancer prevention and therapeutic.

Material and method

Esophageal organoids were derived from WT and K5:Smo transgenic mice with constitutive HH pathway activation, as well as human biopsies. ATAC-seq identified regulatory elements predicted to control Sox9 expression. Bulk and single-cell RNA seq were used to analyze transcriptional changes upon HH pathway activation. NSAIDs treatments were conducted to assess the effect of Sox9 inhibition on cell plasticity.

Result and discussion

Using organoids, we show that Sox9 is not directly regulated by HH pathway. In silico analysis of Sox9 promoter identified Smads, effectors of TGF-β/BMP signaling pathways, as potential transcription regulators. Transcriptomics data confirmed that HH signaling pathway is associated to an increase of TGF-β/BMP signaling in vivo. Activation of these pathways in vivo is the consequence of (1) local extracellular matrix

remodeling, which in turn may activate latent TGF- β , and (2) upregulation of BMP ligands in keratinocytes. Treating organoids with TGF- β and/or BMP demonstrate that TGF- β triggers Sox9 transcription and that BMP further increases Sox9 expression. Interestingly, we observed that NSAIDs inhibited HH-induced Sox9 expression and cell plasticity in vivo. Whereas NSAIDs slightly inhibit TGF- β /BMP signaling in vivo, these drugs prevented TGF- β /BMP-induced Sox9 expression by destabilizing protein expression.

Conclusion

Our findings highlight the role of the microenvironment in regulating esophageal cell plasticity through Sox9 modulation. In addition, that keratinocytes can locally remodel the extracellular matrix to promote their plasticity. Importantly, we report a new role for NSAIDs treatment, which modulates squamous-to-columnar conversion by destabilizing Sox9 expression in keratinocytes. Our results offer new perspectives for improving esophageal mucosal re-epithelialization, particularly after endoscopic resection of metaplasia or pre-cancerous lesions and offer potential strategies for cancer prevention.

Autophagic Cell Death in GBM Cells Following Arginine Deprivation is Mediated by Ferroptosis

M. Abdelkalek¹, Y. El-Jawhari¹, M. Shaheen¹, M. El-Sibai¹, R. Abi-Habib¹

¹Lebanese American University, Department of Biological Sciences, Beirut, Lebanon

Introduction

Glioblastoma Multiforme (GBM) is characterized by high mortality and low survival rates secondary to poor prognosis and the lack of effective treatment options. We had previously demonstrated that GBM cells were auxotrophic for arginine, secondary to the insufficient or lack of expression of argininosuccinate synthetase 1 (ASS1), and sensitive to arginine deprivation induced by a recombinant human arginase [HuArgI (Co)-PEG5000]. We have shown that arginine deprivation is selectively cytotoxic to GBM cells with cell death being caspase-independent, and non-apoptotic. We have also shown, indirectly, that autophagy was activated without determining its impact on cell death. Here, we attempt to decipher the mechanism of cell death in GBM cells after arginine deprivation, by confirming the activation of autophagy, determining its impact on cell death and the potential mechanism of cell death.

Material and method

We tested two GBM cell lines for hallmarks of autophagy, the impact of autophagy on cell survival as well as the potential mechanism of cell death, including accumulation of cytosolic ROS, lipid peroxidation and ferroptosis, following arginine deprivation.

Result and discussion

Arginine deprivation led to marked and sustained activation of autophagy starting at 24 h and lasting up to 120 h post-treatment. Inhibition of autophagy, using chloroquine (CQ), reversed the cytotoxicity of arginine deprivation, indicating that cell death is mediated by

autophagy. Arginine deprivation also led to the accumulation of cytosolic ROS in both cell lines. Addition of the ROS scavenger NAC reversed cytotoxicity of arginine deprivation without affecting the activation of autophagy, indicating that ROS accumulation is downstream of autophagy and upstream of cell death. Next, we show that lipid peroxidation occurs following treatment, indicating that arginine deprivation induces ferroptotic cell death. To further confirm this and link it to the activation of autophagy, we investigated the expression of NCOA4 and FTH1. Results showed increased expression of NCOA4 and decreased expression of FTH1, indicating an increase in the shuttling of ferritin into autophagosomes and an increase in ferritin degradation leading to increased levels of free iron. We also show a decreased expression of the antioxidant protein GPX4 following arginine deprivation. The autophagy-dependent degradation of FTH1, following arginine deprivation, leads to the accumulation of free Fe²⁺, which generates ROS through the Fenton reaction. The loss of antioxidant proteins prevents the neutralization ROS leading to lipid peroxidation and death by ferroptosis.

Conclusion

Our results demonstrate that arginine deprivation in GBM cells leads to the autophagy-mediated activation of ferritinophagy resulting in ferroptotic cell death.

EACR25-1168

Revealing the tumor suppressive sequence within KL1 domain of the hormone Klotho

M. Abboud¹, K. Merenbach-Lamin¹, H. Volcov², S. Ben-neriah¹, H. Ligumsky¹, N. Keren-Khadmy¹, M. Giladi¹, N. Shomron², I. Wolf¹, T. Rubinek¹

¹Sourasky medical center, Oncology, Tel aviv, Israel

²Faculty of medical sciences and health, Bioinformatics, Tel aviv, Israel

Introduction

Klotho, a 1012 amino acid transmembrane protein, is a potent tumor suppressor in different cancer types. Klotho is composed of two internal repeats KL1 and KL2, and the tumor suppressor activity is primarily attributed to the KL1 domain. Despite its significant role in regulating various cancer-related pathways, the precise mechanism underlying its tumor suppressor activity remains unresolved. In this study, we aimed to identify the sequence responsible for the tumor suppressor function of Klotho and gain insights into its mechanism of action.

Material and method

We designed expression vectors of truncated KL1 that included C-terminal truncations: 1-340 (KL340), 1-320 (KL320), and N-terminal truncation: 88-340 (KL88-340). We assessed their anti-cancer activity or regulation of the Wnt- β /catenin pathway by colony formation assay and co-expression in cancer cells. We used several cancer cell lines MCF-7, MDA-MB-231, PANC1, MIA Paca-2 and HCT116. We then performed RNA seq analysis on MCF7 cells over-expressing either KL1 or one of the C-terminal truncated KL340, KL320 to decipher global transcriptome differences. Finally, we performed multiple sequence alignment and utilized the α -fold

predictor tool to further understand the structural properties of the truncated proteins.

Result and discussion

Our findings demonstrated that truncated KL340 effectively inhibited colony formation similar to KL1, while truncated KL320 lost this activity. Furthermore, this correlated with the inhibitory effect of KL1 and KL340 on the Wnt/β-catenin pathway whereas KL320 had no effect. Transcriptomic analysis of MCF-7 cells expressing the constructs revealed enriched pathways associated with tumor suppressor activity in KL1 and KL340. The results show significant enrichment of the necroptosis pathway, MAPK pathway, protein processing in the ER and the ribosome, suggesting that the tumor suppressor activity is driven by several processes leading to cell death. Interestingly, the α-fold predictor tool highlighted distinct differences in the α and β sheets of the TIM barrel fold of the truncated Klotho constructs, adding to our understanding of their structural variations.

Conclusion

This study identified the 340 N-terminal amino acids as the sequence that possesses Klotho's tumor suppressor activity and reveals a critical role the 320-340 sequence for this function. It also provides a foundation for the development of Klotho-based therapeutic approaches for cancer treatment.

⁶*Centre for Biomedical Research (CIBM), University of Granada, Spain, Department of Biochemistry and Molecular Biology III and Immunology, Faculty of Medicine, University of Granada, Spain, Granada, Spain*

Introduction

Pancreatic Ductal Adenocarcinoma (PDAC) is the most common type of pancreatic cancer and is widely associated with Diabetes Mellitus (DM). Notably, up to 85% of patients with PDAC exhibit hyperglycaemia, which frequently manifests 2-3 years before the diagnosis of cancer. Interestingly, PDAC-associated DM may

resolve after tumour resection if sufficient pancreatic islets remain in the residual pancreas. Recent evidence suggests that PDAC not only increases the risk of DM but may also directly disrupt glucose homeostasis, leading to a new onset of DM, referred to as PDAC-associated DM. However, the exact pathogenic mechanisms driving PDAC-associated DM and its role in hyperglycaemia remain incompletely understood.

Material and method

To evaluate the impact of PDAC on pancreatic islets, we utilized a syngeneic mouse model based on the transplantation of organoids expressing the oncogenic KRAS-G12D mutation and p53 loss. This approach allowed us to assess tumor-induced alterations in islet architecture and function within an immunocompetent environment. To enhance the translational relevance of our findings, we further validated our results using a patient-derived xenograft (PDX) mouse model of PDAC.

Result and discussion

Our findings reveal a pronounced disruption of glucose homeostasis, driven at least in part by impaired pancreatic islet architecture and significant beta-cell dysfunction (insulin-secreting cells). These results were further validated using a patient-derived xenograft mouse model of PDAC. Additionally, we found that secreted factors from both murine organoids and human PDAC tumours reduced insulin content and secretion, potentially accounting for the hyperglycaemia observed in these patients.

Conclusion

Our findings indicate that PDAC induces pancreatic islet dysfunction, marked by β-cell impairment and disrupted blood glucose regulation, ultimately contributing to diabetes. Targeting these pathological mechanisms to restore glucose homeostasis could serve as a potential therapeutic strategy to counteract the impact of hyperglycaemia on PDAC progression.

EACR25-1210

Degradation of IDH1 via Chaperone-mediated autophagy inhibits cell cycle progression in glioblastoma

W. Tang¹, B. Chen¹, Q. Zheng², K. Kiang¹, G. Leung¹
¹*The University of Hong Kong, Surgery, Hong Kong, China*

²*The University of Hong Kong, Biomedical Sciences, Hong Kong, China*

Introduction

Chaperone-mediated autophagy (CMA) is a selective protein degradation pathway essential for maintaining cellular homeostasis. The dysregulation of CMA has been implicated in various diseases, including glioblastoma, a highly aggressive brain cancer.

Material and method

This study utilized a combination of established glioblastoma cell lines, patient-derived glioblastoma stem cells, and orthotopic mouse models to investigate CMA's role in glioblastoma.

Result and discussion

CMA deficiency enhances glioblastoma cell growth by impairing the degradation of isocitrate dehydrogenase 1 (IDH1), a critical metabolic enzyme and molecular marker in glioma classification. IDH1, which is

frequently upregulated in glioblastoma, contains a conserved CMA targeting motif and interacts with the CMA chaperone heat shock cognate 71 kDa protein (HSC70). Inhibition of lysosomal function results in IDH1 accumulation in both glioblastoma cells and patient-derived glioblastoma stem cells, indicating that CMA targets IDH1 for lysosomal degradation. Knockdown of the CMA receptor lysosome-associated membrane protein type 2A (LAMP2A) leads to elevated IDH1 expression, disruption of the RB1 cell cycle pathway, and increased glioblastoma cell growth. Suppression of IDH1 mitigates the tumor-promoting effects of CMA inhibition by restoring cell cycle regulation, whereas IDH1 upregulation fuels cell cycle progression, partly through its metabolic product alpha-ketoglutarate (alpha-KG), which stimulates Cyclin D1 expression. Notably, pharmacological activation of CMA suppresses cell growth and reduces IDH1 and Cyclin D1 expression.

Conclusion

These findings reveal a novel mechanism by which CMA modulates cell cycle progression by targeting IDH1 for degradation, thereby inhibiting glioblastoma progression.

EACR25-1214

Increased OGT activity promotes nuclear localization of RNA polymerase II to support oncogenic transcription

S. Pallasaho¹, X. Lu¹, A. Gondane¹, H. Itkonen¹

¹*University of Helsinki, Department of Biochemistry and Developmental Biology, Helsinki, Finland*

Introduction

Prostate cancer is the second most common cancer in men. O-GlcNAc transferase (OGT), the enzyme responsible for all nucleo-cytoplasmic O-GlcNAcylation, is overexpressed in aggressive prostate cancer.

Previously we showed that combined inhibition of OGT and transcriptional cyclin-dependent kinases (tCDKs) is toxic for prostate cancer cells. tCDKs have a fundamental role in regulating transcription of all protein-encoding genes by phosphorylating RNA polymerase II (RNA Pol II) carboxy-terminal domain (CTD). RNA Pol II CTD is also O-GlcNAcylated and here we wanted to establish the functional significance of this modification.

Material and method

The functional significance of RNA Pol II O-GlcNAcylation has remained enigmatic due to the lack of reagents that selectively recognize the O-GlcNAcylated polymerase. Here we developed a novel approach to identify chromatin localization of O-GlcNAcylated RNA Pol II referred to as wChIP. By integrating the results of computational docking, lectin pulldown-experiments and peptide-mapping, we determined a site at which RNA Pol II CTD is O-GlcNAcylated. We used chemically synthesized CTD-peptides to identify proteins that bind to the O-GlcNAcylated RNA Pol II and probed the functional role of this interaction using cell fractionation and assays of cell fitness.

Result and discussion

Using our wChIP approach, we show that O-GlcNAcylated RNA Pol II localizes on promoters of highly expressed genes. These data propose that OGT can

integrate metabolic information to directly control transcription. We confirm serine 5 as a site that is O-GlcNAcylated on RNA Pol II CTD and identify nuclear import protein karyopherin subunit beta 1 (KPNB1) as a selective binding partner of CTD O-GlcNAcylated at this site. In the future, it is important to map the binding partners of the differentially O-GlcNAcylated CTD and probe if they differ across cell types. Functionally, we show that combined inhibition of OGT and KPNB1 reduces nuclear levels of RNA Pol II, and that the combination is more toxic to prostate cancer cells than to cells representing normal prostate.

Conclusion

Our results suggest that RNA Pol II O-GlcNAcylation promotes nuclear entry to maintain high levels of transcription.

EACR25-1231

The Potential Role of PAK4 in PDGF-BB-Mediated EMT and Metastatic Processes in Triple Negative Breast Cancer

F. Kostak¹, S. Pehlivanoğlu¹

¹*Necmettin Erbakan University, Molecular Biology and Genetics, Konya, Turkey*

Introduction

Epithelial-Mesenchymal Transition (EMT) is a biological process enabling epithelial cells to acquire mesenchymal characteristics, including reduced cell-cell adhesion and enhanced motility, thereby facilitating processes such as cancer metastasis and tissue repair. Platelet-derived growth factor-BB (PDGF-BB) is a key regulator of cell proliferation, migration, and angiogenesis, playing a crucial role in wound healing, vascular remodeling, and pathological conditions. PAK4 (p21-activated kinase 4), a serine/threonine kinase, governs essential cellular functions, including cytoskeletal dynamics, proliferation, survival, migration, and invasion.

Material and method

This study aimed to investigate the potential role of PDGF-BB-mediated PAK4 function in EMT process and metastatic properties of MDA-MB-231 triple negative breast cancer (TNBC) cells. For this purpose, cells were stimulated with PDGF-BB and also treated with PAK4 inhibitor PF-3758309, separately and in combination. PAK4 activation and expression levels of EMT markers; E-cadherin, N-cadherin and vimentin were determined by Western blotting. Additionally, an *in vitro* wound healing assay was conducted to assess migration potential.

Result and discussion

According to obtained results, PDGF-BB stimulation did not result in a substantial alteration of the endogenous PAK4 levels, however it induced a 3.63-fold increase in p-PAK4 levels. As expected, PAK4 activation was suppressed in PF-3758309-treated cells despite PDGF-BB stimulation. PAK4 inhibition significantly upregulated E-cadherin (2.91-fold) while downregulating vimentin (2-fold), with no notable change in N-cadherin levels. Even though PDGF-BB stimulation, PAK4 suppression caused a 2.96-fold increase in E-cadherin, a 2.5-fold decrease in N-cadherin, and a 4-fold decrease in vimentin levels. Migration analysis showed that PDGF-BB stimulation promoted cell motility by 32% for 24

hours and 40% for 48 hours compared to control. PF-3758309 reversed this effect and suppressed the PDGF-BB-dependent cell motility. These findings suggest that PAK4 plays a key role in the PDGF-BB-mediated EMT and metastasis processes in TNBC cells.

Conclusion

Consequently, the PDGF-BB/PDGFR/PAK4 axis can be considered a significant therapeutic target in the management of cancer progression.

EACR25-1241

PSMG2 role in tumorigenesis and stemness mediated by protein accumulation, reticulum stress and autophagy

A. Espinosa-Sánchez¹, A. Carnero¹

¹*Instituto de Biomedicina de Sevilla (IBIS) - Hospital Universitario Virgen del Rocío, Universidad de Sevilla - Consejo Superior de Investigaciones Científicas (CSIC), Seville, Spain*

Introduction

Studying genes involved in proteostasis is essential for understanding the mechanisms driving dedifferentiation in cancer, as this process enables tumor cells to acquire stem-like properties, promoting plasticity, resistance, and progression. In head and neck squamous cell carcinoma (HNSCC), a highly aggressive malignancy with poor prognosis, identifying molecular regulators of dedifferentiation is crucial for developing targeted therapies. PSMG2, a chaperone protein that forms a heterodimer with PSMG1, plays a key role in this context by facilitating the assembly of the 20S proteasome. Here, we characterized the role of PSMG2 in tumorigenesis and dedifferentiation in HNSCC cell lines.

Material and method

Protein-protein interaction (PPI) analysis using IntAct and BioGRID identified key interactors of PSMG2, followed by functional enrichment via Gene Set Enrichment Analysis (GSEA). PSMG2 was over-expressed and downregulated in two HNSCC cell lines. Tumorigenesis was analysed using various functional assays, including growth curves, clonogenic assays, tumorsphere assays, and in vivo models. Molecular mechanisms such as apoptosis and autophagy were tested by flow cytometry, Western blotting, and immunofluorescence. Additionally, a reprogramming assay was conducted to assess the impact of gene downregulation on the dedifferentiation process.

Result and discussion

High PSMG2 expression correlated with poor prognosis and reduced survival in HNSCC patients. To explore the molecular networks regulated by PSMG2, we analysed protein-protein interactions (PPI) identifying common interactors. GSEA revealed enrichment in proteostasis, unfolded protein response, and cancer-related signaling pathways. PSMG2 knockdown impaired cell proliferation both in vitro and in vivo and led to a significant reduction in stemness, dedifferentiation, and reprogramming properties. Mechanistically, PSMG2 reduction resulted in the accumulation of polyubiquitinated proteins, triggering endoplasmic reticulum (ER) stress and activating apoptosis and autophagy as compensatory mechanisms.

Notably, PSMG2 downregulation enhanced the response to proteasome inhibitors, suggesting a potential therapeutic vulnerability.

Conclusion

Our findings demonstrate that PSMG2 is a key regulator of proteasome assembly, ER stress, and cellular homeostasis in HNSCC, linking proteostasis with dedifferentiation and therapy resistance. Targeting PSMG2 or the proteasome machinery may represent a promising therapeutic strategy for overcoming tumor plasticity and improving treatment outcomes in HNSCC patients.

EACR25-1243

PP2A inhibitor proteins CIP2A and PME-1 as medulloblastoma oncoproteins and therapy targets

O. Denisova^{1,2}, R. Huhtaniemi¹, M. Pipponen¹, O. Kauko¹, J. Westermark^{1,2,3}

¹*Turku Bioscience Centre, University of Turku & Åbo Akademi University, Turku, Finland*

²*InFLAMES Research Flagship Center, Turku, Finland*

³*Institute of Biomedicine, University of Turku, Turku, Finland*

Introduction

Inhibition of the tumor suppressor protein phosphatase PP2A, through the overexpression of its endogenous inhibitor proteins CIP2A, PME-1, and SET, has been implicated as a potential mechanism underlying kinase inhibitor resistance in various cancers. However, the role of these PP2A inhibitor proteins in the progression of pediatric brain tumor medulloblastoma has not been previously investigated.

Material and method

The expression of endogenous PP2A inhibitor proteins was preliminarily analyzed using publicly available transcriptome data. Functional studies were conducted in vitro and in vivo using medulloblastoma cell lines DAOY (SHH group) and D283-Med (Group 3/4). PME-1 and CIP2A were inhibited using CRISPR/Cas9 approaches [1].

Result and discussion

Transcriptome analysis of 763 primary medulloblastoma tumors revealed that high expression of CIP2A, PME-1, or SET correlates with poor prognosis. Additionally, CRISPR/Cas9 loss-of-function data from the DepMap portal identified PP2A and its regulatory proteins as among the top 10 preferentially essential genes in medulloblastoma, particularly in DAOY cells. In vivo studies further confirmed that knockout of CIP2A and PME-1 significantly reduced tumor growth and progression in mouse models. Notably, CIP2A knockout tumors exhibited a marked reduction in macrophage infiltration, suggesting a potential link between PP2A inhibitor proteins and the tumor immune microenvironment.

Conclusion

Our findings highlight the critical role of PP2A inhibitor proteins CIP2A and PME-1 as medulloblastoma oncoproteins and therapy targets. Further studies are needed to understand the mechanistic basis of the oncogenic activities of individual PP2A inhibitor proteins on tumor

recurrence and their potential as therapeutic targets to overcome resistance in medulloblastoma treatment.

EACR25-1248

AHSG exacerbates malignant progression in lung adenocarcinoma through ubiquitination mediated degradation of GSK3 β

M. Kalia¹, D. Pal¹

¹Indian Institute of Technology Ropar, Biomedical Engineering, Rupnagar, India

Introduction

AHSG, a glycoprotein is produced and secreted by tumor cells. It has a pleiotropic role in tumorigenesis. Lack of AHSG in mammary tumors prolongs mammary incidence and promotes the proliferation of bladder cancer cells. However, studies on AHSG regulation on tumor progression are minimal. Thus, we want to study its role in Lung Adenocarcinoma progression and heterogeneity.

Material and method

The GSE data set was retrieved from the GEO database. The results were validated on patient tissue samples at the gene and protein levels through qPCR and Immunohistochemistry (IHC). In-vitro studies were carried out to determine the AHSG expression in epithelial (BEAS 2B) and LUAD cell lines (A549 and H23). AHSG was silenced and the silencing efficiency was validated on gene and protein levels. The MTT assay ki67 staining and PI staining were performed to assess the effects of AHSG on LUAD cell proliferation. A wound scratch assay was done to assess the wound healing whereas transwell assays were carried out to check the migration and invasion capabilities in AHSG control and silenced LUAD cells. BioGRID analysis was done to check the downstream targets of AHSG. A co-immunoprecipitation was performed to check the interaction between AHSG and GSK3 β . A co-localization study was performed, and the correlation between the two proteins was calculated based on Pearson's coefficient. Western blotting was carried out to determine the influence of AHSG silencing on downstream protein targets of the GSK3 β /β catenin pathway.

Result and discussion

We identified that AHSG is upregulated in LUAD through bioinformatic analysis. This was further confirmed in LUAD patients at both gene and protein levels and in vitro. Through MTT assay, ki67 immunofluorescence staining, and cell cycle analysis it was observed that AHSG promotes LUAD cell proliferation. AHSG control LUAD cells had faster wound healing capacities as well as more migration and invasion capacities in scratch and transwell assays respectively. AHSG propels LUAD cells towards a higher Epithelial Mesenchymal transition (EMT) in a 3D unicellular LUAD model. Protein network analysis revealed that GSK3 β is a part of the AHSG interactome.

Mechanistically, AHSG interacts with glycogen synthase

kinase-3 beta (GSK3 β) and exacerbates the ubiquitination-facilitated degradation of GSK3 β by slowing down the dissociation of the ubiquitin ligase complex. Moreover, AHSG stimulates the Wnt/β-catenin signaling pathway through GSK3 β , thereby promoting the malignant transformation of LUAD. In conclusion, AHSG was a significant promoter of LUAD. The research we conducted identified AHSG as a promising theranostic target for LUAD.

Conclusion

The results of our research will shed light on the fundamental function of AHSG in controlling important cancer signaling networks and emphasize the biological backbone for the possible use of AHSG as a novel LUAD diagnostic indicator for LUAD as well as its therapy.

EACR25-1268

The effect of Ibuprofen on autophagic gene expression in Hepatocellular Cancer

I. Kockar¹, E. Tokay², F. Kockar²

¹Balikesir University, Medical Pharmacology, Balikesir, Turkey

²Balikesir University, Molecular Biology and Genetics, Balikesir, Turkey

Introduction

Ibuprofen is an NSAID-derived drug and is generally used to treat pain, fever and inflammation. Its regular and long-term use has been shown to reduce the risk of cancers, with mostly positive results. Cancer is an abnormal proliferation of the body's cells that undergoes uncontrolled carcinogenesis with metastasis. Hepatocellular Cancer (HCC) is the most common type of primary malignant cancer of the liver. One of the hallmarks of cancer is a tumor promoted by inflammation. Autophagy is defined as the sequestration of bulk cytoplasm and organelles in vesicles, their delivery to their lysosomal system and subsequent degeneration. Autophagy is classified as type 2 cell death. When the studies in the literature were examined, no study was found on the relationship between ibuprofen and autophagic pathways in hepatocellular cancer cells. In this context, this study aims to determine the relationship between the effect of ibuprofen on autophagic pathways in hepatocellular cancer (Hep3B).

Material and method

For this purpose, Hep3B cells were cultured in 10% FCS containing high glucose DMEM and plated out in 6 well plates (5x10⁴ cells/well), then treated with previously determined ibuprofen IC₅₀ dose. As a control group, 1% of DMSO was applied as control. Also, cisplatin was used as positive control. After 24h, 48h and 72h, the cells were trypsinized and total RNA was isolated using cell pelet with RNA extraction kit. Total RNA was reverse transcribed into cDNAs using cDNA synthesis kit. cDNA was used as template for Real-Time Analysis. ATG3, ATG5, ATG7, LC3II and beclin gene expressions related to autophagic pathway were determined using specific primers at mRNA level. Human beta microglobulin gene was used as an internal control.

Result and discussion

As a result of the study, it was determined that there was a statistically significant increase in mRNA levels for

ATG-3, ATG-5, ATG-7 and LC-3II following 72 h of ibuprofen administration. Autophagy-related marker gene expressions were found to increase especially at 72 h compared to cisplatin-treated cell groups.

Conclusion

This study presents the first evidence in the literature regarding the association between ibuprofen and the autophagic cell death pathway in liver cancer cells. Understanding the underlying mechanisms of this effect at a fundamental level is crucial, especially for NSAID derivatives like ibuprofen.

EACR25-1294

Mechanisms regulating the formation of colorectal cancer brain metastasis

F. Khair-Dabbour¹, S. Fuchs¹, I. Greenberg¹, G. Shapira², N. Shomron², A. Zubkov³, T. Rubinek¹, I. Wolf¹

¹Tel Aviv Sourasky Medical Center, Department of Oncology, Tel Aviv, Israel

²Tel Aviv university, The Faculty of Medical and Health Sciences, Tel Aviv, Israel

³Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Institute of Pathology, Tel Aviv, Israel

Introduction

Colorectal cancer (CRC) remains a major cause of cancer-related mortality, with brain metastasis (BMs) posing a growing clinical challenge with limited treatment options. The brain microenvironment imposes metabolic constraints, including low oxygen levels and lipid scarcity, necessitating adaptive mechanisms for metastatic CRC cells. This study aimed to reveal molecular drivers of CRC BMs.

Material and method

KRAS CRC BMs (n = 9) and liver metastasis (LMs) (n = 6) FFPE samples were subjected to transcriptomic analysis, using RNAseq. FOXM1 and FASN expression were assessed by immunohistochemistry (IHC). CRC cell lines were used to validate transcriptomic results using qRT-PCR and western blot and reporter assays. Tumor microenvironment was simulated by culturing CRC cell lines in astrocyte-conditioned media (A-CM), hepatocyte-conditioned media (H-CM) or hypoxia (1% O₂). Analysis of CM was assessed via a growth factor array assay. Intracranial mouse model was used to assess gene expression within brain environment.

Result and discussion

Transcriptomic analysis showed that FOXM1 was significantly upregulated in CRC BMs compared to LMs and these results were confirmed by IHC. Furthermore, an increase in FOXM1 expression was observed following intracranial injection of CRC cells into mouse brain. CRC cells cultured in A-CM exhibited higher FOXM1 expression than in H-CM, suggesting that brain-derived soluble factors contribute to FOXM1 up-regulation, further supporting the finding that the brain microenvironment actively induces FOXM1 expression. Hypoxia, characteristic of brain conditions, induced FOXM1 expression as well as the transcriptional activity. A growth factor array identified HGF as one of the most abundant factors in A-CM. Indeed, HGF treatment upregulated FOXM1 in CRC cells, indicating a role for HGF in FOXM1-mediated tumor adaptation to the brain

microenvironment. Fatty acid synthesis was shown to play a role in cancer cell adaptation, and we observed FOXM1 correlated with FASN, highlighting a possible role for FOXM1 in metabolic reprogramming essential for CRC BM survival.

Conclusion

FOXM1 is a key regulator of CRC BMs, regulated by brain microenvironment. Furthermore, correlation between FOXM1 and FASN expression suggests it plays a role in the metabolic reprogramming required for CRC cells to survive in the brain microenvironment, making it a potential therapeutic target for CRC BM patients.

EACR25-1303

WNT alterations in CRC: Selfish Apc Vs Altruistic Rspo?

N. Nasreddin¹, N. Gunduz¹, A. Ligenza², H. Benoue-Davis², G. Valbuena², S. Leedham², O. Sansom¹

¹CRUK Scotland Institute, Glasgow, United Kingdom

²Centre for Human Genetics, Oxford, United Kingdom

Introduction

Aberrant WNT pathway activation is a hallmark of colorectal cancer (CRC). The principal mechanism of WNT hyperactivation is mutation of key WNT-genes, including loss-of-function mutations in APC and gain-of-function mutations in RSPO. These mutations cause Wnt hyperactivation in different manners and show differential distribution across CRC subtypes. Recently, Apc mutations in LGR5+ve cells have been shown to give rise to super-competitor cells, whereby mutant cells hold an endogenous fitness advantage provided by the intrinsic and constitutive WNT activation, coupled with suppression of neighbouring wild-type cells' stemness and promotion of their differentiation through secretion of NOTUM. This allows Apc-mutant cells to "fix" and outcompete wild-type cells. Here, we assessed the tumorigenic potential of Rspo3 alteration, compared to Apc mutations.

Material and method

Using mouse models of WNT disruption, we compared the impact of Rspo alterations and Apc mutations on the intestinal epithelium. We also evaluated the WNT mutation landscape in precancerous and cancerous CRC subtypes.

Result and discussion

Comparison of our mouse models showed that Rspo3-mutant lesions are phenotypically different from Apc-mutant lesions. Compared to the polyp formation with dysplasia extending through crypt-villus axis seen in the Apc-mutant models, Rspo3-mutant lesions were characterised by hyperplastic lesions marked by proliferating ectopic crypts. Furthermore, in contrast with the super-competitor nature of Apc-mutations, Rspo3 overexpression favoured Paneth cell differentiation and supported the formation of WNT-dependent ectopic stem cell niches. Given their role as source of WNT ligands, an increase in Paneth cells, coupled with the presence of elevated Rspo3, is believed to create a WNT-high environment that promotes stemness in all cells within the milieu. In accordance, cell competition studies showed that whilst Apc-mutant cells colonise the crypt overtime by outcompeting wild-type cells, Rspo3-mutant cells allow for the co-expansion of both Rspo3-mutant

and wildtype LGR5⁺ve clones. Interestingly, when comparing the distribution of these mutations in human CRC, colitis-associated lesions were found to preferentially select for RSPO-mutations, contrary to sporadic CRC precursor lesions, which have predominantly APC mutations. This may be because an RSPO alteration is more favourable in an environment requiring increased regenerative capacity.

Conclusion

Based on these observations, an Apc selfish versus Rspo altruistic model is proposed. In this, Apc mutations in LGR5⁺ve cells give rise to selfish super-competitors, which act by promoting their own stemness while suppressing that of their neighbouring cells. Conversely, Rspo3-mutant cells' expression of RSPO3 supports their own and their neighbouring cells' stemness by potentiating WNT signalling, through secreted RSPO3 and an expansion of Paneth cells.

POSTER IN THE SPOTLIGHT

Senescence Induction Sensitizes Hepatocellular Carcinoma Cells to Immunotherapy

X. Ma¹, S. Wu¹, C. Yang¹, W. Qin¹, C. Wang¹

¹Shanghai Cancer Institute, Shanghai, China

Introduction

Hepatocellular carcinoma (HCC) remains a major global challenge, requiring innovative therapeutic strategies to improve treatment outcomes. Inducing senescence in cancer cells offers a promising approach for tumor elimination, as senescent cells exhibit unique traits that can be targeted for therapy. However, effective strategies to exploit senescence in HCC remain limited. Our goal is to identify novel therapeutic targets, explore their mechanisms, and apply them to HCC treatment.

Material and method

Gene dependency, expression, and prognostic significance were analyzed using data from the DepMap and TCGA datasets. CRISPR screens were conducted to identify genes regulating cell proliferation and synthetic lethal candidates of Aurora B. Colony formation assays were used to assess cell viability. Senescence was confirmed through mRNA sequencing and β-galactosidase staining. Subcutaneous tumor model was established to evaluate the therapeutic efficacy of Aurora B inhibition and its combination with anti-PD-1 treatment. HLA expression, PD-L1 levels, and T cell activity were analyzed by FACS.

Result and discussion

Starting with 1,021 genes, we identified 26 HCC cell-dependent genes that are highly expressed in tumor tissues and associated with poor prognosis. To prioritize clinically translatable targets, we further refined this selection based on targetability and clinical relevance, highlighting Aurora B as a promising candidate. A genome-wide CRISPR screen confirmed that Aurora B knockout significantly inhibited HCC cell growth. Notably, Aurora B inhibition induced a strong senescence response. To explore potential vulnerabilities of Aurora B inhibition-induced senescent cells, we conducted a

secondary CRISPR screen, which identified TTK as a synthetic lethal candidate. However, validation experiments revealed that TTK inhibition further enhanced senescence rather than effectively eliminating senescent cells. Interestingly, Aurora B inhibition upregulated HLA and PD-L1 expression, suggesting a potential synergy with immunotherapy. We therefore combined an Aurora B inhibitor with immune checkpoint blockade anti-PD-1, which led to significant tumor growth suppression, accompanied by increased infiltration of CD8⁺ T cells and elevated IFNγ level. In vitro assays confirmed that Aurora B inhibitor-treated HCC cells stimulated CD8⁺ T cells to produce more IFNγ, and CD8⁺ T cells preferentially targeted the senescent cells.

Conclusion

This study demonstrates that immunotherapy is a potent approach to eliminate drug-induced senescent cells. Conversely, Aurora B inhibition may serve as an effective strategy to enhance the efficacy of HCC immunotherapy.

EACR25-1309

Age-associated mitochondrial dysfunction drives CAR-T cell failure

H. Carrasco Hope¹, J. de Sostoa², P. Ginefra¹, M. Andreatta¹, Y. Chiang¹, P. Ho¹, S. Carmona¹, G. Coukos¹, D. Migliorini², N. Vannini¹

¹University of Lausanne, Lausanne, Switzerland

²University of Geneva, Geneva, Switzerland

Introduction

CAR-T cell therapy is one of the most promising cancer treatments developed over the last decades, and its application is expected to grow exponentially in the coming years. However, different known and unknown hurdles are limiting its application and efficacy. In this context, aging is the first factor associated to cancer, but how aging influences anti-tumor responses and CAR-T cell outcomes is largely unknown.

Material and method

To assess the effect of aging on CAR-T cell therapy we have generated Her2 or mCD19 directed CAR-T cells from young and old mice and have used a murine B16-Her2 or EL4-mCD19 model, respectively, to assess their functionality in vivo. Afterwards, to validate the results obtained using the murine models, we have used PBMCs derived from young and old healthy donors, as well as melanoma patients. Furthermore, to determine how the age of the patients and our target pathways influence the responsiveness to CAR-T cell therapy in the clinic we have analyzed publicly available transcriptomic data of responder and no responder patients.

Result and discussion

Here, we show that CAR-T cells generated from aged mice are unable to maintain an appropriate stem-like phenotype, a key feature of successful CAR-T responses. As a result, aged CAR-T cells fail to survive long-term in vivo and control tumor growth upon adoptive cell transfer. We unveil that in aged CAR-T cells cellular NAD levels are depleted, which drives major mitochondrial dysfunctions. Replenishing cellular NAD levels by supplementing NAD precursors and blocking age-

associated NAD consuming enzymes, such as CD38, restores mitochondrial fitness and functionality of CAR-T cells, ultimately leading to an improved long-term persistence *in vivo* and tumor control capacity.

Moreover, human data analysis reveals that both the age of the patient and NAD metabolism determine the responsiveness to CAR-T cell therapy. Finally, by targeting NAD pathways we were able to recover the mitochondrial function of CAR-T cells derived from older adults.

Conclusion

Altogether, our study demonstrates that aging is a limiting factor to successful CAR-T cell responses. Repairing metabolic and functional obstacles derived from age, such as NAD decline, is a promising strategy to improve current and future CAR-T cell therapies.

Comparative analysis of regorafenib's effects in human and canine osteosarcoma cell lines: an interdisciplinary and translational perspective on bone tumor therapy

K. Marcinkowska¹, N. Romek¹, K. Bilská², A. Raciborska², A. Śmieszek¹

¹Wrocław University of Environmental and Life Sciences, Department of Pharmacology and Toxicology, Wrocław, Poland

²Institute of Mother and Child, Department of Oncology and Surgical Oncology for Children and Youth, Warsaw, Poland

Introduction

Regorafenib (REG) is a multi-kinase inhibitor used to treat various cancers, including colorectal cancer, gastrointestinal stromal tumors, and hepatocellular carcinoma. Recently, REG's potential has extended beyond human oncology, gaining recognition as a promising therapeutic candidate in veterinary medicine. In this context, the effects of REG are being explored for their relevance in canine osteosarcoma (OSA), a highly aggressive bone tumor in dogs that shares many biological and molecular similarities with human OSA.

Material and method

Three cell line models were used: human primary osteosarcoma ARP-1, human cell line MG63, and canine cell line D17. REG's effects were determined using metabolic assays (MTS), cytometric techniques (Annexin V/PI staining, PI staining for cell distribution), while the bioenergetic shift was monitored using Agilent Seahorse XF Real-Time ATP Rate Assay. Changes in molecular markers, including c-MYC, ERK2, PI3K, and AKT, were analyzed using RT-qPCR, while proteins mTOR and PI3K were detected using Western Blot. Cell invasiveness was tested with a wound-healing assay.

Result and discussion

The lowest IC₅₀ for REG was noted in D17 cells. REG decreases ATP production by inhibiting oxidative phosphorylation (OXPHOS) in all cell lines. In APR-1 and MG63, it also significantly reduces glycolytic activity, suggesting a dual mechanism of metabolic disruption. At molecular levels, REG increased anti-apoptotic markers in human cells but induced pro-

apoptotic markers in canine cells. It also reduced invasiveness across all lines.

Conclusion

REG's dual metabolic disruption, species-specific apoptotic effects, and ability to reduce invasiveness highlight its potential as a targeted therapy for osteosarcoma in humans and dogs. These findings provide insights into its mechanisms of action and translational importance. By adopting an interdisciplinary approach that integrates molecular biology, veterinary and human oncology, and pharmacology, this study bridges the gap between species-specific differences and therapeutic applications.

⁴Charles University, Department of Immunology, Prague, Switzerland

⁵ETH Zurich, NEXUS Personalized Health Technologies, Basel, Switzerland

⁶ETH Zurich, Department of Biosystems Science and Engineering, Basel, Switzerland

⁷Department of Obstetrics and Gynaecology, Switzerland

Introduction

The omentum, a visceral adipose tissue with critical metabolic, immunological, and stem cell functions, is the preferred site for ovarian cancer metastasis. However, its role in maintaining homeostasis and responding to metastatic colonization remains incomplete. To address this, we aimed to generate a human omentum cell atlas and investigate mechanisms underlying cancer-induced organ transformation.

Material and method

Single-cell RNAseq was performed on a clinical cohort of 36 omentum tissue samples from patients with benign disease and (pre-) invasive, treatment-naïve high-grade serous ovarian cancer. Samples were collected from multiple anatomical regions within the omentum. Marker validation was conducted using an independent bulk RNA-seq cohort with matched proteomics, complemented by flow cytometry and spatially resolved confocal immunofluorescence.

Result and discussion

The analysis of >110,000 cells identified 12 cell types and over 50 transcriptionally defined states, with distinct enrichment in benign and metastatic samples. Cells adjacent to tumor nodules were classified as inflammatory, while cells in the tumor core aligned with myofibroblast cancer-associated fibroblasts (CAFs). Cancer-associated mesothelial cells and CAFs shared a gene expression program, including immunosuppressive markers, ECM remodelers, and angiogenic factors.

RUNX1 was distinct to trans-differentiating cells, a population enriched in metastases and originating from normal mesothelial and mesenchymal progenitor cells. Moreover, RUNX1 was absent in primary tumors, suggesting a key role in the differentiation of normal omental cells upon metastatic colonization.

Conclusion

Cancer cells orchestrate cell reprogramming through a repertoire of signaling factors affecting both proximal and distal omental tissue. Our cell atlas highlights the cellular and molecular determinants of omentum homeostasis, revealing extensive plasticity and cancer-driven cellular reprogramming.

T. Gunel¹

¹*Istanbul University, Department of Molecular Biology and Genetics, Istanbul, Turkey*

Introduction

Ovarian cancer (OC) is one of the most lethal gynecological malignancies due to its asymptomatic progression and late-stage diagnosis. While primary OC responds to initial chemotherapy, recurrence is common and often associated with chemoresistance and poor prognosis mostly caused by cancer stem cells (CSC). Primary (POC) and recurrent (ROC) ovarian cancers exhibit distinct molecular profiles, with recurrent tumors often demonstrating enhanced stemness and resistance mechanisms. NANOG, SOX2, PROM1, ALDH1A1, ALDH1A2, and ALDH1A3 are key stem cell markers and potential therapeutic targets that have been implicated in OC progression, chemoresistance, and tumor-initiation.

Material and method

The genes of interest (GoI) were examined due to their roles in stem cell characteristics. The methodology includes data collection, processing, normalization and analysis. In data collection step, RNA-seq datasets including ROC and POC from TCGA (The Cancer Genome Atlas), and ovarian CSC (OCSC) from GEO (Gene Expression Omnibus) were collected. These datasets provide FPKM values (Fragments Per Kilobase of transcript per Million mapped reads) which is a widely used method for accurately quantifying gene expression, enabling comparative analysis across different conditions for the genes. Data were transferred into R (v4.4.1) for analysis. DESeq2 analysis was performed to identify differentially expressed genes between conditions, with a focus on log fold change transformation and p-value distribution to understand the statistical significance. The analysis examined the distribution of all genes also the GoI. For the further analysis of the GoI, min-max scaling and log2 transformation were applied. This normalization process rescaled the values to a range of 0 to 1 with preserving differences between datasets, allowing for the identification of those with significant changes in expression. Therefore, it was identified the significant expression patterns and potential biomarkers. Lastly,

gene ontology and network analysis were performed to identify the biological pathways of the GoI.

Result and discussion

Bioinformatics analysis of multiple datasets revealed that the expression levels of NANOG and SOX2 were inversely correlated between POC and ROC groups, with significantly higher levels observed in ROC.

Additionally, a positive correlation was found between the expression of NANOG, SOX2, and PROM1 in both OCSC and ROC, suggesting these genes may contribute to tumor aggressiveness and chemoresistance. ALDH1A1 and ALDH1A3 showed a positive correlation with ROC, similar to NANOG, SOX2, and PROM1, indicating a potential link between these genes and tumor progression.

Conclusion

Our findings suggest that the increased expression of NANOG, SOX2, ALDH1A1 and ALDH1A3 in ROC may play a critical role in tumor relapse and importance as potential biomarkers for tumor aggressiveness.

Introduction

Acute myeloid leukemia (AML) is a hematological malignancy characterized by the proliferation of immature blasts arrested at specific differentiation stages, making differentiation-based therapies a promising alternative to traditional cytotoxic treatments. Our previous study demonstrated that 5-aminoimidazole-4-carboxamide ribonucleoside (AICAr) induces AML differentiation through pyrimidine synthesis inhibition, similar to the DHODH inhibitor brequinar. We also found that cytarabine (AraC), a standard chemotherapy agent, promotes differentiation via replication stress and Chk1 activation, a mechanism shared with pyrimidine synthesis inhibitors. However, the precise link between DNA damage, replication stress, and differentiation remains incompletely understood.

Material and method

Human AML cell lines U937, THP-1, and MOLM-13 were cultured in RPMI-1640 or αMEM medium supplemented with ribonucleosides (rNs) and deoxyribonucleosides (dNs). Metabolomic profiling was performed using liquid chromatography-mass spectrometry (LC-MS). Cell viability, cell cycle distribution, and differentiation were assessed using multiparametric flow cytometry, while Western blotting was used to evaluate ribonucleotide reductase subunit M2 (RRM2) and Wee1 signaling. Inhibition studies were conducted using COH29 and hydroxyurea (HU) as inhibitors of

ribonucleotide reductase (RNR), MK1775 as a Wee1 inhibitor, and siRNA targeting Wee1.

Result and discussion

Metabolomic analysis revealed that pyrimidine and purine nucleotides were among the most differentially regulated metabolites, decreasing in brequinar- and AICAr-treated samples while increasing in AraC-treated samples. When cells were cultured in αMEM supplemented with 10 mg/ml of both rNs and dNs, the effects of all tested agents on proliferation, differentiation, and cell cycle arrest were completely abolished. All agents increased RRM2 expression, suggesting a role for RNR in differentiation. Inhibition of Wee1 kinase with MK1775 blocked RRM2 upregulation and AML differentiation without preventing S-phase arrest. Similar effects on differentiation and the cell cycle were observed in cells treated with COH29, a recently described RNR inhibitor. However, HU, a well-known RNR inhibitor, failed to prevent differentiation. Experiments are underway to further investigate the role of RNR in cells with downregulated expression.

Conclusion

Our findings suggest that ribonucleotide metabolism regulates AML differentiation, with Wee1 and RNR activation occurring downstream of replication stress.

Introduction

Colorectal cancer (CRC) remains a leading cause of cancer-related mortality, driven by complex genetic, epigenetic, and microenvironmental factors. Recent findings implicate the cystic fibrosis transmembrane conductance regulator (CFTR) ion channel in CRC progression, as CFTR levels are notably reduced in sporadic CRCs, particularly in advanced and metastatic tumors, correlating with poorer patient outcomes.

Additionally, cystic fibrosis (CF) patients, who carry CFTR mutations, have a 6-fold increased risk of early-onset CRC. Given recent advances in small-molecule modulators that restore CFTR function in CF patients, this study explored the potential of repositioning these modulators to address CFTR downregulation in sporadic CRC.

Material and method

Using a panel of CRC cell lines, we investigated whether CFTR modulators can increase CFTR functional expression in cells with various genetic backgrounds and

whether such improvements could reduce their oncogenic properties.

Result and discussion

Our data show that treatment with the CFTR folding correctors VX-661 and VX-445 led to a significant, approximately three-fold increase in CFTR abundance in CRC cells expressing reduced but detectable levels of the channel. Additionally, these treatments significantly reduced the migratory and invasive behavior of Caco-2 and DLD-1 cells, particularly when combined with the CFTR potentiator VX-770.

Conclusion

Our findings suggest that CFTR modulators may hinder the oncogenic properties of CRC cells. Further *in vivo* studies are necessary to fully assess their potential benefits for repositioning as a CRC treatment.

Introduction

Acute Myeloid Leukemia (AML), the most prevalent acute leukemia in adults, is a devastating cancer, with a 5-year survival rate of 35–40% in patients under 60 years and only 5–15% in older patients. AML is a heterogeneous disease caused by acquired genetic modifications in stem and progenitor cells. Leukemic cells fail to differentiate and invade the bone marrow, interfering with the renewal of mature blood cells. In this pathology, relapse and resistance to therapies are the primary causes of mortality. Many patients are not eligible for conventional intensive chemotherapy. The standard treatment for these unfit patients is a combination of venetoclax (a BCL2 inhibitor) in association with azacytidine (a DNMTs inhibitor). However, at least 60% of those patients will relapse. Therefore novel treatments remain critically needed to eradicate AML cells, including leukemic stem cells.

Material and method

AML cell lines and primary samples were treated with a combination of CDK6 inhibitors and VDR agonists. Differentiation and cell death were assessed via flow cytometry, caspase activity assays, and RNA sequencing. Clonogenic potential was evaluated using colony-forming unit assays. To better understand our transcriptomic results, chromatin accessibility was analyzed through ATAC-seq. Proliferation and cell death assays were conducted to assess venetoclax sensitivity in resistant models.

Result and discussion

AML cells, including resistant cells, are all sensitive to CDK6 inhibition. We demonstrate that the combination of CDK6 inhibition coupled with the activation of the VDR synergistically induces AML cell differentiation and decreases their clonogenic potential. Furthermore, this combination induces caspase-dependent cell death in AML cell lines and primary cells. Transcriptomic analyses confirm the activation of differentiation signatures, the decreased expression of genes associated with immaturity (HSPC signatures), and the deregulation of genes implicated in apoptosis signatures and other death and stress pathways following treatment. The combination induces extensive chromatin accessibility rearrangements. These accessibility changes correlate with transcriptomic alterations, highlighting the role of chromatin regulation in these changes. We also demonstrate that the combination increases venetoclax-induced cell death. We challenged several models of venetoclax-resistant cells, and our results indicate that some mechanisms of resistance to venetoclax could be completely bypassed by the triple therapy.

Conclusion

In conclusion, the combination of CDK6 inhibitors with VDR agonists exerts pleiotropic effects on leukemic cells including the restoration of cell differentiation, the decrease of immature potential and the promotion of cell death by apoptosis. Considering that all these molecules are FDA-approved drugs, our study advocates for the repositioning of CDK4/6 inhibitors and vitamin D in AML.

EACR25-1364

TGF- β induced EMT may promote tolerance of mitotic errors and genomic instability through inhibition of p53/p21 pathway

L. Lopez-Noriega¹, F. Mendoza¹, A. Guirao¹, V. Comaills¹

¹*Universidad de Sevilla, Departamento de Biología Celular, Sevilla, Spain*

Introduction

Transforming growth factor β (TGF- β) is a cytokine constitutively present in tumor microenvironment that has been associated with tumor progression, metastasis and drug resistance. TGF- β inhibits proliferation of normal epithelial cells, while inducing epithelial to mesenchymal transition (EMT) in epithelial cancer cells. We previously demonstrated that cells undergoing EMT induced by TGF- β are more prone to mitotic dysfunctions. Therefore, in this study we aimed to understand the mechanisms by which TGF- β induced EMT promotes tolerance of mitotic errors and genomic instability.

Material and method

MCF10A and RPE1 cells were treated or not with TGF-beta as well as different mitotic stressors and 5-fluorouracil. Number of chromosomes, DNA damage and P53/P21 expression were assessed through different methods.

Result and discussion

TGF-beta treatment promoted tolerance of mitotic errors and facilitated the appearance of cells with increased ploidy after challenging them with different mitotic stressors in both MC10A and RPE1 cell lines. In line with these results, DNA damage as determined by the number of γ H2AX foci was increased after TGF-beta treatment for 21 days. In contrast, p53 and p21 protein levels were downregulated as determined by western blot and timelapse imaging of RPE-1 cells expressing p53-NeonGreen and p21-mKate reporter genes.

Conclusion

TGF-beta may promote tolerance of mitotic errors and aneuploidy by downregulating p53 and p21 protein levels.

⁴*Great Ormond St Hospital for Children, Department of Paediatric Dermatology, London, United Kingdom*

⁵*Moorfields Eye Hospital NHS Foundation Trust, Ocular Oncology Service, London, United Kingdom*

Introduction

Uveal melanoma (UM) is the most common eye cancer in adults, and it originates from melanocytes in the eye. Mutations in GNAQ and GNA11 genes are initiating events in 90% of UM. Up to 50% of patients develop lethal metastasis to the liver, where cancer cells can remain dormant (quiescent) for a long period before expanding. Identification of approaches to intercept and treat metastatic UM remains an unmet clinical need. GNAQ and GNA11 oncogenic variants also cause mosaic disorders characterised by vascular and pigmentary malformations, where we have previously shown their role in hyper-activating intracellular calcium pathway. Here we aimed to assess UM cells' dependence on mutant GNAQ/GNA11 and the role of these variants in shaping calcium signalling at different stages of tumour progression. As calcium pathways control several oncogenic properties, this analysis may unveil new specific targets.

Material and method

We developed allele-discriminating small interfering RNAs (siRNAs) to specifically silence mutant GNAQ or GNA11 in human UM cell lines. Constitutive calcium signalling activity and intracellular calcium accumulation were measured by IPone assay and fluorescence detection in calcium dye-loaded cells, respectively. Proliferation and apoptosis were measured by an automatic plate imager. We implemented a double genetic reporter strategy to simultaneously track the whole UM cell population and highlight cells undergoing quiescence. We developed a co-culture system of labelled UM cells

with human immortalised hepatocytes, and the fraction of UM cells undergoing dormancy was tracked over time. Calcium oscillations in individual cells loaded with calcium dye were imaged, and data processed via a tailored Fiji/Python pipeline.

Result and discussion

We show that variant GNAQ or GNA11 knock-down reduces both constitutive and ligand-induced calcium signalling in UM cells. This leads to decreased proliferation and triggers apoptosis. Comparison with wild type melanocytes also reveals that UM cells have altered calcium flux across the plasma membrane. We go on to show that co-culture of UM cells with hepatocytes significantly increases the fraction of quiescent UM cells over time compared to co-culture with control cells. Preliminary investigation of the role of hepatocytes in promoting dormancy suggests that calcium signalling may be involved in this process, as suggested by analysis of differential calcium signal activity in dormant and proliferative UM cells.

Conclusion

We demonstrated that GNAQ/GNA11 mutations aberrantly activate calcium signalling in both vascular mosaic diseases and UM. Recapitulating *in vitro* the interaction between UM cells and hepatocytes, we modelled metastatic dormancy and monitored alterations in calcium signalling. This study paves the way to identification of new therapeutic targets for interception of dormant disseminated cells and prevention of metastatic disease.

⁷Huntsman Cancer Institute, Salt Lake City, United States

Introduction

Diet plays a crucial role in colorectal cancer (CRC) development and progression, influencing gut microbiome composition, inflammation, and metabolic pathways that contribute to tumorigenesis. Tryptophan is an essential amino acid and a regular supply via certain foods such as fish, meat, milk, eggs and nuts, is critical for the human body. It is mainly metabolized via the kynurenine pathway, generating metabolites with both pro- and anti-inflammatory properties. The kynurenine-

to-tryptophan (Kyn/Trp) ratio and several kynurenine metabolites have been associated with CRC progression and survival outcomes. Within the FOCUS Consortium, a large cohort of 2,102 prospectively followed stage I–III CRC patients, we have previously shown that tryptophan was significantly associated with improved all-cause mortality. This study therefore aims to elucidate the molecular role of tryptophan in CRC progression using patient-derived organoid models.

Material and method

Organoids were established from patients with stage I–III CRC who underwent primary surgery at the Heidelberg University Hospital, Germany. CRC organoids were treated with 100 µM tryptophan for up to five days. Microscopic imaging, Calcein-AM staining, and CellTiter-Glo 3D viability assays were performed to assess cell proliferation. Western blot analysis was conducted to evaluate the expression of PCNA (proliferating cell nuclear antigen), a marker for cell proliferation, and IDO1 (indoleamine 2,3-dioxygenase 1), the rate-limiting enzyme that catalyzes the initial step of the kynurenine pathway by converting tryptophan into kynurenine.

Result and discussion

The quantification of organoid colonies showed a slight, non-significant decrease in cell proliferation following tryptophan treatment. Additionally, the results of the Calcein-AM staining analysis also indicated a decrease in proliferation of organoids treated with tryptophan. CellTiter-Glo assays showed a significant decrease in proliferation at day 5 in organoids from stage III patients. Furthermore, a significant reduction in PCNA expression in organoids from stage I and II CRC patients after three days, and in organoids from stage III CRC patients after five days was observed. IDO1 levels were significantly elevated in advanced CRC stages compared to stage I, suggesting enhanced kynurenine pathway activation in later stages. Notably, IDO1 expression did not increase following tryptophan treatment.

Conclusion

Our findings suggest that tryptophan may have an anti-proliferative effect on CRC organoids. This aligns with previous studies linking higher tryptophan levels to improved prognosis in CRC patients. Future research will focus on analyzing the impact of kynurenine pathway metabolites on CRC proliferation and exploring potential therapeutic strategies to modulate this metabolic pathway for improved patient outcomes.

¹⁰McGill University, Gerald Bronfman Department of Oncology, Montreal, Canada

Introduction

Genetic alterations in fibroblast growth factor receptor (FGFR) genes have been associated with a broad spectrum of human diseases, from developmental disorders to cancer. In a previous report, we described a germline FGFR1 variant (R661P) in a family with Dysembryoplastic neuroepithelial tumors (DNETs), a subgroup of pediatric low-grade glioneuronal tumors, with secondary oncogenic somatic hits (N546K or K656E) in cis identified in the tumors of those individuals. The pattern of multiple FGFR1 mutations was confirmed in therapy-naïve sporadic cases, suggesting intrinsic mechanisms of selective pressure toward FGFR1 multiple mutational events arising in the context of a quiet genome. This occurrence of intragenic multiple mutations in low-grade, low mutation-burden and predominantly therapy-naïve tumors, represents a striking and unexplained phenomenon.

Material and method

Stable inducible (Flp-In T-REx®) HEK293 cell lines expressing FGFR1-BirA*-Flag fusion proteins have been generated. These cell lines have been used for Proximity-dependent Biotin Identification (BioID) coupled to Mass Spectrometry (MS)-based interactome profiling of FGFR1 Wild-type (WT) protein, single (germline R661P and oncogenic N546K, K656E) and double (N546K/R661P and K656E/R661P) mutants. To study the impact of FGFR1 mutations in a glioma background the human oligodendrogloma (HOG) cell line has been selected and engineered through CRISPR-Cas9 to obtain FGFR1 single- and double-mutant clones.

Result and discussion

The proximity interactome profiling revealed both unique and shared preys among FGFR1 mutants and with the WT protein. The germline R661P clustered differently, compared to the hotspot mutants, both single and double. Analysis of interactome data and western blot assays revealed novel oncogenic functionality for the oncogenic mutations N546K and K656E, linked to altered mechanisms of receptor turnover and increased levels of protein accumulation. Notably, we identified modulatory roles played by the R661P variant, hampering the oncogenic potential of N546K and K656E mutants by reducing affinity for downstream effector PLC γ and rescuing receptor degradation. Notably, the R661P mutation alone abolished the self-renewal capacity of oligodendrogloma cells, an effect that was rescued in double mutant clones. In R661P cells, differential

expression analysis revealed downregulation of genes involved in neurodevelopment and neuro-glial cell fate decisions, which was overcome in the double mutants, unveiling molecular defects associated with the variant R661P during brain development and highlighting potential novel mechanisms of early onset brain tumorigenesis driven by FGFR1 multiple mutations.

Conclusion

This study sheds light on the oncogenic effects associated with multiple FGFR1 alterations and their recurrence in low-mutation burden and therapy naïve brain tumors.

EACR25-1387

Mevalonate Pathway Suppresses Ferroptosis and Promotes Liver Cancer via CoQ10 Production and Selenocysteine-tRNA Modification

Y. Chen^{1,2,3}, D. Lee^{1,2,3}, K. Kwan^{1,2,3}, M. Wu^{1,2}, G. Wang^{1,2}, M. Zhang^{1,2,3}, R. Lo^{1,2}, I. Ng^{1,2}, C. Wang^{1,2}, C. Wong^{1,2,3}

¹University of Hong Kong, Department of Pathology, Hong Kong, Hong Kong, China

²State Key Laboratory of Liver Research,

³Centre for Oncology and Immunology,

Introduction

Hepatocellular carcinoma (HCC), particularly the steatotic subtype linked to metabolic dysfunction-associated steatotic liver disease (MAFLD), poses a significant therapeutic challenge due to its aggressive nature and rising prevalence. Ferroptosis, an iron-dependent cell death mechanism driven by lipid peroxidation, offers potential for HCC treatment, yet cancer cells exploit pathways like glutathione peroxidase 4 (GPX4)/glutathione and ferroptosis suppressor protein 1 (FSP1)/coenzyme Q10 (CoQ10) to evade ferroptosis. This study investigates novel targets to induce ferroptosis in both non-steatotic and steatotic HCC.

Material and method

Multi-omic screening identified the mevalonate pathway enzyme, mevalonate diphosphate decarboxylase (MVD), as a key target. Genetic ablation of TRSP (encoding selenocysteine-tRNA) or TRIT1 (tRNA i6A37 modification writer) and pharmacological inhibition of MVD using 6-Fluoromevalonate or Atorvastatin – a clinical inhibitor of the mevalonate pathway – were evaluated in HCC cell lines and mouse models, including steatotic HCC. Combination therapy with tyrosine kinase inhibitors (TKIs) and PD-1 antibody was tested.

Result and discussion

Isopentenyl pyrophosphate (IPP), a metabolite directly generated by MVD, was critical for CoQ10 synthesis and i6A37 selenocysteine-tRNA modification, stabilizing selenocysteine-tRNA to enable translation of selenoproteins, including GPX4. Disruption of TRSP or TRIT1 impaired selenoprotein production, inducing ferroptosis and suppressing tumor growth. Targeting MVD via 6-FMEV or Atorvastatin – which suppresses upstream mevalonate pathway activity – reduced IPP/CoQ10, destabilized tRNA modification, and triggered ferroptosis. *In vivo*, 6-FMEV monotherapy or combined with TKIs inhibited HCC progression, even in steatotic HCC models. Notably, Atorvastatin also demonstrated

anti-tumor efficacy, underscoring the therapeutic relevance of mevalonate pathway inhibition. This highlights a novel link between the mevalonate pathway, selenoproteins translation, and ferroptosis evasion. Dual targeting of CoQ10 and selenoproteins pathways via MVD or upstream inhibitors offers a synergistic strategy against HCC.

Conclusion

MVD inhibition disrupts IPP-dependent CoQ10 synthesis and selenocysteine-tRNA modification, sensitizing HCC to ferroptosis. The efficacy of 6-FMEV and Atorvastatin – both alone and combined with TKIs – underscores the potential of mevalonate pathway inhibition as a therapeutic strategy for non-steatotic and steatotic HCC, providing actionable insights for drug repurposing and combination therapies.

ROBO receptors act as tumor suppressors in cholangiocarcinoma

A. Inal¹, F. Baeumlisberger¹, M. Huerta Casado¹, Y. Hu¹, R. Sugiyanto¹, K. Gür¹, T. Huth¹, C. Sticht², P. Schirmacher¹, S. Roessler¹

¹Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany

²Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

Introduction

ROBO receptors were discovered as axon-guidance-cues during neuronal development, but were found to be deregulated in many cancers in a context-dependent manner. Genetic alterations resulting in deletion or truncation of ROBO receptors were identified in the invasive form of cholangiocarcinoma (CCA) but not the precursor lesions (Goeppert et.al, 2022). CCA is a rare but highly aggressive malignancy of the bile duct with inadequate therapy options and poor prognosis. The aim of this project was to functionally characterize ROBO receptors in CCA.

Material and method

ROBO1 and ROBO2 were introduced into CCA cell lines with a doxycycline-inducible expression system by lentiviral transduction. Functional assays were performed including viability, migration, and colony formation. RNA-seq analysis was performed to dissect downstream signaling pathways. The proximity-based protein labeling method BioID was used to identify interacting partners of ROBOs. Hydrodynamic-tail-vein injections (HDTV) in murine CCA models served to assess the function of ROBO1 and ROBO2 *in vivo*.

Result and discussion

ROBO1 and ROBO2 reduced cell viability, migration, and clonogenicity of CCA cells *in vitro*. RNA-seq revealed a decrease in cell cycle and DNA-replication whereas an increase in interferon response. BioID identified candidate interaction partners of which the majority is involved in MAPK signaling. *In-vivo* experiments with HDTV showed strong tumor suppressor features of ROBO1 and ROBO2. Mice with ROBO1/2 overexpression had no tumors or significantly less tumors compared to controls. Tumors expressing ROBO1/2 presented limited tumor stroma by reduced fibrosis and inflammation. In addition, a shift in the immune cell

phenotype was observed. ROBO receptors limit tumorigenicity in vitro and in vivo and restrict tumor stroma by means of reduced fibrosis and immune cell modulation. Further experiments will reveal the molecular mechanisms of ROBO downstream signaling. Therefore, our research on ROBO might be useful to provide better therapy options to patients with CCA.

Conclusion

ROBO receptors limit tumorigenicity in vitro and in vivo and restrict tumor stroma by means of reduced fibrosis and immune cell modulation. Further experiments will reveal the molecular mechanisms of ROBO downstream signaling. Therefore, our research on ROBO might be useful to provide better therapy options to patients with CCA.

¹Università degli Studi di Pavia, Molecular Medicine, Pavia, Italy

²Università degli Studi di Pavia, Physics, Pavia, Italy

Introduction

Asparaginase (ASNase), a first-line drug for Acute Lymphoblastic Leukemia (ALL), exerts its anticancer activity hydrolyzing Asn and glutamine (Gln), two conditionally essential amino acids for ALL cells. Previously, we showed that ASNase affects cell cycle, growth, clonogenicity and proliferation in 786-O (renal) and A549 (lung) adenocarcinoma cell lines. Here, we expand our studies to triple negative breast cancer (TNBC), an aggressive tumor lacking molecular targets (ER, PR, HER2), with limited treatment options. We tested ASNase on two TNBC cell lines, BT549 and MDAMB231, to evaluate a possible cytostatic effect of Asn and Gln deprivation.

Material and method

To evaluate the effect of ASNase on proliferation, the doubling time (DT) and the inhibition of clonogenic efficiency (IC50) were determined as a function of increasing ASNase concentration after 72h or 10 d, respectively. Cell cycle analysis was done in the presence of increasing doses of recombinant ASNase. Newly synthesized DNA was marked by adding 5-ethynyl-2'-deoxyuridine (EdU), total DNA was marked using FxCycle (Invitrogen). The molecular effect of ASNase treatment was evaluated by western blot by analyzing canonical markers of drug sensitivity (ASN-synthetase, ASNS and GLN-synthetase, GS) and drug response (Akt, ERK and pS6) only on BT549, as no significant changes in cell cycle were observed in MDAMB231.

Result and discussion

In both cell lines, proliferation was significantly inhibited both in the short term (DT, CTR vs. 1 U/ml ASNase, BT549 18.3 ± 2.7 h vs. 54.8 ± 7.5 h, $p < 0.0001$, and MDAMB231 21.4 ± 3.4 h vs 37.5 ± 5.1 h, $p < 0.0001$), and in the long term (IC50, BT549 0.044 ± 0.003 U/ml, MDAMB231 0.30 ± 0.20 U/ml). The canonical response of the cell cycle to ASNase consists of a blockade in G1-

S transition, visible as an accumulation of cells in G1. In BT549, we observed an accumulation of cells negative for newly synthesized DNA (EdU-) in the S-phase, which suggests a reduced efficiency in DNA synthesis. The same effect was observed in our previous work on 786-O. No perturbation of MDAMB231 cell cycle was observed. Molecular analysis of the treatment effect in BT549 resulted in a significant reduction in S6 activation from 0.5 U/ml ($p = 0.0008$) upward which implies a reduced activation of the mTOR pathway, confirming the effect of ASNase on BT549 cell metabolism. Starting from the same dose of ASNase, ASNS and GS were reduced significantly as well ($p = 0.03$ and $p < 0.0001$, respectively), in accordance to the observed sensitivity of this cell line to the drug. However, no significant changes were seen in canonical upstream regulators of mTOR (Akt and ERK, $p > 0.05$), which suggests a possible alternative pathway of downregulation of mTOR mediated by ASNase in BT549.

Conclusion

We are currently performing single-cell gene expression analysis to better understand the mechanism of ASNase on BT549 cells and developing BT549 organoids to further investigate ASNase effects in a 3D cancer model.

³Sahlgrenska University Hospital, Department of Hematology, Gothenburg, Sweden

Introduction

Deep characterization of the leukemic stem cells (LSC) in chronic myeloid leukemia (CML) may allow for the identification of novel therapeutic targets ultimately leading to a permanent cure of the disease. Compared to scRNA-seq, which provides the information of transcriptome at a single cell level, CITE-seq additionally pairs it with protein expression, which may enable the identification of cell phenotypes, subsequent FACS-based isolation as well as functional characterization. Detection of BCR-ABL1 transcripts, considered the only definitive marker to distinguish CML LSC from healthy hematopoietic stem cells (HSC), remains a significant challenge with current high-throughput 3' end capture-based single-cell sequencing methods.

Material and method

For the present study, we performed CITE-seq analysis of the expression of 597 genes and 51 proteins in >70,000 hematopoietic stem and progenitor cells (HSPCs) from 16 chronic phase CML patients and five healthy donors. Additionally, we combined it with an in-house optimized method allowing parallel BCR-ABL1 expression detection at the single-cell level.

Result and discussion

The results revealed pronounced expansion of mainly erythroid and myeloid progenitors within the CML CD34+ compartment, and high heterogeneity within the traditionally defined CD34+CD38-/low LSC compartment. A detailed analysis of the most immature CD34+ CD38-/low cells identified a subset of cells with a CD45RA-cKIT-CD26+ TKI resistant phenotype. The potential LSC showed expression of previously reported cell-surface markers CD25 and CD26, as well as some unreported gene and protein markers that allowed clear distinction of these cells from their healthy counterparts. Unlike HSC, the immature LSC showed upregulated expression of TIM3 at protein level and the von Willebrand factor gene (VWF) at the transcriptome level. Upregulation of VWF expression within the stem cell population may be linked to the aberrant myeloid-biased nature of the disease. High expression of TIM3 on the other hand could be beneficial for elimination of immature LSC in CML.

Conclusion

In conclusion, we performed detailed proteo-transcriptomic analysis of CML stem and progenitor cell compartment. The findings may have implications for the understanding of differences between leukemic and normal hematopoiesis as well as for the phenotypic definition of CML LSC.

EACR25-1427

Spastin Functions in Glioblastoma Multiforme Migration Through Focal Adhesion Kinase Signaling Pathway

B. Temizci¹, A. Karabay¹

¹Istanbul Technical University, Molecular Biology and Genetics, Istanbul, Turkey

Introduction

Glioblastoma Multiforme (GBM) is a highly proliferative and invasive type of aggressive brain tumor. Since highly migratory GBM cells are known to be more resistant to therapy than proliferative ones, identifying the proteins involved in the invasion process is critical for improving existing therapies. Previously, we discovered that cis trans isomerase enzyme Pin1 interacts with microtubule-severing protein Spastin through phosphorylated Thr292Pro&Thr303Pro Pin1 recognition motifs located in its microtubule-binding domain (MBD), directing it to actin filaments upon this interaction.

Material and method

In order to investigate roles of Spastin phosphorylation in its MBD and molecular signaling pathways targeting Spastin to actin filaments and thereby triggering migration of T98G GBM cells, we analyzed the expression levels of proteins having roles in migration and invasion mechanisms upon Spastin depletion by high-throughput membrane arrays. To reveal signaling pathways connected to Focal Adhesion Kinase (FAK) activation, firstly, FAK expression and phosphorylation status were investigated via immunoblotting upon Spastin silencing or overexpression of phospho-mutant (M87_mutA) or phospho-mimetic (M87_mutD) Spastin mutants. We also examined the localization of FAK by immunocytochemistry analysis. Furthermore, immunoblotting was also used to investigate the level of

expression and/or release of proteins hypothesized to be involved in FAK-related migration or proliferation pathway owing to the absence or phosphorylation of Spastin.

Result and discussion

The results indicated that Spastin could trigger GBM cell migration and invasion only when it is phosphorylated in the MBD and its role in GBM migration is related to Focal Adhesion Kinase (FAK) activation via phosphorylation. Spastin silencing decreased the FAK phosphorylation, whereas M87_mutD overexpression triggered the autophosphorylation of FAK. Moreover, ICC results demonstrated that while inactivated FAK moved to the nucleus upon Spastin silencing, FAK was directed to the cell membrane to become fully activated only when M87_mutD was overexpressed. Western blot analysis revealed that phosphorylated Spastin triggered migration through SPARC-mediated FAK activation; whereas proliferation could be stimulated by reduced expressions of p53 and Snail upon Spastin silencing.

Conclusion

In conclusion, via reduction of p53 expression, highly migratory T98G GBM cells are converted into proliferative form which is known to be more sensitive to chemotherapeutic treatment and Spastin playing a key role in transition of GBM cells from migrative form to proliferative form could be a novel therapeutic target for GBM treatment.

Investigating the effects of culture medium derived from HEK293 cells expressing DDB2^APCNA- protein on microenvironment

P. Ghosh¹, M. Furfaro¹, P. Perucca¹, A. Tricarico¹, E. Prosperi², L. Stivala³, O. Cazzalini¹

¹*University of Pavia, Department of Molecular Medicine, Pavia, Italy*

²*CNR, Institute of Molecular Genetics, Italy*

³*University of Pavia, Department of Molecular Medicine, Italy*

Introduction

DNA damage binding protein 2 (DDB2) is crucial in the early step of DNA damage recognition of the nucleotide excision repair (NER), which is triggered by UV-induced damage. DDB2 interacts with PCNA through a phylogenetically conserved sequence called PIP-box. This interaction is essential for proteosome-dependent degradation of DDB2 after recognizing the DNA damage, a prerequisite for further NER components recruitment. A mutation in the DDB2 PIP-box disrupts its ability to bind PCNA, resulting in defective DNA repair and an accumulation of DDB2 protein within cells. Additionally, when these cells are exposed to UV radiation, the efficiency of NER decreases, resulting in a more aggressive cellular phenotype.

Material and method

This work aims to study the influence of DDB2 in the inflammatory tumor microenvironment and monocyte differentiation. We used THP-1 cell line (monocytes), grown with a medium derived from the HEK293 control culture or HEK293 stably expressing DDB2 wild-type

protein or others unable to interact with PCNA (DDB2^APCNA-), both non-irradiated and collected at different times after irradiation with UV-C (10J/m²), to evaluate if the medium had any molecules inducing macrophage differentiation. The cell morphology and adhesion were assessed at various incubation times using gentian violet staining and then observed through an optical microscope. Immunofluorescence analysis was used to examine CD80 and CD68, which are markers for monocytes and macrophages. Western blot analysis was performed in all irradiated HEK293 cell lines to evaluate inflammatory protein levels.

Result and discussion

Observing the cells under the microscope highlighted that THP-1 cells grown with a medium derived from irradiated HEK293 DDB2^APCNA- adopt an irregular conformation with the presence of multiple extensions/filaments. Immunofluorescence analysis showed that in THP-1 cells treated with the medium from the DDB2^APCNA- cell line, both non-irradiated and at 3- and 7-days post-irradiation the signal for CD80 intensified in the cell membrane. An increase in the fluorescence signal specific for CD68 was also observed, in the intracellular compartment and on the plasma membrane. In both cases, the cells adopt progressively to a more irregular morphology. Preliminary results showed an increasing trend on IL-6, IL-8, and CD38 in irradiated HEK293 cells that express stably DDB2^APCNA- protein.

Conclusion

Taken together, our results suggest that the loss of DDB2-PCNA interaction may also influence the microenvironment.

EACR25-1431

DDB2-PCNA interaction is involved in maintaining genome stability in human UV-irradiated cells

A. Tricarico¹, P. Perucca¹, P. Ghosh¹, M. Furfaro¹, E. Prosperi², L. Stivala¹, O. Cazzalini¹

¹*University of Pavia, Department of Molecular Medicine, Pavia, Italy*

²*CNR, Institute of Molecular Genetics, Pavia, Italy*

Introduction

The DDB2 protein plays a crucial role in the initial step of global genome Nucleotide Excision Repair (NER). Our previous studies have demonstrated that the interaction between DDB2 and PCNA is essential for efficient DNA UV-C lesion removal. Cells expressing a mutant form of DDB2 that cannot bind PCNA (DDB2^APCNA-) exhibit delays in the NER process and display tumor-like characteristics, including the ability to form colonies after UV-C exposure.

Material and method

We conducted clonogenic assays in soft agar using HEK293 cells, both non-irradiated and UV-C irradiated (10 J/m²). These included untransfected cells as well as those expressing either wild-type or mutant DDB2. No colony grew with non-transfected cells or cells expressing the mutated protein while two resistant clones (called Clone 1, and Clone 2) were isolated from cells expressing the mutant protein and subsequently expanded. To assess protein expression levels, flow cytometry, microscopy, and Western blotting (WB)

experiments were performed. Additionally, iCELLigence biosensor technology was used to evaluate cell adhesion, Boyden chamber and wound healing assays were employed to assess cell migration.

Result and discussion

The analysis of the clones is aimed to investigate their possible tumor-like phenotype in comparison with their parental cell line. To study the cellular proliferation, we analyzed the ability to form colonies and the results show that Clone 2 exhibited higher capability after cisplatin and caffeine treatment. The UVC-resistant clones demonstrated reduced adhesion in the first two hours after seeding and faster wound closure. Moreover, both the clones in comparison with their parental cell line displayed increased levels of CD117, CD44 and OCT4, markers associated with cancer progression and cellular plasticity. In the complexity of cancer, an important role is played by the immune system and in particular macrophages. Recent results suggested that the supernatant derived from Clone 1 culture had an effect on THP-1 adhesion, suggesting that factors secreted by these cells might promote monocyte differentiation. Finally, the capacity to form 3D structure was analyzed, and the clones formed spheroids on agar faster than their parental cell line. WB analysis revealed differences in Epithelial to Mesenchymal transition (EMT). SNAI1, Vimentin and ZEB1 expression is higher in parental cell line than in both the clones; instead, NF- κ B showed the highest value in Clone 1.

Conclusion

These findings confirmed that the DDB2⁺PCNA- cell lines exhibit tumor-like features and highlight interesting differences between the two clones. The heterogeneity observed among clones requires further investigation in future studies.

EACR25-1441

The BASP1 signaling protein interferes with the WNT signaling pathway

L. Weber¹, A. Egger-Hörschinger¹, J. Ramos-Pittol¹, M. Kwiatkowski¹, M. Hartl¹

¹*Institute of Biochemistry, Innsbruck, Austria*

Introduction

The MYC oncoprotein represents a transcription factor that regulates crucial cellular processes and is therefore highly regulated by several pathways. For instance, in colorectal cancer the WNT signaling pathway is perturbed resulting in aberrant MYC expression. We found that the brain acid-soluble protein 1 (BASP1), which is downregulated in a variety of MYC-dependent cancer cells, strongly interferes with the WNT signaling pathway not only leading to low MYC protein levels but also reduced MYC-induced cell transformation.

Material and method

Using the human colon cancer cell line SW480 featured by high MYC expression and a silenced BASP1 gene, we further investigated the putative tumor-suppressive property of BASP1. Three different cell types were established in which BASP1 is re-expressed. Whereas two cell lines are characterized by ectopic BASP1 expression, the third one was generated by CRISPR-mediated BASP1 gene activation. Relevant cell lines

were subjected to qPCR and Northern analysis, RNA sequencing, immunoblotting, reporter assays, agar colony assay, and liquid chromatography coupled to mass spectrometry (LC MS).

Result and discussion

Expression of BASP1 in SW480 leads to a decrease of MYC protein and mRNA levels, and a significantly reduced transformed phenotype. Proteome comparison of SW480 cells with those ectopically expressing BASP1 showed that 879 proteins are differentially expressed between the two cell lines, including proteins associated with beta-catenin function. Also, transcriptome analysis revealed a downregulation of the Traf2 and Nck-interacting kinase (TNK), a key protein in the activation of WNT signaling. A TCF reporter assay confirmed that the WNT signaling pathway is strongly impaired in the presence of BASP1 by showing significantly less transcription activity even upon ligand stimulation. By using a TNK inhibitor we could additionally show that MYC protein levels are heavily influenced by TNK functionality as they strongly decrease upon inhibition. We suggest that BASP1 influences MYC protein levels by interfering with the WNT signaling pathway.

Conclusion

Re-expression of BASP1 results in perturbed WNT signaling activity which might be the cause of the reduced MYC protein levels and the drastically reduced transformed phenotype that we observe in these cells.

The Golgi Apparatus Protein TMBIM4 Promotes Glioma Cell Invasion and Metabolic Adaptation

M. Martins^{1,2}, L. Martin³, A. Mutel³, M. Farrim^{1,4}, M. Oliveira⁵, A. Fernandes¹, H. Castel³, N. Saraiva¹

¹*Universidade Lusófona - Centro Universitário Lisboa, CBIOS - Research Center for Biosciences & Health Technologies, Lisbon, Portugal*

²*Universidad de Alcalá de Henares, Department of Biomedical Sciences, Madrid, Spain*

³*Normandie Univ, UNI ROUEN, INSERM, Institute for Research and Innovation in Biomedicine (IRIB), Rouen, France*

⁴*Universidad de Alcalá de Henares, Biología de Sistemas, Madrid, Spain*

⁵*i3S - Institute for Research and Innovation in Health, TMI -Tumor and Microenvironment Interactions, Porto, Portugal*

Introduction

The ability of glioma cells to invade adjacent tissues is a key hallmark of tumour progression and a major determinant of patient outcome. Due to the high tumour heterogeneity and invasiveness of high-grade gliomas (Glioblastoma - GB), the current therapies remain largely ineffective, highlighting the need for novel therapeutic approaches. The Transmembrane BAX Inhibitor Motif Containing (TMBIM) protein family, consisting of six intracellular ion channels, is implicated in multiple cell processes associated with cancer hallmarks. The Golgi-localized TMBIM4 regulates intracellular Ca²⁺ fluxes, apoptosis, and cell motility. Here, we investigate the role

of TMBIM4 in glioma cell invasion and metabolic adaptation.

Material and method

Glioma transcriptomic datasets from TCGA, CGGA, Rembrandt, and Ivy_GAP were analysed to determine TMBIM1–6 mRNA levels and their association with tumour grade and patient survival. The cellular role of TMBIM4 was assessed in human glioblastoma U87 and U251 cells following TMBIM4 KD using siRNA. Cell invasion was measured in 2D and 3D cultures, and an orthotopic mouse model was used to analyse tumour growth/invasion. Lipid peroxidation, DNA damage, and Cystathione Beta-Synthase levels were evaluated by immunofluorescence. Quantitative mass spectrometry was used to assess protein expression.

Result and discussion

TMBIM1, 4, and 6 mRNA were significantly upregulated in gliomas, particularly in GB. Their expression correlated with tumour grade and was associated with reduced patient survival, supporting their potential prognostic value. Interestingly, TMBIM4 exhibited elevated expression in hyperplastic blood vessels and regions of microvascular proliferation, hinting at its involvement in tumour invasion or angiogenesis.

TMBIM4 KD significantly reduced GB cell invasion in both 2D and 3D models without affecting cell viability or proliferation and led to a marked reduction in tumour growth *in vivo*. Lower expression of TMBIM4 increased lipid peroxidation and DNA damage, indicating a role in oxidative stress resistance. Proteomic analysis further uncovered a reprogramming of amino acid and lipid synthesis-related proteins upon TMBIM4 KD. A decreased expression of CBS, a key enzyme in cysteine biosynthesis, was detected in the tumour cells *in vivo*. Supplementation of cell media with glutathione (GSH) rescued the 2D invasive phenotype of TMBIM4 KD cells, suggesting a role for GSH in TMBIM4-dependent tumour invasion.

Conclusion

Our findings suggest that TMBIM4 promotes glioma metabolic reprogramming, contributing to redox homeostasis and cell invasion. Targeting TMBIM4 could represent a novel therapeutic strategy to reduce glioma progression.

The RHO exchange factor VAV3 shows unexpected tumor suppressor roles in non-small cell lung cancer

M. Cuadrado¹, A. Leyton-Pereira¹, A. Abad¹, X. Bustelo¹

¹Molecular Mechanisms of Cancer Program, Centro de Investigación del Cáncer and CIBERONC, CSIC and University of Salamanca., Salamanca, Spain

Introduction

RHO guanine nucleotide exchange factors (GEF), a group of enzymes associated with the catalytic activation of RHO GTPases, have been traditionally associated with protumorigenic functions in a variety of tumor contexts. However, we have found that the VAV3 GEF plays unexpected tumor suppressor roles in the case of non-

small cell lung cancer (NSCLC). In this abstract, we will provide information about this role and the potential signaling mechanism involved.

Material and method

We utilized two mouse NSCLC models: (i) urethane-induced NSCL using wild-type and Vav3^{−/−} mice; and (ii) KrasG12D/+ and KrasG12D+/Vav3^{−/−} mice. We also have used murine and human NSCLC cell lines in which endogenous VAV3 was knockdown by shRNA-mediated approaches. As control, we used similar models in which VAV2, another member of the RHO GEF family, was eliminated using analogous techniques. These models were characterized using signaling and cell biology analyses; rescue experiments with VAV3 mutants and downstream signaling elements; RNA-seq; and LC MS/MS-based proteomics.

Result and discussion

We found that animals lacking Vav3 exhibited increased tumor burden and aggressiveness. In line with this, the elimination of endogenous VAV3 in lung cancer cells lead to increased cell growth and cell cycle progression. This is specific for VAV3, because the elimination of VAV2 induces opposite effects in urethane- and K-RASG12D-driven lung tumorigenesis. Signaling and rescue analyses performed in control and VAV3 knockdown NSCLC cells reveal the implication of specific RHO and PKN kinase family members in this suppressor role. The distal elements that mediate the final suppression effect are now under characterization.

Conclusion

These results demonstrate that VAV3 acts as a tumor suppressor in NSCLC, possibly via the modulation of a RHO–PKN-dependent pathway that impacts on cell cycle progression.

Introduction

Pancreatic Cancer (PC) is a multifactorial disease with various endocrine and non-endocrine subtypes, the most common and aggressive being pancreatic ductal adenocarcinoma (PDAC), accounting for over 92% of cases. More than 50% of PDAC patients present with metastatic disease, primarily in the liver (>70%), making them inoperable. This late diagnosis results in a 5-year overall survival rate of only 2% for metastatic PC (mPC), with a median survival of one year. Available treatments are limited to chemotherapy and palliative care. Metastasis requires tumor cells with self-renewal, plasticity, dormancy, and differentiation capabilities – key traits of cancer stem cells (CSCs). Given these properties, CSC involvement in metastasis is likely. Here, we analyze CSCs' impact on metastatic PDAC (mPDAC) to the liver.

Material and method

We selected a batch of four PDAC cell lines (ASPC-1, MIAPaCa-2, BxPC-3 and PANC-1) with varying levels of aggressiveness and distinct genetic profiles to better simulate the diversity observed in human patients. For tracking purposes, all cell lines stably expressed a luciferase reporter. Following a well-established protocol, CSCs were generated from the 2D cell lines and subsequently characterized by western blot and flow cytometry. Different cell concentrations were then selected for intrasplenic injections, followed by splenectomy to properly develop liver metastasis. Initial analysis and characterization were performed using quantitative PCR, flow cytometry, and immuno-histochemistry.

Result and discussion

We examined CSC-specific markers in vitro, focusing on CD44 isoform v6, associated with PC metastasis, and observed differential protein expression across cell lines. Additional CSC markers, including CD24, ALDH1, and CD133, were assessed. In vivo, ASPC-1-derived CSCs exhibited the highest metastatic potential, surpassing PANC-1, MIAPaCa-2, and BxPC-3. PDAC liver metastases phenotyping revealed differences in CD44v6, CD133, CXCR4, and ALDH1 expression. These markers were crucial for characterizing CSC plasticity and correlating with disease progression. Our findings provide insight into potential CSC-targeted anti-metastatic molecules.

Conclusion

Our research underscores the complexity of PDAC liver metastasis and emphasizes the need for CSCs-targeted therapies to disrupt the metastatic process. By successfully recreating a metastatic liver model, we have provided a robust platform to study the plasticity of CSCs and their involvement in metastatic dissemination. By leveraging insights from cell line studies and molecular pathways, novel strategies can be developed to improve outcomes for patients with PDAC. In this sense, our model serves as a valuable tool for identifying potential therapeutic targets and advancing precision medicine strategies in metastatic PDAC.

EACR25-1500

Identification of TGM2 as a Key Mediator of Autophagy-Driven Chemoresistance in p53-R282W expressing Cancer Cells

S. Chakraborty^{1,2}, A. Sakpal^{1,2}, P. Ray^{1,2}

¹Advanced Centre for Treatment, Research and Education in Cancer, Imaging Cell Signalling and Therapeutics Lab, Navi Mumbai, India

²Homi Bhabha National Institute, Mumbai, India

Introduction

TP53 is well-documented as a pivotal regulator of autophagy. Mutations in TP53, observed in approximately 50% of cancers, perturb its canonical transcriptional programs, thereby rewiring cellular homeostasis. This is particularly pertinent in High-Grade Serous Ovarian Cancer and Gastric Cancer where p53 acts as a driver mutation. Yet their precise role in regulating autophagy remains poorly investigated.

Material and method

A library of p53 hot-spot mutants curated from TCGA database was stably expressed in p53-null SKOV3 (ovarian) and KATO3 (gastric) cancer cells. LC3 turnover assay/p62 degradation, LC3/LAMP1 co-localization and transmission electron microscopy (TEM) were done to study autophagic flux. TGM2 expression was analyzed using RT-PCR. In-vitro migration and invasion were assessed through wound-healing and Boyden chamber assays. Bulk RNA transcriptomics was performed on the Illumina NovaSeq 2006 platform.

Result and discussion

Comprehensive screening of six TP53 hotspot mutants in ovarian cancer cells demonstrated that R282W, a highly resistant mutant, exhibited an active autophagic flux upon platinum treatment. Conversely, other cisplatin-resistant mutants displayed a blockade in autophagic flux suggesting the involvement of alternative resistance mechanisms. To delineate the molecular basis of this differential autophagic regulation, bulk RNA sequencing of R282W cells after cisplatin treatment was performed. Transcriptomic analyses revealed the dysregulation of 16 autophagy regulators in response to platinum. Among them, transglutaminase 2 (TGM2), a canonical p53 target gene involved in aiding autophagosome-lysosome fusion, was upregulated (2.5-fold) by cisplatin. Cisplatin treatment induced a 2-fold higher TGM2 expression in both ovarian and gastric cancer cells harboring R282W, whereas other mutants showed reduced expression of TGM2. Interestingly, LC3-LAMP1 co-localization studies also indicated that the autophagolysosome formation was highest in R282W post platinum exposure. This indicates a putative role of R282W in transcriptionally regulating TGM2 which might be responsible for a high autophagic flux. Additionally, blocking autophagy in R282W significantly attenuated its aggressiveness and re-sensitized the cells to platinum. This highlights autophagy to be a key pathway in acquiring chemoresistance.

Conclusion

Our findings identify R282W mutant of p53 to exclusively exhibit autophagy-mediated chemoresistance, potentially through TGM2 upregulation and enhanced autophagosome-lysosome fusion. The heightened

autophagic flux in R282W expressing cells contributes to their aggressiveness and platinum resistance. Therefore, targeting this pathway may offer a promising strategy to overcome chemoresistance in R282W harbouring cancers. Currently studies are ongoing to elucidate the role of p53R282W in TGM2 regulation associated with autophagy and chemoresistance.

FGF/FGFR System in Medulloblastoma: New Approaches for Tumor Treatment

N. Tassone¹, S. Filiberti¹, E. Somenza¹, C. Tavani¹, M. Turati¹, R. Ronca¹, R. Galli², E. Mariotto³, G. Viola³, P. Poliani¹

¹Università degli studi di Brescia, Brescia, Italy

²Istituto Scientifico San Raffaele, Milano, Italy

³Università degli studi di Padova, Padova, Italy

Introduction

Medulloblastoma (MB) is a highly aggressive childhood brain tumor, accounting for about 20% of pediatric brain cancers. It primarily affects children between 3 and 9 years, though it can also occur in adults. Symptoms often include cerebellar dysfunction, increased intracranial pressure, and hydrocephalus. MB is classified into four main groups based on genomic features: wingless/WNT (MB-WNT), sonic hedgehog/SHH (MB-SHH), group 3 (MB-Gr3), and group 4 (MB-Gr4). These groups differ in genetic profiles, clinical outcomes, and risk levels. Each group can be further subdivided into subtypes, influencing prognosis and treatment. Standard treatment involves surgery, radiotherapy, and chemotherapy, but recurrence rates and mortality remain high, with survival rates varying from 55% to 95% depending on the subtype. Among these groups, MB-Gr3 makes up about 30% of MB cases, often affects infants and young children, and has the worst prognosis with a 5-year survival rate below 30%, especially in cases with MYC gene amplification. Studies have demonstrated that the Fibroblast Growth Factor (FGF)/FGF receptor (FGFR) pathway plays a key role in cancer, impacting processes like cell proliferation and invasion, angiogenesis, and resistance to treatment. To date FGFR inhibitors (FGFRi) have been clinically approved for other cancers, while their potential in MB has yet to be fully investigated. This study seeks to assess the effectiveness of FGFR inhibition as a therapeutic approach for aggressive MB-Gr3, utilizing FDA-approved FGFRi and innovative FGF trap molecules developed in our laboratory.

Material and method

In this study we exploited MB-Gr3 cells (HD-MB03, D425Med and MED411) to assess the expression and activation of the FGF/FGFR system. The inhibition of FGF/FGFR was carried out using a clinical grade FGFR inhibitor (Erdafitinib) and a FGF trap small molecule (UPR1430). Cell proliferation, Western blot and flow cytometry were used to test the effect of the drugs. In vivo, subcutaneous tumor xenograft was performed to validate the therapeutic effect and immunohistochemistry for the analysis of tumor samples.

Result and discussion

Preliminary data confirm that FGFRs are highly expressed and activated in aggressive MB subtypes, correlating with worse prognosis. In vitro studies

demonstrate that both FGFRi (Erdafitinib) and a prototypic FGF trap (UPR1430) significantly reduce MB cell proliferation. Indeed, Western blot analyses confirmed that anti-FGF/FGFR treatments significantly reduced the activation of FGFR and levels of MYC. In vivo, FGFR inhibition resulted in reduced tumor growth and impaired intra-tumor angiogenesis in a subcutaneous model of MB-Gr3 (HD-MB03 cells).

Conclusion

In conclusion, our preliminary data suggest that the FGF/FGFR system plays a role and might represent a promising target for the treatment of MB-Gr3.

³Derio, Spain

⁴Koch Institute for Integrative Cancer Research, Cambridge, United States

Introduction

Cancer metastasis requires the acquisition of genetic, transcriptional and translational features that enable invasion in distant organs. However, the role of non-canonical post-translational modifications and their impact in cancer metabolism and progression is less explored. UFMylation is the last identified ubiquitin-like post-translational modification and participates in essential biological functions.

Material and method

In order to identify key pathways in the metastatic process, we made use of publicly available Prostate Cancer databases using Cancertool and cBioPortal. Furthermore, we developed molecular tools to genetically modify the UFMylation pathway and perform several in vitro proliferation and invasion techniques, and in vivo metastatic assays. We also carry out metabolic tracing assays and glycoprotein identification experiments. Finally, to identify UFMylated proteins, we developed several stable cell lines expressing BioID and TurboID fusion proteins and analysed them via immunoblot, immunofluorescence, and biotin-affinity purification-based proteomics.

Result and discussion

Through a bioinformatics search we identified protein UFMylation as a process altered in prostate cancer metastasis, where the expression of UFL1 and UFM1 was consistently downregulated in metastatic lesions compared to primary tumors in multiple prostate cancer patient cohorts. Our in vitro and in vivo results showed that reducing UFMylation in prostate cancer cells favours cancer cell invasion and metastatic dissemination at the expense of proliferation. Mechanistically, we identified a novel UFMylated protein, namely the glycolytic enzyme phosphofructokinase (PFKAP). Consistent with a role for

UFMylation in the regulation of PFKAP activity, loss of UFMylation increases the flux of glucose from glycolysis towards the hexosamine biosynthesis pathway, the production of precursors for protein glycosylation, and the glycosylation of integrins that participate in the process of cancer cell dissemination.

Conclusion

Our results reveal PFKAP as a new UFMylation target and support a metabolic role for UFMylation in metastasis through the pivotal contribution of PFKAP regulation in this process.

Introduction

Glioblastomas (GBM) are the most common and aggressive malignant brain tumors, characterized by high invasiveness, resistance to therapies, and poor prognosis. These tumors exhibit marked cellular heterogeneity, comprising a more differentiated bulk tumor population and a subpopulation of Glioblastoma Stem Cells (GSCs), which retain stem-like properties. Evidence suggests that GSCs play a crucial role in therapy resistance and tumor relapse, yet conventional treatments primarily target the bulk tumor cells, leaving this resilient subpopulation largely unaffected. Thus, a better understanding of the mechanisms governing stemness in GSCs is urgently needed to identify novel therapeutic targets. CITED2, a co-transcriptional modulator, is a key regulator of pluripotency in both embryonic and adult stem cells. Its role in cancer is complex, with both pro-tumorigenic and anti-tumorigenic functions reported across different malignancies. This study aims to investigate whether CITED2 influences GBM biology, with a particular focus on its impact on both GSCs and bulk tumor cells.

Material and method

To model both the bulk tumor population and Glioblastoma Stem Cells (GSCs), we cultured GBM cell lines under two distinct conditions: (i) differentiated bulk tumor cells, grown in 2D cultures with fetal bovine serum (FBS), which promotes cell differentiation, and (ii) GSC-enriched populations, cultured in 3D, low-adherence conditions using a neural stem cell-adapted medium,

which supports stemness properties. To assess the role of CITED2 in GBM biology, we modulated its expression through overexpression and knockdown approaches. The resulting cell populations were subjected to functional assays to evaluate self-renewal, proliferation, migration, viability, and tumorigenic potential.

Result and discussion

Functional assays revealed that CITED2 overexpression enhances cancer stem cell properties, including increased clonogenic potential and metabolic activity. Conversely, CITED2 knockdown significantly reduced the clonogenic capacity of GBM cells, suggesting a key role in tumor cell self-renewal. Additionally, sphere formation assays demonstrated reduced aggregation and smaller spheroid size in CITED2-overexpressing cells, which may indicate alterations in cell-cell adhesion or changes in the stem-like properties of these populations.

Conclusion

Altogether, our results suggest that CITED2 may contribute to the self-renewal and tumorigenic properties of GBM. Therefore, modulating CITED2 expression in this context may be an effective therapy approach that deserves further study.

EACR25-1512

Elucidating how nutrient dynamics in the tumor microenvironment modulates cancer metastasis

S. Laine¹, P. Castillo¹, P. Sánchez², M. Guarini²,

A. Rodriguez², E. Balsa¹

¹Centro de Biología Molecular Severo Ochoa, Madrid, Spain

²2. Institute for Research in Biomedicine, Barcelona, Spain

Introduction

Metastasis is the leading cause of cancer-related mortality, yet the metabolic adaptations driving this process remain poorly understood. While primary tumor metabolism has been extensively studied, metastatic cells exhibit distinct metabolic demands. Nutrient availability in the tumor microenvironment contributes to metabolic heterogeneity, potentially promoting invasive cell states. Identifying the nutrients, metabolites, and metabolic pathways that enhance metastatic potential remains a major challenge. We hypothesize that nutrient fluctuations induce metabolic stress, triggering adaptive reprogramming that enhances metastatic potential via epigenetic memory. To investigate this, we developed a high-throughput, multiplexed screening platform to systematically assess metabolite influence on melanoma, the deadliest skin cancer.

Material and method

To determine whether nutrient perturbations drive metastatic states, we designed an innovative multiplexed strategy for evaluating metabolite contributions to metastasis. Our approach leverages lentiviral genetic barcoding, enabling the unique identification of cancer cell clones via PCR and NGS. We first performed untargeted metabolomics on tumor interstitial fluid (TIF) and plasma from melanoma-bearing mice, identifying

over 500 metabolites, with 25% showing significant differences. To functionally assess these metabolites, we utilize our platform, which enables parallel testing of 14 stable murine melanoma cell lines, each carrying a unique genetic barcode. The 14 barcoded cell lines are cultured under distinct nutrient conditions, pooled, and injected into the circulation of wild-type mice. Lung metastases are then analyzed via barcode DNA sequencing to quantify representation and assess metastatic impact. If significant changes are detected, single-cell RNA sequencing is performed to identify metabolic pathways driving metastasis.

Result and discussion

Using this platform, we have tested various metabolic conditions, including metabolites differentially present in tumor-derived TIF and others linked to distinct physiological or pathological contexts (e.g., essential amino acids, vitamins, microbiota-derived metabolites). Our results demonstrate that specific metabolites modulate the metastatic potential of melanoma cells. Furthermore, we are validating key findings and exploring the underlying molecular mechanisms through scRNA-seq, uncovering gene expression changes and pathways associated with the pro-metastatic phenotype.

Conclusion

We have developed a powerful multiplexed screening platform to systematically investigate how metabolic conditions shape melanoma metastasis. This scalable approach identifies nutrient-driven vulnerabilities in metastatic cells, providing new insights into tumor metabolism and potential therapeutic targets.

³*University of Palermo, Department of Health*

Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (PROMISE), Palermo, Italy

Introduction

The nerve growth factor receptor (NGFR) plays a key role in neuronal plasticity and is implicated in tumor progression in colon cancer. Within the tumor bulk, colon cancer stem cells (CR-CSCs) are characterized by self-renewal capacity, tumor growth promotion, metastasis, and chemoresistance. Recent studies have highlighted that CR-CSCs reprogram their lipid metabolism to sustain stemness, enhance metastasis, and confer chemotherapy resistance. Notably, CR-CSCs accumulate lipid droplets (LDs) more than healthy cells. Under metabolic stress, LDs release free fatty acids (FFAs), which can be utilized for ATP generation via fatty acid oxidation (FAO). Dysregulated lipid metabolism is a critical factor in cancer development, and increased lipid uptake enhances the tumor-initiating capacity of CR-CSCs.

Material and method

CR-CSCs were transduced with lentiviral vectors to overexpress NGFR. Metabolism-associated gene expression profiles were analyzed via RT-PCR using a customized gene panel, including lipid metabolism genes, in NGFR-overexpressing cell lines. Intracellular lipid content was evaluated via Nile Red staining (1 µM). Additionally, NGFR-overexpressing cells were treated with chemotherapeutic agents – 5-fluorouracil, oxaliplatin, and irinotecan – at 1, 2, and 10 µM for 72 and 96 hours to evaluate whether NGFR is directly or indirectly involved in the acquisition of a chemoresistant phenotype.

Result and discussion

Analysis from public databases (GEPIA) was performed to identify genes mostly associated with NGFR expression in CRC, revealing several genes involved in CR-CSCs lipid metabolism, including GPIHBP1, CD36, PLIN1, and FABP4. Gene Set Enrichment Analysis (GSEA) highlighted significant enrichment in pathways related to adipogenesis, lipid localization, and transport. Transcriptomic analysis of NGFR-overexpressing cells showed upregulation of lipid metabolism genes such as FASN, FADS1, FADS2, PLIN1, and ACSL5, suggesting that NGFR regulates lipid metabolic pathways in CR-CSCs. Nile Red staining confirmed increased lipid droplet accumulation in NGFR-overexpressing cells, reinforcing NGFR's role in lipid metabolism. Given the putative association between high fatty acid content and resistance to chemotherapy-generated ROS, we hypothesized that NGFR plays a crucial role in the acquired chemoresistance to standard treatment. Our data confirmed this hypothesis, demonstrating that NGFR expression induces resistance to 5-FU, oxaliplatin, and irinotecan.

Conclusion

NGFR-overexpressing CR-CSCs boost lipid metabolism, with a consequent increase in intracellular lipid droplet accumulation, suggesting a critical role for NGFR in regulating lipid metabolism, which may contribute to chemoresistance in CRC. Accordingly, NGFR could represent a potential therapeutic target in overcoming chemoresistance in the future.

C/EBPα coordinates key metabolic pathways driving the resistance to targeted therapies in FLT3-mutated acute myeloid leukemia

L. Lauture¹, L. Goupille¹, E. Saland¹, A. Sahal¹, E. Boët², C. Mazzotti³, J. Corre³, P. Dumas⁴, C. Récher³, J. Sarry¹

¹*Cancer Research Center of Toulouse, Toulouse, France*

²*Translational Research Center in Onco-Hematology, Genève, Switzerland*

³*Toulouse University Cancer Institute Oncopole, Toulouse, France*

⁴*Bordeaux Institute of Oncology, Bordeaux, France*

Introduction

Acute myeloid leukemia (AML) are heterogeneous malignancies characterized by the uncontrolled proliferation of immature myeloid cells in the bone marrow. FLT3 mutations, present in approximately 30% of patients, drive leukemic cell survival by enhancing

glucose metabolism, amino acid utilization, and redox homeostasis. These metabolic adaptations contribute to therapy resistance, leading to high relapse rates and poor prognosis. Therefore, targeting the specific metabolic vulnerabilities of this patient subgroup could offer new therapeutic opportunities.

Material and method

To investigate novel FLT3-specific non-genetic mechanisms of therapeutic resistance, we performed a combination of bulk and single-cell multiomics analyses with functional approaches, alongside *in vivo* experiments, using FLT3-mutant AML cell lines and primary specimens from AML FLT3-mutated patients.

Result and discussion

In this context, we identified the transcription factor C/EBP α as a key regulator of lipid metabolism and FLT3 inhibitors response in FLT3-mutated AML. We demonstrated that its inhibition perturbs lipid homeostasis by reducing phospholipid production and increasing PUFA accumulation, sensitizing leukemic cells to ferroptosis, a lipid peroxidation-driven cell death. Notably, we found that ferroptosis inducers potentiate the effects of FLT3 inhibitors through the C/EBP α -SCD pathway, uncovering a metabolic vulnerability that could be therapeutically exploited. Beyond resistance to FLT3 inhibitors, FLT3-mutated AML also exhibits poor response to venetoclax/azacitidine (VEN/AZA), the current frontline therapy for newly diagnosed patients ineligible for intensive chemotherapy. However, the mechanisms underlying the response to VEN/AZA remain poorly understood in this mutational context. Our current study reveals that mitochondrial transaminases play a critical role in VEN/AZA resistance in FLT3-mutated cells. Mechanistically, C/EBP α regulated mitochondrial function and amino acid metabolism through glutamate-pyruvate transaminase 2 (GPT2) expression. Since amino acid metabolism is crucial in VEN/AZA response, we further showed that genetic and chemical inhibition of mitochondrial transaminases GPT2 or glutamate-oxaloacetate transaminase 2 (GOT2) (and not cytosolic transaminase GOT1) triggered mitochondrial oxidative stress and markedly sensitized FLT3-mutant AML cells to VEN/AZA treatment *in vivo*.

Conclusion

Together, our findings establish a novel role of C/EBP α in regulating both lipid and amino acid metabolism, affecting therapeutic response in FLT3-mutant AML. By identifying lipid biosynthesis enzymes and mitochondrial transaminases as key metabolic drivers of FLT3 inhibitors or VEN/AZA resistance, respectively, our study highlights promising targets to enhance treatment efficacy in this high-risk patient subgroup.

Crosstalk between autophagy and apoptosis induced by unsymmetrical bisacridines in pancreatic cancer cells

A. Kurdyn¹, B. Pezala¹, E. Augustin¹

¹*Gdańsk University of Technology, Department of Pharmaceutical Technology and Biochemistry, Gdańsk, Poland*

Introduction

Pancreatic cancer (PC) is an aggressive malignancy with a poor prognosis, highlighting the urgent need for novel therapeutic strategies. Our previous studies demonstrated that unsymmetrical bisacridines (UAs) exhibit high anti-cancer activity against PC cells by inducing apoptosis and decreasing c-Myc protein levels. Autophagy plays a complex, dual role in tumor progression, including PC, where increased autophagy correlates with poor prognosis. This study aimed to evaluate the impact of UAs on autophagy and its crosstalk with apoptosis in PC cells.

Material and method

We used four human pancreatic cancer cell lines (Panc-1, MIA PaCa-2, AsPC-1, BxPC-3), one normal pancreatic cell line (hTERT-HPNE), and three UAs (C-2028, C-2045, C-2053). Cell viability was assessed using the MTT assay, and apoptosis was detected with Annexin V-FITC and caspase 3/7 cytometric assays. Autophagy was evaluated by observing acidic vesicular organelles (AVOs) using acridine orange and Western blot analysis of autophagy-related proteins: LC3, p62, Beclin1, and Bcl-2.

Result and discussion

UAs exhibited lower activity against normal cells than PC cells, and IC₈₀ doses were several times higher in normal cells (C-2028: 0.04-0.10 μ M for PC vs 0.366 μ M for normal cells). These compounds preferentially induced apoptosis in PC cells (C-2028: 27.4-57.0% for PC vs 26.7% for normal cells). The strongest apoptosis induction was triggered by the derivative that also most severely caused autophagy (C-2028 for MIA PaCa-2 and AsPC-1; C-2045 for Panc-1; C-2053 for BxPC-3), confirmed by increased LC3-II levels, decreased p62, and change in the AVOs amount. In the AsPC-1 and BxPC-3 cells, a decrease in Beclin1 levels was observed with no significant changes in Bcl-2, while in Panc-1 cells, both Beclin1 and Bcl-2 levels decreased, suggesting Beclin1/Bcl-2-independent activation of autophagy in these three cell lines. In contrast, in MIA PaCa-2 cells, UAs caused an increase in Beclin1 and Bcl-2 levels, with the lowest Bcl-2 induction for C-2028. Only in MIA PaCa-2 cells was p62 accumulation observed with weak LC3-II induction after treatment with C-2045 and C-2053, suggesting autophagy inhibition. The use of chloroquine (CQ), an autophagy inhibitor, combined with UAs had little effect on cell survival, except in BxPC-3, where CQ enhanced C-2053's cytotoxic effect, evidenced by increased caspase 3/7 activity (C-2053 - 12.1%; C-2053 + CQ - 23.4%). This implies a protective role of autophagy in BxPC-3 cells.

Conclusion

UAs exhibit a preferential cytotoxic effect on PC cells, with significantly reduced activity in normal cells. These compounds induce autophagy in PC cells in a manner dependent on both the cell line and UA derivative. Strong autophagy induction correlates with increased apoptosis, suggesting autophagy's dual roles based on cellular stress. After exposure to UAs, the protective effect of Bcl-2 is insufficient, leading to autophagy disruption and apoptosis dominance.

Introduction

Pancreatic cancer (PC) is a disease with a poor prognosis due to its low survival. Despite the efforts made by medicine, current treatments to fight PC are not effective. Part of the problem is the late diagnosis of the disease. Once diagnosed, most patients receive chemo-therapy regimens as FOLFIRINOX, which is formed by the combination of leucovorin, 5-fluorouracil (5-FU), irinotecan and oxaliplatin. Regrettably, resistance mechanisms are recurrent causes of treatment failure. A potential strategy to overcome these resistance phenotypes is to dissect them in genetically-defined model systems that take into account the heterogenous genetic landscape of these tumors, to then develop better therapeutic strategies. KRAS is an oncogene, which is activated in more than 95% of patients with pancreatic ductal adenocarcinoma (PDAC), and can be found altered differently among patients. Recent studies have shown that common altered mechanisms of chemoresistance may be link to KRAS activation. The main objective of this project is to evaluate the mechanisms underlying acquired resistance to the combination of three cytostatic agents: 5-FU, SN-38 and Oxaliplatin (FIRINOX) in PDAC in the context of distinct KRAS mutations. To achieve this goal, we have set up two types of models: 1) in vitro by using mouse pancreatic organoids (KPOs) and 2) in vivo by performing orthotopic transplantation of KPOs in syngeneic mice.

Material and method

KPOs were previously generated by transfecting LSL-KrasMUT organoids (G12D, G12V and G12R) with a plasmid expressing Cre recombinase and a sgRNA targeting Tp53. We have chosen three prevalent mutations in PDAC as KRAS-G12D (40%), KRAS-G12V (32,5%) and KRAS-G12R (18%), to then, induced chemoresistance in the different KPOs by continuously treating them with increasing concentrations of FIRINOX

regimen. To assess the acquisition of chemoresistance, cell viability was measured. Then, chemoresistant (chr) and non-chemoresistant KPOs were transplanted orthotopically into the tail of the pancreas of syngeneic mice (C57Bl/6N). Harvested tumors have been profiled by immunohistochemistry and flow cytometry at final time point.

Result and discussion

We have already induced chemoresistance to FIRINOX in 3 KPO-KRASG12D, 3 KPO-KRASG12V and 3 KPO-KRASG12R lines. Preliminary data shows that in vitro chr-KPO lines tolerate a higher concentration of FIRINOX regimen. The initial characterization in vivo exhibits phenotypic changes among chr and non-chr-tumors expressing specific KRAS mutations.

Conclusion

This preliminary data is the seed to continue our research strategy, that seeks to unravel the connection between specific-KRAS mutations, tumor heterogeneity and treatment resistance. In the near future, we hope to identify new vulnerable targets to design new therapy approaches depending on the specific KRAS mutation in the context of chemoresistance.

EACR25-1545

Unbiased Phosphoproteomic and Metabolic Profiling in WT and KRAS Mutant Colorectal Cancer Cells Reveals Molecular Interplay Between Protein Regulation and Metabolic Rewiring

E. Stancliffe¹

¹*Panome Bio, St. Louis, United States*

Introduction

KRAS mutations cause significant metabolic and protein dysregulation in cancer, leading to alterations in cellular signaling pathways, promoting uncontrolled cell growth and proliferation. The metabolic reprogramming of altered KRAS function includes increased glucose, amino acid, and lipid metabolism. The changes in the cellular proteome stem from modifications in protein expression and phosphorylation. Understanding the interplay between these metabolic and protein-level alterations is crucial for developing targeted therapeutic strategies against KRAS-driven cancers. Accordingly, we performed an integrated metabolomic and phosphoproteomic analysis of HCT116 cells with and without a KRAS mutation.

Material and method

HCT-116 cells containing wildtype (WT, n = 5) and mutant KRAS (MUT, n = 5) were profiled to assess metabolite, protein, and phosphoprotein levels between WT and MUT cells. Metabolomic profiling was completed with LC/MS to capture polar and lipid metabolites. Data was processed through an in-house untargeted metabolomic analysis pipeline. For phosphopeptide analysis, enriched phosphopeptides and flow-through peptides were analyzed with DIA LC/MS/MS. The resulting data was processed with DIA-NN and combined into aggregated protein and phosphosite profiles.

Result and discussion

The multi-omic analysis profiled 2,025 metabolites, 6,654 proteins, and 10,034 phosphosites. When considering each data type individually, all three analyte types separated the WT and MUT cells through PCA analysis, underscoring the magnitude of dysregulation from KRAS mutation. When considering the metabolites, proteins, and phosphosites that reached statistical significance, 85 metabolites and 145 proteins were differentially abundant. Strikingly, 1,036 phosphosites were unique to either KRAS and WT samples, with ~800 of these being unique to KRAS samples. The results of a joint pathway analysis identified >70 pathways that reached significant enrichment ($p < 0.05$) and had support at both the protein, metabolite, and phosphosite level. The most enriched pathway was RAS signaling. Other enriched pathways include selenocysteine synthesis, sialic acid metabolism, ROS detoxification, and respiration.

Conclusion

This study showed extensive differential phosphorylation in KRAS mutant cells, suggesting a widespread rewiring of signaling networks that impacts diverse cellular functions. The multi-omic approach taken enabled the identification of previously known and novel pathways affected by KRAS signaling, offering potential new targets for therapeutic intervention in KRAS-driven cancers.

⁶*Helmholtz Zentrum München, Institute for Diabetes and Cancer, Munich, Germany*

Introduction

Neuroendocrine tumors (NETs) are a heterogeneous group of neoplasias that originate from neuroendocrine cells in various organs, including the pancreas and pituitary gland. Pancreatic NETs (PanNETs) and pituitary adenomas/NETs represent clinically relevant subtypes, typically characterized by the expression of somatostatin receptors (SSTRs). These receptors represent key therapeutic targets for both somatostatin analogs (SSAs) and peptide receptor radionuclide therapy (PRRT). Currently approved SSAs exhibit high affinity for specific SSTR subtypes, with octreotide and lanreotide targeting SSTR2, while pasireotide binds to SSTR5, SSTR3 and SSTR2. Despite the availability of these

SSAs, these peptides may not be suitable for all patients due to variable SSTR expression, limited efficacy in aggressive or advanced tumors, and the potential development of resistance. As a result, developing novel compounds targeting NET-specific pathways is crucial to improving patient outcomes. In this study, we tested 5 newly synthesized SSAs having high affinity for SSTR2 and SSTR5 that are being developed as SSAs and PRRT.

Material and method

As experimental models, we selected the NT-3 and AtT-20 cell lines, derived from a human well-differentiated pancreatic NET (Pan-NET) and a murine pituitary adenoma cell line, respectively. NT-3 cells were chosen based on their low proliferation rate, sustained SSTR expression, and insulin-secreting capability, making them a representative in vitro model for Pan-NETs. Similarly, AtT-20 cells, which secrete ACTH, serve as a well-established model for pituitary adenomas/NETs. Since SSAs are expected to inhibit tumor growth and suppress hormone secretion, we assessed the short-term effects of the five peptides on these features using proliferation/viability assays (WST-1, cell count) and hormone secretion measurements (ELISA for insulin or ACTH) in 2D cultures.

Result and discussion

In the pancreatic NT-3 cell model, all tested peptides strongly inhibited insulin secretion at doses ranging from 5 to 100 nM, and significantly blunted proliferation compared to untreated controls. In the pituitary AtT-20 cell model, two out of five peptides had clear inhibitory effects on ACTH secretion, while the peptides also appeared to limit tumor cell growth.

Conclusion

These results indicate that the newly synthesized SSAs effectively inhibit both hormone secretion and cell proliferation in NET models. Further investigations in 3D cultures and in vivo models will be essential to confirm their therapeutic potential and optimize their clinical applicability.

EACR25-1555

CK2α and CHIP crosstalk: uncovering its role in tumorigenic processes

S. Karmakar¹, M. Chatterjee¹, D. Ghosh¹

¹*IICB, CBID, Kolkata, India*

Introduction

Casein Kinase II (CK2) is a ubiquitously expressed eukaryotic serine/threonine protein kinase known for its heightened activity in proliferating and cancerous tissues. The catalytic subunit, CK2α, phosphorylates a wide array of substrates, including both tumor suppressors and oncogenes, thereby playing a pivotal role in modulating signaling pathways that drive cell proliferation in cancer. The Carboxy Terminus of Hsc70 Interacting Protein (CHIP), a dual-function co-chaperone and E3 ubiquitin ligase, is crucial for maintaining protein homeostasis by targeting misfolded or damaged proteins for degradation.

Material and method

Assays for ubiquitination, overexpression, cycloheximide chase, and inhibition were used to measure changes in protein levels. Additionally, Liquid chromatography-mass spectrometry (LC-MS), immunocytochemistry

(ICC) and co-immunoprecipitation (Co-IP) were carried out. To assess the therapeutic importance of these results, additional studies included spheroid modelling, migration and invasion assays performed.

Result and discussion

Our findings explores the interaction between CK2 α and CHIP in cancer development. Preliminary analysis indicated an inverse relationship between the two proteins, suggesting CK2 α may regulate CHIP degradation and inhibit apoptosis. This degradation stabilizes the oncogenic kinase AKT that leads to possible phosphorylation by CK2 for its super-activation and promoting tumorigenesis. Functional assays supported these findings, demonstrating CK2 α 's role in controlling CHIP protein levels.

Conclusion

This study unveils a potential CK2 α -CHIP regulatory axis in cancer, offering new insights into the molecular mechanisms driving tumor progression. However, further research is essential to fully elucidate the complexities of this regulatory pathway and its broader implications in cancer biology. Understanding this mechanism could pave the way for novel therapeutic strategies targeting the CK2 α -CHIP axis in cancer treatment.

Investigating the role of PTX3 in the biology of glioblastoma

C. Tavani¹, E. Somenza¹, S. Filiberti¹, F. Pagani², P. Poliani³, C. Boccaccio⁴, F. Orzan⁴, F. De Bacco⁴, P. Martini⁵, R. Ronca¹

¹*University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy*

²*University Medical Center Hamburg-Eppendorf, Laboratory for Translational Research, Hamburg, Germany*

³*Ospedali Civili of Brescia, Pathology Unit, Brescia, Italy*

⁴*Candiolo Cancer Institute, Laboratory of Cancer Stem Cell Research, Candiolo, Italy*

⁵*University of Brescia, Biology and Genetics Section, Brescia, Italy*

Introduction

Glioblastoma Multiforme (GBM) is the most common and aggressive brain tumor in adults, classified as grade IV tumor by WHO. Common therapies include surgical removal, chemotherapy and radiotherapy; however, relapses are inevitable. In addition, it is hypothesized that the relapses are mainly due to a subpopulation of stem cells with self-renewal properties, called glioblastoma stem cells (GSC) localized in specialized niches. These cells are resistant to conventional treatments thanks to their ability to escape apoptosis and activate DNA repair mechanisms. Pentraxin 3 (PTX3) is a soluble pattern recognition receptor belonging to the humoral arm of the innate immunity that is also involved in several aspects of tumor growth, angiogenesis, metastasis and cancer immunoregulation. To date, a correlation between PTX3 and tumor aggressiveness in GBM has been described, but studies regarding its role in GSC are still missing, as well as the identification of the biological pathways involved. In order to investigate this issue, we used different in vitro and in vivo models, increasing the

complexity system and moving closer to the pathological scenario found in humans.

Material and method

We used human GSC BT302 cells, derived from glioblastoma specimens diagnosed according to WHO criteria, to obtain PTX3 silenced cells. PTX3 presence and production was assessed by Western blot, qPCR, ELISA and immunostainings. We analysed the cell culture features and we generated organoids as in vitro models, while we performed subcutaneous and orthotopic injection in immunodeficient mice to evaluate the effect in PTX3 knockdown in vivo. Proliferation, invasion and angiogenic assays were performed to analyse the effects of PTX3 silencing. In addition, RNA microarray analysis was conducted in order to identify the up- and down-regulated pathways, in response to PTX3 modulation. According to the output of the bioinformatic analysis, a further characterization through immunohistochemical stainings has been carried out.

Result and discussion

Preliminary observations revealed a wide expression of PTX3 in GSC, and specific silencing in a GSC line revealed a significant reduction of cell growth, invasiveness and angiogenic capacity in GSC after PTX3 knockdown. In vivo this resulted in decreased tumorigenic capacity. Furthermore, bioinformatic analysis revealed a modulation of apoptotic and hypoxia-related pathways, whose activation seems to be altered after PTX3 silencing. Accordingly, immunohistochemical characterization revealed an effective increase in hypoxia levels and a decrease of the proliferation rate in the PTX3 silenced conditions.

Conclusion

Our data suggest that PTX3 is expressed and may play a relevant role in GSC cells. In this context, PTX3 silencing may impair tumor features in vitro and in vivo. These data set the basis for further characterization of the pro-tumoral role of PTX3 in glioblastoma.

EACR25-1564

Trigger ferroptosis in breast cancer cells (BC) by targeting xCT and FATP1

B. Abreu¹, C. Mendes², J. Serpa²

¹*Nova Medica School, Lisboa, Portugal*

²*Nova Medica School, Portugal*

Introduction

Cancer cells can reprogram their cellular metabolism to proliferate. Cysteine and fatty acids metabolism are two pathways that work synergistically to support breast cancer (BC) progression and protect these cells against damages caused by lipid peroxidation. We aimed to induce BC cell death by inhibiting two transporters that play pivotal roles in cysteine and fatty acids uptake, xCT and FATP1, using the compounds selenium chrysin (SeChry) and 5k piperazine, through ferroptosis, a cell death caused by excessive lipid peroxidation.

Material and method

The human TNBC cell lines MDA-MB-231 and HCC1806, and Luminal A and Luminal B cell lines MCF7 and BT474 were used and exposed to SeChry (EC50 concentration: 24 μ M for HCC1806; 7 μ M for MDA-MB-231; 23 μ M for BT474, and 19 μ M for MCF7), and 5k (12.5 μ M) in separate or in combination,

in regular media and stearic acid (C18) enriched media. Cell death, reactive oxygen species (ROS), and lipid peroxide levels were assessed using Annexin-V and PI, and the DCF-DA (2 μ M) and Bodipy 581/591 C11 (2 μ M) probes by flow cytometry, respectively. xCT and FATP1 expression was observed by immunofluorescence and lipid droplet (LD) levels were examined by fluorescence microscopy, using Nile red (1 μ L /mL) staining. Xenograft orthotopic mice models of MDA-MB-231 cells were developed and treated with SeChry encapsulated in a nanoparticle (SeChry@PUREG4-FA2) and SeChry@PUREG4-FA2 + 5k. Primary tumors were collected, measured, frozen, and embedded in optimal cutting temperature (OCT) compound. Tumor sections were stained with Nile red and Bodipy 581/591 C11 probe and analyzed by fluorescence microscopy.

Result and discussion

The EC50 concentration of SeChry showed that the MDA-MB-231 cell line was the most sensitive to SeChry, which tended to decrease FATP1 and LD levels in all cell lines. Exposure to 5k resulted in increased cell death and lipid peroxide levels in BC cells cultured in C18-enriched media. It was confirmed that ferroptosis was occurring, as evidenced by the decrease in ROS levels caused by SeChry, along with an increase in lipid peroxides, indicating that ROS are consumed during lipid peroxidation. Exposure to a C18-enriched medium significantly enhanced ferroptosis in TNBC cell lines, suggesting they have a greater susceptibility to ferroptosis. Treatment with SeChry@PUREG4-FA2 reduced the volume of BC xenograft tumors with decreased LD accumulation and increased lipid peroxide levels, which was not seen in treatment with SeChry@PUREG4-FA2 and 5k. This disclosed a protective role that 5k has over SeChry, because it reduces fatty acid uptake.

Conclusion

Upon increased levels of cell death, decrease in mice tumor size, and accumulation of lipid peroxides both in vitro and vivo, we confirmed the potential of SeChry@PUREG4-FA2 as a promising therapeutic strategy. However, 5k decreased the anti-cancer efficacy of SeChry by lowering the amount of fatty acids to undergo peroxidation, thus inhibiting ferroptosis.

EACR25-1571

Attaching to and Crossing Endothelial Barriers

G. Follain¹, S. Ghimire², J. Pylvänen¹, J. Ivaska¹, G. Jacquemet²

¹University of Turku, Turku, Finland

²Åbo Akademi University, Turku, Finland

Introduction

Leukocyte extravasation is a key component of the innate immune response, while circulating tumor cell extravasation is a critical step in metastasis formation. Despite their importance, the mechanisms underlying leukocyte and tumor cell extravasation remain incompletely understood.

Material and method

Here, we developed an imaging pipeline that integrates fast, label-free live-cell imaging with deep learning-based

image analysis to quantitatively track and compare the initial steps of extravasation – cell landing and arrest on an endothelial monolayer – under physiological flow conditions.

Result and discussion

We find that pancreatic ductal adenocarcinoma (PDAC) cells exhibit variable adhesion strength and flow sensitivity. Remarkably, some PDAC cells demonstrate comparable endothelial engagement as leukocytes, preferentially arresting at endothelial junctions, potentially due to increased stiffness at these sites, which leads to exposure to the underlying basal extracellular matrix. PDAC cells also tend to cluster in regions with high, heterogeneous expression of the endothelial CD44 receptor. Simulations suggest that clustering results from the combination of CD44-mediated attachment and localized flow disturbances that facilitate subsequent cell attachment. Targeting CD44 using siRNA or function-blocking antibodies, or degrading its ligand hyaluronic acid (HA), almost completely abolishes PDAC cell attachment.

Conclusion

Overall, we demonstrate that cancer and immune cells share both common and unique features in endothelial adhesion under flow, and identify CD44 and HA as key mediators of PDAC cell arrest.

EACR25-1573

Apoptotic and cytotoxic effect of hispolon in human colorectal adenocarcinoma cell line (HT-29)

A. Chinnaiyan¹, P. Deivasigamani¹, B. Pandiyarajan¹, N. Ahamed², S. Kathiresan²

¹Thanthai Periyar Government Arts and Science College (Autonomous)-Affiliated to Bharathidasan University, Post Graduate and Research Department of Biochemistry, Tiruchirappalli, India

²Annamalai University, Department of Biochemistry and Biotechnology, Annamalai nagar, India

Introduction

Cancer remains a major global health challenge, characterized by uncontrolled cell growth and metastasis. Colorectal cancer (CRC) is one of the most common malignancies worldwide, and the need for effective treatments is imperative. This study aims to evaluate the therapeutic potential of hispolon in HT-29 human colorectal adenocarcinoma cells, focusing on its effects on cell viability, oxidative stress markers, and apoptosis.

Material and method

HT-29 cell line were obtained from National Centre for Cell Science (NCCS), Pune, India. For hispolon treatment, 8% purity of hispolon was obtained from Santa Cruz Biotechnology(sc-221726), Dallas, Texas, USA. HT-29 cells were treated with varying concentrations of hispolon. Cell viability was assessed using the MTT assay. Lipid peroxidation was measured by determining malondialdehyde (MDA) formation. The activities of antioxidant enzymes, including superoxide dismutase (SOD), catalase, and glutathione peroxidase (GPx), were evaluated. The levels of reduced glutathione (GSH) were also quantified. ROS generation was assessed using a fluorescent probe. Apoptosis was

analyzed using acridine orange/ethidium bromide (AO/EtBr) staining.

Result and discussion

Hispolon treatment resulted in a dose-dependent (10–100 μM) manner. The treated cell line showed significant cytotoxic activity against HT-29 cell line with an IC₅₀ value of 48 μM decrease in cell viability, as demonstrated by the MTT assay. A significant increase in lipid peroxidation and MDA formation was observed, indicating oxidative stress induction. Hispolon treatment also led to alterations in antioxidant enzyme activities, with increased SOD and catalase activities and decreased GPx activity. The levels of reduced glutathione (GSH) were significantly reduced in hispolon treated cells. Furthermore, hispolon treatment induced a substantial increase in ROS generation. AO/EtBr staining revealed a marked increase in apoptotic cell population following hispolon treatment.

Conclusion

The findings suggest that hispolon exerts potent anti-cancer effects on HT-29 cells by inducing oxidative stress, modulating antioxidant enzyme activities, and promoting apoptosis. The dose-dependent cytotoxicity, increased lipid peroxidation, ROS generation, and alterations in antioxidant defences highlight the potential of hispolon as a therapeutic agent for colorectal cancer. Further studies are warranted to elucidate the underlying molecular mechanisms and explore the clinical applications of hispolon in cancer treatment.

⁸*i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal*

Introduction

Cell-cell adhesion is a biomarker of circulating tumor emboli, a hallmark of aggressive Inflammatory Breast Cancer (IBC).

Material and method

This work aims to explore if cell-cell adhesion disruption has an impact on the survival of circulating IBC emboli. Using 3D spheroids of IBC models, E- and/or P-cadherin were silenced in SUM149PT and MDA-IBC-3 cells.

Result and discussion

Initial observation showed that E- and P-cadherin compensate each other to maintain adhesion in SUM149PT, while E-cadherin plays a dominant role in cell-cell adhesion in MDA-IBC-3. Disruption of cell-cell adhesion in SUM149PT cells reduced anoikis resistance ($p = 0.0040$) and slightly decreased calcein/PI intensity ($p = 0.0002$), but no significant changes in caspase 3/7 activation or ROS production were observed. In MDA-IBC-3 cells, anoikis resistance was unaffected, but the viability of cells increased with E-cadherin KD ($p = 0.011$) and double KD ($p = 0.045$). Thus, cell death induction was not as pronounced as initially expected. Proteomics was then conducted to uncover the mechanisms that enable IBC cells to resist cell death upon cell-cell adhesion disruption. Interestingly, in the double KD, the results indicated an upregulation of “negative regulation of apoptotic processes” and “regulation of stress granule assembly”. G3BP2, a key scaffolding protein for stress granule assembly, was highly expressed at protein, mRNA, and ultrastructural levels when E/P-cadherin were silenced in SUM149PT cells. This was accompanied by increased expression of stress granule-associated genes (e.g., G3BP1, YTHDF1-3, FMR1, ATXN2L) and pluripotency/EMT-related genes (e.g., OCT4, KLF4, ZEB1, CDH2, SLUG, SOX2, TWIST). Additionally, recent evidence indicates that treating SUM149PT IBC double knockdown (KD) spheroids with an integrated stress response inhibitor (ISRB) significantly reduces cell survival. However, no significant changes were observed in single knockdowns of either cadherin.

Conclusion

In conclusion, the upregulation of stress granule assembly may enable IBC cells to survive to cell-cell adhesion disruption. Then targeting cell-cell adhesion and stress granule assembly holds promise as a potential therapeutic strategy for this aggressive disease.

EACR25-1588

Dual Cyclin-CDK Inhibition by Plant-Derived Hexadecanoic Acid Triggers G1/S Arrest

S. Wright¹, K. Wallace², H. Asemota²

¹*University of the West Indies Mona, Biomedical Engineering, Kingston, Jamaica*

²*University of the West Indies Mona, Biochemistry, Kingston, Jamaica*

Introduction

Prostate cancer is the second most common cancer among men, with the Caribbean experiencing the highest mortality rates globally. Conventional treatments rely on chemotherapy, often leading to resistance and adverse effects. This has spurred interest in alternative therapies with targeted mechanisms. Hexadecanoic acid, a naturally occurring saturated fatty acid, has demonstrated anticancer properties, including apoptosis induction and cell cycle modulation. This study examines the effects of hexadecanoic acid-enriched extracts from *Dioscorea cayenensis* and *Dioscorea alata* on prostate cancer cells.

Material and method

Hexadecanoic acid-enriched extracts from *D. cayenensis* and *D. alata* yams were tested on DU145 prostate cancer

and RWPE-1 normal prostate cells. Cytotoxicity was assessed via MTS assay (IC₅₀ determination). Morphological changes were observed microscopically. Flow cytometry evaluated G1/S arrest, and Western blotting analyzed cyclin D and CDK4 expression.

Result and discussion

Treatment of DU145 cells with hexadecanoic acid-enriched extracts resulted in significant antiproliferative effects, with an IC₅₀ of 18 µg/mL, while RWPE-1 cells exhibited minimal cytotoxicity (IC₅₀ >200 µg/mL). Morphological changes were observed in DU145 cells following treatment, suggesting cellular stress or apoptosis. Flow cytometry analysis confirmed that treatment induced G1/S cell cycle arrest, indicating disruption of cell cycle progression. Western blot analysis revealed a marked reduction in cyclin D and CDK4 expression, further supporting the role of hexadecanoic acid in regulating cell cycle progression. These findings suggest that hexadecanoic acid exerts its anti-cancer effects through dual inhibition of cyclins and CDKs, leading to G1/S arrest in prostate cancer cells.

Conclusion

Hexadecanoic acid-enriched extracts from *D. cayenensis* and *D. alata* demonstrate selective cytotoxicity against DU145 prostate cancer cells while sparing normal prostate cells. The observed G1/S cell cycle arrest and downregulation of cyclin D and CDK4 indicate a targeted mechanism of action. Given its selective anticancer properties, hexadecanoic acid may serve as a promising natural therapeutic agent for prostate cancer. Further molecular and *in vivo* studies are necessary to validate its clinical potential.

EACR25-1590

The impact of the microsporidia *Encephalitozoon intestinalis* on colorectal carcinogenesis

L. Vercruyse¹, V. Bonnin¹, A. Dubuffet², M. Bonnet¹, C. Nourrisson¹, P. Poirier¹

¹*Clermont Auvergne University, M2iSH, UMR INSERM 1071, INRAe 1382, Clermont-Ferrand, France*

²*Université Clermont Auvergne, CNRS, Laboratoire Microorganismes: Génomes et Environnement, Clermont-Ferrand, France*

Introduction

Colorectal cancer is a multifactorial disease influenced by genetic, environmental and microbial factors. Among the latest, the intestinal microsporidia *Encephalitozoon intestinalis* which is known to disrupt the cell cycle and inhibit host cell apoptosis could be a potential pro-carcinogenic actor. Recent epidemiological studies, notably by our team (Nourrisson et al., 2024), suggest a link between microsporidia and CRC. Indeed, sero-prevalence of the *Encephalitozoon* genus is significantly higher in CRC patients. Aim of this study is to precise impact of infection on epithelial cells.

Material and method

In vitro cellular infection models using Vero E6 and HT-29 cells were used to study the effects of *E. intestinalis* infection for 24H et 48H, with infection efficiencies approaching 80%. Their impact on apoptosis, cell cycle, and proliferation was evaluated by flow cytometry (using

TUNEL assays and cell cycle analysis), by immunofluorescence (targeting p53 and Ki67), by RT-qPCR and Western Blot analyses to assess the expression of genes such as PCNA, Cyclins (E, A, and D), Retinoblastoma, and p21. A cell culture inserts system (which prevents the passage of spores) was also used to study the effect of the secretome from *E. intestinalis*-infected cells (above) on non-infected cells (below).

Result and discussion

We observed that *E. intestinalis* induced cell cycle arrests in the S and G2 phases, as well as increased protein accumulation of cyclins E (24H) and A (48H), and a decrease in the protein proliferation marker PCNA (48H). There was also a decrease in gene expression of p53 and bax and protein expression of p21. These results suggest that microsporidia block the host cell in metabolically and energetically favorable phases for reproduction, while inhibiting the induction of cell apoptosis. Recent experiments with the cell culture insert system have shown cell cycle arrest in S and G2 phases in uninfected cells below infected cells, suggesting that the secretome of infected cells can induce cell cycle arrest in neighboring uninfected cells.

Conclusion

These results indicate that *E. intestinalis* disrupts host cell cycle regulation by inducing cycle arrest, decreased proliferation and inhibition of apoptosis. In addition, these infected cells appear to secrete molecules that induce these same phenotypes in neighboring cells. This could enable potentially damaged adjacent cells to survive. Together, these alterations may initiate a pro-tumor environment favoring genomic instability and cell survival, potentially contributing to the development and progression of colorectal cancer.

Therapeutic approaches to primary NRAS-driven leptomeningeal melanoma

M. Rabii^{1,2}, P. Jones^{1,2}, I. del Valle Torres^{1,2}, A. Sauvadet^{1,2}, A. Pasquier³, M. Jiang³, M. Howell³, D. Bryant^{1,2}, V. Kinsler^{1,2,4}, D. Zecchin⁵

¹*The Francis Crick Institute, Mosaicism and Precision Medicine Laboratory, London, United Kingdom*

²*UCL Great Ormond Street Institute of Child Health, Genetics and Genomic Medicine, London, United Kingdom*

³*The Francis Crick Institute, High-throughput Science Technology Platform, London, United Kingdom*

⁴*Great Ormond St Hospital for Children, Paediatric Dermatology, London, United Kingdom*

⁵*Institute of Ophthalmology UCL, London, United Kingdom*

Introduction

Primary NRAS-driven leptomeningeal melanoma is a rare childhood cancer most often seen in the context of mosaic disorder congenital melanocytic naevus syndrome. It is universally and rapidly fatal, although treatment with MEKi trametinib confers temporary symptomatic benefit. We sought to explore other therapeutic options, small interfering RNA (siRNA) to oncogenic NRAS, which has recently been shown to induce apoptosis in dermal melanocytic naevus cells¹,

and a high throughput FDA approved small molecule screen.

Material and method

Antisense siRNAs to siNRASQ61K (NM_002524.5 (NRAS):c.181C>A,p.(Q61K)) and siNRASQ61R (NM_002524.5(NRAS:c.182A>G,p.(Q61R))) were designed to be variant allele-specific, and transfected into the following cell lines: NRAS-variant primary leptomeningeal cells from three patients with leptomeningeal dysplasia, the precursor to leptomeningeal melanoma; NRAS-variant primary leptomeningeal cells from one patient with leptomeningeal melanoma; two control wild-type immortalised melanocyte cell lines hTERT-dermal melanocytes and HERMES-1. In parallel, an in vitro drug screen of 2529 FDA-approved drugs was performed in primary leptomeningeal cells from one patient with leptomeningeal dysplasia and the two wild-type melanocyte cell lines, with validation of potential hits in all patient and control lines. IncuCyte® repeated phase-contrast imaging was used to measure confluence and a DNA-binding fluorescent caspase 3/7 dye to measure apoptosis across both experiments.

Result and discussion

We report here that oncogenic driver knockdown with siNRASQ61K or siNRASQ61R triggers apoptosis in all leptomeningeal patient cells, dysplastic or malignant. Furthermore, addition of current clinical standard of care trametinib to siNRAS further elevates levels of apoptosis over siNRAS alone, despite a complete lack of apoptosis with trametinib alone. Mechanistic exploration demonstrates siNRAS treatment leads to downregulation of antiapoptotic genes BIRC5 and ARL6IP1, a gene protective against ER stress recently identified as downstream of NRAS. Additionally, we report here that the top four drug hits from the FDA screen epirubicin, tucidinostat, dasatinib and valemestat suppress proliferation in patient cells significantly more than in controls, with epirubicin having the greatest effect. None of these small molecules, however, has any effect on apoptosis. Lastly, we explore the genome-wide expressional profiles of dysplastic and malignant cells pre- and post-treatment with epirubicin, trametinib and siNRAS.

Conclusion

Precision targeting of oncogenic NRAS driver alleles using siRNA is more promising than repurposing of small molecule inhibitors in currently untreatable leptomeningeal dysplasia and melanoma, potentially in combination with trametinib.

EACR25-1598

Investigating the Therapeutic Potential of Antidiabetic Drugs, Metformin and Canagliflozin, in Papillary Thyroid Carcinoma

M. Gonçalves¹, M. Castanho¹, N. Jesus¹, P. Soares², V. Máximo²

¹*Faculdade de Medicina, Universidade do Porto (FMUP), Porto, Portugal*

²*Instituto de Patologia e Imunologia Molecular da Universidade do Porto (Ipatimup), Porto, Portugal*

Introduction

Thyroid cancer (TC) is the most common endocrine neoplasia. The incidence of TC has been increasing, mainly due to the increased incidence of papillary thyroid carcinoma (PTC). Generally, PTC patients have a good prognosis, however, 10 to 15% of cases can evolve to a more aggressive state, leading to recurrence and metastasis. The cause of this change in PTC's biological behaviour is unknown, making it essential to predict cases at risk of progression. Metformin and canagliflozin are antidiabetic drugs, and recent studies suggest that these drugs influence various cancer cell lines, affecting proliferation, invasion, migration, growth, morphology, metabolism, cell cycle, and autophagy. However, the available data are still controversial and limited. Our aim is to evaluate the effects of metformin and canagliflozin on PTC cells, assessing their impact on key cellular and molecular processes. This may help determine their potential as therapeutic agents for PTC patients who don't respond to conventional treatments.

Material and method

Two PTC cell lines, TPC-1 and BCPAP - with different genetic alterations (RET/PTC rearrangement and BRAFV600E, respectively) - and one non-neoplastic thyroid cell line, Nthy Ori 3-1, were chosen. We optimized drug concentrations to evaluate their effects on cellular and molecular parameters, including proliferation, viability, apoptosis, cell cycle dynamics, metabolic activity, mitochondria, and cell morphology and migration, using techniques such as Prestoblue and EdU assays, fluorescence bioimaging, Seahorse XFe24 Analyzer, flow cytometry, electron microscopy and wound healing assay.

Result and discussion

Our results show that the viability of the cancer cell lines decreased with statistical significance from the concentration of 20 mM metformin and 20 µM canagliflozin, with the strongest effect at 48h post-treatment. This effect wasn't observed in Nthy Ori 3-1. Based on these results, 20 mM metformin and 20 µM canagliflozin were selected for further studies. When treated, TPC-1 and BCPAP cell proliferation were significantly reduced ($p < 0.01$) with both drugs, while there was no effect in Nthy Ori 3-1. Regarding migration, canagliflozin delayed wound closure in cancer cells, while metformin inhibited wound closure only in BCPAP. In contrast, migration in Nthy Ori 3-1 wasn't affected by either drug. Treatment also altered mitochondrial morphology and increased mitochondrial number in BCPAP and TPC-1. Notably, lipid droplets emerged in treated tumour cell lines with a statistically significant increase. We are currently assessing the impact of these drugs on cell cycle and in metabolism.

Conclusion

The observed effects on viability, proliferation, migration, mitochondrial dynamics, and lipid droplet formation suggest a potential therapeutic benefit of metformin and canagliflozin for PTC patients. Further insights into their impact on cell cycle and metabolism would complement these findings.

EACR25-1599**Nucleotide imbalance sensed by p53 leads to an upregulation of pyrimidine salvage transporter hCNT1**

M. Mata-Jurado^{1,2}, A. Mata-Ventosa^{1,2}, J. Soler-Raig^{1,2}, F. Battistini^{3,4}, J. Gelpí⁵, M. Pastor-Anglada^{1,2}, S. Pérez-Torras^{1,2}

⁴*The Barcelona Institute of Science and Technology, Institute for Research in Biomedicine, Barcelona, Spain*

⁵*University de Barcelona, Department of Biochemistry and Molecular Biomedicine, Barcelona, Spain*

Introduction

Increased biosynthesis of nucleotides (NTPs) and deoxy-nucleotides (dNTPs) is a hallmark of cancer, driven by the need to support DNA replication and repair, transcription, ribosome biogenesis and post-translational protein glycosylation. Nucleotide biosynthesis encompasses a complex network of enzymes and transporters that can be divided into de novo synthesis pathways and salvage reactions from nucleosides and nucleobases. Wild type p53 plays an important role in nucleotide metabolism regulation inhibiting pentose phosphate pathway and purine de novo synthesis. However, when activated upon DNA damage, p53 can activate dNTP synthesis through RRM2B to favor DNA repair. Moreover, gain of function activities of mutant p53 contribute to nucleotide metabolism reprogramming to support proliferation and invasion. This study aims to define a p53 regulation over some essential elements of nucleoside salvage, such as nucleoside transporters (NTs), which are also responsible for the internalization of nucleoside analog drugs. Our work focuses on Concentrative Nucleoside Transporter 1 (hCNT1, encoded by SLC28A1), a unidirectional pyrimidine transporter whose expression has been reported to be decreased in a wide variety of tumors.

Material and method

NTs expression was determined after wtp53 restitution by RT-PCR in different models. Possible binding sites for p53 in SLC28A1 promoter were found by bio-informatics approaches. Promoter-luciferase reporter assays and ChIP-RT-PCR were performed to validate them. Induction of hCNT1 expression has been studied in p53 WT and KO HCT-116 cells. In order to induce DNA damage or an imbalance on nucleotide pools, cells were subjected to different treatments, including Etoposide or Brequinar. The role of mutant p53 has been also studied.

Result and discussion

Our data indicates that wtp53 overexpression specifically induces hCNT1 expression in a non-tumoral background. Putative binding sites for wtp53 in hCNT1 promoter have been identified and validated. Blockage of pyrimidine de novo synthesis with Brequinar or induction of DNA damage with Etoposide lead to an upregulation of hCNT1 expression largely dependent on p53 activation,

suggesting that p53 could play a role in connecting de novo and salvage pathways to maintain nucleotide pools. Interestingly, this regulation induced by wtp53 is not replicated by restoring different mutant p53 expression in a p53 KO model, which could contribute to hCNT1 expression reduction observed in tumors and the consequent decrease in some nucleoside analogs incorporation.

Conclusion

wtp53 regulates nucleoside salvage pathway transporter hCNT1 expression. Besides, in cell contexts where wtp53 is induced by DNA damage or imbalance of nucleotide pools transcription of hCNT1 is potentiated. However, mtp53 fails to induce hCNT1 expression.

Introduction

Pyroptosis is an inflammatory cell death process in which Gasdermin family protein plays a central role as final effectors. Gasdermins (GSDM, six members in human GSDMA-F), consist of a pyroptotic N-terminal domain (NTD) with the pyroptotic role, and a C-terminal domain (CTD), with auto-inhibitory capacity, both linked by a hinge region. In response to specific stimuli, the NTD is released, oligomerizes at the plasma membrane and forms pores that ultimately lead to cell death by pyroptosis. Interestingly, while activating GSDM lytic function in tumors could be a promising therapeutic anticancer approach, the overexpression of GSDMB or GSDMD has also been associated with pro-tumor activities. Thus, GSDMB promotes anti-HER2 therapy resistance and poor prognosis in HER2+ breast and gastric tumors, whereas high GSDMD associates with chemotherapy resistance and lower survival in lung cancer and osteosarcoma. However, the functional roles of GSDMB and GSDMD in endometrial cancer (EC) remain unknown. EC is the most common malignant gynecological tumor in developed countries and the eighth in incidence in women. While surgery is the primary treatment, it is often insufficient for advanced or recurrent cases with poor prognosis and there are few effective targeted therapies. Consequently, to identify novel predictive and prognostic biomarkers and to develop new therapeutic opportunities for aggressive

EC tumors, we focus our multidisciplinary study on the implication of GSDMB and D in these tumors.

Material and method

We first evaluated GSDMB and GSDMD expression by immunohistochemistry in a cohort containing different subtypes of ECs. We also analyzed the pyroptotic capacity of GSDMB and GSDMD in different EC cell lines, by western blotting and live-cell confocal microscopy.

Result and discussion

In the EC cohort, GSDMB and GSDMD expression associated with distinct clinicopathological variables, such as prognosis and histological subtype. Furthermore, we observed a differential expression of GSDMB and GSDMD within different EC cell lines. We generated diverse models expressing the cytotoxic NTDs of GSDMB or GSDMD and observed increased cell death capacity. Moreover, we also proved that distinct GSDMB isoforms exhibit differential pyroptotic capacity, when EC are cocultured with NK cells.

Conclusion

Our study advances in the characterization of pyroptosis in EC, discovering key differences between the expression of GSDMB or GSDMD in EC tumor samples and cell lines, as well as in the ability of these Gasdermins to conduct cell death under different cellular contexts.

EACR25-1615

Evaluation of Anti-Cancer Effects of Omeprazole in Prostate Cancer Cells

N. Memiş¹, B. Gundogdu¹, U. Demir²

¹*Yıldız Technical University, Molecular Biology and Genetics, Istanbul, Turkey*

²*Istanbul Medeniyet University, Molecular Biology and Genetics, Istanbul, Turkey*

Introduction

Prostate cancer is the second most common cancer in men worldwide. Proton pump inhibitors (PPIs), widely used for gastritis, are being repurposed as anti-cancer agents. Omeprazole, an FDA-approved PPI, has shown anti-cancer potential in various cancers. WZB117 is a selective GLUT1 inhibitor. This study aims to investigate the effects of Omeprazole on prostate cancer cells and its potential synergy with WZB117.

Material and method

The prostate cancer cell lines were treated with Omeprazole to evaluate its effects on viability, colony formation, migration, and lipid droplet accumulation. The crystal violet staining assessed cell viability, while fluorescence microscopy visualized lipid droplets. The molecular docking simulations analyzed Omeprazole's binding affinity. To assess synergy with WZB117, the combinatorial treatments were applied, followed by viability assays. 3D spheroid formation assays were performed, and the glucose consumption and pH changes were measured to evaluate metabolic shifts.

Result and discussion

IC50 values for PC-3, LNCaP, and CCD1072-SK cells were determined as 175.3, 77.4 and 481.4 μM respectively. Omeprazole reduced PC-3 colony formation and inhibited lipid droplet accumulation in LNCaP cells. The docking analysis confirmed high binding affinity to

target proteins. Omeprazole and WZB117 showed synergistic effects, reducing spheroid size in 3D cultures. While the glucose consumption and acidity of medium were increased in omeprazole treated cells, the combined treatment with WZB 117 and omeprazole lowered the acidity and glucose consumption in LNCaP cells. Our findings suggest that Omeprazole exerts anti-cancer effects in prostate cancer by inhibiting colony formation, migration, and lipid metabolism. Molecular docking analysis confirmed its strong binding affinity to target proteins. The synergistic effect observed with WZB117 indicates that dual targeting of lipid and glucose metabolism may enhance therapeutic efficacy. The metabolic shift, evidenced by increased acidity in treated cancer cells, suggests significant alterations in cellular metabolism. Notably, the differential response in normal cells highlights potential selectivity.

Conclusion

Omeprazole, especially in combination with WZB117, shows promise as an anti-cancer agent in prostate cancer, warranting further investigation for preclinical applications.

EACR25-1635

Therapy-induced senescence shapes tumor biology and treatment outcome in hepatoblastoma

L. Fankhänel¹, B. Bosco², Á. del Río Álvarez³, M. Kiefer¹, D. Montuori¹, M. Taube⁴, C. Armengol Niell³, J. Dörr¹

¹*Experimental and Clinical Research Center, Charité Berlin, MDC Berlin, Berlin, Germany*

²*Experimental and Clinical Research Center, Charité Berlin, MDC Berlin, Germany*

³*Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain*

⁴*MDC Berlin, Berlin, Germany*

Introduction

Hepatoblastoma is the most common malignant liver tumor in children with poor survival rates in high-risk cases. Due to the very few recurrent genetic aberrations targeted therapies remain unavailable. Therefore, dynamic changes in hepatoblastoma cell states upon cytotoxic therapies, such as senescence, need to be characterized to unveil new targets for synthetic lethal or senolytic treatment approaches. Therefore, we investigate changes in hepatoblastoma biology upon therapy-induced senescence (TIS) with the goal to identify senescence-specific vulnerabilities that can be exploited to improve the therapy with “one-two punch” treatment approaches.

Material and method

Hepatoblastoma cell lines (HepG2, Hep293TT, Huh6), patient-derived xenografts (PDX), Myc-/Ctnnb1-driven mouse models generated by hydrodynamic tail vein infection (HTVI) in C57Bl/6 mice with defined senescence-specific genetic defects (Suv39h1- or CDKN2A-/-) were treated with doxorubicin or cisplatin. TIS was assessed in cell lines in vitro and tissue sections in situ by H3K9me3 and Ki67 immunofluorescence (IF) as well as SA-β-gal staining. Similarly hepatoblastoma patient samples from different molecular risk groups were analyzed to correlate senescence status to treatment outcome. Changes in tumor cell biology and micro-

environment were analysed by RNA sequencing, flow cytometry and spatial multiplex imaging (MACSima, Miltenyi). A high-throughput pharmaceutical screen with the European Biology Chemical pilot library (ECBL) combined with cytological profiling by Cell Painting was performed to identify senescence-specific vulnerabilities.

Result and discussion

Senescence was induced upon treatment with Doxorubicin in hepatoblastoma and PDX-derived cell lines, and Myc- and Ctnnb1-driven hepatoblastomas upon exposure to Doxorubicin and Cisplatin *in vivo* as evidenced by increased H3K9me3 levels, reduced Ki67 staining and higher SA- β -gal activity. Hepatoblastoma patient samples showed signs of senescence by RNAseq and immunofluorescence analysis. Importantly, low molecular risk groups (MRS1, MRS2) displayed higher levels of senescence than with improved overall survival by Kaplan Meier analysis. Senescent cells displayed higher immunogenicity, including the upregulation of MHC class I proteins and CD80. MACSima analysis demonstrated increased infiltration of macrophages and T cells into senescent hepatoblastomas. In the ECBL screen cell painting analyses of untreated vs. senescent HepG2 cells identified five highly selective senolytic compounds targeting mitochondrial and endoplasmic reticulum function.

Conclusion

The results highlight senescence as a key treatment response in hepatoblastoma that strongly impacts on tumor biology and overall survival. Given the absence of targeted therapies, senolytic “one-two punch” approaches represent a promising strategy to improve outcomes for high-risk hepatoblastoma patients.

Characterization of Patient-derived xenograft (PDX)- derived organoids (PDXOs) to Find New Treatment Strategies for LKB1-Mutated NSCLC

A. Paffetti¹, M. Colombo¹, C. Folloni², A. Cerrone¹, L. Rosso³, P. Mendogni³, C. Grasselli¹, A. Panfili¹, M. Broggini¹, E. Caiola¹

¹*Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy*

²*IRCCS Istituto Clinico Humanitas, Milan, Italy*

³*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*

Introduction

Lung cancer is the leading cause of cancer-related death, with 2.2 million new cases and 1.8 million deaths in 2020. Non-small cell lung cancer (NSCLC) accounts for 85% of cases, with lung adenocarcinoma (LUAD) as the most common subtype. Despite improved NSCLC survival due to personalized therapies, LKB1-inactivating mutations, found in 30% of cases, reduce response to immune checkpoint inhibitors (ICIs) and exclude targeted therapy options, conferring poor prognosis and an unmet clinical need. Our research group explores ERK inhibitors as alternative treatments using patient-derived xenografts (PDXs) and PDX-derived organoids (PDXOs). Thanks to the collaboration with Fondazione

Ca' Granda in Milan, we access fresh tumor samples, as PDXOs better model tumor complexity than 2D cultures, which fail to fully replicate NSCLC heterogeneity and biology.

Material and method

PDXOs were generated by mechanically disaggregating fresh tumor biopsies, followed by enzymatic digestion with collagenase to obtain single-cell suspensions, which were cultured in ultra-low attachment (ULA) plates. STR analysis confirmed genetic matching between PDXOs and original tumors. Organoid growth curves were assessed by seeding disaggregated PDXOs in 96-well ULA plates at xx cells/ml, monitoring viability using CellTiter-Glo assay every 24 hours. Human and murine cell composition was evaluated by real-time PCR using actin gene analysis. Flow cytometry and immunofluorescence analyses of fixed PDXOs identified lung, epithelial, and mesenchymal markers. Whole exome sequencing (WES) determined specific alterations. Pharmacological treatments on suspended PDXOs commenced 48 hours post-seeding, followed by seven-day incubation and viability assessment via CellTiter-Glo.

Result and discussion

In the past year, we successfully generated five new PDXOs and re-established four previously obtained. Two newly derived long-term (>10 passages) LKB1-mutant PDXOs were stabilized, adding to three pre-existing ones. Histological and flow cytometry analyses confirmed the expression of lung cancer, epithelial, and mesenchymal markers, while molecular profiling demonstrated preservation of alterations in both patient samples and PDXs. PDXOs displayed heterogeneous growth rates, partially mirroring their PDX counterparts. Preliminary pharmacological characterization validated ERK inhibitor efficacy in LKB1-null cells. WES data will guide combination strategies to enhance treatment responses based on specific alterations identified.

Conclusion

PDXOs represent reliable preclinical models for studying NSCLC biology and vulnerabilities, particularly in LKB1-mutant tumors, for which therapeutic options remain limited. Our findings support the use of ERK inhibitors in combination with other targeted therapies, opening new perspectives for treating this tumor subpopulation.

EACR25-1645

Highlighting the Small GTPase RhoA as a New Therapeutic Target in ALK+ ALCL

V. Mugoni¹, G. Mura¹, F. Pancioni¹, C. Pighi¹, M. Russo¹, M. Di Marco¹, M. Maccagno¹, R. Piazza², R. Chiarle^{1,3,4}, C. Voena¹

¹*University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy*

²*University of Milan-Bicocca, Department of Medicine and Surgery, Milan, Italy*

³*Harvard Medical School, Department of Pathology, Boston Children's Hospital, Boston, United States*

⁴*European Institute of Oncology IRCCS, Division of Haematopathology, Milan, Italy*

Introduction

Rho GTPases are critical players in the biology of T cell lymphoma. Recurrent genetic lesions of RhoA and dysregulation have been reported in different T cell lymphoma, including Angioimmunoblastic T-cell lymphoma (AITL) and Peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS). In ALK+ anaplastic large cell lymphoma (ALCL) oncogenic ALK regulates the Rho family GTPases CDC42 and RAC. We have demonstrated that the cytoskeleton regulators WASP and WIP are frequently downregulated resulting in hyper-activation of the RhoGTPase CDC42 and the MAPK pathway. Therefore, hyperactivated CDC42 and MAPK pathway represent a therapeutic vulnerability in ALK+ ALCL. We have previously demonstrated that RhoA activity is repressed by ALK, but its specific role in ALK-driven lymphomagenesis is not yet elucidated.

Material and method

To explore the contribution of RhoA in NPM-ALK lymphomagenesis, we generated the NPM-ALK/CD4Cre/RhoAfl/fl Tg mouse models from which we derived primary murine cell lines to dissect cell-autonomous alterations in vitro. We also abrogated RhoA expression by the CRISPR/Cas technology in human ALK+ lymphoma cell lines TS, JB6 and COST. We assessed cellular rewiring in the absence of RhoA by measuring cell proliferation and metabolism, analyzing actin organization through immunofluorescence and signaling by Western blot. We also performed RNA Sequencing analysis to evaluate changes of the transcriptome profile in RhoA knock-out cells. We tested in vitro the combination of ALK tyrosine kinase inhibitors (TKIs) and the ROCK inhibitor Y-27632.

Result and discussion

In vivo RhoA deletion impaired lymphoma development resulting in significant extension of survival of NPM-ALK/RhoAfl/fl mice. In vitro, in both murine and human cell lines, RhoA deletion affected lymphoma cell proliferation and migration, and caused changes in cell morphology and actin organization. RhoA knock-out ALK+ lymphoma cells underwent transcriptional rewiring to repress genes for mitotic spindle organization, cell cycle checkpoint regulation and reprogram metabolic processes for energy production. Moreover, the ratio of glucose/lactate production and oxygen consumption were significantly decreased in RhoA knock-out cells. In addition, RhoA knock-out ALK+ lymphoma cells showed increased sensitivity to ALK TKI crizotinib and inhibition of the RhoA downstream effector ROCK in combination with ALK-TKI, further potentiated the effects of crizotinib.

Conclusion

Overall, our findings suggest that RhoA plays a critical role in ALK-driven lymphomagenesis, with its deletion impairing lymphoma progression and increasing sensitivity to ALK-targeted therapies. In addition, RhoA deletion alters cell proliferation, migration, and metabolism, suggesting its potential as a therapeutic target in ALK+ lymphomas.

EACR25-1661

Deciphering the Role of CMA in Platinum Resistance: The Impact of LAMP2A in OCCC

G. Yılmaz Demir¹, İ. Durmaz Şahin²

¹Koç University, Research Center for Translational Medicine (KUTTAM), Istanbul 34450, Turkey

²Koç University, Graduate School of Health Sciences, Istanbul, Turkey

Introduction

Ovarian clear cell carcinoma (OCCC) is often diagnosed at early stages; however, its poor responsiveness to chemotherapy remains a significant clinical challenge. The limited efficacy of platinum-based chemotherapeutic agents frequently leads to disease recurrence and poor patient outcomes. Identifying alternative therapeutic targets is therefore critical. Chaperone-mediated autophagy (CMA), a selective autophagy pathway, regulates protein turnover in cancer cells, influencing their survival and progression. CMA has been reported to play dual roles in cancer, acting as both a tumor-promoting and tumor-suppressive mechanism depending on the context. As lysosomal-associated membrane protein type 2A (LAMP2A) is the key mediator of CMA, elucidating its role in drug resistance mechanisms in OCCC may provide valuable insights for novel treatment strategies.

Material and method

The JHOC-5 OCCC cell line was used to investigate the role of LAMP2A in platinum-based drug responses. LAMP2A knockout (KO) cells were generated using CRISPR/Cas9 genome editing. Whole-genome sequencing confirmed the absence of off-target effects and the successful knockout of the LAMP2A-specific sequence. Drug response was assessed in parental, plasmid control, and KO cells using the Sulforhodamine B (SRB) assay following cisplatin and carboplatin treatment. Further characterization of LAMP2A depletion effects included analysis of apoptosis-associated proteins, drug resistance mechanisms, and cell cycle distribution. Additionally, cell migration was assessed via the wound healing assay, while the colony formation assay was used to evaluate proliferative capacity.

Result and discussion

Loss of LAMP2A expression conferred increased resistance to cisplatin and carboplatin in JHOC-5 cells. In the wound healing assay, LAMP2A KO cells exhibited more aggressive behavior and enhanced migration. Similarly, in the colony formation assay, LAMP2A KO cells displayed an increased colony-forming ability compared to control cells. Further molecular analyses, including apoptosis-associated protein expression and cell cycle distribution, provided additional insights into how LAMP2A modulates drug response pathways.

Conclusion

These findings suggest that LAMP2A plays a modulatory role in chemotherapy resistance in OCCC. A deeper understanding of CMA's involvement in platinum-based drug response mechanisms may contribute to the development of more effective therapeutic strategies, particularly for drug-resistant ovarian cancer subtypes.

EACR25-1662

Ferrodoxin 2 is critical for tumor suppression and lipid homeostasis but dispensable for embryonic development

J. Zhang¹, X. Chen¹

¹University of California, Davis, Surgical Radiological Sciences, Davis, United States

Introduction

Ferrodoxin 1 and 2 (FDX1/2) constitute an evolutionarily conserved FDX family of iron-sulfur cluster (ISC) containing proteins. FDX1/2 are cognate substrates of ferredoxin reductase (FDXR) and serve as conduits for electron transfer from NADPH to a set of proteins involved in biogenesis of steroids, hemes, ISC and lipoylated proteins. Recently, we showed that Fdx1 is essential for embryonic development and lipid homeostasis. However, the biological function of FDX2 remains to be characterized.

Material and method

Genetic mouse model generation; Cell culture, siRNA transfection, RNA isolation and RT-PCR analysis, Plasmid construction and cell line generation, Western blot analysis, Nile Red staining, Measurement of cellular cholesterol and triglycerides, Histological analysis, Untargeted lipidomic analysis using LC-MS/MS

Result and discussion

To explore the physiological role of FDX2, we generated Fdx2-deficient mice. Interestingly, we found that unlike Fdx1-null embryos, which were dead at embryonic day 10.5 to 13.5, Fdx2-null mice were viable. We also found that both Fdx2-null and Fdx2-heterozygous mice had a short lifespan and were susceptible to spontaneous tumors and steatohepatitis. Moreover, we found that FDX2-deficiency increased whereas overexpression of FDX2 decreased cytoplasmic accumulation of lipid droplets. Consistently, we found that FDX2 deficiency led to accumulation of cholesterol and triglycerides. Mechanistically, we found that FDX2 deficiency suppressed expression of cholesterol transporter ABCA1 and activated master lipid transcription regulators SREBP1/2, thus leading to altered lipid metabolism. Untargeted lipidomic analysis showed that FDX2 deficiency led to altered biosynthesis of various lipid classes, including cardiolipins, cholesterol, ceramides, triglycerides, and fatty acids.

Conclusion

In summary, our findings underscore an indispensable role of FDX2 in tumor suppression and lipid homeostasis at both cellular and organismal levels without being a prerequisite for embryonic development.

EACR25-1668

Modeling gastric intestinal metaplasia in organoids: role of TP53 loss-of-function

M. Reines¹, S. Ertmann², H. Berger³, M. Sigal³, S. Müllerke³, V. Brinkmann⁴, S. San Miguel⁴, T. Meyer⁴

¹Technical University Berlin, Medical Biotechnology, Berlin, Germany

²Christian Albrechts University Kiel (CAU) and University Clinics Schleswig-Holstein (UKSH), Kiel, Germany

³Charité University Medicine, Berlin, Germany

⁴Max Planck Institute for Infection Biology, Berlin, Germany

Introduction

The gastric bacterium *Helicobacter pylori* chronically colonizes approximately half of the world's population

and triggers a cascade of inflammatory responses that can ultimately lead to gastric intestinal metaplasia (GIM) and gastric cancer (GC). While the early stages of this pathological cascade are reversible with *H. pylori* eradication via antibiotic treatment, GIM often represents a point of no return, placing patients at high risk for cancer. GIM is defined as the replacement of the gastric mucosa with an epithelium of intestinal identity, characterized by the appearance of goblet cells in the stomach. While the architectural features of this lesion are well characterized, the underlying molecular mechanisms remain largely unclear.

Material and method

Using CRISPR/Cas9 technology, we generated TP53 loss-of-function mutations in gastric organoids and functionally characterized them through RNA-seq, microscopy and infection experiments. Moreover, we validated our findings in TP53-mutant mice and patient-derived samples.

Result and discussion

TP53 mutant gastric organoids showed clear signs of reprogramming toward intestinal cells, including the activation of key intestinal markers such as the mucin MUC2 and CDX2, a hallmark of GIM. Interestingly, TP53 mutation in gastric organoids increased the production of antimicrobial peptides, including DMBT1. This antimicrobial protein, which was only expressed in metaplastic cells, showed potent activity against *H. pylori*.

Conclusion

Our results suggest that TP53 loss-of-function mutations drive GIM in the stomach and may contribute to its irreversible progression to gastric cancer. Furthermore, the identification of DMBT1 as a mutant p53-dependent antimicrobial factor provides new insights into the mechanisms underlying *H. pylori* clearance in the precancerous stage of GIM.

EACR25-1675

Modulation of SUMOylation machinery complex proteins induces cell death in human colorectal cancer cells

M. Salih¹, R. Williamson², H. Elrewey¹, S. Kantamneni¹

¹University of Bradford, Institute of Cancer Therapeutics, Bradford, United Kingdom

²University of Bradford, 1. School of Pharmacy & Medical Sciences, Bradford, United Kingdom

Introduction

Colorectal cancer is the second most frequently diagnosed cancer in women and the third most common cancer in men. There are multiple therapies available for the treatment of colon cancer, but the problem of drug resistance and metastasis is a major concern.

Understanding drug resistance pathways such as post-translational modification will provide insights into disease progression including new therapeutic opportunities. SUMOylation is a multi-step enzymatic post-translational modification cascade that facilitates the attachment of SUMO proteins to target substrates. This process involves an E2-conjugating enzyme (Ubc9, encoded by the UBE2I gene) and is regulated by deSUMOylating enzymes such as sentrin-specific

protease 1 (SENP1). This deSUMOylation step has been implicated in various tumours, including processes such as cell proliferation, survival, and DNA repair, making it a potential target for cancer therapies. The SUMOylation pathways in naked mole-rats (NMRs) are not well understood. NMRs have unique traits such as their longevity, resistance to cancer, and hypoxic adaptations and gaining insight into how SUMOylation is regulated in these pathways may provide insights. This study aimed to investigate the regulation of SENP1 and Ubc9 machinery between NMR intestinal tissues compared to human colorectal cancer cells, to find novel targets for cancer therapy.

Material and method

DLD-1 and HCT116 cell lines were used as colorectal cancer cell models. We used techniques such as cell culture, qPCR, Western blotting, colony formation, and invasion assays including genetic manipulations such as sh-knockdown and CRISPR knock-out cells.

Result and discussion

Here we report low expression levels of SENP1 and Ubc9 gene and protein in NMR tissues compared to DLD-1 colorectal cancer cells. SUMOylation machinery expression levels from NMR are recapitulated in DLD-1 and HCT116 colorectal cancer cells either by knockdown or knockout of the SENP1 and UBE21 to study functional effects. The knockdown and knockout of SENP1 or UBE21 reduces the colony formation, and invasions. The genetic manipulation also induces apoptotic mechanisms looking at Bcl-2 and BID expression in colorectal cancers compared to controls.

Conclusion

Our data revealed significant differences in the SUMOylation machinery between NMRs and colorectal cancer cells. This work provided substantial proof for further study to understand SUMOylation pathways to provide new strategies to target colorectal cancer.

α -Mangostin as a potential adjuvant in HER2+ breast cancer treatment

D. Amador-Martínez¹, L. Díaz¹, E. Avila¹, M. Ibarra-Sánchez², J. Esparza-López², R. García-Becerra³, F. Larrea¹, J. García-Quiroz¹

¹*National Institute of Medical Sciences and Nutrition Salvador Zubirán, Reproductive Biology Dr. Carlos Gual Castro, Mexico City, Mexico*

²*National Institute of Medical Sciences and Nutrition Salvador Zubirán, Biochemistry Unit Dr. Guillermo Soberón Acevedo, Mexico City, Mexico*

³*Biomedical Research Institute, Department of Molecular Biology and Biotechnology, Mexico City, Mexico*

Introduction

Breast cancer (BC) is the most prevalent neoplasia among women worldwide. It is classified into: estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-positive (HER2+), and triple-negative (TN) subtypes. Despite subtype-specific treatments, adverse effects often limit their clinical efficacy. Our previous in vitro studies demonstrated that α -mangostin (AM), a phytonutrient from mangosteen, enhances the anti-proliferative effects of 5-fluorouracil and tamoxifen in TN and ER+ BC cell models, enabling dose-reduction

without losing efficacy. This study evaluates the in vitro effects of AM in combination with the HER2 inhibitor lapatinib (LAP) on cell growth, LAP dose-reduction, and pharmacological interactions in HER2+ BC cells.

Material and method

All reagents were of analytical grade. Cell culture treatment conditions and pharmacological interactions: MBCDF (HER2+) BC cells were previously generated from an explant obtained during a radical mastectomy of a patient diagnosed with stage IV ductal infiltrating carcinoma. The cells were treated in sextuplicate with LAP [0–6 μ M], AM [0–10 μ M], or a combination of LAP [0–4 μ M] with AM [0, 2, 4, and 6 μ M] for six days. Cell proliferation was assessed by the sulforhodamine B (SRB) assay. The inhibitory concentration at 50% (IC50) was determined using nonlinear logistic regression. Combination index (CI), efficacy index (EI), and dose reduction index (DRI) were calculated to evaluate the compounds' interaction; anticancer efficacy; and drug reduction potential.

Result and discussion

The LAP-AM combination significantly inhibited MBCDF cell proliferation in a dose-dependent manner. Notably, AM enhanced LAP's antiproliferative effects, reducing its IC50 from 0.94 μ M (LAP alone) to 0.84 μ M, 0.60 μ M, and 0.34 μ M when combined with AM at [2 μ M, 4 μ M, and 6 μ M], respectively. Higher AM concentrations in the co-treatment induced a synergistic effect. DRI analysis indicated that LAP concentration could be reduced without compromising efficacy. The anticancer efficacy, measured by EI, was significantly enhanced in a dose-dependent manner. The addition of AM at 6 μ M to the LAP curve showed the maximum efficacy. These findings suggest that AM could be an adjuvant in HER2+ BC treatment, potentially reducing LAP dosage and its associated toxic effects. These results warrant future *in vivo* studies.

Conclusion

AM enhances the antiproliferative effect of LAP in HER2+ BC cells, enabling dose reduction without efficacy loss. Moreover, improved EI supports AM's potential as an adjuvant agent for LAP therapy.

This study was partially funded by the Department of Reproductive Biology, INCMSZ (BRE-2606). D.A.-M. received a research assistant fellowship from SECIHTI (Mexico) under the supervision of L.D. No conflicts of interest were declared.

EACR25-1712

Epigallocatechin-gallate (EGCG) augments the anti-leukaemic effect of L-asparaginase in childhood B-cell acute lymphoblastic leukaemia cells

B. Vergov¹, Y. Feodorova¹, E. Kovacheva¹, M. Kazakova¹, Y. Sbirkov¹, V. Sarafian¹

¹*Medical University of Plovdiv, Medical Biology, Plovdiv, Bulgaria*

Introduction

The dependency of childhood acute lymphoblastic leukaemia (CALL) cells on exogenous asparagine has made L-Asparaginase (ASNase) one of the key therapeutics in this haematological malignancy. Besides the relatively frequent immune-mediated inactivation of the enzyme, a number of molecular mechanisms of

resistance to ASNase have been described. The complex interplay between the activation of amino acid response, autophagy, MEK/ERK, mTORC1, Wnt signaling and other pathways, implicated in the response to asparagine (and glutamine) deamination and subsequent metabolic adaptation and survival, has raised interest not only in cALL, but in a number of other malignancies. Therefore, in order to tackle ASNase-resistant refractory or relapsed cALL, new therapeutic approaches addressing the bioenergetic plasticity of lymphoblasts need to be investigated. The green tea polyphenol flavonoid EGCG is a well-established inhibitor of glutamate dehydrogenase 1 and 2 (GLUD1/2), but also of IDH1 and other cell metabolism related targets making it an attractive pleiotropic therapeutic. In this study we aimed to characterize the response to ASNase and to EGCG and to investigate the potential of EGCG to concomitantly block potential rescue metabolic mechanisms in cALL cells and thus augment the anti-leukaemic effect of ASNase.

Material and method

REH, Sup-B15, and SEM B-cell cALL cell lines were examined after treatment with L-asparaginase and the epigallocatechin gallate (EGCG). Metabolomics analysis of cells, MTT assays, glutamine/glutamate luminescent assay, Annexin V/PI apoptosis test were applied, as well as assessment of mitochondrial function and ATP production by Seahorse XFp Analyzer (Agilent).

Result and discussion

We found that L-Asparaginase alters a number of amino acid biosynthesis pathways as well as purine and pyrimidine synthesis. These metabolic changes are accompanied by a significant reduction of mitochondrial function and ATP production. Furthermore, there is a distinct cellular response to the minimal clinically recommended concentrations of 0.1 IU/ml of ASNase, and a relatively wide range of IC₅₀ values for the three cell lines for EGCG – from ~8, 18 and 35 uM. Upon following the progression of cell proliferation and cell death on days 1, 3 and 7 after treatment, the three lines exhibited diverse dynamics spanning from apoptosis as early as on day 1 to delayed additive effects of the combination that were observed only beyond 72h.

Conclusion

We observed distinct metabolomic alteration patterns and different dynamics in the response to L-Asparaginase in all three cell lines. However, targeting cALL metabolism with EGCG holds potential to enhance the cytostatic and cytotoxic effects of this key chemotherapeutic.

Age-related effects in cancer therapy are driven by local and systemic changes in immune response

A. Vitlic¹, E. Romano¹, X. Wang¹, S. Valletta¹, J. Honeychurch¹

¹*University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom*

Introduction

There is a strong bidirectional relationship between ageing and cancer. Ageing of the immune system, immunosenescence, is characterised by immune dysfunction. This compromises immune-surveillance and is associated with an increased development of malignant tumours. Therapies that can directly activate anti-cancer immunity, such as radio-and immunotherapy, may also be affected by age-related changes in the immune system which may limit their efficacy. Therefore, it is important that cancer therapies are understood through the lens of ageing, by using aged mouse models in preclinical cancer research.

Material and method

Old mice (18-month-old ~65 years in humans) and their younger counterparts (8–10 weeks old mice ~20-year-old humans) on C57/Bl6 background were subcutaneously injected with 4434 melanoma cell line and treated with dual radio-immunotherapy (3x8Gy and aPD-L1, respectively) or left untreated. Tumour growth was monitored to compare age-related efficacy of therapy combination. A separate cohort was culled immediately prior to treatment (when tumours were ~100mm³) and tumours, draining and contralateral lymph nodes (LN), spleen and blood profiled using multi-parameter flow cytometry. Photoconvertible KikGR (Kikume Green Red) mice were used to monitor patterns of migration from draining LN into tumour and other immune organs, and how those change with age.

Result and discussion

The efficacy of combination therapy was significantly reduced in aged versus young mice. High-dimensional analysis of early tumours revealed a dominance of exhausted T cell clusters in old, whilst in the tumour microenvironment (TME) of young mice, clusters with higher IFNg and Granzyme B production, and a higher percentage of “stem-like” TCF1+ cells were more prevalent. This suggests that the more functionally suppressed TME of aged mice is leading to poorer therapy response. Similar age-related differences were seen in other immune-related organs from aged mice, except for draining lymph nodes where, despite increased PD-1+ phenotype, robust immune response, assessed through IFNg production, was observed. Migration experiments using KikGR mice demonstrated that T cells were less migratory in older mice, with a higher percentage of photoconverted cells staying trapped in the LN over time compared to younger counterparts. Thus, it appears that effector IFNg-producing T cells do not readily migrate to tumours in old mice.

Conclusion

Older mice show a significant decrease in the efficacy of anti-cancer therapy that is associated with localised age-related changes within immune-relevant tissues, including the TME and secondary lymphoid organs, as well as systemic changes in migration of immune effector cells. These data suggest that age-related changes in the anti-cancer immune response are important to consider when assessing the efficacy of cancer therapy.

Functional Characterization of UBX Domain Protein 7 (UBXN7) in

Glioblastoma: Implications for Tumor Progression

M. Domènech¹, M. Costa¹, M. Rezaeipour², A. Golebiewska², F. Grau¹, C. Vendrell¹, A. Martínez-Cardús¹, C. Carrato¹, C. Balañà¹, E. Martínez-Balibrea¹

¹Badalona, Spain

²Luxembourg, Luxembourg

Introduction

Glioblastoma (GB) is the most common primary brain tumor, with limited therapeutic options and a median overall survival of approximately 15 months. The GLIOCAT group conducted a genome-wide expression analysis of 151 GB patients treated homogeneously with the Stupp protocol, identifying UBX Domain Protein 7 (UBXN7) as an unfavourable prognostic biomarker (Clin Cancer Res, 2021). UBXN7 is involved in proteasomal degradation and ubiquitin-mediated signaling, and previous studies suggest that its overexpression may reduce HIF1α degradation, potentially contributing to GB progression. The aim of this work is to validate the role of UBXN7 in GB.

Material and method

We generated a UBXN7 knockout (KO) LN229 cell line using the CRISPR/Cas9 system, the absence of expression of UBXN7 was by western blot. To assess the impact of UBXN7 depletion, we performed proliferation and migration assays, comparing the UBXN7-KO-LN229 model to the non-targeting control (NT-LN229). Proliferation was monitored using the Incucyte® live-cell imaging system, while migration was evaluated using both wound-healing and transwell Boyden chamber assays. Additionally, cell viability was assessed using the MTT assay following a 5-day treatment with temozolomide (TMZ). HIF1α expression was analyzed at different time points under hypoxic conditions (O₂: 0.01%) during 24 hours. RNAseq was performed to compare the transcriptome patterns between the KO cell line and its negative control (NC). Data was analyzed using GraphPad Prism 8.

Result and discussion

The LN229-UBXN7-KO cells exhibited reduced proliferation under normoxic conditions ($p = 0.039$) but showed no significant differences under hypoxia compared to NC-LN229. A significant decrease in migration was observed in UBXN7-KO cells, as demonstrated by the transwell (t-test $p = 0.023$) and wound-healing assays (2way ANOVA $p = 0.002$). In a 24-hour hypoxia experiment, HIF1α expression was lower in LN229-UBXN7-KO cells compared to the NT condition (2way ANOVA $p = 0.04$). No significant differences in cell viability were detected after 5 days of temozolomide (TMZ) treatment in normoxia conditions. The expression of several genes was found to be altered between KO and NC cells.

Conclusion

KO of UBXN7 in LN229 cells resulted in reduced proliferation and migration, as well as decreased HIF1α expression under hypoxia. These findings suggest that UBXN7 could be a potential therapeutic target in GB patients by modulating the HIF1α pathway.

EACR25-1730

NRF2 activation by myeloid cell-derived oxidative stress induces SNAI-driven EMT and metastasis in breast cancer

M. Kaya¹, O. Johnsson¹, S. Paul¹, N. Issdisai¹, C. Wiel², A. Dongre³, K. Hellstrand⁴, A. Martner¹

¹University of Gothenburg, Department of Microbiology and Immunology, Gothenburg, Sweden

²University of Gothenburg, Department of Surgery, Gothenburg, Sweden

³Cornell University, Department of Biomedical Sciences, New York, United States

⁴University of Gothenburg, Department of Infectious Diseases, Gothenburg, Sweden

Introduction

Metastasis is facilitated by epigenetically regulated transcription programs that enhance epithelial-to-mesenchymal transition (EMT). In this process, epithelial cancer cells gain mesenchymal features with migratory and invasive capacity. Breast cancer tumors are commonly infiltrated by myeloid cells that have been shown to stimulate EMT and metastatic outgrowth by mechanisms that include production of pro-inflammatory cytokines. Myeloid cells are also major producers of reactive oxygen species (ROS) via the NOX2 enzyme, but the potential impact of NOX2-derived ROS for breast cancer metastasis remains poorly understood.

Material and method

Co-culture experiments were conducted to investigate the role of ROS from wild type (WT) and Nox2-deficient (Nox2-KO) myeloid cells in triggering EMT in human and murine breast cancer cell lines. The EMT status of breast cancer cells was defined by expression of EMT transcription factors and migratory capacity. Moreover, we administered the NOX2-inducing peptide WKYVMVm intratumorally to orthotopically implanted 4T1 or EO771 breast cancer tumors in WT and Nox2-Ko mice. The effects of exogenous hydrogen peroxide (H₂O₂), the ROS scavenger catalase, and a NOX2 inhibitor were also evaluated in vitro and in vivo.

Result and discussion

Our study demonstrated that both exogenously added H₂O₂ and NOX2-derived ROS released from neighboring myeloid cells induced an EMT response in adjacent breast cancer cells, resulting in enhanced migratory and metastatic potential. ROS upregulated the EMT transcription factors SNAI1 and SNAI2 via the redox-sensitive transcription factor NRF2. Inhibition of NRF2 significantly reduced H₂O₂-induced SNAI1 and SNAI2 gene expression. In vivo, intratumoral administration of H₂O₂ and the NOX2 activator WKYVMVm increased EMT marker expression and metastasis, effects reversed by NOX2 inhibition. In accordance, myeloid cells from Nox2-deficient mice were less prone to induce EMT in breast cancer cells in vitro and in vivo. Analysis of publicly available human breast cancer datasets showed correlations between NOX2 and EMT-related gene expression within the tumor microenvironment. Additionally, high expression of NOX2 subunit genes and SNAI1 associated with reduced distant metastasis-free survival.

Conclusion

Collectively, these findings suggest that myeloid cell-derived ROS initiate SNAI-driven EMT in breast cancer cells. Targeting myeloid cell-derived ROS could be a potential strategy to limit metastasis in breast cancer.

², Institute of Mother and Child, Department of Oncology and Surgical Oncology for Children and Youth, Warsaw, Poland

³Wroclaw Medical University, Clinical Department of Paediatric Bone Marrow Transplantation, Wroclaw, Poland

⁴St. Jude Children's Research Hospital, Departments of Global Pediatric Medicine and Oncology, Memphis, United States

Introduction

Histiocytic disorders are marked by the uncontrolled proliferation of histiocytes, frequently driven by oncogenic mutations contributing to disease progression. Among these, the BRAFV600E mutation has emerged as a critical molecular target, leading to the clinical adoption of vemurafenib (VEM), a selective BRAF inhibitor, as part of targeted therapeutic approaches. Although VEM has proven effective in limiting tumor growth, its broader influence on cellular bioenergetics and regulating molecular stress responses remains inadequately characterized. The study aimed to evaluate the cytotoxic effects of vemurafenib (VEM) on the mitochondrial bioenergetics of the RAB-1 cell line, a primary cell line derived from histiocytic lesions (DSM ACC3377; patent: P.447749). Additionally, the investigation assessed VEM's impact on the expression of critical molecular biomarkers linked to mitochondrial metabolism.

Material and method

Vemurafenib cytotoxicity was assessed using an MTS assay to establish IC₅₀ and IC₂₅ doses. Mitochondrial bioenergetics included measuring basal respiration, maximum respiratory capacity, and ATP production rates in real time through oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) measurements. The measurements were performed using a Seahorse XF HS Mini Analyzer (Agilent). The transcript levels of mitochondrial biomarkers were examined with RT-qPCR to explore the molecular changes induced by VEM.

Result and discussion

The study revealed that VEM decreased mitochondrial respiration in the RAB-1 cell line in a dose-dependent

manner, with reductions in both basal respiration and maximum respiratory capacity. Furthermore, VEM reduced ATP production, as reflected by lower OCR and ECAR values, though this effect was not dose-dependent. Molecular analysis showed increased mRNA levels of fission-1 (FIS-1) and myeloid cell leukemia-1 (MCL-1), along with elevated levels of lncRNA TUG-1 following VEM treatment.

Conclusion

Vemurafenib impairs the mitochondrial bioenergetics of the RAB-1 cell line primarily by reducing respiration and ATP production. These changes are associated with altered expression of mitochondrial biomarkers, suggesting a disruption of cellular energy metabolism. Exploring the molecular mechanisms by which VEM influences mitochondrial dynamics and stress responses may offer insights into the drug's efficacy and potential side effects. By integrating a multidisciplinary approach, the study highlights the importance of combining molecular, cellular, and clinical insights to optimize therapeutic strategies for histiocytic lesions.

EACR25-1743

Aurora-A-mediated Maf1 phosphorylation plays a novel role by regulating mitochondrial function in hepatocellular carcinoma

Y. Kuan¹, S. Yang^{2,3}, L. Hung¹

¹National Cheng Kung University, Department of Biotechnology and Bioindustry Sciences, Tainan, Taiwan

²National Cheng Kung University, The Institute of Basic Medical Sciences, Tainan, Taiwan

³Albert Einstein College of Medicine, Department of Cell Biology, New York, United States

Introduction

Transfer RNA (tRNA) biosynthesis is essential for processes like protein synthesis, cell cycle progression, mitochondrial function, and cell proliferation. Dysregulated tRNA biosynthesis contributes to diseases such as hepatocellular carcinoma (HCC). Maf1 is a key inhibitor of RNA polymerase III (Pol III), regulating tRNA biosynthesis by blocking the interaction between Pol III and transcription factors TFIIB and TFIIC. Maf1 also suppresses tumor growth and the AKT/mTOR pathway by enhancing PTEN expression. mTOR phosphorylates Maf1 at Ser-75, leading to its export to the cytosol and subsequent ubiquitination, promoting protein synthesis and cell cycle progression in HCC. Aurora-A, a serine/threonine kinase, is crucial for cell cycle regulation, and its overexpression is linked to cancer progression. However, the relationship between Maf1 and Aurora-A remains unclear.

Material and method

HCC cells were transfected with pGFP-Aurora-A and pHA-Maf1 to investigate their correlation. Alisertib was added to inhibit Aurora-A activity. RT-qPCR was performed to determine the RNA expression of Aurora-A, Maf1, pre-tRNALeu and pre-tRNAiMet. Western blot was performed to analyze expression levels of Maf1 and Aurora-A. Translational inhibitor cycloheximide was added to observe the protein stability of Maf1. The

protein interaction between Aurora-A and Maf1 was determined by co-immunoprecipitation and proximity ligation assay. The subcellular localization of Maf1 was observed by cell fraction assay and immunofluorescence. The cell proliferation was analyzed by CCK-8. The glycolytic activity was analyzed by Extracellular Acidification Rate (ECAR) assay.

Result and discussion

Aurora-A interacts with the Maf1 C domain to promote its cytosolic localization and enhance its protein stability in a kinase-dependent manner. Mutation of one potential Aurora-A phosphorylation site on Maf1 results in the nucleolus localization and decreased the protein stability. In the cytosol, Maf1 may regulate mitochondrial function by reducing OXPHOS levels. Notably, overexpression of the Maf1 mutant (Maf1-MT) failed to suppress tRNA biosynthesis and restore mitochondrial function. Additionally, HCC cells with Maf1 overexpression were more sensitive to Aurora-A inhibitor.

Conclusion

Aurora-A promotes the protein stability and cytosolic localization of Maf1 via interacting with its C domain in a kinase-dependent manner in HCC cells. Aurora-A phosphorylation site mutant of Maf1 can promote nucleolar localization and lost the RNA polymerase III suppressor function and regulation of mitochondria. In Maf1 overexpressed HCC cells, Aurora-A inhibitor has a higher efficacy in inhibiting cell growth. In HCC patients with high Aurora-A and Maf1 expression, treatment with Aurora-A inhibitors can be a promising strategy in cancer therapy.

Serum-related Metabolic stress and Breast Cancer: Differential Responses in Metastatic versus Non-Metastatic Cells

G. Mukhtarova¹, E. Acikgoz², D. Ece¹, G. Guler³, C. Gunduz⁴, A. Caner¹

¹Ege University, Basic Oncology, Izmir, Turkey

²Yuzuncu Yil University, Histology and Embryology, Van, Turkey

³Izmir Institute of Technology, Physics, Izmir, Turkey

⁴Ege University, Medical Biology, Izmir, Turkey

Introduction

Starvation in breast cancer (BCa) cells is a complex adaptive phenomenon that promotes tumor survival and progression through diverse molecular mechanisms and signaling pathways. Understanding these mechanisms is critical for developing targeted therapeutic strategies. This study investigates the impact of serum-related metabolic stress on BCa cells in a dose- and time-dependent manner, focusing on morphology, metabolism, metastatic potential, stemness, gene expression, and drug sensitivity.

Material and method

BCa cells were subjected to short-term (72 h) and long-term (≥ 30 days) serum restriction and high-serum conditions. Morphological changes were monitored via inverted microscopy. Glycogen and lipid accumulation were analyzed using Periodic Acid-Schiff (PAS) and Oil Red O staining. Fourier-transform infrared (FTIR) spectroscopy was employed to assess biochemical alterations. Metastatic potential was evaluated through

wound-healing and invasion assays. Cancer stem cell (CSC) properties were assessed by flow cytometric analysis of CD44+/CD24- markers, colony formation, and spheroid assays. Drug response was determined using the XTT assay. RNA sequencing was performed to identify gene expression changes.

Result and discussion

Serum related metabolic stress triggers a reaction in cancer cells, leading to noticeable transformations in cell composition. Specifically, we found that metastatic BCa cells display distinct modifications in morphology and behavior such as migration and spheroid formation capacity when deprived of nutrients. Based on the IR data that supported by RNA sequencing results, significant alterations are observed in the spectral regions of proteins, lipids, nucleic acids and glycogen in BCa cells, indicating structural/compositional alterations. Although serum-related stress caused an increase in the expression of CSCs markers, it also increased drug sensitivity. PAS and Oil Red staining images reveal increments in the glycogen and lipid droplet contents in metastatic BCa compared to non-metastatic counterpart under starvation, suggesting a high metabolic activity.

Conclusion

Our integrative approach combining spectroscopic, transcriptomic, and functional assays provides critical insights into the metabolic plasticity of BCa cells under nutrient deprivation. The differential adaptive responses observed between metastatic and non-metastatic cells underscore the role of metabolic reprogramming in tumor progression. These findings offer a foundation for therapeutic strategies targeting metabolic vulnerabilities in aggressive breast cancer subtypes.

EACR25-1761

Increased intracellular hydrogen sulfide production reduces chemically-induced hepatocarcinoma progression and extends lifespan in mice

J. Pino-Pérez¹, R. López-Fernández¹, M. Cáliz-Molina¹, M. Camacho-Cabrera¹, M. Vilches-Pérez¹, A. García-Ruiz¹, A. Martín-Montalvo¹

¹CSIC-CABIMER, Seville, Spain

Introduction

Liver cancer is the 6th most diagnosed and 3rd leading cause of cancer-related death. Hydrogen sulfide (H2S), which diffuses through cell membranes to induce intracellular responses, is generated by enzymatic and non-enzymatic production and modulates protein activity through cysteine persulfidation. This study examined the effects of increased H2S production on liver cancer carcinogenesis and progression.

Material and method

For a short-term study, male C57/Bl6J mice were treated with the sulfur donor compound α (150 mg /kg of food) for a week. Then, mice were injected with diethyl-nitrosamine (DEN) (100 mg/kg) to induce carcinogenic events. 48 hours after, mice were injected with 5-bromo-deoxyuridine (BrDU; 100 mg/kg). 2 h after BrDU injection mice were euthanized and liver tissue harvested. Liver sections were stained with γ H2ax, p53 and BrDU antibodies to determine DNA damage, stress responses

and compensatory proliferation, respectively. mRNA levels of inflammatory mediators and detoxifying enzymes were measured by PCR. For a long-term study, male mice were injected with DEN (5 mg/kg) at day 16 of life. The same day mice were treated with compound α , in a treatment sustained for the remaining of their lives. A High Fat Diet treatment was initiated on day 21. Body weight and caloric intake were monitored weekly. Two cohorts ($n \leq 12$) were sacrificed to assess tumor progression, while the remaining mice ($n \leq 45$) were monitored for health and lifespan. Physical health was assessed by rotarod, wire hang, grip strength and indirect metabolic calorimetry tests ($n \leq 25$). Finally, H₂S production was measured using the lead sulfide method, and persulfidated proteins were detected by DAz-2: Cy-5 Click labeling.

Result and discussion

In the short-term study, compound α -treated mice showed lower amount of DNA breaks (γ H2ax), higher p53 expression and unchanged compensatory proliferation (BrDU). mRNA levels of inflammatory regulators Ppary and Tnf α were lower, while IL-10 (anti-inflammatory marker) was higher. Finally, other interleukins and detoxification enzymes were unaffected. In the long-term study, compound α increased mean life expectancy (12.96 %) and reduced body weight gain without affecting energy intake. At first sacrifice, treated mice showed reductions in number and weight of tumors. Tumor weight remained reduced in the advanced stage of the disease. Furthermore, compound α increased grip strength, rotarod performance and wire suspension, but did not affect treadmill performance. Lastly, tumor enzymatic H₂S production was lower than in the healthy liver.

Conclusion

Compound α improved health and survival in mice with chemically induced liver cancer and reduced body weight gain. Compound α protected against damage induced by DEN and reduced tumor progression, reflected in fewer and smaller tumors in the early stages of the disease, maintaining a lower weight of tumors in advanced stages.

EACR25-1767

The role of CEMIP and CTCF in castration-resistant prostate cancer: A novel insight from 3D spheroid model

S. Ali¹, Y. Chi¹, R. Shi¹, R. Na¹

¹*The University of Hong Kong, Surgery, HKSAR, Hong Kong, China*

Introduction

Prostate cancer (PCa) affects 12.5% of men globally, making it one of the leading causes of mortality and morbidity. Cell migration inducing hyaluronidase 1 (CEMIP) facilitates hyaluronan catabolism and has a role in cell metastasis, invasion, and motility. Dysregulated CEMIP expression results in tumor development and prognosis. In this study, we aim to investigate the epigenetic change and possible role of cell migration inducing hyaluronidase 1 (CEMIP) that drives tumor metastatic phenotypes in castration-resistant prostate cancer.

Material and method

We analyse public database from ChIP-Atlas and UCSC Genome Brower to investigate epigenetic shift of CEMIP among prostate cancer cell lines. To further investigate, CEMIP were knock-downed (si-RNA) and overexpressed (OE) with lentivirus in androgen-insensitive (DU145, PC-3) and androgen-sensitive (LNCaP) human prostate cancer cell lines. Total RNA was extracted from the cells using the Trizol reagents before performing RT-qPCR with different cDNA concentration (25 ng, 50 ng and 100 ng) to confirm a successful knockdown and overexpression. We then performed MTT assay, 3D spheroid model (aggregwell method), transwell migration, invasion assay and cell cycle analysis furtherly confirmed that the knock-down and overexpression of CEMIP were more significant in castration-resistant prostate cancer cell lines with statistical analysis from GraphPadPrism software.

Result and discussion

The results from ChIP-Atlas and UCSC Genome Brower revealed that there is significant epigenetic shift of CEMIP at promoter region with 11-zinc finger protein or CCCTC-binding factor (CTCF) binding to it. The results from RT-qPCR confirmed the successful knock-down and overexpression. The knock-down displayed cytotoxic effects against cancer cells ($p < 0.05$) while the overexpression of CEMIP increased cancer cells proliferation ($p < 0.05$). Moreover, cancer cells form less aggregation (3D spheroid) after si-CEMIP but oe-CEMIP showed that cancer cells form better 3D structure. The MTT assay, migration, invasion, cell cycle analysis furtherly confirmed that the knock-down and over-expressed effect were more significant in castration-resistant prostate cancer cell lines ($p < 0.05$). Thus, we confirmed that CEMIP drives tumor metastasis and 3D spheroid formation in castration-resistant prostate cancer cell lines. Our investigations provide compelling and novel evidence that CEMIP has role as oncogene in androgen-resistant prostate cancer.

Conclusion

Our research provides fresh perspectives into the epigenetic change of CEMIP in prostate cancer with novel 3D model for validation. CEMIP can be a key oncogene in androgen-resistant prostate cancer. Further in vitro and in vivo validation of these results are required to examine whether the promising results are clinically translational. Overall, our outcomes reveal that CEMIP may have potential as a future therapeutic target in prostate cancer.

⁴*University of Cologne, Cologne, Germany*

⁵Maastricht University, Radiotherapy, Maastricht, Netherlands

Introduction

Lung cancer remains a leading cause of cancer-related mortality, with therapeutic resistance driven by tumor heterogeneity and adaptive survival mechanisms. tRNA modifications at the U34 position have emerged as critical regulators of mRNA translation, influencing tumor progression and drug resistance. Our previous work identified mTORC2-PI3K signaling as a key modulator of U34 tRNA modifications, specifically regulating ELP1, the structural subunit of the Elongator complex, in melanoma. While therapy-resistant non-small cell lung cancer (NSCLC) exhibits mTORC2 overexpression, its impact on U34 tRNA modifications remains unexplored.

Material and method

To investigate U34-enzyme regulation in lung cancer, we utilized NSCLC cell lines (A549, H460, H23) and assessed ELP1 stability under different genetic and pharmacological conditions. Immunoprecipitation assays were performed to evaluate direct binding and ubiquitination of ELP1 by FBXW7. The effect of GSK3 inhibition on ELP1 ubiquitination was assessed to determine its role in ELP1 turnover. To identify global translational changes, proteomic analysis was conducted to examine codon-dependent mRNA translation patterns in lung cancer cells upon FBXW7 depletion. Gene Set Enrichment Analysis (GSEA) was applied to the FBXW7-ELP1 proteome to identify key biological pathways regulated by this axis. Functional assays, including wound healing and transwell migration assays, were performed to evaluate the role of ELP1 in tumor cell migration.

Result and discussion

We demonstrate that ELP1 stability is regulated by the mTORC2-AKT-GSK3-FBXW7 axis. Immunoprecipitation assays confirmed direct binding and ubiquitination of ELP1 by FBXW7, with this ubiquitination abolished upon GSK3 inhibition, validating the role of mTORC2-AKT-GSK3-FBXW7 signaling in ELP1 turnover. Proteomic analysis revealed that FBXW7 loss enhances the translation of U34-sensitive codon-enriched genes, establishing a mechanistic link between mTORC2-FBXW7 signaling and codon-biased translation in lung cancer. GSEA analysis of the FBXW7-ELP1 proteome identified migration as a key pathway regulated by this axis. Functionally, ELP1 depletion blocked the increased migration of lung cancer cells induced by FBXW7 loss, demonstrating its critical role in FBXW7-mediated tumor cell motility.

Conclusion

This study identifies mTORC2-AKT-GSK3-FBXW7 as a key regulatory axis of ELP1 stability, linking U34 tRNA modifications to oncogenic translation and tumor cell migration in lung cancer. Our findings reveal a mechanistic connection between FBXW7 loss, ELP1 regulation, and lung cancer progression, suggesting that targeting this axis may present novel therapeutic opportunities for drug-resistant NSCLC.

⁵Faculty of Medicine at TU Dresden, Institute for Medical Informatics and Biometry, Dresden, Germany

⁶University Cancer Center at University Hospital Carl Gustav Carus, Skin Cancer Center, Dresden, Germany

Introduction

While current standard therapies have shown effectiveness against metastasized melanoma, achieving lasting responses in melanoma brain metastases remains challenging. This is largely due to brain-specific resistance mechanisms, highlighting the need to investigate underlying differences between intracranial and extracranial metastases. Although the mutational profile is mainly unaltered, epigenetic regulation is diverging. Through methylome and transcriptome analyses of 16 matched intra- and extracranial metastases, 38 protein candidates with distinct promoter methylation and corresponding expression were identified. Eight promising candidates were validated by immunohistochemistry and had a significantly higher protein expression in intracranial metastases (PMID: 36716920). In this study, we wanted to investigate the role of two likely cancer-promoting candidates, named protein kinase C zeta (PRKC ζ) and growth factor receptor bound protein 10 (GRB10), which are upregulated in intracranial metastases.

Material and method

Various melanoma cell lines were screened on their PRKC ζ /GRB10 expression level and PRKC ζ /GRB10 protein level, siRNA-mediated knockdown was applied to selected lines. Functional validation was performed in a cell viability crystal violet assay, a propidium iodide-based cell cycle analysis, a 2D wound closure scratch assay and pathway analyses.

Result and discussion

We found a wide range of PRKC ζ and GRB10 gene expression in various established as well as in-house patient-derived melanoma cell lines, independent from the metastasis site. Cell lines with either high or moderate PRKC ζ or GRB10 expression were chosen for further functional investigation. Under GRB10-knockdown, only BRAF-mutated melanoma lines showed increased phospho-AKT levels, a component of the cancer-promoting PI3K/AKT signaling pathway, and increased viability, concomitantly. A decreased viability and G1 cell cycle arrest was seen in PRKC ζ -knockdown cells independent from mutation status. No clear link to PI3K/AKT and MAPK signaling could be drawn, though. A network-based pathway analysis with RNA data

predicted a connection between PRKC ζ and cell adhesion processes. Therefore, a 2D wound closure scratch assay was developed and revealed a decreased wound-closure capacity (migratory potential) in PRKC ζ -knockdown cells, accordingly.

Conclusion

Different from initial findings, GRB10 acted as a tumor suppressor in our cell culture-based setting. Contrastive, PRKC ζ promoted cell viability, cell cycle progression and migration in melanoma cells. Melanoma brain metastases could therefore benefit from high PRKC ζ levels in comparison to lower levels in extracranial metastases.

Loss of LKB1 in non-small cell lung carcinoma favours EMT-independent metastasis

A. Martínez-Turtos¹, P. Naidu Gollavilli¹, A. Mohammad Siddiqui¹, A. Askehøj Rømer¹, V. Ramesh¹, L. Pinna¹, M. Demirdizen¹, A. Leal Egaña², P. Ceppi¹

¹University of Southern Denmark, Biochemistry and Molecular Biology, Odense, Denmark

²Institute of Molecular Systems Engineering and Advanced Materials, Heidelberg, Germany

Introduction

Lung cancer is the most diagnosed type of cancer and the leading cause of cancer-related deaths. Non-small cell lung carcinoma (NSCLC) is the most common type of lung cancer accounting for 85% of lung cancer cases. Multiple oncogenic drivers underlie NSCLC but hyperactivating mutations in Kras (K) are frequently found in patients in combination with loss-of-function mutations in p53 (P) or/and LKB1 (L). Occurrence of co-mutations increases NSCLC aggressiveness as indicated by the higher metastatic potential of KP tumors upon LKB1 loss (KPL tumors) as compared to KP tumors bearing wild-type LKB1. Despite progress in therapeutic strategies, the 5-year survival rate of advanced NSCLC patients is less than 20%. This poor prognosis is in part due to therapy resistance, tumor relapse and metastasis. Indeed, most NSCLC patients reach terminal states with metastatic outgrowths. In this regard, the epithelial-to-mesenchymal transition (EMT) occurring in tumor cells is widely accepted as a key cellular program for acquisition of metastatic potential. As metastasis represents a threat for NSCLC patients' prognosis, we aim to unravel the molecular mechanisms of NSCLC metastasis beyond EMT to target lung cancer spread in the future.

Material and method

To study the metastatic potential of LKB1 loss in Kras- and p53 mutated NSCLC tumors, we generated NSCLC mouse models which develop either double-mutated KP or triple mutated KPL lung tumors in CRISPR/Cas9 mice upon intubation with mutation-containing viruses.

Result and discussion

Whereas KPL tumors significantly shorten mouse survival to a greater extent as compared to KP tumors, KPL tumor cells isolated from transgenic mice display a more epithelial-like phenotype. Indeed, KPL tumor cells are characterized by a cobblestone-shaped morphology, upregulation and downregulation of canonical epithelial

and mesenchymal markers, respectively as well as less focal adhesion contacts and reduced cell motility in vitro. Accordingly, RNA sequencing shows a significant enrichment of EMT signatures in KP tumor cells. In addition, as compared to NSCLC patients' tumors that were ordered according to their EMT score calculated based on transcriptomic data, KP and KPL tumor cells were positioned closer to the most mesenchymal and most epithelial NSCLC tumors, respectively.

Interestingly, when growing in the lungs of the transgenic mice, only KPL tumor cells form lymphnode metastasis. However, KP cells home the lungs faster than KPL cells when engrafted into mice via systemic circulation.

Conclusion

This study points towards the existence of molecular pathways beyond the canonical EMT program that govern NSCLC metastasis upon LKB1 loss within the native tumoral niche. Our research might reinforce the concept of hybrid and reversible EMT phenotypes and in parallel, shed light on a novel model of metastasis, where the metastatic potential of LKB1-mutated NSCLC is rather dictated by EMT-independent cellular processes.

EACR25-1818

Kv1.3 potassium channel-linked signaling networks based on STAT3 function are crucial for melanoma tumorigenesis

L. Todesca¹, V. Carpanese¹, B. Angi¹, L. Cendron¹, V. Checchetto¹, I. Szabo¹

¹University of Padova, Padova, Italy

Introduction

Ion channels are emerging oncological targets since their aberrant expression and function have been linked to altered proliferation, apoptosis, and migration of cancer cells both in vitro and in vivo. Importantly, most ion channels can be pharmacologically targeted by specific inhibitors to block ion fluxes. However, the view is emerging that these proteins may also affect cancer cell behavior by taking part in signaling complexes and actively modulating cancer-relevant intracellular signaling events. The Kv1.3 voltage-gated potassium channel represents a promising case; however, how it is involved in cancer progression is not yet clear. We hypothesize that Kv1.3, showing enhanced expression in various cancer cells, modulates cancer-relevant cell signaling through its direct interaction with STAT3, leading to STAT3 activation and to p53 stabilization. We furthermore hypothesize that interruption of these connections leads to profound changes in cancer-related signaling events.

Material and method

Given that Kv1.3 is functional both in the plasma membrane and in mitochondria (mitoKv1.3), we aim to understand i) whether inhibition of the former or latter population is sufficient to decrease STAT3 activation and increase p53 stabilization; ii) whether inhibition of the channel activity or lack of Kv1.3 protein is required to exert these effects. To this end, we exploited membrane-impermeant toxin inhibitors Margatoxin (Mgtx) and Stichodactyla toxin (Shk) or the mitochondria-targeted Kv1.3 inhibitor PAPTP. To exploit differences in biological processes between WT and KO cells, an

RNAseq has been performed, while, effects on the global protein translation have been confirmed by flow-cytometry experiments based on a click chemistry-based assay.

Result and discussion

Our results show that deletion of Kv1.3 resulted in stabilization and activation of p53, while decreasing stability and activation of STAT3. At the same time, pharmacological inhibition of the mitochondrial Kv1.3 channel also induces p53 stabilization and STAT3 inactivation. Moreover, the interaction between STAT3 and Kv1.3 is strongly suggested by proximity ligation assay on HEK239 cells overexpressing Kv1.3 channels. The RNAseq performed on Kv1.3-KO and WT melanoma cells analyses indicated a reduced expression of genes related to protein translation. Western blot, performed on B16F10 WT and Kv1.3 KO, suggests that in KO cells or WT cells treated with PAPTP, expression of three ribosomal proteins and a mitochondrial ribosomal protein is down-regulated. Down-regulation of ribosome proteins correlates with the reduction of the global protein synthesis, in the same conditions.

Conclusion

This represents a novel tumor-promoting Kv1.3-interactome landscape and mechanism of protein translation inhibition, that is driven by the down-regulation of potassium channel expression/activity and is currently being elucidated.

EACR25-1821

TGF- β Resistance as a Collateral Mechanism to Senescence Escape and Tumor Aggressiveness in Hepatocellular Carcinoma

M. Kalyoncu¹, D. Demirci¹, S. Eriş^{1,2}, F. Liu³, S. Şentürk^{1,2}

¹*Izmir Biomedicine and Genome Center, Izmir, Turkey*

²*Izmir International Biomedicine and Genome Institute, Department of Genomics and Molecular Biotechnology, Izmir, Turkey*

³*Rutgers Cancer Institute of New Jersey, Center for Advanced Biotechnology and Medicine, Susan Lehman Cullman Laboratory for Cancer Research, Ernest Mario School of Pharmacy, New Jersey, United States*

Introduction

Transforming growth factor- β (TGF- β), a potent senescence inducer, paradoxically promotes aggressive cancer cell traits in hepatocellular carcinoma (HCC), such as epithelial-to-mesenchymal transition (EMT), reshaping the tumor microenvironment, and enhancing invasion and metastasis. The underlying mechanisms of the transition from a TGF- β -sensitive state to a TGF- β -resistant state remain understudied.

Material and method

In this context, we developed TGF- β -sensitive and TGF- β -resistant subclones in epithelial HCC cell lines, Huh7 and Hep3B. We assessed senescence markers, cell cycle dynamics, and TGF- β signaling using various techniques, including SA- β -Gal staining, BrdU incorporation, flow cytometry, Western blotting, and reporter assays. We established the correlation between TGF- β resistance and aggressive characteristics through EMT gene expression

analyses, 2D and 3D assays, and invasion and metastasis. Transcriptomic analysis was performed to identify gene expression changes. Gene function was validated using RNAi and CRISPR/Cas9-mediated gene knockout, followed by functional assays.

Result and discussion

The transition from a sensitive state to a resistant state induced escape from senescence in epithelial HCC cells through defective Smad3 activation and nuclear trafficking, leading to increased proliferation and mesenchymal characteristics. Transcriptomic analyses revealed upregulation of EMT and angiogenesis pathways in resistant cells. MARK1 and GRM8 were identified as critical regulators of TGF- β resistance by disrupting Smad signaling dynamics. Depletion of these genes restored TGF- β sensitivity and Smad nuclear localization. These findings highlight the dynamic nature of senescence and suggest that HCC cells can exploit senescence plasticity to counteract TGF- β -mediated tumor suppression and progress towards more aggressive phenotypes.

Conclusion

Loss of TGF- β sensitivity in epithelial HCC cells is associated with aggressive cancer hallmarks. Our findings help further explain the differential responses of epithelial and mesenchymal HCC cell lines to TGF- β treatment. Furthermore, our findings suggest potential avenues for restoring the TGF- β /senescence axis in advanced HCCs exhibiting elevated TGF- β , representing a promising area of investigation, particularly concerning anti-tumor mechanisms and senescence escape.

EACR25-1845

C6ORF15 is a driver of lymph node metastasis through upregulation of EMT in colorectal cancer

D. Chan¹, Y. Wei Ni¹

¹*National University of Singapore, Surgery, Singapore, Singapore*

Introduction

Lymph node involvement in colon cancer affects clinical treatment and portends a worse overall survival. Molecular features associated with lymph node metastasis in colon cancer remain poorly described. In this study, we sought to identify and validate molecular targets of lymph node metastasis.

Material and method

Analysis of TCGA data was performed. Colon cancers were divided into two groups. The "expanding" phenotype represented cancers which were >5cm without lymph node metastasis, while the "metastatic" group denoted cancers which were <=5 cm with lymph node metastasis. Transcriptomic data from these two groups were compared, and analysed using GSEA. SW480 and HCT116 cell lines were used to validate findings by generating isogenic C6orf15 knockout clones. RNAseq was performed to analyse transcriptomic differences. Further validation of the effect of C6orf15 was performed using western blot, as well as proliferation, invasion and migration assays.

Result and discussion

378 colon cancers were analysed on TCGA. The median size of colon cancer in this group was 5.375cm, such that

5cm was used as the cutoff for the "expanding" and "metastatic" phenotype groups. There was no statistically significant difference in nodal positivity between this size cutoff and lymph node positivity, suggesting that these were independent variables (Fishers exact test, $p = 0.6381$). Kaplan-Meier comparison of "expanding" and "metastatic" phenotypes confirmed worse overall survival in the latter group ($p = 0.0145$). Comparing transcriptomic differences between these two groups demonstrated that one of the top differentially expressed gene was C6orf15 ($\text{LogFC} = 2.37$, $p = 2.06E-07$). GSEA using the Hallmark gene sets revealed epithelial-mesenchymal transition (NES 1.81, FDR q-value = 0) as the most enriched Hallmark in the "metastatic" group. C6orf15 knockout clones in SW480 and HCT116 cell lines were generated and validated using western blot, and Sanger sequencing. RNAseq of HCT116 wildtype and C6orf15 mutant clones demonstrated that EMT was down-regulated in the C6orf15 mutant population. This was validated using both HCT116 and SW480 cell lines on western blot, which revealed decreased presence of SNAI1, SLUG and CDH2. Functional assays of proliferation, invasion and migration also revealed decreased activity in C6orf15 knockouts. Finally, C6ORF15 expression was analysed on immunohisto-chemistry staining of patient derived tissue which fulfilled our criteria of the "expanding" and "metastatic" phenotypes. This revealed stronger expression of C6ORF15 in the "metastatic" group compared to the "expanding" group.

Conclusion

Using TCGA data, we identified C6orf15 mediated EMT as a potential pathway of lymph node metastasis in colon cancer. This raises the possibility of C6orf15 directed interventions as novel therapeutic targets to reduce the incidence of lymph node metastasis, therefore improving colon cancer overall survival.

EACR25-1846

Investigation of novel heterocyclic fused naphthalimides as DNA-intercalating agents with antitumor potential

Z. Vlahova¹, M. Mutovska², Y. Zagranjarski², I. Ugrinova¹

¹Institute of Molecular Biology "Roumen Tsanev", Bulgarian Academy of Sciences, Sofia, Bulgaria

²Faculty of Chemistry and Pharmacy, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria

Introduction

The 1,8-naphthalimides are a class of heterocycles distinguished by a π -deficient planar aromatic system, exhibiting remarkable antiproliferative effects largely due to their ability to intercalate into DNA. The structures we introduce are conceptually novel and have no known analogues in the scientific literature. These molecules were designed to enhance the therapeutic potential of the well-established cytotoxic agent mitomycin C by combining its scaffold with the DNA intercalating tricyclic planar chromophore dibenzofuran into a single entity. The aim of this study is to evaluate the biological activity of these newly developed compounds.

Material and method

A549 and NCI-H1299 human non-small cell lung carcinoma cell lines, along with MRC-5 normal lung fibroblasts, were utilized for analysis. A series of experiments were performed to examine the cytotoxic and antiproliferative properties of over twenty novel derivatives. Additionally, various assays were conducted on selected candidates to explore their impact on the cell cycle and the mechanisms underlying cell death.

Result and discussion

The results revealed that the benzofuran-1,8-naphthalimides exhibited greater cytotoxic potency compared to mitomycin C and other intercalating agents. Notably, incorporating an additional nitro group into the benzofuran core led to an increase in cellular toxicity. Moreover, a distinction was observed among three positional isomers containing this modification. Cell cycle analyses indicated a different pattern of response to treatment in the two cancerous cell lines. These naphthalimide-based compounds were shown to induce apoptosis, inhibit DNA replication, and cause accumulation of damage in the genetic material.

Conclusion

The present study demonstrates that benzofuran-1,8-naphthalimides exhibit potent cytotoxic activity by inducing apoptosis and disrupting DNA replication.

These findings support their potential as promising anticancer agents. Acknowledgments: This work was supported by grant K11-06-H61/1 from 13.12.22 of the Bulgarian National Science Fund.

EACR25-1847

Tackling oxidative phosphorylation of glioblastoma-initiating cells by specifically impairing 1 transmembrane Chloride Intracellular Channel 1

F. Cianci¹, G. Rey¹, A. Fantin¹, M. Mazzanti¹

¹Università degli studi di Milano, Milano, Italy

Introduction

One of the major challenges in cancer treatment is tackling the metabolic reprogramming of tumor cells, which requires higher energy and biomolecules than healthy cells. Glioblastoma (GB) cells, as well as the other cancer types, adapt their metabolism by switching between glycolysis and oxidative phosphorylation (OXPHOS). These processes are dependent on transmembrane proteins' response to the extracellular environment. Our research identified the transmembrane form of Chloride Intracellular Channel 1 (tmCLIC1) as a marker of malignancy and a potential therapeutic target. Thus, tmCLIC1 is upregulated in several solid tumors promoting cancer growth and progression, while it is mainly absent in healthy cells. Here, we found that the antidiabetic drug metformin, an OXPHOS inhibitor in cancer cells, reduces tmCLIC1 activity.

Material and method

All the experiments were performed in GB cells with several CLIC1 genetic background obtained with CRISPR-Cas9-Technology. We performed NMR and patch clamp recording to demonstrate tmCLIC1-metformin interaction. Moreover, we analyzed metabolism modulation given by metformin through OCR and EACR measurement. In addition, PP2A-GSK3 β -MCL-1 axis was analyzed through Western Blot. Our in

vitro results were further confirmed in vivo with Zebrafish embryo and in murine.

Result and discussion

Metformin impairs the tmCLIC1 function by a direct and specific binding coordinated by arginine 29 in the tmCLIC1 sequence. Mutation of this residue nullifies metformin inhibitory effects on cell proliferation, mitochondrial respiration, and tumor progression in *in vitro* and *in vivo* models. Additionally, in conditions of hypoglycemia, metformin induces cancer cell apoptosis by inhibiting the Cancerous Inhibitor of Protein Phosphatase 2A (CIP2A) and activating PP2A subunit B56 δ . This, dephosphorylates Glycogen Synthase Kinase 3 Beta (GSK3 β), leading to degradation of the pro-survival 53 protein MCL-1 and subsequent cell death. Based on previous data, it is possible to sustain a reasonable metformin mechanism of action in cancer cells. We suppose that tmCLIC1's role in reactive oxygen species (ROS) balance is crucial for GB cells metabolic re-programming, and its impairment sensitizes resistant tumor cells. Metformin is an extremely low-priced drug that can be repurposed as an adjuvant in cancer treatment with minor side adverse effects.

Conclusion

We demonstrate that tmCLIC1 is essential for this metformin-mediated antineoplastic effect, particularly through regulating the PP2A-GSK3 β -MCL-1 axis under hypoglycemic conditions. Given tmCLIC1's role in GB progression, our findings pave the way to optimize the molecular interactions between tmCLIC1 and metformin or related molecules, enhancing their therapeutic efficacy.

EACR25-1848

Structural Regulation of Gasdermin B Cytotoxic Activity: Insights into its Potential as a Therapeutic Target in Cancer

S. Colomo del Pino^{1,2}, *S. Ballesteros-Sánchez*^{1,2},
*C. Silvestre Muñiz*¹, *G. Moreno-Bueno*^{1,2,3}, *D. Sarrió*^{1,2}

³*Fundación MD Anderson Internacional (FMDA), Madrid, Spain*

Introduction

Gasdermin B (GSDMB) is a pore-forming protein involved in inflammatory cancer cell death and immune responses. Its activation requires the proteolytic release of the N-terminal domain (NTD) by granzyme A (GZMA), a protease secreted by cytotoxic lymphocytes. However, in solid tumours where GSDMB is over-expressed but immune infiltration is low, this mechanism may be inefficient, making alternative activation strategies therapeutically relevant. GSDMB over-expression correlates with poor prognosis in cancers like HER2+ breast cancer, though its precise role remains controversial. This may be linked to the existence of four isoforms (GSDMB1-4) which differ in sequence within the linker region between NTD and C-terminal domain (CTD), influencing its pyroptotic potential upon GZMA

cleavage. Before cleavage, the pore-forming NTD remains inhibited by intramolecular interactions with the CTD. Recent structural studies have predicted key residues within this inhibitory interface, but their functional relevance is unclear. Since full-length GSDMB has not been crystallized in its auto-inhibited state, direct structural validation is also limited. Given the isoform-dependent cytotoxicity, understanding the structural determinants of isoform-specific activation is crucial for therapeutic purposes. Here, we assess whether disrupting these inhibitory interactions is sufficient to activate GSDMB isoforms.

Material and method

In this study, we mutated various CTD residues predicted to mediate NTD inhibition, based on preceding structural analyses and comparisons across the Gasdermin family. The functional impact of mutations was assessed via propidium iodide staining and lactate dehydrogenase (LDH) release in cancer and control cell lines. Western blot and confocal microscopy were used to analyse expression and subcellular localization respectively.

Result and discussion

Tandem mutations disrupting hydrophobic and hydrogen-bond interactions in the full-length (FL) GSDMB3 isoform failed to induce cell-death, suggesting a stronger autoinhibition compared to other gasdermins. Moreover, structural elements may reinforce auto-inhibition in the GSDMB3 FL variant compared to other isoforms, with the linker region contributing to these stabilizing structural forces. Ongoing studies will determine whether equivalent mutations activate other isoforms, which would support the existence of isoform-specific regulatory mechanisms.

Conclusion

Our results demonstrate that disrupting predicted NTD-CTD interactions is not sufficient to activate GSDMB3 cytotoxic capacity, highlighting additional structural forces that reinforce its auto-inhibited state. Understanding isoform-specific regulation could guide the development of therapeutic strategies to induce GSDMB-mediated cancer cell death in cold tumours, potentially boosting anti-tumour immunity.

Unraveling CIP2A's impact on DNA damage response in basal-like triple-negative breast cancer

*P. Doan*¹, *O. Kauko*¹, *S. Nagelli*², *J. Westermarck*^{1,3}
¹*Turku Bioscience Centre, University of Turku and Åbo Akademi University, Turku, Finland*

²*Turku Bioscience Centre, University of Turku and Åbo Akademi University, Finland*

³*Institute of Biomedicine, University of Turku, Turku, Finland*

Introduction

Basal-like triple-negative breast cancer (BL-TNBC) is an aggressive malignancy characterized by a high mutational burden, frequently driven by BRCA mutations or defects in homologous recombination (HR) pathways. CIP2A, a known inhibitor of protein phosphatase 2A (PP2A), is a driver protein for BL-TNBC initiation and progression. Emerging phosphoproteomic data suggest that CIP2A impairs PP2A-mediated dephosphorylation of

several DNA damage response (DDR) proteins. However, the functional consequences of these phosphorylation events in BL-TNBC remain unclear. This study investigates the role of CIP2A in DDR regulation and its impact on BL-TNBC cell survival and therapeutic response.

Material and method

A functional dependency analysis using DepMap data was conducted to assess CIP2A's association with key DDR proteins. Site-specific CRISPR/Cas9 mutagenesis screening was employed to examine the impact of CIP2A-regulated phosphosites in BL-TNBC cells. Additionally, CRISPR/Cas9 mutagenesis under ATR inhibitor treatment was performed to evaluate phosphosite-specific contributions to therapy response. Functional assays, including cytotoxicity and colony formation assays, were carried out in TNBC cells expressing a PP2A-binding defective CIP2A mutant in combination with DDR-targeting agents to further elucidate the relationship between CIP2A and DDR.

Result and discussion

CIP2A was found to exhibit functional co-dependency with multiple DDR proteins. Phosphoproteomic analysis confirmed CIP2A-mediated inhibition of PP2A-dependent dephosphorylation within the TopBP1-associated DDR complex. CRISPR/Cas9 mutagenesis revealed differential cell fitness effects upon phosphosite-specific modifications. Furthermore, TNBC cells expressing the PP2A-binding defective CIP2A mutant displayed altered sensitivity to DDR inhibitors, underscoring the functional significance of CIP2A-mediated regulation in therapy response.

Conclusion

Our findings demonstrate that CIP2A plays a crucial role in DDR phosphoregulation, influencing BL-TNBC cell survival and therapeutic vulnerability. By leveraging site-specific CRISPR/Cas9 mutagenesis, we aim to identify additional DDR targets modulated by CIP2A. These insights may pave the way for novel therapeutic strategies targeting CIP2A-dependent DDR vulnerabilities in BL-TNBC.

MyomiR-133b suppresses colorectal cancer cell proliferation and modulates expression of multiple gene targets

J. Babulicová¹, L. Slobodová¹, J. Ukropc¹, B. Ukropcová^{1,2}, T. Kurdičová¹

¹Biomedical Research Center of Slovak Academy of Sciences, Department of Metabolic Disease Research, Institute of Experimental Endocrinology, Bratislava, Slovakia

²Faculty of Medicine, Comenius University, Institute of Pathophysiology, Bratislava, Slovakia

Introduction

Colorectal cancer (CRC) is one of the most common types of cancer worldwide. Epidemiological and experimental evidence suggests that regular physical activity reduces CRC risk and progression partly due to exercise-induced circulatory factors, exerkines. Here, we investigated the effect of muscle-derived miR-133b on CRC cell proliferation and gene expression and studied

the effect of exercise-conditioned human plasma, a potential source of exercise-regulated miR-133b, on CRC cell proliferation. Muscle-derived miRNAs, myomiRs, can modulate cancer-related molecular pathways, such as myomiR-133b, that has been shown to regulate cell growth, differentiation, and apoptosis in different cancer types. However, its direct role in CRC remains unclear.

Material and method

HCT116 cells (a colorectal cancer cell line) were transfected with miR-133b mimic (30 nM), inhibitor (50 nM), or their negative controls. Cell proliferation was determined by BrdU and MTT assays at 0h, 24h, 48h, and 72h after transfection. HDAC4, LIF, SIRT1, SRF, TIMP1, TP53 and VEGF expression was assessed by qPCR 48h after transfection. Human plasma was obtained before, after and 60 min after indoor cycling (70% VO_{2max}, sedentary individuals with obesity; age $31,6 \pm 1,3$ years; BMI $35,4 \pm 4,4$ kg/m²), and its effect on HCT116 cell proliferation was assessed by BrdU. Exercise-related changes of miR-133b in human plasma were measured by qPCR.

Result and discussion

Transfection of HCT116 cells with miR-133b mimic decreased the proliferation rate of cancer cells at the 72-h time point, as measured by both MTT assay and BrdU incorporation ($n = 3$; $p < 0.01$). This was accompanied by a concomitant decrease in lactate release into the media ($p < 0.01$), suggesting a reduced cell number. Gene expression analysis ($n = 3$) revealed downregulation of SIRT1 and TP53 ($p < 0.01$), alongside with upregulation of HDAC4, LIF and SRF ($p < 0.001$), and no change in TIMP1 and VEGF. Despite no effect of miR-133b inhibitor on HCT116 cell proliferation, possibly due to low miR-133b levels in cancer cells, we observed upregulation of TP53 ($p < 0.01$), SRF ($p < 0.05$) and VEGF expression ($p < 0.05$). Exercise-conditioned plasma collected 60 min after acute exercise significantly reduced HCT116 proliferation ($n = 14$; $p < 0.01$). This reduction was not associated with increased miR-133b in exercise-conditioned plasma ($n = 4$) suggesting other inhibitory exercise mediators in plasma.

Conclusion

This study provides evidence that myomiR-133b suppresses CRC proliferation, which may be mediated through the regulation of transcription factors (SRF), deacetylases (Sirtuin1, HDAC4) and genes related to cancer cell proliferation and apoptosis (P53, LIF). The mechanisms of tumour-suppressing effect of exercise-conditioned human plasma will require further research.

Genetic ablation of NOX2 boosts anti-tumor immunity yet accelerates metastasis in the PyMT-MMTV breast cancer model

M. Kaya¹, R. Kiffin¹, K. Hellstrand¹, A. Martner²

¹TIMM Laboratory, Sahlgrenska Center for Cancer Research, Department of Microbiology and Immunology, Gothenburg, Sweden

²TIMM Laboratory, Sahlgrenska Center for Cancer

Research, Department of Infectious Diseases,
Gothenburg, Sweden

Introduction

Myeloid cells are strong determinants of metastatic spread and outgrowth. Myeloid cells express the enzyme NOX2 that generates reactive oxygen species (ROS). We and others have demonstrated that NOX2-derived ROS contribute to an immunosuppressive microenvironment by suppressing the function of cytotoxic lymphocytes, polarizing macrophages towards a tumor-promoting M2 phenotype, and increasing regulatory T cell (Treg) populations. Additionally, our previous study suggests that NOX2-derived ROS stimulates EMT in breast cancer cells. To further investigate the effects of myeloid-derived ROS on the tumor microenvironment, we genetically ablated Nox2 in the PyMT-MMTV breast cancer model, allowing systematic evaluation of tumor progression and the immune landscape.

Material and method

Nox2^{-/-} mice were crossed with PyMT-MMTV mice. Female Nox2^{-/-} PyMT-MMTV mice were compared with age-matched littermate wild-type (WT) PyMT-MMTV controls. Mice were sacrificed, tumor weight was measured, lung metastasis was quantified via H&E staining, and splenic weights were recorded as an indicator of systemic inflammation. Tumor and spleen single-cell suspensions were assessed by flow cytometry for T cell activation, regulatory T cells, macrophage polarization, and neutrophil populations. Expression of EMT markers was evaluated by flow cytometry and Western blot, while intratumoral cytokine levels were quantified via qPCR.

Result and discussion

Nox2^{-/-} PyMT-MMTV mice showed accelerated tumor growth and enhanced metastasis. This concurred with a pronounced systemic expansion of granulocytic myeloid cells and splenomegaly. The Nox2^{-/-} animals showed signs of improved anti-tumor immunity with enhanced CD8+ T cell activity, reduced levels of Tregs, and reduced frequency of immunosuppressive M2 macrophages in the tumor and systemically, but this was not sufficient to prevent tumor progression. The paradoxical role of NOX2 in the PyMT-MMTV model may stem from the dysregulated inflammatory response, evident by the significant myeloid cell expansion. The tumors of the Nox2^{-/-} mice contained increased IL-6 levels and showed elevated EMT markers. In vitro experiments supported that macrophages differentiated in the presence of pharmacological inhibition of NOX2 produce enhanced levels of IL-6. Collectively, these inflammatory factors may override the benefit of a heightened CD8+ T cell response.

Conclusion

This study demonstrates that a favorable immune landscape does not guarantee improved outcomes in cancer and suggests that inflammatory cytokines, such as IL-6, may drive disease progression. Our findings challenge the current paradigm in cancer biology that mesenchymal tumors inherently possess more immunosuppressive microenvironments. These insights underscore the importance of comprehensive therapeutic strategies that address both adaptive immunity and myeloid cell regulatory networks for optimal clinical efficacy.

Targeting glycation stress in chemoresistant colon cancer: Effects on cancer stem cells

F. Lardinois¹, V. Mohring¹, L. Martin Morales¹, N. Maloujahmoum², F. Agirman¹, A. Chariot², F. Rapino², O. Peulen², C. Corbet³, A. Bellahcene²

¹University of Liège, Liège, Belgium

²University of Liège, Belgium

³University of Louvain, Belgium

Introduction

Our team recently demonstrated that KRAS-mutated colorectal tumors exhibit methylglyoxal (MG) glycation stress. This stress is linked to the reprogramming of glucose metabolism, a crucial event observed in many cancers during tumor progression and therapy resistance. A growing body of evidence suggests that cancer stem cells (CSCs) are primarily responsible for cancer aggressiveness, drug resistance, and tumor relapse. Based on these results, we decided to prioritize the study of MG stress in colorectal cancer CSCs.

Material and method

We compared cells grown under 2D conditions to 3D spheroids to assess their enrichment in CSCs. High levels of stem cell markers such as ALDH1A1, OCT-4, and CD133 were successfully detected in 3D cultures and correlated with elevated levels of CD44 and cyclin D1, indicating activation of the Wnt pathway. RNA sequencing analysis performed on colorectal cancer cells under endogenous MG stress revealed enhanced expression of several Wnt activators, including CTNNB1 (coding for β-catenin), WNT6, WNT7B, WNT9A, LEF1, and TCF4.

Result and discussion

Altogether these data suggest that MG stress could, at least in part, contribute to Wnt activation in colorectal cancer cells. Consistently, preliminary results point to a dose-dependent accumulation of MG protein adducts paralleled by increased TCF1 expression in colorectal cancer cells. CSCs characterized by high ALDH activity showed a significant increase in intracellular MG and MG protein adducts, suggesting a correlation between MG and this stemness marker.

Conclusion

The recent demonstration of chemotherapy-induced promotion of stemness in colorectal cancer indicate that therapy resistant preclinical models under study may recapitulate the sequence of CSCs enrichment associated with glycolysis, followed by MG stress and terminated by Wnt activation. We propose that neutralizing MG in CSCs could significantly enhance the efficacy of therapy in colorectal cancer. Understanding the energy metabolic modalities of CSCs and their ability to adapt in response to therapy promises numerous applications that can help improve cancer patient care.

EACR25-1889

Identifying the role of PLEKHS1 in cancer

E. Gill¹, C. Perks¹

¹University of Bristol, Translational Health Sciences, Bristol, United Kingdom

Introduction

The PLEKHS1 gene is mutated in multiple cancers, with approximately 40% of bladder cancer cases and 9% of thyroid cases carrying this mutation. However, very little is known about the consequences of this or the function of the protein for which PLEKHS1 codes. PLEKHS1 tumour DNA can be detected in urine of those with bladder cancer, and therefore interest has been paid to the possibility of its use as a detection biomarker with very little physiological understanding of PLEKHS1. As we have shown previously, PLEKHS1 is present in cell lines from multiple cancer types as well as 'normal' cell lines. Now the aim has moved to identifying the possible function of PLEKHS1, and to further our understanding of the protein.

Material and method

Immunofluorescence and immunoprecipitation experiments were carried out on bladder, prostate, and breast cancer cell lines.

Result and discussion

It was observed that PLEKHS1 is present in the cytoplasm but is largely localised to the nucleoli and the Golgi apparatus, which was further confirmed when analysing the immunoprecipitation results showing proteins that interact with PLEKHS1 are largely nucleolar and Golgi apparatus based proteins.

Conclusion

These results confirm the localisation of the PLEKHS1 protein and are vitally important in starting to unravel the function of PLEKHS1.

⁶Institute for Interdisciplinary Research, University of Coimbra, Coimbra, Portugal

⁷School of Pharmacy and Medical Science, Griffith University, Southport, Qld, Australia

Introduction

Mitochondrial localization is crucial for meeting the energetic demands required for cell migration. The leading edge of migrating cells requires an adequate supply of ATP, which is facilitated by the redistribution of mitochondria toward this area. In the context of cancer, cell migration is a critical step in the invasion

process, being the initial step of metastasis. Miro1, a Rho GTPase located in the outer mitochondrial membrane, is a key regulator of mitochondrial trafficking. However, its role in cancer cell migration and the mechanisms underlying its function are poorly understood. The present study aims to evaluate the role of Miro1 in regulating cell invasion and the formation of metastases.

Material and method

Miro1-deficient B16 melanoma cells were generated by CRISPR-Cas12a. Oxygen consumption rates and extracellular acidification rate were measured using Seahorse XFe96 extracellular flux analyzer, and the ATP/ADP ratio was assessed by ratiometric imaging of Perceval HR. Cell migration and invasion were evaluated by scratch assay (Incucyte), spheroid outgrowth, invadopodial activity (gelatin degradation assay), and vinculin and F-actin staining. For in vivo studies, C57BL/6J mice were injected intravenously with B16 and B16 Miro1-deficient cells, with subsequent examination of the lungs for the presence of metastatic tumors through H&E staining.

Result and discussion

Miro1-deficient B16 cells showed a decrease of approximately 20% in ATP production rate and reduced ATP/ADP ratio in the leading edge of migrating cells, driven by impaired glycolysis rather than mitochondrial respiration. Consistently, depletion of Miro1 also led to a decrease in the wound healing area (50%), as well as the invasion index (60%), and the outward migration rate of cells from spheroids (45%). Additionally, Miro1-deficient cells showed reduced focal adhesion size, lower ability to degrade gelatin (60%), and alterations in the actin cytoskeleton. These findings support the idea that mitochondrial positioning, facilitated by Miro1, is crucial for efficient energy distribution during migration and invasion. Notably, in vivo data showed that mice injected with Miro1-deficient cells developed fewer metastatic foci in the lungs when compared to control cells, highlighting Miro1's essential function in metastatic progression.

Conclusion

Our results demonstrate that Miro1 plays a crucial role in regulating the migratory and metastatic potential of B16 cancer cells by controlling the positioning of mitochondria, ATP distribution, and coordinating the actin cytoskeleton. These findings suggest that targeting Miro1 could be a promising therapeutic strategy.

EACR25-1902

Identifying novel regulators of the BH3-only protein PUMA using whole genome CRISPR/Cas9 KO screens to enhance the efficacy of cancer treatment

D. Kaloni¹

¹Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

Introduction

The intrinsic apoptotic pathway, regulated by the BCL-2 protein family, is a key mechanism in regulating cell

death. BH3-only proteins, such as PUMA, BIM, BID, and NOXA, are crucial for initiating apoptosis, particularly in response to anti-cancer agents. PUMA (Bbc3) is a critical BH3-only protein that triggers apoptosis via both Trp53-dependent and Trp53-independent pathways. The expression of PUMA is directly regulated by Trp53, a tumor suppressor commonly mutated in cancers. This study aims to identify novel regulators of Puma expression in both Trp53-dependent and -independent ways in blood cancers, with the potential for developing new therapeutic targets.

Material and method

We engineered a Puma-tdTomato reporter mouse model by replacing the Puma coding region (Bbc3) with the tdTomato gene, maintaining the endogenous regulatory regions to track Puma expression in real-time. We generated pre-clinical AML models by introducing retroviruses expressing AML-driving oncogenes into hematopoietic stem and progenitor cells (HSPCs) from the Puma-tdTomato reporter mice. These modified HSPCs were injected into irradiated recipient mice, resulting in AML-like tumors. We also crossed the Puma-tdTomato mice with the Eu-Myc transgenic mouse model to generate lymphoma cell lines. To identify Puma regulators, we performed CRISPR/Cas9 whole-genome knockout (KO) screens in Puma-tdTomato-expressing AML cell lines. After isolating the top and bottom 3% of tdTomato-expressing cells, we conducted Next Generation Sequencing (NGS) to identify enriched single-guide RNAs (sgRNAs). Validation was performed in both Trp53-expressing and Trp53-deficient AML cell lines.

Result and discussion

The Puma-tdTomato model allowed real-time tracking of Puma expression in response to apoptotic stimuli in AML and lymphoma cells. Treatment with anti-cancer drugs led to upregulation of Puma, indicated by increased tdTomato fluorescence. In the CRISPR/Cas9 KO screen, several novel genes regulating Puma expression were identified. Validation in Trp53-deficient cell lines confirmed that some of these genes regulate Puma expression independently of Trp53.

Conclusion

Our study demonstrates that the Puma-tdTomato reporter model is an effective tool for identifying regulators of Puma expression in blood cancer models. The CRISPR/Cas9 screen revealed novel genes that could serve as potential therapeutic targets for enhancing Puma expression, especially in Trp53-deficient cancers. These findings suggest new strategies to promote cancer cell death and provide a foundation for future therapeutic development.

Flow-Based Cell Deformation Reveals EMT-Driven Mechanical Phenotype Changes in Metastatic Prostate Cancer

J. Gumulec¹, J. Navratil¹, M. Raudenska¹, T. Vicar², L. Orlova³

¹Masaryk University, Faculty of Medicine, Brno, Czech Republic

²Brno University of Technology, Faculty of Electrical

Engineering and communication, Brno, Czech Republic
³Brno University of Technology, Faculty of Mechanical Engineering, Brno, Czech Republic

Introduction

Mechanical alterations in cancer cells are critical markers of metastasis, reflecting profound molecular and metabolic reprogramming. In this study, we explore the interplay between cytoskeletal reorganization, metabolic shifts, and cellular stiffness in prostate cancer.

Material and method

To assess cellular mechanics, adherent cells were exposed to controlled fluid shear in microchannels, and their deformation was analyzed using a Kelvin–Voigt viscoelastic model. Complementary finite element simulations were performed to capture the complex mechanical response, incorporating not only the actin cortex but also atypical contributors such as intermediate filaments, microtubules, and organelles. This integrative approach enabled robust correlation of molecular alterations – such as EMT marker redistribution and metabolic reprogramming – with observed changes in cell stiffness.

Result and discussion

By employing zinc treatment as a modulatory intervention, we induced phenotypic changes in metastatic PC-3 cells that mirror a partial epithelial-mesenchymal transition (EMT) reversal. Specifically, zinc exposure led to reduced vimentin expression, enhanced E-cadherin levels, and a distinct perinuclear redistribution of caveolin-1. These molecular alterations were paralleled by increased ATP production, enhanced spare respiratory capacity, and modified mitochondrial distribution, collectively indicating a shift toward a more energetically efficient state. Importantly, the zinc-induced molecular and metabolic modifications were directly associated with an increase in cell stiffness. Complementary computational simulations suggest that this stiffening results not solely from actin cortex reorganization but also from contributions by intermediate filaments and organelle dynamics.

Conclusion

These findings highlight a critical link between the regulation of EMT markers, metabolic reprogramming, and the biomechanical properties of cancer cells. Overall, our results provide valuable insights into the molecular mechanisms underpinning metastasis and suggest that targeting the interconnection between cellular metabolism and mechanics could inform novel diagnostic and therapeutic strategies in cancer management.

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is the most common type of pancreatic cancer and is strongly associated with cancer-associated cachexia (CAC), a systemic metabolic disorder that worsens prognosis. In the prediagnostic phase of PDAC, profound metabolic alterations and soft tissue changes occur, which may serve as early biomarkers. While white adipose tissue (WAT) has been widely recognised as a key player in tumour progression by supplying growth factors, inflammatory cytokines, and metabolites, recent evidence suggests that brown adipose tissue (BAT), a thermogenic fat depot, may also modulate tumour metabolism. BAT is a critical regulator of systemic energy homeostasis and glucose metabolism, both of which are central to PDAC progression. We hypothesise that metabolic dysfunction driven by alterations in BAT activity contributes to tumour progression in PDAC.

Material and method

To investigate the role of BAT in PDAC, we established a mouse model of pancreatic cancer in which BAT was surgically removed (BATectomy). Tumour growth, metastasis, and CAC parameters were assessed and compared between BAT-intact (Sham) and BAT-depleted (BATectomy) mice. To characterise the metabolic alterations associated with BAT loss, we performed comprehensive metabolic profiling, including metabolomic and lipidomic analyses, as well as glucose homeostasis assessments. Additionally, histological and molecular characterisation of tumour and adipose tissues was conducted.

Result and discussion

Our findings indicate that BAT plays a crucial role in PDAC progression. Mice subjected to BATectomy exhibited significantly increased tumour burden and metastatic spread compared to their Sham counterparts. Furthermore, BAT depleted mice displayed impaired glucose and lipid metabolism, alongside severe lipid

dystrophy, highlighting the systemic metabolic consequences of BAT loss in the context of cancer.

Conclusion

These results underscore the critical impact of BAT on tumour progression and metabolic dysfunction in PDAC. Understanding the interplay between thermogenic fat and cancer metabolism could pave the way for novel therapeutic strategies aimed at restoring metabolic homeostasis and improving patient outcomes.

Peroxidasin promotes epithelial-mesenchymal transition and invasion in metastatic melanoma

C. Smith-Diaz¹, A. Kumar², K. Chitcholtan³,

C. Winterbourn¹, M. Paumann-Page¹

¹University of Otago, Centre for Redox Biology and Medicine, Christchurch, New Zealand

²University of Otago, Department of Pathology, Dunedin, New Zealand

³University of Otago, Department of Obstetrics and Gynaecology, Christchurch, New Zealand

Introduction

Peroxidasin, an extracellular peroxidase enzyme that generates the strong oxidant hypobromous acid, is upregulated in many types of cancer including invasive metastatic melanoma, breast, brain, ovarian and prostate cancer. Its expression is associated with increased cell invasion and cancer progression. However, it is not known how peroxidasin contributes to cancer malignancy.

Material and method

We have analysed the transcriptomes of 70 metastatic melanoma cell lines with variable levels of peroxidasin expression from the New Zealand melanoma cell line panel. To determine transcriptional patterns associated with high and low peroxidasin expression, cell lines with high peroxidasin expression ($n = 22$) were compared against cells with low peroxidasin expression ($n = 22$). Pathway analysis (ReactomePA, R) and gene set enrichment analysis (FGSEA) using genes of the epithelial-mesenchymal transition (EMT) pathway and genes linked to different melanoma phenotypes (invasive/undifferentiated, neural crest-like, proliferative/melanocytic) were performed. To assess the functional role of peroxidasin in metastatic melanoma, we performed a knockout of peroxidasin in a highly invasive, high peroxidasin expressing cell line (NZM40) using CRISPR-Cas9 technology. We investigated the effect of knockout and inhibition of activity with the inhibitor phloroglucinol on cancer cell invasion using functional invasion assays and gene transcription (RNAseq).

Result and discussion

Transcriptomic analysis of metastatic melanoma cell lines highlighted the strong association between high peroxidasin expression and the expression of EMT genes as well as hallmark genes of the undifferentiated invasive melanoma phenotype, inferring a role of peroxidasin in melanoma cell invasion. Pathway analysis on down-regulated genes in the low peroxidasin expressing cell lines identified biological processes pertaining to

extracellular matrix remodelling including ECM organisation, collagen and elastic fibre formation and extracellular matrix degradation. Both knockout of peroxidasin and inhibition of its activity with phloroglucinol led to reduced cancer cell invasion in invasion assays. Transcriptomic analysis showed decreased EMT and invasive gene expression in both the peroxidasin knockout and the wild type treated with the inhibitor phloroglucinol. Phloroglucinol led to peroxidasin-specific differential gene expression, however, fewer genes were differentially expressed and smaller effect sizes were observed compared to the knockout.

Conclusion

Transcriptomic analysis of the NZM cell line panel confirmed peroxidasin as strongly associated with an invasive phenotype. Knockout and inhibition of peroxidasin identified a functional role in melanoma invasion by reducing EMT and invasive gene expression. These findings highlight peroxidasin as a promising novel target to reduce cancer cell invasion.

EACR25-1948

mTORC2 but not mTORC1 governs cellular metabolic landscape in Calreticulin (CALR) mutated

myeloproliferative neoplasm (MPN)

S. Naseer¹, A. Singh¹, S. Chowdhury¹, S. Srivastva¹, A. Roy¹

¹IIT Delhi, Kusuma School of Biological Sciences, New Delhi, India

Introduction

Myeloproliferative neoplasm (MPN) is classified as the disorder of hematopoietic progenitor cells with various mutations being implicated in its pathogenesis, including JAK2, MPL, and CALR driver mutations. We focused on CALR, an ER chaperone involved in protein folding and calcium homeostasis. The CALR mutations are primarily observed in Exon 9, resulting in partial (CALR ins5) or complete (CALR del52) deletion of negatively charged amino acids present in the CALR WT tail. While both the CALR mutations activate TpoR mediated JAK/STAT signalling, they differ significantly in their phenotype and prognosis, hinting at differential regulation of downstream signalling cascades. Consistently, co-targeting PI3K-mTOR and JAK-STAT signalling through BEZ235 and Ruxolitinib, increased the efficacy of these drugs in mice models and in MPN progenitor cells. Therefore, we aimed to dissect the interplay between CALR mutations implicated in MPN and mTOR signalling to pave the way for potential future targeted therapeutics.

Material and method

We utilized CALR overexpression systems (WT, Del52, Ins5) in HEK cells to investigate the regulation of mTOR (mTORC1 and mTORC2) signalling cascade through immunoblotting. As these mutations target the CALR tail, we created CALR WT truncation mutants to understand the extent of activation of mTOR signalling. Furthermore, we used inhibitors to assess any distinction between CALR mutations in the inhibition of mTOR cascade. We have compared the glucose uptake and cellular energetics through ATP levels in the cell between CALR WT and mutations. We also performed mass

spectrometry studies, siRNA-based knockdowns, and overexpressed mTOR complex-specific protein overexpression to establish the molecular axis behind the observed phenotype.

Result and discussion

We have established differential activation of mTORC2 but not mTORC1 by CALR mutants, with mTORC2 being significantly downregulated in CALR Del52. This further resulted in a shift in the lysosomal count, distribution, mTOR colocalization, and transcriptional activity of the TFE3 gene, a key component for lysosomal biogenesis and autophagy induction. Our mass spectrometry data reveals the potential interactors that play a role in the lysosomal distribution in the cells.

Conclusion

We have studied the effect of CALR mutants on different pathways and found that CALR ins5 mutant triggers high mTORC2 (S2481) activation compared to CALR WT or CALR del52. This selective activation of mTORC2 by CALR mutant and its downstream implications on lysosomal distribution and biogenesis is an interesting finding. This study highlighted the difference between CALR mutants del52 and Ins5 in differential modulation of mTOR pathway and its downstream impact on lysosomes.

EACR25-1950

Modification of β-Catenin by MCPIP1 endonuclease Activity regulates the metastatic potential of ccRCC

J. Górká¹, P. Marona¹, M. Główczyk², R. Myrczek^{1,3}, J. Ryś⁴, J. Jurał¹, K. Miękus¹

²School of Medicine, University of Virginia, Department of Pathology, Charlottesville, United States

³Jagiellonian University, Doctoral School of Exact and Natural Sciences, Cracow, Poland

⁴Centre of Oncology Maria Skłodowska-Curie Memorial Institute, Cracow Branch, Department of Tumor Pathology, Cracow, Poland

Introduction

Renal cell carcinoma (RCC) is one of the most common urological neoplasms in the world, with ccRCC being the most common subtype, accounting for approximately 75% of RCC cases. Among the many pathways implied in ccRCC, the Wnt/β-catenin pathway has emerged as a key contributor. To overcome these challenges, acquiring a comprehensive understanding of the underlying biology of ccRCC is crucial. Among the endonucleases, the ZC3H12a gene encoding Monocyte Chemoattractant Protein-1 Induced Protein, has a suppressive effect in renal cell carcinoma. Our recent study revealed that MCPIP1 may act as a tumor suppressor in ccRCC that prevents EMT by stabilizing Wnt inhibitors and decreasing the levels of active β-catenin and EMT inducers.

Material and method

To investigate the role of MCPIP1 in ccRCC development and progression, we used *in vivo*, *in vitro* models and the samples from patients. We conducted a comprehensive analysis, including the assessment of

crucial genes and proteins of the Wnt/β-Catenin pathway, using Western blot, microarray analysis, quantitative PCR, immunofluorescence, and immunohistochemistry staining.

Result and discussion

In this study we demonstrate that the endonuclease activity of MCPIP1 may mediate tumor progression by controlling the transcriptional and post-transcriptional modification of β-catenin. We found that MCPIP1 regulates the level of genes binding to the CTNNB1 gene promoter, which encodes β-catenin. Moreover, MCPIP1 influences not only on the level of β-catenin, but also on its post-transcriptional modifications, including phosphorylations of Y654 and S675 which regulate its activity. Furthermore, we observed a dramatic decrease in the level of inactive, degradation-promoted, phosphorylated β-catenin (Ser45) in advanced stages of ccRCC compared to early clinical stages. In contrast, the level of active, phosphorylated β-catenin significantly increases with the progression of the disease. Microarray analysis indicated that the expression of genes binding to the CTNNB1 gene promoter, encoding β-catenin, may affect the progression of ccRCC.

Conclusion

Our studies suggest that MCPIP1 plays a significant role in the progression of ccRCC by regulating the post-transcriptional modifications of β-catenin. The level and location of phosphorylated β-catenin may be crucial at every stage of ccRCC development.

EACR25-1962

The pro-invasive MAP4 kinases promote tissue invasion and selectively modulate interactions with the neuralTME in medulloblastoma

M. Lin¹, D. Hochuli¹, J. Petr², B. Ciraulo¹, D. Versamento¹, M. Schönholzer¹, S. Yan¹, M. Modena³, M. Baumgartner¹

¹University Children's Hospital, Oncology, Zürich, Switzerland

²ETH Zürich, Department of Biosystems Science and Engineering, Basel, Switzerland

³ETH Zurich, Department of Biosystems Science and Engineering, Basel, Switzerland

Introduction

Medulloblastoma (MB) is the most common malignant pediatric brain tumor, sub-grouped into WNT, SHH, Grp3, and Grp4 MB with different biological and clinical characteristics. Despite advancements in molecular diagnostics, therapeutic intervention for patients with MB remains limited. The neural contributions of the tumor microenvironment (TME) of MB are incompletely characterized. Specifically, the interferences between tumor and neural cells, as well as their functional consequences, remain largely unknown and present a significant barrier to advancing targeted and effective interventions for pediatric MB.

Material and method

We combine classical cell biology, 3D-invasion studies, and quantitative imaging with an advanced organotypic cerebellum slice culture model of SHH and Grp3 MB,

to uncover molecular insights into tissue invasion and the interactions between MB tumor cells and the neural tumor microenvironment (nTME) in the cerebellum. By implementing tissue perfusion and functional fluorescence imaging, we enabled the longitudinal analysis of tumor cell interaction with the nTME, cerebellar tissue invasion, and the visualization of dynamic processes in the tumor-nTME interaction.

Result and discussion

We found that the pro-invasive Ser/Thr kinase MAP4K4 cooperates with striatin 3 (STRN3), a central component of the Striatin-interacting phosphatase and kinase (STRIPAK) complex, to drive tissue invasion downstream of growth factor signaling. Mechanistically, STRN3 links MAP4K4 to the protein phosphatase 2A, which suppresses the growth-inhibitory functions of MAP4K4. Simultaneously, STRN3 enables growth factor-induced PKCθ activation and direct phosphorylation of VASP at S157 by MAP4K4, both essential for efficient cell invasion. High-resolution tumor imaging in the cerebellar tissue environment revealed the tight interaction between invading tumor cells and cerebellar astrocytes, accompanied by increased astrocytic calcium signaling. Notably, the pharmacological interference with MAP4K function increased these interactions, leading to the formation of extended junctional complexes and altered astrocyte reactivity. Phosphoproteomic and functional studies suggest that MAP4Ks drive MB-nTME interaction by promoting the targeted phosphorylation and re-localization of cell-cell junctional proteins. Collectively, our findings uncover a direct, functional interplay between MB tumor cells and astrocytes and identified MAP4 kinases as pivotal regulators of this process.

Conclusion

The interaction between MB tumor cells and the neural microenvironment in the cerebellum, along with the resulting TME remodeling, is intrinsically regulated by MAP4 kinases, opening new avenues for innovative therapeutic strategies.

EACR25-1967

Cell-free DNA (cfDNA) regulates metabolic remodeling influencing cancer cell proliferation, quiescence, and chemoresistance

I. Lemos^{1,2}, C. Freitas-Dias^{1,2}, A. Hipólito^{1,2}, J. Ramalho¹, F. Carteni³, L. Gafeira Gonçalves⁴, S. Mazzoleni³, J. Serpa^{1,2}

¹Nova Medical School, Lisbon, Portugal

²Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal

³Lab Applied Ecology and System Dynamics, Napoli, Italy

⁴Instituto de Tecnologia Química e Biológica António Xavier, Oeiras, Portugal

Introduction

Cell-free DNA (cfDNA) holds significant potential as a valuable tool in cancer diagnosis, monitoring, and patient management. While its clinical relevance in oncology has gained recognition, cfDNA biological relevance in tumor

malignancy remains unknown. Tumor-derived systemic signals are crucial for coordinating metabolic and signaling pathways that support cancer survival and dissemination. In a biological point of view, cfDNA emerges as a potential master regulator of metabolic adaptation and cell functioning control, allowing disease progression. Our aim is to unravel the role of cfDNA in cancer cells metabolic regulation, contributing to cancer establishment and progression.

Material and method

CfDNA was isolated from the conditioned media of breast cancer (MDA-MB-231) and ovarian cancer (ES-2) cell lines cultured at different glucose availability conditions. Four cfDNA variants were obtained based on glucose availability and cell culture duration: Early-cfDNA-Gluc (6 h with glucose), Early-cfDNA-NoGluc (6 h without glucose), Late-cfDNA-Gluc (48 h with glucose), and Late-cfDNA-NoGluc (48 h without glucose). The impact of these cfDNA variants on cell proliferation (proliferation curve), migration (wound-healing assay), metabolism (¹H-NMR spectroscopy), and cisplatin resistance (flow cytometry), was evaluated in new batches of MDA-MB-231 and ES-2 cultures. Additionally, we studied the protein levels of DNA-sensitive Toll-like receptor 9 (TLR9) by immunofluorescence and its colocalization with lysosome associated membrane protein 1 (LAMP-1).

Result and discussion

In MDA-MB-231 cell line, cfDNA influenced the metabolic adaptation by regulating glucose and glutamine consumption. In ES-2 cells, cfDNA prompted metabolic profiles similar to the initial cell cultures (cell-of-origin of cfDNA). Both cell models revealed that certain cfDNA variants favor cisplatin resistance, with specific cfDNA variants offering protection depending on the cell line and culture conditions. Our findings showed that TLR9 levels decreased in both cell lines over time, with inversed trends: ES-2 cells exhibited increased TLR9-LAMP-1 colocalization, while MDA-MB-231 cells displayed decreased TLR9-LAMP-1 colocalization. These results suggest the involvement of TLR9 in cfDNA-mediated remodeling, with cell-specific dynamics. Additionally, in both models, extending cfDNA exposure from 48 hours to 4 weeks induced quiescence in a subset of cancer cells, emphasizing the long-term impact of cfDNA on tumor behavior.

Conclusion

These findings highlight cfDNA as a key player in the tumor microenvironment, facilitating communication between cancer cells, supporting their survival and adaptation under stress, modulating the metabolic reprogramming, cell proliferation, and quiescence thereby contributing to different steps of disease progression and therapy resistance.

EACR25-1982

Novel liposomal nanoformulations containing cannabidiol, celecoxib and 2,5-dimethylcelecoxib induce cell cycle arrest and apoptosis in glioblastoma cells

A. Majchrzak-Celińska¹, A. Rybarczyk¹, L. Piwowarczyk², V. Krajka-Kuźniak³

¹Poznan University of Medical Sciences, Chair and Department of Pharmaceutical Biochemistry, Poznań, Poland

²Poznan University of Medical Sciences, Chair and Department of Pharmaceutical Chemistry, Poznań, Poland

³Poznan University of Medical Sciences, Chair and Department of Pharmaceutical Biochemistry, Poland

Introduction

Glioblastoma (GBM) is the most common primary brain tumor with patient survival below 18 months following diagnosis. The rigorous treatment regimen including surgical resection, radiotherapy, and chemotherapy with temozolamide, remains inefficient. Cannabidiol (CBD), celecoxib and 2,5-dimethylcelecoxib (DMC) exert promising anticancer properties, while liposome-based drug delivery systems offer a new way to reach tumor cells. Thus, the aim of this study was to verify the anti-glioma properties of CBD, celecoxib and DMC-loaded nanocarriers, and analyze their impact on cell cycle and apoptosis in U-138 MG glioblastoma cells.

Material and method

Liposomal nanoformulations loaded with CBD, celecoxib, DMC, and their combinations, as well as empty carriers were prepared via thin-film hydration method, followed by extrusion. The effect on U-138 MG cells viability following 48 h incubation with the analyzed nanoformulations (in a concentration range of 1–50 µM) was verified using the MTT assay, while their impact on cell cycle distribution and apoptosis was determined using flow cytometry with Muse Cell Cycle kit, and Muse Annexin V & Dead Cell Kit, respectively.

Result and discussion

Our results revealed that among the single agent-loaded nanoformulations, the one with celecoxib was the most cytotoxic, followed by CBD, and DMC. Combinatory treatment also induced dose-dependent reduction in cell viability. Empty carriers did not have negative impact on the viability of U-138 MG cells. All the analyzed nanoformulations in 5 µM and 10 µM concentration halted the cell cycle and induced apoptotic cell death of glioblastoma cells. The most pronounced effects were observed after the treatment with CBD.

Conclusion

The pro-apoptotic properties of novel liposomal formulations containing CBD, celecoxib and DMC have been highlighted in our research. The observed alterations in cell cycle phases distribution and apoptosis induction require further investigation to clarify the role of these nanoformulations in modulation of cellular signaling. Continued research, including *in vivo* models, will be essential to thoroughly evaluate their full potential as anticancer agents.

Understanding the role of desmoglein 2 in preserving the epithelial phenotype of breast cancer cells

O. Vacek^{1,2,3}, L. Knapeková^{1,3}, J. Ondřejová^{1,2}, Z. Kahounová¹, P. Beneš^{3,2}, K. Souček^{1,2,3}

¹Institute of Biophysics of the CAS, Department of Cytokinetics, Brno, Czech Republic

²St. Anne's University Hospital, Brno, International Clinical Research Center, Brno, Czech Republic

³Masaryk University, Department of Experimental Biology, Brno, Czech Republic

Introduction

Desmoglein 2 (DSG2) is a surface protein that plays a physiological role in desmosomal cell-cell adhesion and in maintaining epithelial tissue integrity. In cancer, the role of DSG2 remains controversial, as it has been reported to exhibit both pro-tumorigenic and tumor-suppressive effects. Given that the connection between DSG2 and the metastatic cascade in cancer is under-explored, we focused on its association with epithelial-mesenchymal transition (EMT) traits in breast cancer cells.

Material and method

CRISPR-Cas9 knockout (KO) cells were validated using western blotting, immunofluorescence, and sequencing of gRNA targets to confirm the loss of DSG2 in the T-47D cell line. DSG2 KO cells were tested for their attachment to ECM matrix components utilizing the ECM Select® Array Kit Ultra-36 (Advanced Biomatrix). Multicolor spectral flow cytometry was used to detect the epithelial-mesenchymal transition (EMT) surface profile of the DSG2 KO cells, assessing markers such as EpCAM, Trop2, CD9, CD29, CD49c, GD2, and ITGB5.

Result and discussion

To evaluate the impact of DSG2 loss in vitro, we established a T-47D DSG2 CRISPR knockout model and successfully confirmed the deletion of DSG2. We investigated the capacity of DSG2 knockout cells to adhere to various extracellular matrix (ECM) proteins and noted a general reduction in cell adhesion to most individual ECM components. The measurement of an in-house developed and validated EMT surface panel indicated the upregulation of multiple mesenchymal markers in DSG2 knockout cells and the downregulation of epithelial markers.

Conclusion

Our study demonstrates that in the T-47D breast cancer cell model, the loss of DSG2 results in a reduced capacity to adhere to various ECM components. These alterations are also evident in the overall mesenchymal-like cell surface profile of DSG2 KO cells. We conclude that DSG2 in the tested model is associated with EMT and may play a role in suppressing the metastatic process.

EACR25-1996

Impact of androgen receptor expression on the efficacy of anti-androgen therapies in triple negative breast cancer

B. Crespo¹, J. Illera¹, G. Silvan¹, M. Illera¹, S. Cáceres¹

¹Veterinary Medicine School. University Complutense of Madrid., Department of Physiology, Madrid, Spain

Introduction

Triple negative breast cancer (TNBC) is the most aggressive type of breast cancer, characterized by the lack of expression of estrogen and progesterone

receptors, and HER-2 overexpression. However, most of TNBC cases express the androgen receptor (AR) and its variants, such as ARV7. Also, ARV7 has been associated with resistance to endocrine therapies. Besides, the hormonal environment seems to play a determining role in tumor progression. Therefore, this study aims to analyze the impact of AR antagonists on cell proliferation, cell migration, and hormonal environment in TNBC cell lines, evaluating the effectiveness of inhibiting the AR expression and its variants, and the potential of those compounds as a targeted therapy for TNBC.

Material and method

To this purpose, the TNBC cell lines, IPC-366 and SUM149, were maintained in culture flasks in their corresponding supplemented media under controlled conditions (5% CO₂ and 37°C). Cells were treated with different AR antagonists: bicalutamide (that bind to AR inhibiting its function), and ailanthone (that block AR at transcriptional level), at dose of 1 μM of each compound. Cell viability and migration assays were performed in order to evaluate the effect of the compounds in TNBC cell lines. To determine the AR, phosphorylated AR (p-AR), and ARV7 expression, western blot techniques were performed. Besides, dihydrotestosterone (DHT) and 17β-estradiol (E2) levels were measured to evaluate the DHT/E2 ratio as a good indicator of endocrine therapy effectiveness.

Result and discussion

Results revealed that IPC-366 had higher expression of AR, p-AR, and ARV7 than SUM149, which may explain the different responses to treatment observed in both cell lines. Although bicalutamide and ailanthone produced significant reductions in cell viability and cell migration in both cell lines, only ailanthone reduced cell viability in SUM149. The DHT/E2 ratio increase under both treatments with IPC-366, while in SUM149 decrease with bicalutamide. Thus, a higher DHT/E2 ratio seems to be associated with increased effectiveness of endocrine therapies. Finally, while in IPC-366, AR and ARV7 expression decrease with all treatments, p-AR expression increases. In SUM149, all treatments decrease AR, p-AR, and AR-V7 expression. Specially, ailanthone blocks ARV7 expression in both cell lines. Consequently, a reduction in AR expression and its variants has been observed to decrease cell growth and migration, being anti-androgen therapies a viable treatment option for TNBC.

Conclusion

These results revealed that targeting AR and its variants may serve as an effective therapeutic approach for TNBC, especially with the use of ailanthone. In addition, the DHT/E2 ratio could be a valuable indicator for predicting the efficacy of endocrine therapies.

EACR25-2006

Exploring the oncogenic role of the deubiquitinase USP7 in pancreatic cancer using PROTAC technology

S. Urban¹, N. Klink², J. Seier³, B. Adhikari⁴, M. Schwalm⁵, E. Wolf⁴, S. Knapp⁵, A. Paschen³, M. Gersch², B. Grüner¹

¹University Clinics Essen, West German Cancer Center, Essen, Germany

²MPI & Technical University Dortmund, Dortmund, Germany

³University Clinics Essen, Dermatology, Essen, Germany

⁴University of Kiel, Institute of Biochemistry, Kiel, Germany

⁵Goethe University Frankfurt, Frankfurt, Germany

Introduction

Ubiquitin serves as a versatile post-translational modifier, regulating both degrading and non-degrading cellular processes through the activity of E3 ligases. Counter-balancing these processes, deubiquitinases (DUBs) play a critical role in maintaining protein homeostasis by modulating ubiquitin-encoded signals. Targeting DUB activity with small molecules offers a promising approach to modulate previously "undruggable" proteins implicated in cancer biology. However, chemical tools that interrogate DUBs with high specificity in cancer and that can be used to distinguish catalytic from non-catalytic functions have remained scarce.

Material and method

We synthesized a USP7-targeting degrader library and identified potent USP7 PROTACs in our panel of cell lines. Compound specificity was subsequently characterized in a suite of assays, including mass spectrometry analysis. To distinguish between USP7-catalytic and scaffolding effects we performed Seahorse analysis, multiplexed live cell migration and tested metastatic seeding of PDAC cells w/o USP7 targeting compounds *in vivo*.

Result and discussion

Here, we employ an integrated chemical biology strategy to study the deubiquitinase USP7 in pancreatic cancer using complementary approaches of pharmacological inhibition and targeted degradation. In a multiplexed live cell migration screen with a curated library of DUB inhibitors, treatment with USP7 inhibitors led to an invasive cell state switch in pancreatic cancer. Furthermore, cells reprogrammed their metabolism as treatment with the USP7-inhibitor FT671 led to a disruption of mitochondrial respiration and the switch to a glycolytic program. Notably, we observed significant phenotypic differences among commonly used USP7 inhibitors, which led to the development of a USP7-targeting chemical toolbox, comprising a novel USP7 inhibitor and a potent and selective USP7 proteolysis-targeting chimera (PROTAC). Strikingly, cells exhibited distinct cellular phenotypes when USP7 was depleted through targeted protein degradation or pharmacological inhibition.

Conclusion

Collectively, our work provides a curated toolbox of highly specific and well characterized small molecules to distinguish on-target catalytic-phenotypes which will aid to understand the role of DUBs in malignant diseases. More broadly, our data highlights the value of elevated specificity through PROTAC-mediated target degradation.

EACR25-2009 Mitochondrial damage triggers therapy-induced senescence

C. Baltira¹, F. Alkan², F. Jochems³, A. Their¹, D. Fedorushkova¹, W. Faller⁴, R. Bernards³, J. Silva⁴, O. van Tellingen¹, M. de Gooijer¹

¹Netherlands Cancer Institute, Division of Pharmacology, Amsterdam, Netherlands

²Netherlands Cancer Institute, Division of Oncogenesis, Amsterdam, Netherlands

³Netherlands Cancer Institute, Division of Molecular Carcinogenesis, Amsterdam, Netherlands

⁴Netherlands Cancer Institute, Division of Oncogenomics, Amsterdam, Netherlands

Introduction

Glioblastoma (GBM) is a fatal brain tumor with a critical need for better therapies. It is known that the PI3K, MAPK, and CDK4/6 signaling pathways are hyper-activated in these tumors; however, previous studies have used very high concentration of inhibitors to assess their importance, with mixed results. Here we developed PMCI, a combination approach that targets all three pathways simultaneously, at clinically-relevant doses.

Material and method

To characterize the mechanism of PMCI-induced senescence *in vitro*, we use a combination of techniques: cell proliferation assays, quantitative Western blot, SA-β-galactosidase assays, single cell colony outgrowth assays, live-cell imaging, immunofluorescence and electron microscopy, RNAseq, proteomics, flow cytometry, chemo/cytokine arrays, qPCR, p0 cells and Seahorse assays. *In vivo*, we employed an orthotopic glioblastoma mouse model for efficacy experiments, monitored pharmacokinetics using LC-MS/MS, and assesses pharmacodynamics and toxicity using blood parameter analysis and immunohistochemistry.

Result and discussion

PMCI effectively suppresses GBM cell proliferation *in vitro* and *in vivo*, and outperforms monotherapies and dual combinations. PMCI acts by inducing cellular senescence, which is mediated solely by the mitochondria, and, unlike other forms of senescence, is independent of nuclear damage. This phenotype is caused accumulation of dysfunction mitochondria, triggering a reactive oxygen species (ROS)/cGAS-STING senescence-associated secretory phenotype (SASP) signaling cascade that acts in a paracrine manner to establish and maintain senescence.

Conclusion

Our results demonstrate that mitochondrial damage can be sufficient to drive senescence, and that this can be leveraged to target GBM cells.

EACR25-2018

SUMOylation of S6K2 May Confer Its Stabilization Contributing To The Survival of Breast Cancer Cells

N. Sever¹, S. Altay²

¹Pamukkale University, Department of Molecular Biology and Genetics, Denizli, Turkey

²Pamukkale University, Department of Biology, Denizli, Turkey

Introduction

S6K2 (S6 Kinase 2) protein is an PI3K/Akt/mTOR signaling pathway effector protein, which augments the evasion of breast cancer cell from apoptosis by activating

Akt via a positive feedback mechanism. Besides, S6K2 has many other substrates which contribute to the survival of breast cancer cells. Therefore, elucidation of the mechanisms which regulate S6K2 signaling has an important role in breast cancer therapy. Many post-translational mechanisms which play roles in S6K2 regulation still remains to be unraveled. SUMO (small ubiquitin like modifier) is a 11kDa protein which binds to target proteins via their Lys residues generally found in ψ KxE consensus motif (ψ - hydrophobic amino acid, x - any amino acid). There are 4 different SUMO proteins named as SUMO 1-4. SUMOylation of proteins, a post-translational modification, regulate proteins by altering their longevity, subcellular localization, protein interactions and functions. SUMOylation uses a mechanism similar to ubiquitination. In general, SUMOylation prevents ubiquitination and therefore prolongs longevity of proteins. We aim to identify whether S6K2 is SUMOylated and how this SUMOylation affects the longevity and pro-survival function of S6K2 protein.

Material and method

Our bioinformatics analysis revealed that human S6K2 has a ψ KxE consensus motif at residue 196 (189-GIIYRDLKPENIMLS-203). Therefore, we speculate that S6K2 is susceptible to SUMOylation. We will transfet MCF7 cells with FLAG-S6K2 and Myc-SUMO 1/2/3/4 and perform immunoprecipitation (with anti-FLAG antibody) followed by Western blot to observe whether S6K2 is SUMOylated by any of these SUMO proteins. FLAG-S6K2 K196R mutant plasmid will also be transfected and then immunoprecipitation and Western blot will be conducted to determine K196 is the actual SUMOylation site. Moreover, with the same experimental setting (FLAG-S6K2 WT or S6K2 K196R and Myc-SUMO transfection), MCF-7 cells will be treated with cycloheximide with increasing timepoints to investigate whether SUMOylation affects the half-life of S6K2 protein. Also, MCF-7 apoptosis upon TNF treatment will be tested using flow cytometry in the same experimental setting to investigate if S6K2 SUMOylation supports breast cancer cell survival. Finally, the addition of HA-Ub to the same experimental setting along with MG132 treatment will reveal whether S6K2 ubiquitination is affected by SUMOylation.

Result and discussion

We expect to find S6K2 K196 is the S6K2 SUMOylation site and this modulation will prolong S6K2 longevity by preventing its ubiquitination. Also, we expect an increase in MCF-7 cell survival upon TNF treatment when SUMO is overexpressed. On the other hand, the K196R mutant S6K2 overexpression is expected to decrease in S6K2 half-life and MCF-7 cell survival upon TNF treatment.

Conclusion

Based on our findings, S6K2 pro-survival function will be modulated. Therefore, one of the barriers of chemoresistance in breast cancer will be overcome.

EACR25-2025

Endothelial pyrimidine synthesis restricts tumor growth

P. Hyrossova¹, I. Milisav¹, P. Jakoube¹, S. Magalhaes Novais¹, M. Milosevic¹, J. Rohlena¹, K. Rohlenova¹

¹Institute of Biotechnology of the Czech Academy of Sciences, Laboratory of Cellular Metabolism, Vsetec, Prague-West, Czech Republic

Introduction

Cancer cells rely on nucleotide synthesis for proliferation, and antimetabolites targeting nucleotide metabolism remain a cornerstone of cancer therapy. Despite their clinical success, these agents often face high rates of resistance, potentially due to interactions with stromal cells within the tumor microenvironment.

Material and method

To investigate the impact of altered nucleotide metabolism in the tumor microenvironment, we suppressed de novo pyrimidine synthesis in mice by generating a whole-body inducible knockout of dihydroorotate dehydrogenase (DHODH), the essential enzyme in this pathway.

Result and discussion

Unexpectedly, systemic DHODH deficiency led to accelerated growth of orthotopic lung tumors. Single-cell transcriptomics of tumor-bearing lungs revealed that DHODH loss significantly affected stromal cells, including immune cells and, notably, endothelial cells. To dissect the specific role of endothelial metabolism, we generated a mouse model with inducible, endothelium-specific DHODH deletion. Strikingly, selective loss of de novo pyrimidine synthesis in endothelial cells recapitulated the whole-body knockout phenotype, creating a more permissive environment for tumor growth. Transcriptomic analysis of the endothelial-specific model identified alterations in the immune composition of the tumor microenvironment, particularly in monocytes, which was further validated by spectral flow cytometry. Ongoing studies aim to elucidate the precise mechanisms by which endothelial pyrimidine deficiency promotes tumor progression.

Conclusion

Our findings reveal an unexpected pro-tumorigenic effect of systemic pyrimidine synthesis inhibition, driven by changes in the endothelial compartment. These results highlight a previously unrecognized role of endothelial pyrimidine synthesis in shaping the tumor microenvironment and raise concerns about the unintended consequences of targeting this pathway in cancer therapy.

EACR25-2031

Targeting Tumor Metabolism to Prevent the Development of Resistance to Cisplatin in Ovarian Cancer

E. Capellini¹, L. Perotti¹, G. Bianchi¹, G. Damia¹, F. Ricci¹

¹Mario Negri Pharmacological Research Institute, Experimental Oncology, Milan, Italy

Introduction

Ovarian cancer is the deadliest gynecological malignancy in Western countries, with a 5-year survival rate of approximately 40%. Although 85% of patients initially respond to cisplatin (DDP)-based therapy, around 70% relapses with a resistant disease. Among the various mechanisms of resistance, metabolic plasticity is emerging as a key factor and potential therapeutic target. Metformin (MET), a widely used antidiabetic drug,

modulates metabolism and exhibits promising anticancer effects. Our previous studies demonstrated that the addition of MET to DDP can delay the onset of DDP resistance in ovarian cancer patient-derived xenografts (PDXs). This project aims to explore how the combination of DDP and MET can delay resistance, with the purpose of preventing its emergence.

Material and method

Murine ovarian cancer ID8 F3 cell lines sensitive to DDP (S) were used to develop DDP-resistant cells (R) by gradually increasing DDP concentrations. Parallel to this, cells were treated with a combination of DDP and MET (SDM). Resistance was assessed using cytotoxicity assays. Metabolic profiling was performed using a Seahorse® extracellular flux analyzer in both S ID8 cell lines and PDXs, as well as their R sublines derived from *in vitro* and *in vivo* DDP treatments and co-treatment with DDP and MET (SDM, partially resistant to platinum). Protein and gene expression assays were conducted to investigate the mechanisms underlying the delayed development of resistance.

Result and discussion

Resistant ID8 cells showed a five-fold increase in IC₅₀ (50% inhibitory concentration) compared to parental S ID8 F3 cells, while SDM cells exhibited intermediate sensitivity, with only a two-fold increase in IC₅₀. Metabolic profiling revealed that R cells relied more on oxidative phosphorylation, while S and SDM cells depended more on glycolysis. Similar results were observed in ex-vivo cultures derived from S, R and SDM PDX models. Western Blot analyses indicated that the preventing effect of the addition of MET is AMPK-dependent and likely linked to autophagy. An increase in the pAMPK/totAMPK ratio, leading to the inhibition of mTOR, was observed in co-treated cells compared to resistant cells. In the same manner, the co-treated SDM cells exhibited a higher expression of autophagy markers (LC3-I and LC3-II) compared to the R, similar to the parental S cells.

Conclusion

These findings suggest that combining cisplatin and metformin effectively delays the development of cisplatin resistance by modulating tumor metabolic plasticity. Ongoing and future research aims to clarify the underlying mechanisms and explore more specific approaches to prevent resistance development.

³St. Anne's University Hospital in Brno, International Clinical Research Center, Brno, Czech Republic

⁴Masaryk University, CEITEC, Brno, Czech Republic

⁵Faculty of Science, Masaryk University, Department of Chemistry, Brno, Czech Republic

Introduction

Haspin is an atypical Ser/Thr kinase that is critical during mitosis. It has been specifically shown to regulate chromosome alignment and ensure the timely segregation of sister chromatids. Although its well-characterized functions are limited to mitosis, Haspin is present throughout the entire cell cycle. This observation raises the possibility that Haspin may have additional roles in other cell cycle phases. Understanding these potential roles requires investigating the Haspin interactome, which encompasses the network of protein-protein interactions involving Haspin.

Material and method

To analyze the interactome of Haspin, we employed the BioID method. This proximity-dependent biotinylation technique labels potential interaction partners based on their spatial proximity to the protein of interest. BioID was executed in HeLa cells, followed by mass spectrometry analysis to identify biotin-tagged proteins. Subsequent bioinformatics analyses were conducted to determine the putative interaction partners and evaluate their association with various cell cycle stages.

Result and discussion

We identified 127 proteins as potential interaction partners of Haspin kinase through mass spectrometry. Some proteins, such as Pds5b, were previously recognized as Haspin interaction partners. However, most identified proteins had no known association with Haspin, suggesting novel functional links. Furthermore, a subset of these proteins exhibited variations in their interaction patterns across different cell cycle stages, indicating that Haspin's interactome may be dynamically regulated throughout the cell cycle. These findings imply that Haspin might have broader cellular roles beyond mitosis, possibly influencing other cell cycle phases. In the next step, we refined our approach by employing the Fucci2 reporter system, which allowed cell sorting based on specific cell cycle phases before proteomic analysis. This strategy facilitated the elucidation of the dynamic changes in Haspin's interactome and its broader biological significance.

Conclusion

Our study offers insights into the interactome of Haspin kinase and its potential role in cell cycle regulation beyond mitosis. The discovery of new interaction partners emphasizes untapped facets of Haspin's function.

An oncogenic ubiquitin E3 ligase promotes lung cancer metastasis by regulating the HIPK2-Slug axis

⁴Institute of Translational Medicine and New Drug Development, China Medical University, Taichung, Taiwan

⁵Institute of Biomedical Sciences, Academia Sinica, Department of Internal Medicine NTU College of Medicine, Taipei, Taiwan

Introduction

Lung cancer remains the leading cause of cancer-related deaths worldwide, with metastasis being a major factor in poor prognosis. Epithelial-to-mesenchymal transition (EMT) plays a crucial role in metastasis, with Slug acting as a master regulator by promoting cell migration and invasion. Our group previously demonstrated that Slug levels are tightly regulated by the p53-MDM2 and GSK3 β -CHIP ubiquitin-proteasomal pathways. Deficiencies in these pathways lead to non-degradable Slug accumulation, E-cadherin repression, and increased metastasis. However, it remains unclear how metastasis suppressors or promoters influence Slug degradation under normal and disease conditions.

Material and method

A yeast two-hybrid screen identified novel Slug-interacting partners. The migratory and invasive abilities of CL-series lung cancer cells were assessed using transwell assays. Western blot and immunohisto-chemistry were used to analyze protein levels in cell lines and patient tissues. The metastatic activity of CL1-5 lung cancer cells was evaluated in an orthotopic lung cancer model via intrathoracic implantation in nude mice. In vitro kinase assays and mass spectrometry (MS) identified Slug phosphorylation sites via its key binding partner, HIPK2. Using Global Protein Stability (GPS) profiling with a CRISPR/Cas9 ubiquitin degradation sgRNA library and IP-MS analyses, we identified an oncogenic ubiquitin E3 ligase regulating the HIPK2-Slug axis.

Result and discussion

We found that HIPK2 interacts with and destabilizes Slug by phosphorylating it at Serine (S)104, promoting degradation via ubiquitin-proteasomal pathways. HIPK2 may also prime GSK3 β -dependent Slug phosphorylation at S100, S96, and S92, facilitating CHIP-dependent degradation. Overexpression of HIPK2 in highly invasive CL1-5 cells reduced Slug levels, increased E-cadherin expression, and suppressed metastasis, while these effects were absent in kinase-dead HIPK2 mutants. Although HIPK2 protein levels negatively correlate with invasiveness in CL-series cell lines, its mRNA levels do not match protein expression, and no significant differences in HIPK2 mRNA levels were observed across lung cancer stages. These findings suggest that HIPK2 protein stability control plays a critical role in metastasis, potentially regulated by an oncogenic ubiquitin E3 ligase. Using a CRISPR/Cas9 GPS screen and IP-MS analysis, we identified Zinc Finger Protein X (ZFPX) as a key regulator of HIPK2 stability. Inhibiting ZFPX increased HIPK2 stability, leading to Slug destabilization and impaired EMT-driven metastasis.

Conclusion

Our findings provide insights into the molecular mechanisms controlling HIPK2 stability and propose targeting ZFPX as a novel therapeutic approach to inhibit Slug-mediated lung cancer metastasis.

⁴Faculty of Science, Department of Mathematics, Zagreb, Croatia

Introduction

Osteosarcoma (OS) is a malignant bone tumor that affects adolescents and young adults. Its high heterogeneity and low prevalence hinder research and the development of targeted therapies. Despite treatment advances, survival rates remain poor, especially for metastatic OS. Cancer stem cells (CSCs) contribute to OS progression and poor outcomes due to their ability to evade therapies, drive metastasis, and promote tumor recurrence. This study aimed to characterize CSCs by examining key hallmarks, including immortality, metastatic potential, chemoresistance, and by using scRNA-seq transcriptomic profiling to uncover changes in cellular subpopulations and molecular pathways governing these processes.

Material and method

The study was performed on osteosarcoma samples from a single patient, collected at three stages of disease: diagnosis, post-chemotherapy resection, and recurrence. Immortality was characterized by measuring hTERT expression by qRT-PCR, and the relative telomere length by qPCR. Changes in metastatic potential were monitored through a spheroid formation efficiency (SFE) test. Cell migration was assessed using a wound healing assay, where the migration rate was observed after 24 hours. Chemoresistance was evaluated in 2D and 3D cultures treated with cisplatin, doxorubicin, and methotrexate. Transcriptomic changes were analyzed using scRNA-seq, and the data were processed with Cell Ranger. Downstream analysis was performed using Seurat to identify CSC subpopulations and related gene expression.

Result and discussion

Using scRNA-seq analysis, this study identified a cluster with aggressive properties, suggesting it may represent the CSC population. This cluster was significantly increased in the recurrent sample, showing expression of CSC markers, metastasis-associated genes, epithelial-mesenchymal transition-related genes, and transcription factors promoting CSC properties. CSC isolated from these samples did not show hTERT expression, suggesting they achieved immortality via alternative telomere extension, with transcriptomic analysis confirming the presence of enzymes associated with the ALT mechanism and their expression levels increasing as the disease progressed. As the disease progressed, telomere length shortened, while tumor initiation

capacity and invasiveness increased, as evidenced by higher SFE and enhanced migratory ability. These cells demonstrated selective responsiveness to chemotherapy, showing sensitivity only to doxorubicin.

Conclusion

This study reveals the key role of CSCs in OS progression. Using experimental data and scRNA-seq analysis, we identified mechanisms driving tumor evolution, chemoresistance, and recurrence. These findings emphasize how CSCs adapt to therapeutic pressure, enabling the tumor to acquire immortality, enhanced migration, and selective chemoresistance, ultimately resulting in a more aggressive phenotype.

EACR25-2065

The long non-coding RNA H19 promotes cell proliferation, migration, and invasion in breast cancer through the H19/miR-X/BST2 axis

K. Klouyovo¹, E. Peperstraete¹, J. Louvieux¹, J. Marmuse¹, L. Mabille¹, X. Le Bourhis¹, C. Lagadec¹, É. Adriaenssens¹

¹Univ. Lille, CNRS, INSERM, CHU Lille, UMR9020-U1277-CANTHER-Cancer Heterogeneity Plasticity and Resistance to Therapies, ONCOLille Institute, 59000 Lille, France

Introduction

H19 is the first identified lncRNA and is expressed from the H19/IGF2 locus, located on chromosome 11 (p15.5) and spanning 140 kbp. Previously, our team has shown that H19 overexpression in breast cancer cells promotes key tumorigenic processes, including proliferation, migration, and cell invasion. More recently, transcriptomic analyses conducted on cell lines stably overexpressing H19 revealed a direct correlation with increased expression of BST2, a type II transmembrane protein initially described for its antiviral role. However, a growing number of studies highlight its involvement in tumor progression, particularly in gastric cancer, where BST2 contributes to metastasis formation.

Material and method

Four cell lines were used : MDA-MB-231, MCF-7, T47D, and SUM159-PT. To overexpress or inhibit H19 and BST2, stable transfection and siRNA transfection were performed. Relative mRNA level were measured by RT-qPCR and protein expression by western blot or flow cytometry. To perform tumorigenesis assay, SCID mice were used. Finally, to explore the binding of the miR-X on H19 and BST2 RNA, we used reporter systems allowing luciferase expression combined with miRNA mimics and anti-miRNAs.

Result and discussion

We demonstrated that in our cell lines, H19 overexpression or inhibition is associated with an increase or decrease, respectively, in BST2 expression, both at the transcriptional level and protein level. Remarkably, we also observed that BST2 modulation directly influences H19 expression: BST2 overexpression leads to an increase in H19 expression, while its inhibition reduces it. This finding highlights a cross-regulation between these two molecular players. Furthermore, our in vitro and in vivo experiments revealed that BST2

overexpression reproduces the oncogenic effects of H19, resulting in enhanced proliferation, migration, invasion, and tumor growth. Finally, our analyses revealed that the cross-regulation between H19 and BST2 relies on post-transcriptional regulation involving a microRNA capable of simultaneously controlling the expression of both molecular players. To explore this hypothesis, we used reporter systems combined with miRNA mimics and anti-miRNAs, allowing direct evaluation of this microRNA's impact on H19 and BST2. Our results show that microRNA X specifically binds to nucleotide sequences of H19 and BST2, leading to a coordinated regulation of their expression. This post-transcriptional regulatory mechanism suggests that H19 and BST2 share a common control network, where the activity of microRNA X finely modulates their expression levels.

Conclusion

These findings highlight a novel molecular regulatory axis involved in breast cancer progression and open new perspectives for the development of therapeutic strategies targeting this microRNA-dependent interaction. Finally, these results have led us to the preparation of a scientific article currently under submission.

³Vilnius University Hospital Santaros Clinics, National Cancer Center, Thoracic Surgery and Oncology Department, Vilnius, Lithuania

Introduction

Metastasis is the leading cause of cancer-related deaths. Early detection of tumor progression before metastasis formation could improve treatment outcomes, requiring biomarkers specific to different metastatic stages. Epigenetic regulation, including microRNA (miRNA)-mediated control, plays a crucial role in metastasis by enabling cancer cells to adapt to new environments. By regulating gene expression post-transcriptionally, miRNAs are involved in epithelial-mesenchymal transition, migration, invasion, and organ colonization. Their expression profiles correlate with tumor development, progression, and therapy response, highlighting their potential as biomarkers and therapeutic targets. Previous studies in our laboratory identified 77 miRNAs, including miR-500, that are potentially related to non-small cell lung cancer metastasis. This study aims to further investigate the role of miR-500 in metastasis-related processes.

Material and method

The CRISPR/Cas9 system was used to knockout (KO) miR-500 in LLC1 cells. Transcriptional analysis of KO cells was performed using RNA sequencing, and differential gene expression was analyzed with DESeq2 software. GO and KEGG enrichment analyses were carried out using clusterProfiler. In vitro functional analysis of LLC1 miR-500 KO cells was performed in

monolayer culture, including cell proliferation assay with AlamarBlue, cell cycle analysis by flow cytometry, and cell migration assay via the wound healing method. 3D spheroid formation was assessed using a scaffold-free, self-assembly method.

Result and discussion

Genome editing using CRISPR/Cas9 successfully generated LLC1 cell lines with biallelic deletions of the miR-500 sequence, leading to significantly reduced expression of miR-500. RNA sequencing of LLC1 miR-500 KO cells revealed 1163 differentially expressed genes (DEGs), of which 391 were upregulated and 772 downregulated. GO enrichment analysis identified that these genes are associated with development, morphogenesis, cell migration regulation, cell-substrate adhesion, and actin cytoskeleton organization. KEGG analysis showed DEGs were enriched in signaling pathways, including extracellular matrix-receptor interactions, Rap1, Wnt, TNF, MAPK, and focal adhesion. Functional assays demonstrated that miR-500 does not affect proliferation or the cell cycle, whereas the wound healing assay revealed that it is involved in migration. Additionally, miR-500 was found to be important for LLC1 cells in forming 3D spheroids.

Conclusion

Our study demonstrates that miR-500 is involved in metastasis-related processes in LLC1 cells. However, further research is required to elucidate the molecular mechanisms underlying its role in lung cancer metastasis.

Introduction

Gliomas are heterogeneous primary brain tumors arising from glial cells, with aggressive nature and poor prognosis. Mutations in isocitrate dehydrogenase (IDH) genes, found in 80% of gliomas, lead to neomorphic enzyme activity, resulting in 2-hydroxyglutarate (2-HG) accumulation. 2-HG has been implicated in several oncogenic effects, and studying its impact on glioma metabolism and genomic instability is crucial. This study characterizes the DNA damage response (DDR) and metabolic profile in IDH1-mutant glioma cells.

Material and method

Experiments were conducted in U-87 MG glioma cells (wildtype IDH1) and IDH1-mutant U-87 (isogenic, R132H). Chromosomal damage (cytokinesis-block micronucleus assay) and double-strand breaks (DSB; fast halo assay) were evaluated in basal conditions and after exposure to four DNA-damaging/repair-interfering agents, to establish repair kinetics (0, 1, 24, 48 h). For metabolic studies, glucose and mitochondrial dependence, glycolytic and fatty acid/amino acid oxidation capacity were assessed by SCENITH™ assay. To confirm the identified metabolic profiles, metabolic activity was measured (resazurin assay) after incubation with a glycolysis inhibitor (2-deoxy-D-glucose; 2-DG), oxidative phosphorylation inhibitor (oligomycin), and culture in glutamine-depletion (glutamine-free media). Glucose uptake was measured with 18F-FDG. Metabolism-related genes were evaluated by qPCR. Mitochondrial membrane potential (JC-1 probe), superoxide anion levels (DHE probe), and intracellular peroxides (DCF probe) were analyzed by flow cytometry.

Result and discussion

IDH1-mutant cells presented higher baseline chromosomal damage (2.2-fold, $p < 0.0001$) and DSB levels (1.3-fold, $p=0.0053$) than U-87 MG. Sensitivity to the DNA damaging/repair-interfering agents was also higher in IDH1-mutant cells, as shown by increased damage levels immediately after exposure (0 h), higher maximum damage peaks, and impaired repair kinetics ($p < 0.05$). IDH1 mutation increased mitochondrial dependence (2.6-fold, $p = 0.0353$), fatty acid and amino acid oxidation capacity (1.6-fold, $p = 0.0064$), and 18F-FDG uptake ($p < 0.05$). Cells' metabolic activity was reduced by 2-DG and oligomycin in a cell line-dependent manner, thus confirming the identified dependences. The mutation also rendered cells more sensitive to glutamine depletion ($p < 0.05$), which was linked to increased GLS1, GLUD1, and GLUD2 expression ($p < 0.05$). MYC levels also increased (1.5-fold, $p < 0.05$). Mitochondrial membrane potential was reduced (1.4-fold, $p = 0.0027$), and super-oxide anion and intracellular peroxides elevated (1.2-fold, $p = 0.0464$ and 1.6-fold, $p = 0.0024$), possibly indicating mitochondrial dysfunction.

Conclusion

IDH1 mutations induce DNA repair deficiencies and distinct metabolic profiles. Such alterations can render IDH1-mutant gliomas more susceptible to DNA repair inhibition and metabolism-interfering strategies.

EACR25-2085**Hypoxia-Driven Fatty Acid Metabolism Regulates Angiogenesis in Gastrointestinal Cancers**

A. Biagioli¹, E. Andreucci¹, S. Peri², N. Di Menna², M. Pinto¹, L. Magnelli¹, L. Papucci¹

¹*University of Florence, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Florence, Italy*

²*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy*

Introduction

Gastrointestinal cancers represent a heterogeneous group of diseases including gastric, pancreatic and colorectal cancer and hepatocellular carcinoma. In this complex scenario of different etiology and clinical management, oxygen limitation is one common condition that fosters cancer malignancy through a metabolic rewire, stimulating glycolysis and inhibiting mitochondrial activity. In particular, hypoxia is involved in fatty acids (FA) and lipid de novo synthesis and import, which in turn play an important role in cancer cell migration, invasion and angiogenesis regulation. Indeed, the hypoxic microenvironment is usually generated by scarce or aberrant vascularization. In this scenario, FA are reported to be capable on one hand of stimulating the expression of FA-binding proteins which are positive regulators of angiogenesis and on the other, drugs blocking FA oxidation decrease endothelial cell proliferation.

Material and method

Nine different cancer cell lines (gastric, pancreas and colon cancer) were subjected to hypoxia (0.5% O₂) for 24 or 72 hours as acute or chronic stimuli in a gas-tight manipulator and their mitochondrial mass and membrane potential assayed through MitoTracker and TMRM via flow cytometry, respectively. Their metabolic profile and the capacity to β-oxidate FA were evaluated via the Seahorse platform, while the hypoxic gradient was monitored continuously thanks to the Hypoxia Green dye. FA were measured in cells and conditioned media (CM) via Nile Red staining. The vessel formation capacity was assessed through 2D and 3D angiogenic models.

Result and discussion

A chronic hypoxic stimulus was capable, with respect to an acute one or normoxic oxygen tension, to induce an increased FA storage, as intracellular neutral lipids. The secretion of FA produced by cancer cells in lipid-depleted media was measured and human endothelial cells were subjected to the collected CM in standard conditions. We observed that the CM could regulate vessel formation in an inversely proportional manner to the amount of FA in the media. We validated this negative tendency by using drugs blocking the FA oxidation (Etomoxir), the FA synthase (Denifanstat) or the FA uptake (Sulfosuccinimidyl oleate) and by administering increasing doses of palmitic acid.

Conclusion

Our findings suggest that chronic hypoxia induces a metabolic shift in gastrointestinal cancer cells, leading to increased FA storage and secretion, which in turn modulates endothelial cell behavior and angiogenesis.

The inverse correlation between secreted FA levels and vessel formation highlights a potential mechanism for aberrant tumor vascularization. Interestingly, gastric cancer cells appear to follow a distinct metabolic pattern, warranting further investigation. Overall, these results provide new insights into the interplay between hypoxia, FA metabolism, and angiogenesis, offering potential therapeutic targets for modulating tumor vascularization.

EACR25-2093**The Oncofetal Protein ROR1 Drives Cancer Stemness and Metastasis in Hepatocellular Carcinoma through Actin Cytoskeleton Remodelling**

⁶*The University of Hong Kong, State Key Laboratory of Liver Research, Hong Kong, Hong Kong, China*

Introduction

Hepatocellular carcinoma (HCC) is one of the most common and aggressive types of liver cancer worldwide, with poor prognosis, and high relapse and metastasis rates, highlighting the need for novel therapeutics. Phenotypic plasticity is recognised as one of the hallmarks of cancer and has been proposed to play a key role in driving tumor relapse and metastasis. Oncofetal reprogramming, the process by which cancer cells hijack the stem cell signaling pathway to reactivate fetal transcriptional programs, has been linked as a potential mechanism for cancer cells to acquire phenotypic plasticity. Although some oncofetal proteins, such as AFP, have been widely accepted as markers of less differentiated tumors, their poorly defined functional roles and presence in the regenerative liver make them less than ideal targets for HCC treatment. Therefore, we aim to identify a targetable oncofetal antigen in HCC and assess its role and mechanism in HCC tumorigenesis.

Material and method

Transcriptomics data from the TCGA-LIHC, human hepatocyte and fetal liver, and the Cell Surface Protein Atlas datasets were used to identify oncofetal antigens in HCC. In vitro and in vivo assays were performed using human HCC cell lines and xenograft mouse models to assess the functional role of the oncofetal candidate.

Transcriptome sequencing and affinity purification mass spectrometry (AP-MS) were used to determine the downstream pathway.

Result and discussion

We identified the receptor tyrosine kinase-like orphan receptor 1 (ROR1) as a potential oncofetal antigen in HCC. Although ROR1 is well characterized for regulating cell polarity and differentiation during fetal development, research of ROR1 in HCC is limited. Clinically, high expression of ROR1 was correlated with advanced tumor stage and worse prognosis. Functionally, ROR1 increased the ability to migrate, invade and initiate tumors in both in vitro and in vivo models.

Transcriptome profiling revealed the enrichment of the actin cytoskeleton in HCC cells with ROR1 over-expression. In vitro assays confirmed that ROR1 enhances actin polymerization. Treatment with actin polymerization inhibitors rescued the enhanced actin polymerization and reversed the pro-tumorigenic effects of ROR1. Since ROR1 functions as a pseudokinase and requires a binding partner for downstream signaling, we performed AP-MS coupled with interactome analysis and identified CD147 as the downstream effector of ROR1 for remodelling the actin cytoskeleton. Mechanistically, actin remodelling by ROR1 drove epithelial-mesenchymal transition (EMT), potentially leading to enhanced HCC tumorigenesis.

Conclusion

Our research demonstrates that the oncofetal protein ROR1 promotes HCC stemness and metastasis by facilitating actin remodelling and activating EMT. Current efforts are directed towards evaluating the therapeutic benefits of inhibiting ROR1 in HCC.

¹*Institute of Biology and Experimental Medicine, Buenos Aires, Argentina*

²*CNIO, Madrid, Spain*

³*Institute of Biomedicine, Aveiro, Portugal*

⁴*Hospital General de Pacheco, Tigre, Argentina*

⁵*Institute of Institute of Biology and Experimental Medicine, Buenos Aires, Argentina*

Introduction

Most diagnosed breast cancers express progesterone receptor (PR) isoforms A (PRA) and B (PRB).

Imbalanced levels of PR isoforms (PRA>PRB: PRA-H; PRB>PRA: PRB-H) are associated with differential responses to mifepristone treatment. Few studies investigate the biological characteristics of PRA-H and PRB-H tumors and the impact of PR isoforms on breast cancer metabolism remains under-explored.

Material and method

We performed transcriptomic and proteomic studies on frozen breast cancer specimens from the "Magdalena V de Martinez" Hospital, Argentina. The study was IRB-approved. Primary tumors were categorized as PRA-H or PRB-H by western blot. Eleven PRA-H and eight PRB-H samples were Poly(A) RNA sequenced. Nuclear (Nuc)

and cytosolic (Cyt) protein fractions from nine PRA-H and nine PRB-H samples were studied by LC-MS/MS.

Result and discussion

The transcriptomic study unveiled 129 deregulated genes, while the proteomic assay displayed 289 differentially deregulated proteins in Cyt and 301 in Nuc extracts ($\log_{2}FC > 1$, $p\text{val} < 0.05$). In PRA-H tumors, Gene set enrichment analysis (GESEA) of protein fractions showed an up-modulation of biological processes related to pyruvate metabolism and citric acid cycle ($p\text{val} = 0.0014$), fatty acid oxidation ($p\text{val} = 0.001$), and the metabolism of amino acids and derivatives ($p\text{val} = 0.006$). An up-modulation of arginine, proline, alanine, aspartate, and glutamate metabolism (KEGG, $p\text{val} < 0.05$) was also observed. Accordingly, proteins involved in BCAA metabolism, cystine uptake, and glutathione production ($p < 0.1$), all related with redox homeostasis and linked to cell invasiveness, were overrepresented. In PRB-H tumors, GESEA indicated an up-modulation of Glycolysis ($p\text{val} = 0.0415$) and Peroxisomal lipid metabolism ($p\text{val} = 0.01$) suggesting that these metabolic pathways provide their main energy source.

Transcriptomic data supported proteomic results

Conclusion

In summary, the proteomic and transcriptomic studies highlight metabolic differences related to imbalanced PR isoform expression in breast cancer and provide potential metabolic vulnerabilities that might be therapeutically exploited.

EACR25-2128

PIK3CA modulates oncogenic and stemness properties in Cervical Cancer

R. Mishra¹, M. Kumar², P. Agarwal¹, B. Das¹

¹*Amity University, Amity Institute of Molecular Medicine and Stem Cell Research, Noida, India*

²*Amity University, Amity Institute of Genome Engineering, Noida, India*

Introduction

Human Papillomaviruses (HR-HPVs) infection are known to be the major cause of cervical cancer along with other factors. Cancer stem cells (CSCs) are also known to be involved in tumorigenesis and drug resistance, which is one of the challenges in treatment. It is therefore important to identify novel genetic alteration(s) which can serve as target(s) for effective treatment of cervical cancer. Hence, we performed a meta-analysis of exome sequencing data of cervical cancer patients from public databases and found that PIK3CA is having highest 37% gene alteration. PIK3CA, the catalytic subunit of PI3K, plays crucial role in cell growth and metabolism. We also found that PIK3CA was highly expressed in cervical CSCs. However, the molecular mechanism of PIK3CA in cancer stemness is still unclear and hence, we aimed to unravel the role of PIK3CA in modulating stemness properties in cervical cancer using CRISPR/Cas9 approach.

Material and method

CRISPR-Cas9 constructs targeting PIK3CA were designed at two different exon 2 and 9 (harbouring E542K and E545K hotspot regions) and transfected into SiHa cervical cancer cells. PIK3CA knock out (KO)

clones were screened by western blotting and sanger sequencing. PIK3CA KO clones were characterized using various phenotypic experiments. Cervical cancer stem-like cells were isolated and enriched from SiHa cells using flow cytometry. The self-renewal capacity of these CSCs was evaluated by spheroid formation assays. Expression levels of oncogenic genes and stemness markers were checked via qPCR.

Result and discussion

PIK3CA Knockout cells were generated using CRISPR-Cas9 gene editing. Total 46 PIK3CA KO clones forming single colonies were screened through western blotting and sanger sequencing, where 2 clones were identified as knockout clones. PIK3CA KO showed loss of AKT activation, impaired proliferation and colony formation. A remarkable reduction in cellular migration was observed in PIK3CA KO cells along with reduction in EMT markers such as ZEB1 and TWIST. Further, PIK3CA KO cells underwent G2/M phase arrest leading to cellular apoptosis due to microtubular defects. The stemness markers (OCT4, ALDH1) were downregulated in PIK3CA KO cells suggesting a reversal of stemness phenotype. Observing high expression of PIK3CA and c-Myc oncogenes in SiHa derived CSCs suggested a potential PIK3CA/c-MYC axis. Notably, PIK3CA KO cells lost c-Myc expression, which is reported to regulate stemness via PDK1/PLK1 axis, which is under investigation. These results provide new insights into CSC regulation in cervical cancer and underscore the potential of targeting the PIK3CA-c-Myc axis to enhance treatment efficacy.

Conclusion

PIK3CA regulates CSCs most likely via c-Myc, and targeting this axis may offer a promising therapeutic strategy to combat CSCs and enhance the effectiveness of current treatments.

EACR25-2141

Unraveling the PKM2 Nexus: Metabolic Reprogramming, Nuclear Regulator, and p38 MAPK-Signaling Driven Drug Resistance in Colorectal Cancer

Z. Attar¹, S. Wolf¹

¹Heidelberg University, Institute for Pharmacy and Molecular Biotechnology, Heidelberg, Germany

Introduction

Colorectal cancer (CRC) remains a leading cause of cancer-related mortality, with therapy resistance driven by metabolic reprogramming, stress signaling, and cancer stem cells (CSCs). Pyruvate kinase M2 (PKM2) plays a dual role in CRC by regulating glycolysis and translocating to the nucleus, where it interacts with transcription factors like HIF-1α to promote tumor survival and drug resistance. PKM2 has been linked to the modulating of p38 MAPK, facilitating adaptation to oxidative stress and chemotherapy-induced DNA damage. High glucose levels in the tumor microenvironment further enhance PKM2 expression and nuclear translocation, reinforcing CRC cell survival under therapeutic stress. Additionally, the p38 mitogen-activated protein kinase (p38 MAPK) pathway is activated in response to metabolic stress and chemo-

therapy, further supporting CRC cell adaptation and resistance mechanisms. Understanding the interplay between glucose-driven PKM2 regulation, nuclear PKM2 functions, p38 MAPK signaling is essential for overcoming CRC chemoresistance. This study explores how glucose sensing influences PKM2 expression and function and investigates PKM2 and p38 MAPK inhibition as potential therapeutic strategies.

Material and method

Using CRC cell lines and patient-derived tumor samples we investigate the expression and functions of PKM2, and MAPK pathway signaling. Flow cytometry were used to evaluate CSC populations. RNA interference (RNAi) and small-molecule inhibitors were employed to modulate PKM2 and p38 MAPK activity. Chemoresistance assays were conducted applying 5-fluorouracil (5-FU) and oxaliplatin. Phosphoprotein microarray, western blotting and qRT-PCR were performed to assess changes in gene and protein expression and cell signaling.

Result and discussion

Our findings reveal that glucose availability significantly upregulates PKM2 expression and promotes its nuclear translocation, as observed in CRC cells exposed to high-glucose media. In contrast, glucose deprivation reduced nuclear PKM2 levels, suggesting a strong link between glucose sensing and PKM2 function. PKM2 overexpression correlated with chemoresistance, as drug-resistant CRC cells exhibited increased PKM2 expression and nuclear localization. Additionally, down regulation of PKM2 enhanced p38 MAPK pathway activation, further supporting chemoresistance.

Conclusion

Our results feature glucose-driven PKM2 regulation as a key mechanism in CRC drug resistance and CSC survival.

EACR25-2157

Assessing the impact of endolysosomal Two-pore channel 2 (TPC2) on malignant melanoma aggressiveness

M. Meucci¹, S. Petrungaro¹, F. Palombi¹, A. Riccioli¹, C. Grimm^{2,3}, A. Filippini¹

³Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research IIPImmunology, Infection and Pandemic Research IIP, Munich/Frankfurt, Germany

Introduction

Two-pore channel 2 (TPC2) is a Na⁺/Ca²⁺ ion permeable channel located on the membrane of intracellular acidic organelles, including endo-lysosomes and melanosomes. It plays a crucial role in tumour progression across various cancers, including melanoma, one of the most aggressive and treatment-resistant malignancies, often driven by mutations in the serine/threonine kinase BRAF. This project aims to explore the involvement of TPC2 in melanoma progression,

comparing its role in primary and metastatic disease, to determine whether it could serve as a potential therapeutic target for tailored melanoma treatments.

Material and method

Two pairs of human melanoma cell lines (IGR and WM) were analyzed, each pair derived from the same patient at different stages of tumor progression and genetically characterized by BRAF mutation. The primary melanoma cell lines were IGR39 and WM115, while the metastatic melanoma cell lines were IGR37 and WM266-4. TPC2 expression levels were compared between the primary (IGR39 and WM115) and metastatic (IGR37 and WM266-4) cell lines. The expression of EMT markers, including N-cadherin, E-cadherin, and Vimentin, was assessed to examine the EMT transition. Additionally, migratory capability was measured using a scratch assay, and the ability of the cells to adhere to type 1 collagen was evaluated. To investigate the role of TPC2 in cellular behaviour, the TPC2 inhibitor SG-094 was applied to these cell lines.

Result and discussion

We found that all these human melanoma cell lines exhibit heterogeneous expression of EMT markers and display different behaviours in terms of migratory capability and adhesion to type 1 collagen. Notably, cells derived from the primary tumour site (IGR39 and WM115) have lower TPC2 expression than metastatic cells (IGR37 and WM266-4). Our results demonstrated that, pharmacological inhibition of this channel using the TPC2 inhibitor SG-094 significantly reduces the migratory capability of IGR and WM cell lines, as well as the adhesiveness of IGR lines to type 1 collagen, highlighting the role of TPC2-dependent intracellular Ca²⁺ signalling. Notably, SG-094 treatment also led to a decline in the proliferative potential of these cells, suggesting an additional impact on tumour progression. Additionally, our studies reveal that the effect of SG-094 may involve the microphthalmia-associated transcription factor (MITF), a master regulator of melanocytes implicated in metastasis tumour aggressiveness and survival.

Conclusion

The data demonstrate that TPC2 activity plays a crucial role in the aggressive traits of melanoma. The complex regulation of TPC2 in melanoma progression warrants further investigation. These findings suggest potential therapeutic strategies that combine TPC2 inhibition with existing treatments to try to overcome therapy resistance in melanoma patients.

The SuSe Model: A Dual-Marker Approach to Investigate the Impact of Senolytic Therapy in Cancer

M. Lalinde-Gutiérrez¹, S. Pérez-Ramos², V. Rodilla³, J. Arribas¹

¹VHIO and HMRI, Barcelona, Spain

²VHIO, Barcelona, Spain

³Josep Carreras Institute, Barcelona, Spain

Introduction

Cellular senescence is a terminal cell cycle arrest induced by a variety of stresses, including oncogenes or certain

anti-tumor therapies. The effect of cellular senescence on tumor progression remains a contentious issue. While some reports show that cellular senescence is a tumor defense barrier, others show that senescent cells may contribute to tumor progression. Several mouse models have been developed to study cellular senescence, all of them based exclusively on the expression of p16. However, these models can also target non-dividing cells, including terminally differentiated ones, that overexpress p16. To address this limitation, we considered that senescent cells also undergo functional changes, such as the secretion of inflammatory factors like interleukin-6 (IL-6), and developed the SuSe (Suicidal Senescence) model. This novel transgenic system uses both p16 and IL-6 as dual markers of senescence, providing a more accurate approach to studying senescence *in vivo*.

Material and method

We developed a double transgenic mouse model, SuSe, expressing IL6pro-FKBP/Cas8-GFP and p16pro-FRB/Cas8-Cherry, which allows tracking and elimination of senescent cells upon AP21967 treatment. SuSe mice were crossed with the MMTV-PyMT model to study oncogene induced senescence. Mice were treated at early and late tumor progression stages, and tumor growth and metastasis were monitored. Additionally, we established two syngeneic models based on the SuSe system to study therapy induced senescence. Mice were treated with chemotherapy to induce senescence, followed by AP21967 administration. Tumor growth and metastasis were assessed. Single Cell RNAseq and IHC were used for analysis.

Result and discussion

Our findings show that early senolysis accelerates tumor growth and metastasis, whereas late senolysis has the opposite effect, suggesting that senescent cells initially restrain tumor growth but later promote progression and metastasis. Results from the syngeneic models further reinforce the idea that persisting senescence is detrimental. When senolysis was combined with chemotherapy, tumor regression and reduced metastasis were observed, emphasizing the therapeutic potential of targeting senescent cells at later stages. Additionally, we found that the interplay between senescent cells and the immune system is crucial in understanding their dual role. In the case of early senolysis, the accelerated tumor progression is mediated by an accumulation of immunosuppressive macrophages, which prevent infiltration of CD4+ and CD8+ T cells. In contrast, the beneficial outcome of late senolysis is associated with increased lymphocyte infiltration, promoting an effective antitumor response.

Conclusion

Using our transgenic model, which tracks and eliminates senescent cells, we highlight the importance of timing in senolytic therapies, influencing immune modulation and, therefore, tumor progression.

EACR25-2217

Dual-targeted therapy: Novel interventions to inhibit metastasis and chemoresistance in cervical cancer

C. Eksteen¹, M. Bhaga¹, A. Engelbrecht¹, C. de Sousa¹

¹Stellenbosch University, Physiological Sciences, Cape Town, South Africa

Introduction

Cervical cancer remains a critical global health issue, largely driven by high-risk human papillomavirus (HPV) infections. Despite treatment advances, chemoresistance and metastasis limit therapeutic effectiveness, resulting in poor outcomes. This study investigates the role of cluster of differentiation 44 (CD44) in these processes and evaluates the potential of resveratrol as an alternative treatment option to toxic chemotherapy drugs. By utilising ex vivo and in vitro models, we aim to uncover the molecular mechanisms behind treatment resistance and metastatic behaviour in cervical cancer.

Material and method

Ex vivo model - Ethical approval was obtained from Stellenbosch University (HREC - N22/04/037). Cervical tumour biopsies were cultured and treated with doxorubicin, carboplatin, gemcitabine, and paclitaxel. Cell viability was assessed via MTT assay, and western blotting analysed CD44 and EMT marker expression. A scratch assay measured wound closure rates, while immunofluorescence detected circulating tumour cells (CTCs) in patient blood. In vitro 2D model - An MTT assay evaluated cell viability in CaSki, SiHa, and HeLa cervical cancer cell lines. Western blotting assessed CD44 and EMT marker expression levels. A scratch assay measured wound closure, and clonogenic survival assays visualised survival post-treatment. In vitro 3D spheroid model - Immunocytochemistry examined CD44 expression both before and after carboplatin and resveratrol treatment. Scanning electron microscopy analysed spheroid topography.

Result and discussion

Ex vivo model: Patients exhibited significant chemo-resistance to multiple drugs, accompanied by elevated EMT markers and CD44 expression. Immunofluorescence confirmed CTC presence, indicating enhanced metastatic potential.

In vitro 2D model: Treatment significantly reduced cell viability across all lines. Carboplatin and resveratrol showed effective IC₅₀ values. Western blotting revealed enhanced CD44 and EMT marker expression levels.

In vitro 3D spheroid model: Immunocytochemistry indicated elevated CD44 expression, suggesting treatment resistance.

Conclusion

Evidence of treatment resistance and metastasis in advanced-stage cervical cancer patients requires the need to further investigate the molecular underpinnings of causality through targeting CD44 metastatic mechanisms and exploring the beneficial use of an alternative treatment option, such as resveratrol.

²IKERBASQUE, Basque Foundation for Science, Bilbao, Spain

³CIBERfes, Madrid, Spain

⁴Biogipuzkoa HRI, Infectious Diseases Area, San Sebastian, Spain

⁵Donostia University Hospital, Department of Gastrointestinal Surgery, San Sebastian, Spain

Introduction

Gastric Cancer (GC) is a major health problem, with 968,350 new cases and 659,853 deaths per year worldwide. GC exhibits a high tendency for recurrence and early-stage metastasis development. Consequently, the prognosis for GC patients is poor, with an average 5-year survival rate of 36%, dropping to only 10% for patients presenting distant metastases. However, the molecular determinants governing GC progression and metastasis are currently unknown.

Material and method

We took advantage of publicly available GC datasets from TCGA for the identification of matched genes among the 100 genes most associated with overall survival (OS) and disease-free survival (DFS). We confirmed the association of the identified genes with poor prognosis in the ACRG GC cohort and in over 2000 GC cases obtained from the integration of several cohorts using our own analysis pipeline. The Kaplan-Meier method and multivariate Cox regression analyses were used to determine prognostic significance, and linear modelling and correlation analyses were used to assess associations with clinicopathological parameters and biological hallmarks. Moreover, we performed in vitro and in vivo functional studies and transcriptomics (RNA sequencing) in GC cells to assess the role and mechanism of the most promising candidate gene among the initially identified genes.

Result and discussion

ANKRD6, ITIH3, SORCS3, NPY1R, and CCDC178 were the matched genes among the 100 genes most associated with overall survival (OS) and disease-free survival (DFS) in the TCGA GC cohort. High expression of these genes, individually and as a signature, was associated with reduced survival, recurrence, and node invasion in different GC cohorts. Moreover, the expression of ANKRD6 and ITIH3 was significantly higher in metastasis, and their levels correlated with markers of Epithelial to Mesenchymal Transition (EMT) and stemness in GC samples. In line with this, RNAseq analysis identified EMT among the pathways significantly altered in ANKRD6-silenced GC cells.

Accordingly, ANKRD6 silencing in GC metastatic cells showed abrogation of tumorigenic and metastatic traits in vitro and in vivo.

Conclusion

Our investigation uncovered a novel gene signature implicated in GC malignancy and prognosis and identified, for the first time, the pro-metastatic activity of ANKRD6 in the disease.

EACR25-2221

Epigenetic and Metabolic Consequences of JMJD5 Loss in Hepatocellular Carcinoma

Z. Khan¹, J. Marques Junior¹, E. Jarman¹, P. Gautier¹,

G. Grimes¹, L. Boulter¹, A. von Kriegsheim¹

¹The University of Edinburgh, Institute of Genetics and Cancer, Edinburgh, United Kingdom

Introduction

Liver cancer is the third leading cause of cancer-related deaths worldwide, with hepatocellular carcinoma (HCC) accounting for 85% of primary liver cancers. HCC progression involves profound metabolic and epigenetic alterations, including transcription factor dysregulation, increased lipogenesis, and reactive oxygen species generation. JmjC domain-containing protein 5 (JMJD5), a 2-oxoglutarate-dependent dioxygenase predominantly expressed in hepatocytes, is significantly downregulated in HCC patients, suggesting a potential role as a tumour suppressor.

Material and method

Here, we employ a multi-omics approach to investigate the consequences of JMJD5 silencing in liver cancer cells. Proteomic analysis of JMJD5 knockout HepG2 cells revealed dysregulation of proteins involved in liver metabolism, DNA damage repair, histone methylation, and transcriptional regulation. Metabolomics using heavy carbon labelling demonstrated increased TCA cycle activity, nucleotide biosynthesis, and fatty acid production upon JMJD5 loss. Lipidomic profiling further revealed elevated phospholipid synthesis and diglyceride accumulation in JMJD5-deficient cells. These changes were indicative of increased cell-proliferation, which was confirmed by our proliferation, cell-survival and clonogenic assays.

Result and discussion

Additionally, we identified an enzymatic activity-dependent interaction between JMJD5 and histone methylation regulators NSD2 and DOT1L. Consequently, JMJD5 silencing led to increased dimethylation of H3K36 and H3K79, accompanied by DNMT3A upregulation. Notably, we observed a striking anti-correlation between JMJD5 and DNMT3A expression in both cell lines and patient data, suggesting that JMJD5 loss drives DNMT3A-mediated DNA hypermethylation, potentially contributing to transcriptional regulation of the metabolic signature.

Conclusion

Overall, our findings indicate that JMJD5 silencing disrupts proteome homeostasis, leading to the loss of a ‘liver-like’ phenotype, increased proliferation, and potential cellular dedifferentiation. Moreover, JMJD5 deficiency phenocopies the metabolic remodelling observed in HCC patients, reinforcing its role as a tumour suppressor. We further demonstrate that this metabolic shift is a downstream consequence of JMJD5-dependent epigenetic reprogramming.

EACR25-2227

Nuclear receptor NR5A2 negatively regulates HIF-1alpha signaling to inhibit tumor-specific metabolic adaptations in glioblastoma cells: potential novel therapeutic implications via NR5A2 targeting

D. Gkikas¹, P. Milioti¹, S. Diplari¹, E. Markidi¹,

V. Kaltezioti¹, G. Vatselas², D. Valakos¹, P. Politis¹

¹Biomedical Research Foundation of the Academy of Athens, Center for Basic Research, Athens, Greece

²Biomedical Research Foundation of the Academy of Athens, Greek Genome Center, Athens, Greece

Introduction

Glioblastoma multiforme (GBM) is a highly lethal brain tumor characterized by altered metabolism. To sustain rapid proliferation rates, GBM cells favor glycolysis over oxidative phosphorylation (Warburg effect), driven by hypoxia-inducible factor-1α (HIF-1α). High HIF-1α expression correlates with more aggressive tumor phenotypes and poor prognosis, making it a key therapeutic target. To this end, by using a series of transcriptomic analyses in human GBM cells, we identified the orphan nuclear receptor NR5A2 as an inhibitor of HIF-1α signalling and associated GBM metabolic reprogramming. Specifically, RNA sequencing reveals NR5A2’s role in modulating hypoxia response, glycolysis, and fatty acid metabolism. Here we further explore NR5A2 function in GBM metabolic regulation and its potential as a therapeutic target.

Material and method

Human GBM cells were treated with DLPC to activate NR5A2 and with cobalt chloride to mimic hypoxia. Gene expression was analyzed using RNA-seq (transcriptomic changes), real time RT-qPCR, and Western blot. Cotransfection of HIF-1α and NR5A2 plasmids in GBM cells assessed their functional interaction. An orthotopic xenograft mouse model was used to evaluate DLPC effect on tumor growth, monitored via molecular and histological markers.

Result and discussion

RNA sequencing approaches showed that NR5A2 activation by its direct agonist (DLPC) in human GBM cells altered key metabolic pathways, including hypoxia response, glycolysis, and fatty acid metabolism. Over-expression of NR5A2 reduced glucose uptake and repressed HIF-1α downstream targets. NR5A2 over-expression in GBM cells decreased HIF-1α protein levels under both normoxic and hypoxic conditions, independently of prolyl hydroxylase pathway. Pharmacological activation with DLPC mimicked these effects, reducing tumor growth and aggressiveness in an orthotopic mouse xenograft model.

Conclusion

These results render NR5A2 as a key regulator of glioblastoma metabolism via the suppression of HIF-1α. Pharmacological targeting of NR5A2 reverses the HIF-1α-mediated metabolic adaptations in GBM cells, reducing glucose uptake, glycolysis, and tumor cell proliferation ex vivo as well as tumor growth in vivo. Targeting NR5A2 offers a promising strategy to suppress the GBM specific metabolic rewiring and tumor progression, warranting further preclinical and clinical investigation.

In vitro transformation of primary uveal melanocyte into uveal melanoma

A. Darchen¹, A. Lefranc¹, A. Bortolini Silveira¹, A. Le Ven¹, A. Goncalves¹, A. Matet¹, M. Stern¹, M. Rodrigues¹, O. Ganier¹

¹*Institut Curie, Paris, France*

Introduction

Uveal Melanoma (UM) is a rare and aggressive eye tumor arising from melanocytes of the uveal tract. The tumorigenesis process is thought to rely on solely 2 genetic events: the acquisition of a Gαq pathway activating mutation as first event, and deleterious or change-of-function mutation in either BAP1, SF3B1 or EIF1AX gene as the second so called BSE event. Although these BSE events are well-established UM drivers, their molecular and cellular impacts triggering tumorigenesis remain largely unknown. Here, we aim to recapitulate the stepwise UM transformation in vitro to identify and decipher the molecular and cellular oncogenic mechanisms triggered by the Gαq constitutive activation and BSE events.

Material and method

Choroid and tumor samples were collected from UM patients undergoing enucleations at Institut Curie. Melanocytes and UM cells were purified and seeded in culture to establish cell lines. The GNAQQ209L activating mutation and BAP1 inactivating mutations were introduced in normal melanocytes using lentiviral transduction and CRISPR/Cas9 system, respectively. Both Gαq constitutive activation and BAP1 knock-out were validated using Western Blot, immunofluorescence and PCR.

Result and discussion

We established 27 uveal melanocyte and 23 uveal melanoma cell lines. Moreover, we successfully introduced both the GNAQQ209L activating mutation and BAP1 inactivation by CRISPR/Cas9 in one uveal melanocyte cell line. BAP1 knock-out was validated by TIDE (Tracking of Indels by Decomposition) analysis at the DNA level and Western-Blot and immunofluorescence at the protein level. Wild-type, GNAQQ-209L and GNAQQ209L + BAP1 knock-out uveal melanocytes are being characterized and will be compared to tumor cells from the same patient

Conclusion

As a proof of concept, we successfully introduced UM specific mutations in primary uveal melanocytes derived from UM patients. The development of an in vitro model will allow us to decipher the tumorigenic mechanisms involved in UM and to address key questions such as genetic predispositions, and BSE mutations contribution in UM. Furthermore, such models will constitute a unique tool for in vitro drug testing.

EACR25-2238

Luminal breast cancer cell migration is reduced by depletion of BCL6 transcriptional repressor

J. Dyson-Jorge^{1,2}, P. Jordan^{1,2}, P. Barros^{1,3}, P. Matos^{1,3}

¹*Instituto Nacional de Saúde Dr. Ricardo Jorge, Departamento de Genética Humana, 1649-016 Lisboa, Portugal*

²*BioISI – Instituto de Biosistemas e Ciências Integrativas, Faculdade de Ciências, Universidade de Lisboa, 1749-016 Lisboa, Portugal*

³*BioISI – Instituto de Biosiste, Faculdade de Ciências, Universidade de Lisboa, 1749-016 Lisboa, Portugal*

Introduction

Breast cancer (BC) incidence has risen over the past two decades, now being the most prevalent cancer worldwide and the second leading cause of cancer-related deaths. Despite advancements in BC treatment, challenges like acquired resistance, recurrence, and metastasis persist. BCL6, a transcriptional repressor, acts as an oncogene in BC, being overexpressed in about half of primary tumors of all subtypes and associated with disease progression and poor patient prognosis. This underscores the need to better understand BCL6 role in BC development.

Material and method

This study used RNA interference to explore the impact of BCL6 depletion on the oncogenic progression of MCF-7 cells, a low-tumorigenic estrogen receptor-positive cell line.

Result and discussion

While BCL6 is known to regulate mammary cell proliferation and differentiation, its depletion did not affect MCF-7 cell proliferation or viability but significantly reduced their individual and collective migratory properties. RNA microarray analysis identified a set of genes upregulated following BCL6 depletion, including S100A7, previously reported to inhibit MCF-7 cell migration and invasion by reducing MMP9 secretion. However, our findings showed that S100A7 downregulation alone did not affect MCF-7 migration. Moreover, simultaneous depletion of BCL6 and S100A7 failed to restore MCF-7 cell migratory behavior.

Conclusion

Our results suggest that increased expression of BCL6 is linked to increased cell migration but independent on S100A7 upregulation. Further studies are required to clarify the role of BCL6 in BC, including disease progression.

EACR25-2251

Exploiting senolytic drugs to strike brain tumors metabolic vulnerabilities

M. Canton¹, C. Marchioro¹, L. Persano¹, G. Viola¹, E. Mariotto¹

¹*University of Padova, Department of Woman's and Child's Health, Padova, Italy*

Introduction

Brain tumors remain one of the most challenging issues in pediatric oncology, since they represent the primary cause of cancer-related death in childhood. Despite extensive efforts to discover new treatments, the standard-of-care has not radically changed over the past decades, including highly toxic and non-specific chemotherapy, and resulting in treatment failure and high risk of recurrence. Most of drug screening campaigns described so far were not able to translate identified drugs into clinic, due to unrealistic culturing conditions using monolayer cell cultures with overestimated nutrients and oxygen tension. On the contrary, it has been widely described that the in vivo tumor microenvironment is characterized by low oxygen tension, glucose and growth factors deprivation, lactate accumulation and consequent acidosis. The identification of novel therapeutic

vulnerabilities for pediatric brain tumors thus necessitates the use of more accurate and realistic preclinical models.

Material and method

Patient-Derived Brain Tumor (PD-BT) cell cultures have been cultured in two opposite conditions: standard PD-BTs (st-PD-BTs) were cultured as monolayers, enriched in nutrients and growth factors, while exhausted PD-BT (ex-PD-BTs) were chronically adapted to hypoxic, acidic, exhausted medium conditions and grown as neuro-spheroids. St-PD-BTs and ex-PD-BTs were characterized from both transcriptomic and metabolomic point of view and then tested against a library of more than 3500 compounds using a High-Throughput Screening (HTS) approach.

Result and discussion

Here we present a simplified in vitro 3D model able to recapitulate a more representative tool for brain tumors drug screening. Multiomic characterization revealed that ex-PD-BT exhibited a more aggressive phenotype, sustained by purine metabolism rewiring, and altered DNA damage repair along with senescent features. Exposing both st-PD-BTs and ex-PD-BTs to High-Throughput Screening, we demonstrated that many identified hits in standard setting resulted unsuccessful in hostile tumor-like conditions. Conversely, we identified the class of senolytics as highly selective drugs for ex-PD-BTs, nonetheless strongly synergizing with conventional chemotherapy in st-PD-BTs, suggesting a possible role as adjuvant therapy in first-line chemotherapy.

Conclusion

Collectively, the proposed in vitro model, closely resembling the in vivo brain tumor microenvironment, allowed the identification of underestimated druggable vulnerabilities, suggesting senolytics as new therapeutic option for pediatric brain tumors.

EACR25-2267

Therapeutic overactivation of oncogenic signaling to improve outcomes in Ewing sarcoma

A. Amparo¹, N. Pouliopoulou¹, C. Lieftink², B. Morris², R. Bernards¹, M. Henrique Dias¹

¹*The Netherlands Cancer Institute, Division of Molecular Carcinogenesis, Oncode Institute, Amsterdam, Netherlands*

²*The Netherlands Cancer Institute, Division of Molecular Carcinogenesis, NKI Robotic and Screening Center, Amsterdam, Netherlands*

Introduction

Ewing sarcoma (EwS) is a pediatric cancer of the soft tissue and bone with a 5-year survival rate of 15% for metastatic disease. The standard of care for EwS is multimodal therapy, which carries a risk for long-term disabilities, including lower fertility and severe cardiac and pulmonary complications. Therefore, there is an unmet clinical need for therapies to increase overall survival without long-term disabilities. The cytostatic and cytotoxic consequences of Fibroblast growth factor 2 (FGF2) in EwS have been previously described, and we have shown that sustained overactivation of the MAPK pathway underlies this toxicity. The toxicity of MAPK

overactivation by FGF2 in EwS conceptually aligns with our published proof-of-concept paper demonstrating the efficacy of “paradoxical activation”, now known as Therapeutic OVERactivation of oncogenic signaling (TOVER), in colorectal cancer. We hypothesize that FGF2-induced overactivation of MAPK signaling is a vulnerability of EwS and that combination of overactivation and stress-targeted inhibition is a viable therapeutic strategy.

Material and method

We previously designed a stress-focused drug library of 164 compounds targeting stress response pathways associated with malignant phenotypes (DNA damage, metabolic, mitotic, oxidative, and proteotoxic stresses and senolytics). These drugs were screened in 4 EwS cell lines (SKES-1, A673, MHES-1/TR/shEF, TC-71/TR/shEF) at 15 concentrations in the presence and absence of a sub-lethal dose of FGF2 to identify the compounds to which there was increased sensitivity with FGF2 treatment. We also utilized EwS cell lines with a doxycycline-inducible shRNA construct targeting the oncogenic driver, EWS-FLI fusion protein, to determine whether toxicity of potential combinations can be attenuated by depletion of EWS-FLI.

Result and discussion

Consistent with the literature, we show that FGF2 toxicity in EwS is driven by overactivation of MAPK signaling, which is attenuated by MEK inhibition and EWS-FLI knockdown. Moreover, in a stress-focused drug screen, we identified compounds exploiting proteotoxic and oxidative stress-related vulnerabilities of EwS models under MAPK overactivation. These findings were validated in a panel of EwS cell lines with varying intrinsic sensitivities to FGF2 in both short- and long-term viability assays. Ongoing experiments aim to dissect the mechanistic network underlying the toxicity of FGFR/MAPK agonism in the presence and absence of inhibition to stress-response in EwS. Furthermore, we are evaluating alternative activators of MAPK in combination with the aforementioned stress targets.

Conclusion

These data show that EwS is a promising tumor type for TOVER as a treatment strategy as evaluated in a panel of EwS cell lines. With FGF2 as our activator, we identify multiple potential combinations with targets of stress-response pathways, forming a basis for further preclinical investigation.

³*Istituto Nazionale Tumori IRCCS- Fondazione "G. Pascale", Department of Melanoma, Cancer*

Immunotherapy and Development Therapeutics, Naples, Italy

Introduction

Melanoma is the most aggressive skin cancer due to its high metastatic potential. Despite the beneficial effects of targeted therapies, drug-resistance frequently arises, leading to melanoma progression and metastatic disease. Recent evidence links the androgen receptor (AR) expression with poor prognosis and metastatic potential of melanoma, and AR blockade even enhances the response to BRAF/MEK-targeted therapy in preclinical melanoma models. However, the molecular mechanisms by which AR promotes melanoma progression appears still debated. The present data aim to fill this gap and dissect the role of AR in melanoma invasion and immune escape.

Material and method

A multi-approach strategy was employed. AR expression was assessed by Western blot, while the impact of androgens was evaluated by migration, invasion and spheroid growth assays. Co-immunoprecipitation approach was used to analyze AR-ADAM10 interaction and expression of the NKG2D ligand, MICA/B, was evaluated by western blot and immunofluorescence. Soluble MICA/B (sMICA/B) levels from cell culture supernatants and patient sera were quantified by ELISA. The impact of AR in immune evasion was assessed by measuring cytotoxicity in co-cultures of melanoma cells with primary human NK cells. AR blockade was achieved using bicalutamide, while GI254023X was used to inhibit the ADAM10 activity. Cytotoxicity assays and live-dead staining were lastly done in spheroid co-cultures with NK cells to assess the involvement of AR and ADAM10 in melanoma immune escape.

Result and discussion

Our results show that ligand-bound AR enhances the melanoma invasion, the growth of melanoma-derived spheroids as well as the immune-escape of melanoma cells from NK cell attack. Biochemical approaches indicated that androgens promote the assembly of AR/ADAM10/β1-integrin complex, which then activates ADAM10 and triggers MICA shedding. The latter event lowers MICA/B surface expression and increases sMICA levels, thus impairing NK cell function through NKG2D downregulation. Pharmacological blockade of AR or ADAM10 counteracts these effects and rescues the immune recognition of melanoma cells. Taken together, these findings support the role of AR in diagnostic guidance and therapeutic approach of melanoma.

Conclusion

The present study underscores the therapeutic relevance of AR blockade in melanoma outcome. The finding that high serum levels of sMICA/B correlate with a poor prognosis in melanoma patient's further highlights the clinical relevance of AR-mediated immune escape. Combining a more tailored AR blockade with immunotherapy would enhance immune-response and improve melanoma patient's survival. Future investigations are envisaged to optimize this strategy and validate our findings in clinical setting.

Introduction

Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer that presents significant treatment and management challenges due to its poor response to standard therapies. Research into the tumor secretome, the set of proteins secreted by cancer cells, is providing key insights into the molecular mechanisms underlying tumor progression. These include the epithelial-mesenchymal transition (EMT), a process associated with invasion and metastasis. In this context, the aim of this study was to investigate the role of secretome-derived proteins from TNBC MDA-MB-231 cells in response to an inflammatory condition, and their impact on the inflammatory response and invasion of non-cancerous human breast epithelial cells (MCF10A).

Material and method

The TNBC cell line MDA-MB-231 was exposed to an inflammatory treatment combination of estradiol (E2, 10 nM), TNFα (10 ng/ml) and IL-6 (50 ng/ml), termed ETI. Conditioned medium from these treated cells was collected and evaluated in MCF10A cells, focusing on key inflammatory signaling pathways identified by previous proteomic analysis of the secretome. Gene expression levels of EMT (CDH1, CDH2, MMP9) and inflammation-related genes (CXCL8, IL6, IL6R) were analyzed by qPCR. Activation of STAT3, a key regulator of inflammation and cancer progression, was assessed by Western blot. In addition, the effect of the conditioned medium on MCF10A cell migration was evaluated using the wound healing assay.

Result and discussion

Gene expression analysis revealed a significant upregulation of EMT markers (CDH2, MMP9) and pro-inflammatory genes (CXCL8, IL6, IL6R) in MCF10A cells treated with the conditioned medium of ETI-exposed MDA-MB-231 cells. Interestingly, STAT3 was highly activated in these cells, further supporting the involvement of inflammatory pathways. In addition, MCF10A cells treated with the conditioned medium showed increased migratory capacity in the wound healing assay, suggesting that the secretome of ETI-treated breast cancer cells promotes an EMT-like phenotype and enhances cell migration.

Conclusion

These findings highlight the key role of the inflammatory secretome in promoting EMT and cell migration in non-cancerous breast epithelial cells. Therefore, focusing on understanding the involvement of cellular signaling processes may be critical for identifying novel prognostic biomarkers and potential therapeutic targets for TNBC, which may lead to improved treatment strategies to mitigate the aggressive behavior of this disease.

EACR25-2297

Synergistic cell cycle blockade with the combination of CDK4/6 PROTACs and a CDK2 inhibitor as a potential anticancer strategy

A. Slota¹, L. Skalniak¹, J. Kocik-Krol¹, J. Plewka¹, K. Magiera-Mularz¹

¹Jagiellonian University, Organic Chemistry, Krakow, Poland

Introduction:

Combination therapies represent a highly effective strategy to cancer treatment. This approach offers the possibility of inhibiting different molecular targets, increasing efficacy, and minimizing the risk of treatment resistance. Proteolysis-targeting chimeras (PROTACs) are chimeric compounds that bind to target proteins and lead to their selective proteasomal degradation. Monotherapies based on PROTACs are currently in clinical trials with promising results, however, their effectiveness in combination therapies has not yet been described. Our study focused on PROTACs targeting cyclin-dependent kinases 4 and 6 (CDK4/6), which are based on FDA-approved CDK4/6 inhibitors for breast cancer treatment.

Material and method

We incubated various mouse and human cancer cell lines (CT26.WT, B16-F10.WT, MC38-hPD-L1, and RKO.WT) with increasing concentrations of CDK4/6 PROTAC, cyclin-dependent kinase 2 (CDK2) inhibitor, and their combination. We determined the protein levels (such as phosphorylated retinoblastoma and CDK4/6) by western blot method, while BrdU-based cell cycle analysis was conducted using flow cytometry. Further, we evaluated the effects of these therapeutic strategies on the proliferation of human peripheral blood mononuclear cells (PBMCs). For this purpose, we isolated PBMCs from whole blood, activated them for proliferation, stained with dilution dye and incubated with increasing concentrations of inhibitors. The proliferation inhibition was likewise observed by flow cytometry. The results

were analyzed in GraphPad Prism 8.0 software, and statistical significance was calculated using t test.

Result and discussion

We investigated the effect of combining CDK4/6 PROTACs with a cell cycle inhibitor targeting CDK2 on cancer cells. Our results demonstrated that this combination synergistically promotes cell cycle arrest in the G1/G0 phase in both mouse and human cancer cell lines. Furthermore, western blot hybridization revealed a dose-dependent reduction of the level of CDK4/6 proteins after treatment of cells with CDK4/6 PROTAC, as well as changes in the level of phosphorylated retinoblastoma protein (Rb) for cells treated with individual compounds and their combination. Additionally, treatment with either CDK4/6 PROTAC or CKD2 inhibitor alone showed partial inhibition of the proliferation of PBMCs, while their combination led to an almost complete arrest of those cells proliferation.

Conclusion

Our findings highlight the potential of CDK4/6 PROTACs and the CDK2 inhibitor in combination therapies to enhance therapeutic strategies in oncology while excluding the application of this dual cell cycle blockade in synergy with immunotherapy.

EACR25-2301

Induction of ferroptosis and senescence in epithelial ovarian cancer cell line: Implications of targeted therapeutic strategies

L. Berjawi¹, F. Alarcon², I. Lopez², S. Lucio², R. Mato², M. Quintos³, M. Quintela⁴, A. Vizoso², M. Arufe⁵, C. 2024⁵

³CHUAC, La Coruña, Spain

⁴European Cancer Stem Cell Research Institute, Cardiff, United Kingdom

⁵UDC- INIBIC- CICA, La Coruña, Spain

Introduction

Senescence is a critical cellular process in both aging and cancer, marked by irreversible growth arrest, DNA damage, and the secretion of pro-inflammatory cytokines, collectively known as the senescence-associated secretory phenotype (SASP). Senescent cells play tumor-suppressive roles but can also alter the tumor microenvironment, promoting cellular proliferation. Ferroptosis, a form of iron-dependent cell death driven by lipid peroxidation, has emerged as a promising therapeutic strategy against chemotherapy-resistant cancer cells. This study investigates the effects of senescence and ferroptosis inducers on two distinct epithelial ovarian cancer (EOC) cell lines, SKOV-3 and OVCAR-3, using qPCR to assess the expression of various biomarkers.

Material and method

SKOV-3 and OVCAR-3 EOC cell lines were treated with ferroptosis inducers (RSL3, Erastin, FSP1i, Brequinar) and senescence inducers (Etoposide, Olaparib, Carboplatin, Cisplatin). Cells were treated with varying

drug concentrations (0.25–2 µM) and harvested for RNA extraction at Day 7. Gene expression of biomarkers associated with ferroptosis (NCOA4, CP) and senescence (p16 (CDKN2A), p21 (CDKN1A), IL6, IL8) was assessed by quantitative PCR. Cell viability was measured by crystal violet staining.

Result and discussion

In response to RSL3 (1 µM) and FSP1i (2 µM), both SKOV-3 and OVCAR-3 cells showed ferroptosis induction. After treatment with RSL3, SKOV-3 showed an increase in CDKN1A and a decrease in CDKN2A, while no significant modulation was observed in other genes. In contrast, in OVCAR-3, there was an increase in CDKN1A and IL8, along with a decrease in NCOA4 and CP. Notably, these ferroptosis-related biomarkers were modulated independently of the cell line, indicating a common response to RSL3 treatment across both SKOV-3 and OVCAR-3. For SKOV-3, treatment with Etoposide (1 µM) led to a reduction in CDKN1A, CDKN2A, and IL8, with a further decrease in IL8 at 2 µM, suggesting that IL8 downregulation could serve as a genetic marker of senescence in SKOV-3. In OVCAR-3, Etoposide (1 µM) increased CDKN1A, CDKN2A, IL8, and NCOA4, and at 2 µM, CDKN1A and CDKN2A were further elevated. This suggests that p16 and p21 could be markers of senescence induction in OVCAR-3 cells.

Conclusion

This study highlights the potential of targeting both senescence and ferroptosis in epithelial ovarian cancer. Ferroptosis-related biomarkers, such as NCOA4 and CP, were modulated independently of cell line, indicating a common response to ferroptosis induction. Senescence was more cell line-dependent, with CDKN1A and CDKN2A serving as markers of senescence induction in OVCAR-3. These findings provide valuable insights into the molecular pathways governing ferroptosis and senescence in ovarian cancer, suggesting that combining therapies that target both processes could be a promising strategy to overcome chemotherapy resistance and improve treatment outcomes in EOC.

Screening for senolytics by live monitoring the cell fate of senescent cancer cells

B. Haspels¹, M. Huang², J. Kros², M. Kuijten¹

¹Erasmus MC, Department of Molecular Genetics, Rotterdam, Netherlands

²Erasmus MC, Department of Pathology, Rotterdam, Netherlands

Introduction

Cellular senescence is a highly regulated cell-cycle arrest, important for embryonic development and aging, that can be induced prematurely for instance by DNA damage. Therapy-induced senescence (TIS) is a promising anti-cancer strategy, especially when combined with senolytic compounds which clear senescent cells by targeting anti-apoptotic factors expressed by these cells. We developed a dual senescence and apoptosis reporter system to live monitor the cell fate of senescent cells, allowing to screen for novel senolytic agents.

Material and method

To monitor senescence, we made a reporter construct based on transgenic lamin A and B1 expression, and to monitor apoptosis we used a FRET reporter. The reporter constructs were validated in cancer cells by inducing senescence with irradiation and apoptosis with staurosporine. To identify potential senolytic compounds, cells were first irradiated to induce senescence followed by treatment with a panel of drug candidates. To follow cell fate, time-lapse imaging was performed by confocal or high-content imaging. Senescent and non-senescent cells were identified based on the mean intensities of transgenic lamins. The loss of FRET signal in the nuclei and the translocation of mNeogreen into the cytoplasm were used to identify apoptotic cells.

Result and discussion

Our dual reporter system allowed imaging of four different fluorescent proteins in cells without cross-talk. The FRET efficiency of the uncleaved apoptosis reporter was around 40%. Senescent cancer cells could be distinguished from non-senescent cells by their increased transgenic lamin intensities. The apoptosis cleavage site was effectively and specifically cleaved after induction of apoptosis, resulting in decreased FRET signal and translocation of mNeogreen from the nucleus to the cytoplasm. The signal of the senescence reporter was not influenced by apoptosis and vice versa. The efficiency of senolytics could be measured by monitoring senescent cells that went into apoptosis. Our dual reporter system is both compatible with confocal imaging and the Opera Phenix high content screening system.

Conclusion

We show that our dual reporter system can be successfully applied for live monitoring of senescence and apoptosis cell fates and for live screening of the efficacy of senolytics in cancer treatment.

EACR25-2333

Investigating the relationship between IGF signalling, androgens and amyloid precursor protein (APP) processing in prostate cancer

R. Barker¹, M. Alhadrami², C. Perks²

¹University of Bristol, Cancer Endocrinology Group, Bristol, United Kingdom

²University of Bristol, Cancer Endocrinology Group, United Kingdom

Introduction

Both prostate cancer and Alzheimer's disease (AD) are major causes of death globally and despite having similar risk factors, epidemiological studies have shown an intriguing inverse relationship between the two. A key hallmark of AD is amyloid β (A β), a peptide produced by the cleavage of amyloid precursor protein (APP) by β -secretase (BACE1). APP may also be cleaved by α -secretases, including ADAM-10 and ADAM-17; this cleavage pathway is protective in an AD context as it precludes A β production, but has been shown to promote cell proliferation and migration in some cancers, including prostate. Effects of androgens and insulin-like growth factor-I (IGF-I) on APP processing have previously been investigated in AD, but in prostate cancer are currently unknown.

Material and method

In prostate epithelial cells, APP expression was silenced using siRNA in the presence or absence of IGF-I or dihydrotestosterone (DHT). The impact of inhibiting the IGF1R and androgen receptor (AR) on APP and its processing was investigated using AG1024, a receptor tyrosine kinase inhibitor, and enzalutamide, an anti-androgen, respectively. Effects on cell viability were assessed using a Muse Cell Analyser and the impact on components of the APP processing pathways, the IGFIR and AR were assessed by western blot.

Result and discussion

Silencing APP expression did not induce cell death in normal prostate epithelial cells, but cell viability was significantly reduced in both androgen sensitive LNCaP and androgen insensitive PC3 cancer cells. APP silencing reduced the abundance of AR in LNCaP cells and the IGFIR in PC3 cells, consistent with the inability of exogenously added IGF-I or androgen to rescue cells from apoptosis induced by APP silencing. In PC3 cells, IGF-I caused an increase in abundance of APP, α - and β -secretases and soluble APP- α and APP- β cleavage products. AG1024 resulted in increased cell death and reduced abundance of APP, α -secretases and soluble APP- α and APP- β . Similarly, in LNCaP cells, DHT caused a significant increase in levels of APP, α -secretases and soluble APP α , whilst enzalutamide resulted in reduced APP, α -secretases and soluble APP α .

Conclusion

Androgens are the key driver of development and progression of androgen sensitive prostate cancer, whilst IGF-I signalling has been shown to contribute to development and progression, metastasis, castration resistance and more aggressive disease. Previous studies in the brain have shown that both IGF-I and androgen regulate APP and promote survival, and our results indicate similar regulation of APP and associated growth in prostate cancer cells. Prostate cancer still has significant unmet therapeutic limitations and a better understanding of the relationship between APP and both AR and IGF signalling in prostate cancer biology may provide new approaches to optimising current treatments.

LZTR1 acts as a potent tumor suppressor gene in liver cancer by safeguarding aberrant MAPK activity via posttranslational control of RAS GTPases

P. Macsek¹, M. Breinig¹, L. Böse¹, A. Seretny¹, L. Butthof¹, L. Wendler-Link¹, D. Tschaharganeh¹

¹*German Cancer Research Center (DKFZ), Cell Plasticity and Epigenetic Remodeling, Heidelberg, Germany*

Introduction

Hepatocellular carcinoma (HCC) ranks among the cancers with the highest rate of mortality, yet treating this carcinoma remains challenging due to late diagnosis and poor patient stratification, thereby preventing the utilization of targeted therapeutical approaches. Using human genome sequencing data, we identified frequent deleterious alterations of Leucine-zipper-like

transcriptional regulator 1 (LZTR1), which plays a crucial role in regulation of RAS-like GTPases (e.g. RIT1) and downstream pathways, such as the mitogen activated protein kinase (MAPK) pathway. Elucidating the oncogenic driver potential of LZTR1 loss of function could subsequently warrant the usage of MAPK inhibitors, which are currently utilized in other cancers with aberrant MAPK activity.

Material and method

In vivo approach: Hydrodynamic tail-vein injection (HTVI) allows us to achieve liver-specific knockouts/overexpressions by inducing *in vivo* transfection of hepatocytes. This system allows stable expression of transgenes via Sleeping-Beauty transposons as well as editing genomes of cells via delivery of CRISPR/Cas9 constructs. Additional perturbations are introduced utilizing CRISPR/Cas9 or Cas12a(Cpf1) system, as well as knockdowns by short hairpin RNAs delivered via lentiviral vectors. **In vitro approach and read-outs:** Cell viability and/or proliferation is the primary cytometric read-out, measured in settings most appropriate for investigation: Colony formation assay (CFA) for low-seed, long-term cultivation experiments; multicolor competition assay (MCA) for long-term co-cultivation measured by flow-cytometry (FwC) and CellTiter-Blue®(CTB) assay for short cultivation experiments determining cell viability. Immunoblotting of phosphorylated ERK was set as the primary read-out of MAPK activation. Western blotting (WB) and quantitative polymerase chain reaction (qPCR) were used to estimate levels of protein or gene expression, respectively.

Result and discussion

We reveal that loss of function of LZTR1 promotes tumorigenesis *in vivo* as well as cell growth *in vitro*, an effect accompanied by elevated RIT1 expression and subsequent MAPK pathway activation. Moreover, truncated forms of LZTR1 lacking domains crucial for its interaction with RAS molecules phenocopied the effect of LZTR1 loss, further suggesting that this interaction is crucial for tumor suppression. Finally, expression of mutant RIT1 proteins rendering RIT1 non-degradable by LZTR1 in murine livers resulted in liver tumorigenesis comparable to LZTR1 loss.

Conclusion

Our findings suggest that LZTR1 safeguards MAPK signaling by controlling RAS GTPases in the liver and could therefore potentially be utilized to stratify HCC patients for usage of small molecule inhibitors targeting MAPKs, which are currently only employed in other carcinomas.

Introduction

Endometrial cancer (EC) remains a clinical challenge, where cancer stem cells (CSC) have been associated with chemoresistance and recurrence. In particular, a relevant expression of aldehyde dehydrogenase (ALDH) on EC has been involved in disease progression and is associated with stemness pathways, proposing its double potential as a biomarker and a molecular target. To investigate more effective and minimally invasive treatments for EC, our research focuses on a novel approach using CSC-targeted photodynamic therapy (PDT) based on modified 4,5,6,7-tetrahydropyrazolo[1,5-a]pyridine-fused chlorins (PX).

Material and method

A refined sphere-forming protocol was performed to obtain endometrial CSC from ECC-1, RL95-2 and HEC-1-A cell lines. To evaluate the effectiveness of a CSC-targeted PDT strategy in EC, the colocalisation of a novel class of tetrahydropyrazolo[1,5-a]pyridine-fused chlorins functionalised with aldehyde moieties (A-PX) with ALDH was verified using confocal microscopy. Then, endometrial CSC were incubated with a range of A-PX concentrations (2.5 – 10 µM) for 2 hours, followed by a light irradiation (7.5mW/cm², 10J). To assess the expression of CSC markers, the effect of CSC-targeted

PDT on CD44 and CD24 was examined through flow cytometry. Viability and cell death were determined through luminescence and confocal microscopy.

Result and discussion

After evidence that ALDH interacts with A-PX in vitro and converts aldehydes into carboxylic acids and A-PX can internalise and accumulate in endometrial CSC, preliminary confocal studies pointed out that A-PX localise in CSC ALDH-enriched zones, facilitating the expected action mediated by ALDH. Moreover, initial findings revealed a high percentage of CD44+/CD24+ cells, confirming CSC-like characteristics. CSC-targeted PDT seems not to modulate the stemness features of the ECC-1 CSC-enriched populations. Nevertheless, A-PX-based PDT notably contributed to eliminating endometrial CSC, resulting in a significant reduction in viability and the induction of cell death.

Conclusion

In conclusion, these results emphasise the potential of the A-PX-mediated strategy to target ALDH in vitro and within CSC, as well as the effectiveness of A-PX-based PDT for eradicating EC cells. This research represents the first steps towards developing a conservative and minimally invasive therapeutic option for challenging cases of EC.

Introduction

Triple-negative breast cancer (TNBC) accounts for ~15% of breast cancer cases. Due to the lack of targeted therapies, chemotherapy remains the main strategy. However, drug resistance limits its efficacy. This study explores the role of MBNL1 in doxorubicin resistance in TNBC.

Material and method

To model chemo-resistance, we used MDA-MB-231 cells with acquired resistance to doxorubicin (MDA-MB-231R) and its parental counterpart MDA-MB-231. Cytotoxicity was assessed by WST-1, flow cytometry, and western blot (c-CASP3, c-PARP). Drug accumulation was tested by flow cytometry and fluorescence microscopy. In vitro gain/loss of function studies were performed via transient transfection of plasmids or siRNAs, respectively. For in vivo experiments, MDA-MB-231 cells with stable MBNL1 KD/OE were orthotopically injected into BALB/C nude mice ($n = 8/\text{group}$) and treated with vehicle or doxorubicin (1.6 mg/kg, twice weekly, 4 weeks). An in-house cohort of 29 TNBC primary tumors treated with anthracycline + taxane neoadjuvant regimens were analyzed for MBNL1 and BIN1 gene expression by qRT-PCR. Results were validated in silico (GSE164458, $N = 407$). Ethical approvals were obtained. Statistical analyses were conducted by GraphPad Prism.

Result and discussion

MBNL1 expression in treatment-naïve tumors positively correlates with response to chemotherapy in our cohort ($p < 0.01$) and in public patients' data. MBNL1 was down-regulated in MDA-MB-231R. In vitro MBNL1 KD increased doxorubicin resistance ($\text{IC}_{50} (\mu\text{M})$: Scr = 0.07, siMBNL1-A = 0.20, siMBNL1-B = 0.27; $p < 0.001$) while OE restored sensitivity ($\text{IC}_{50} (\mu\text{M})$: pBABE = 0.45, MBNL1 = 0.22; $p = 0.001$). This result was confirmed in mouse models. MBNL1 KD tumors treated with doxorubicin showed a final volume of 184.6 and 532.8 mm³ for shMBNL1-A and B, respectively, compared to 37.7 mm³ in doxorubicin-treated control tumors ($p < 0.01$). MBNL1 OE tumors showed enhanced response to doxorubicin as shown by a final volume of 57.82 mm³ compared to 170.5 mm³ in treated control tumors ($p < 0.01$). Moreover, 50% of MBNL1 OE tumors achieved complete regression. Mechanistically, MBNL1 KD upregulates ABCC1 and ABCG2, reducing intracellular doxorubicin accumulation (~20%, $p < 0.01$), whereas MBNL1 OE increases drug retention (~20%, $p < 0.01$). Besides, MBNL1 directly inhibits BIN1, leading to increased doxorubicin resistance through downregulation of c-MYC and PARP1, ($\text{IC}_{50} (\mu\text{M})$: Scr = 0.15, siBIN1-A = 0.35, siBIN1-B = 0.31; $p < 0.001$). BIN1 OE restored doxorubicin sensitivity ($\text{IC}_{50} (\mu\text{M})$: pBABE = 0.58, MBNL1 = 0.35; $p < 0.001$). Furthermore, BIN1 expression was also validated as a predictive biomarker for doxorubicin response in the above-mentioned patient cohorts.

Conclusion

Loss of MBNL1 drives doxorubicin resistance in TNBC through regulation of ABC transporters and Bin1/Myc/ PARP1 axis. In vivo studies and clinical data analysis highlight its potential as a predictive biomarker of chemotherapy response and therapeutic target.

EACR25-2359

Translational control of BRAF and NRAS oncogene-driven MAPK signaling in malignant melanoma

N. Vadovicova¹, A. Dorotikova¹, S. Uldrijan¹

¹Masaryk University, Faculty of Medicine, Brno, Czech Republic

Introduction

Oncogenic BRAF and NRAS mutations, which activate the RAS/RAF/MEK/ERK mitogen-activated protein kinase (MAPK) pathway, are key drivers of malignant melanoma. However, due to the strong activating potential of the mutations, excessive extracellular signal-regulated kinase (ERK) MAPK signaling must be tightly regulated by negative feedback mechanisms to allow for optimal tumor growth. The upstream regulators that orchestrate ERK signaling negative feedback control and the extent of the MAPK pathway's spare signaling capacity remain largely unknown. The eukaryotic translation initiation factor eIF4F is a promising therapeutic target in various cancers. In melanoma, eIF4F has been implicated in the development of resistance to BRAF and MEK kinase inhibitors. However, its role in controlling ERK activity in melanoma remains to be fully elucidated.

Material and method

To investigate the potential role of eIF4F in modulating ERK activity in melanoma, we employed western blotting and luciferase reporter assays in human melanoma cell lines harboring BRAF and NRAS mutations. Additionally, we used eIF4F inhibitors and RNAi-mediated knockdown of eIF4F subunits to dissect its functional role.

Result and discussion

Our data reveal that eIF4F-mediated translation plays a crucial role in restraining ERK MAPK pathway activity in melanoma via the dual-specificity phosphatase DUSP6. This phosphatase, characterized by its short half-life in melanoma cells, requires continuous production in an eIF4F-dependent manner to prevent excessive ERK activation driven by oncogenic RAF/RAS mutations. Moreover, we demonstrate that small-molecule compounds disrupting the eIF4F-DUSP6 axis can induce potent hyperactivation of the ERK pathway and over-expression of its downstream targets FOS and EGR1. Our results further suggest that, under steady-state conditions, only a small fraction of the total ERK signaling capacity is utilized in BRAF- and NRAS-mutant melanoma cells, as eIF4F-dependent feedback actively keeps the majority of ERK molecules in an inactive state.

Conclusion

This study uncovers a critical interplay between the eIF4F translation initiation complex, which contributes to melanoma resistance, and the ERK signaling pathway, the primary therapeutic target in melanomas bearing BRAF and NRAS mutations. Targeting eIF4F-dependent regulation of ERK activity may offer new therapeutic opportunities to overcome resistance to MAPK pathway inhibitors.

³CNR, Institute of Clinical Physiology, Pisa, Italy

Introduction

Combination therapies, such as chemo- and radiotherapy, are the first choice in the treatment of pancreatic ductal adenocarcinoma. Induction of chemoresistance can induce different metabolic alterations acting at several levels from membrane composition alteration to detoxification efficacy of drugs and reactive oxygen species (ROS), adversely impacting on the efficacy of therapeutic options based on ROS production such as radiotherapy. Understanding common and cell-specific mechanisms linked to chemoresistance acquisition could enable the development of improved therapeutic strategies based on co-administration of adjuvant agents.

Material and method

Two pancreatic cancer cell lines (PANC-1 and MIA PaCa-2) were made resistant to a generic drug mixture (Folfirinox©) by gradually increasing drug concentration during cell culture. Mitochondrial and cytosolic ROS levels were assessed using MitoSOXTM and dichlorodihydrofluorescein diacetate (DCFH-DA). Glutathione reductase (GSR), glutathione S-transferase (GST), and catalase activities were assessed spectrophotometrically. Cell viability was measured by protein content (BCA) and resazurin assay. Membrane order alterations were visualized by confocal microscopy using Nile Red dye, and activation of cell damage and stemness markers (p38, p53) by immunofluorescence. Changes in lipid profile were determined by lipidomic analysis.

Result and discussion

Both cell lines show increased resistance to the drug, with no sign of cell damage and morphology alteration. GSR activity increases only in MIA PaCa-2 cells, whereas catalase activity decreases in both cell lines. GST activity significantly increases in both cell lines. Cytosolic and mitochondrial ROS decrease in PANC-1 and increase in MIA PaCa-2 cells. Ratio between resazurin- and BCA-derived viability curves evidences a significant increase in reductase activity of resistant MIA PaCa-2 cells. Membrane order analysis evidences alteration correlated with chemoresistance acquisition, with increased fluidity in PANC-1 resistant cells.

Lipidomic analysis evidences alteration in both cell lines that encompasses both unsaturation degree and average length of lipid chains. These findings suggest that increased resistance of both cell lines is related to a rewiring of redox homeostasis, although exploiting not superimposable strategies.

Conclusion

Induction of chemoresistance in different cell lines highlights a variegated scenario with common traits and cell-specific features that affect both redox homeostasis and lipid composition. These findings underscore the

heterogeneity of chemoresistance mechanisms and provide new insights into potential vulnerabilities that could be targeted with adjuvant strategies to overcome resistance and improve treatment outcomes.

EACR25-2387**Role of MRPL15 in mitochondrial dynamics, cell cycle, and EMT regulation in different breast cancer subtypes.****Implications for tumor progression**

³3. CIBER Fisiopatología Obesidad y Nutrición (CB06/03), Instituto de Salud Carlos III, Madrid, Spain

Introduction

Mitochondrial ribosomal proteins (MRPs) are crucial for mitochondrial function and have been linked to cancer progression. MRPL15, a component of the large mitochondrial ribosomal subunit, has been associated with tumor growth and metastasis, but its role in breast cancer remains unclear. This study aims to evaluate the effects of MRPL15 silencing on migration, mitochondrial dynamics, and epithelial-to-mesenchymal transition (EMT) markers in different molecular subtypes of breast cancer cell lines.

Material and method

MCF7 (luminal A), BT-474 (luminal B), and MDA-MB-231 (triple-negative) breast cancer cell lines, were transfected with small interfering RNAs targeting MRPL15. Cell migration was evaluated through wound-healing assays. Cell cycle was evaluated by flow cytometry. Quantitative PCR (qPCR) was performed to analyze the expression of mitochondrial markers (COXI and COXIV), mitochondrial dynamics (MFN1, MFN2, OPA1, OMA1, DRP1, FIS1) and EMT-related genes (VIM, CDH1, CDH2). Moreover, an *in silico* proliferative analysis was performed using the cBioPortal tool.

Result and discussion

MRPL15 silencing led to a slight reduction in mitochondrial markers, and induced cell cycle modifications characterized by an increase in subG0/G1 and G0/G1 phases and a decrease in G2/M phase, suggesting a shift towards lower proliferation, except in MDA-MB-231 cells. These findings were consistent with *in silico* analysis of a cohort of ER+PR+HER2- breast cancer patients, which revealed more proliferative tumors associated with high expression of both MRPL15 and CDH2. Additionally, MRPL15 silencing significantly reduced migration in all breast cancer cell lines, with the strongest effect observed in MDA-MB-231 cells. EMT marker analysis revealed a notable decrease in vimentin (VIM) and N-Cadherin (CDH2) expression, suggesting a switch to a more epithelial phenotype. Moreover, qPCR analysis of mitochondrial dynamics related genes showed

an increase in mitochondrial fusion in MDA-MB-231 cells and a decrease in MCF7 cells, highlighting a subtype-dependent response to MRPL15 silencing in breast cancer cells. These findings indicate that mitochondrial dynamics may be linked to both cell cycle modifications and EMT regulation in breast cancer cells.

Conclusion

Our findings suggest that MRPL15 plays a role in cell cycle, mitochondrial dynamics, and EMT in breast cancer cells lines, with its inhibition leading to reduced tumor aggressiveness, modulating proliferative features or driving a shift towards an epithelial-like phenotype. Targeting MRPL15 could represent a novel therapeutic approach to limit breast cancer progression.

ABCC1 is responsible for invasive phenotype development in colon cancer

W. Ciszewski¹, A. Blažov², K. Sobierajska¹

¹*Medical University-Plovdiv, Department of Medical Biology, Plovdiv, Bulgaria*

²*University of Lodz, Lodz, Poland*

Introduction

Colorectal cancer is one of the leading causes of morbidity and mortality from cancer in the world. Most deaths due to colon cancer are associated with metastatic disease. It is believed that one of the key processes involved in metastasis progression is an epithelial-mesenchymal transition (EMT). Recently, a novel possible role of EMT in cancer drug resistance has been suggested. One of the best-described mechanisms of cancer drug resistance involves reducing drug accumulation mediated by the ATP-binding cassette (ABC) transporter family proteins.

Material and method

We employed colon cancer cells isolated from different stages of tumour development and a panel of cells expressing multidrug resistance proteins. The elongation ratio, cell migration, invasion assay, and MMP-7 secretion were applied to analyse the cell behaviour. Western blot assay examined important epithelial and mesenchymal markers characteristic of EMT at the protein level. The role of ABCC1 in modulating the EMT process was confirmed by its up- and down-regulation, activity inhibition, secretion of leukotriene, and targeting leukotriene-dependent action.

Result and discussion

In this study, we investigated the role of the ABCC1 protein in developing an invasiveness phenotype by EMT-mediated changes in colon cancer cells. We demonstrated that chemotherapeutics inducing the multidrug resistance phenomenon by ABCC1 over-expression lead to the activation of the EMT process and the enhancement of cells' invasion abilities. We also observed that stable transfection with ABCC1 induced EMT and increased cell invasiveness. Furthermore, silencing ABCC1 expression by siRNA resulted in the opposite effect, i.e., EMT reversal and cell invasion capacity inhibition. A similar effect on the inhibition of invasive capacity was observed after the use of ABCC1 inhibitors. We revealed that ABCC1-dependent invasion abilities were due to leukotriene efflux, one of the primary ABCC1 substrates.

Conclusion

Our report provides new insights into the relationship between drug resistance and the development of invasion phenotypes, which may be important in finding optimal strategies for cancer treatment.

EACR25-2416

Additive Effect of Equol on Chemotherapeutics Using 3D Bioprinted Colorectal Cancer Cells

D. Molander¹, T. Ivanova¹, Y. Sbirkov¹, V. Sarafian²

¹*Medical University-Plovdiv, Department of Medical Biology, Plovdiv, Bulgaria*

²*Medical University-Plovdiv, Department of Medical Biology, Bulgaria*

Introduction

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths worldwide. Because of CRC's increasing incidence, chemotherapy resistance and lack of drug effectiveness, the hypoxic tumor environment demands further research. The tissue microenvironment is oxygen-poor and leads to processes promoting progression of CRC. Therefore, new therapeutic approaches are needed. 3D bioprinted models provide reliable platforms for drug testing including natural products like Equol, which is associated with high anticancer activity. 3D bioprinted tumors are morphologically and biochemically like primary carcinomas and demonstrate more pronounced resistance to standard chemotherapeutics. There are no published reports on the additive effect of Equol on chemo-therapeutics within 3D bioprinted CRC models.

Material and method

This study investigates the efficacy of therapeutic regimens consisting of the standard chemotherapeutic (5-FU), autophagy inhibitor (Chloroquine) and Equol, alone, and in combination, on 2D models and 3D bioprinted HCT-116 CRC cells under normoxic and hypoxic conditions. The HCT-116 CRC cell line was grown as 2D and 3D cultures; each of them in conditions of normoxia and hypoxia. All cells were treated for 72 hours with 5-FU, Chloroquine, Equol and combinations of 5-FU + Equol and Chloroquine + Equol and compared to untreated control cells. The cells were 3D bioprinted and the spheroids were cultured for 10 days. The MTT assay was used to determine IC₅₀ values. Additionally, fluorescence assessment of cell viability was performed.

Result and discussion

HCT-116 cells were treated with 5FU - 5.5 μM, Chloroquine - 40 μM and Equol - 19.28 μg/mL. The cells were also treated with a combination of 5FU + Equol and Equol + Chloroquine under normoxic and hypoxic conditions. A higher inhibitory effect of Equol and 5-FU in hypoxia was detected for both 2D and 3D cultures compared to normoxia. When a combination of 5-FU + Equol and Chloroquine + Equol was applied on hypoxic 3D cultures, the additive effect of Equol on cell proliferation was more pronounced when used in combination. The results of the MTT test were confirmed by fluorescence analysis of cell viability.

Conclusion

In conclusion, our data demonstrate the application of Equol in combination with 5-FU and Chloroquine result in higher cytotoxicity on 3D CRC cell models and gives grounds for subsequent tailoring of anticancer treatment regimens. Therefore, Equol has the potential to be employed as an alternative supplement in the adjuvant therapy of CRC.

Role of the NEDD4 family of E3 ubiquitin ligases in regulating the size of connexin43-based gap junctions in cervical cancer cells

M. Totland¹, N. Rasmussen², M. Larsen¹, V. Elster¹, J. Moe¹, V. Sørensen³, Y. Omori⁴, T. Aasen⁵, R. Lothe¹, E. Leithe¹

⁴Akita University Graduate School of Medicine, Department of Molecular and Tumour Pathology, Akita, Japan

⁵Vall d'Hebron Research Institute, Vall d'Hebron University Hospital, Translational Molecular Pathology, Barcelona, Spain

Introduction

Intercellular communication via gap junctions has important roles in maintaining tissue homeostasis and is frequently lost during cancer development. Such loss may contribute to increased cancer cell growth and affect their response to radio- and chemotherapy. Connexin43 (Cx43) is the most ubiquitously expressed gap junction channel protein in human tissues. Cx43 has a relatively high turnover rate, and by modulating the rate at which Cx43 undergoes endocytosis and degradation, cells can rapidly adjust the level of functional gap junctions in response to intracellular or extracellular cues. Many oncogenes and tumor promoters, such as the protein kinase C activator TPA, induce loss of gap junctions by increasing the Cx43 endocytosis and degradation rate. The NEDD4 family of E3 ubiquitin ligases comprises nine members, several of which have been shown to display oncogenic or tumor suppressor functions. Here, we have investigated the role of the NEDD4 family in controlling the size of Cx43-based gap junctions in cervical cancer cells under basal conditions and in response to TPA treatment.

Material and method

Experiments were performed on HeLa cells or HeLa cells stably transfected with Cx43 as well as c-33a cells, which express Cx43 endogenously. Cells were transfected with plasmids or siRNA for overexpression or knockdown studies, respectively, using cationic lipid-mediated transfection. The subcellular localization of Cx43 was determined by confocal immunofluorescence microscopy. The size of Cx43-based gap junctions in confocal microscopy images was quantified by using NIS-elements AR software. Co-immunoprecipitation was

used to study Cx43 ubiquitination and for protein-protein interaction analyses. Gap junction intercellular communication was measured using the quantitative scrape loading-dye transfer assay. Protein levels were analyzed using SDS-PAGE and western blotting.

Result and discussion

Simultaneous depletion of three members of the NEDD4 family - NEDD4, ITCH, and SMURF2 - by siRNA resulted in significantly reduced Cx43 ubiquitination and Cx43 degradation rate compared with their single depletion. The combined knockdown of these E3 ubiquitin ligases also caused an additive increase in the cellular level of Cx43 and in gap junction size. In addition, the triple knockdown strongly counteracted the TPA-induced degradation of Cx43.

Conclusion

Collectively, these data suggest that NEDD4, ITCH, and SMURF2 act together to mediate the basal and TPA-induced degradation of Cx43 in cervical cancer cells. To our knowledge, this study represents the first evidence that Cx43 ubiquitination and degradation and, consequently, the size of gap junctions, is controlled by the concurrent participation of multiple E3 ubiquitin ligases.

EACR25-2434

Naringenin's Role in Mitophagy and Apoptosis: A Study in Cancerous and Healthy Cells

E. Bertan¹, S. Vural Korkut¹

¹Yildiz Technical University, Molecular Biology and Genetics, Istanbul, Turkey

Introduction

Mitochondria regulate cellular homeostasis, energy production, and apoptosis through fusion, fission, and mitophagy. Disruptions in these processes are linked to cancer and neurodegenerative diseases, with mitophagy playing a key role in stress responses. Naringenin, a citrus flavonoid, exhibits antioxidant, anti-inflammatory, and anticancer effects. While it influences mitochondrial dynamics, its impact on mitophagy remains unclear. This study examines its role in mitophagy and apoptosis, particularly in the PINK1-Parkin pathway and mitochondrial fission.

Material and method

HepG2 and HDF were maintained under standard culture conditions. The cytotoxic effects of naringenin were assessed using MTT assays to determine IC₅₀ values, while colony formation assays were conducted to evaluate long-term viability and proliferation.

Additionally, a wound healing assay was performed to investigate the effects of naringenin on cell migration. A sterile tip was used to create a scratch in the cell monolayer, and wound closure was monitored over time to assess its influence on motility. Mitochondrial membrane potential changes following naringenin treatment were examined using JC-1 staining. Apoptotic activity was further investigated by analyzing cytochrome c release and Bax expression through Western blotting.

Additionally, DAPI staining was used to observe nuclear integrity and morphological alterations in treated cells. Mitophagy levels were assessed via real-time PCR and Western blotting, focusing on key markers in the PINK1-

Parkin pathway. Mitochondrial fission was evaluated by monitoring DRP1 protein expression.

Result and discussion

Naringenin treatment led to increased mitophagy, with PINK1 and Parkin expression being more pronounced in HepG2 cells compared to HDF cells. This suggests that naringenin promotes mitophagy more effectively in cancerous cells, possibly as a stress response mechanism. Mitochondrial fission, indicated by DRP1 expression, was higher in HepG2 cells, whereas it was less evident in HDF cells. This suggests a differential regulatory effect of naringenin on mitochondrial dynamics depending on cell type. Apoptotic markers showed that cytochrome c release was significantly elevated in HepG2 cells, while Bax was expressed in both cell types. This indicates that naringenin promotes apoptosis in both cancerous and healthy cells but has a stronger effect on cancer cells. These findings highlight naringenin's dual role in mitochondrial quality control and apoptosis regulation.

Conclusion

This study provides new insights into naringenin's effects on mitophagy and apoptosis. Its ability to modulate the PINK1-Parkin pathway and mitochondrial fission suggests a potential role in cancer therapy. While further research is needed, these results indicate that naringenin may serve as a promising compound for targeting mitochondrial dysfunction in cancer.

Introduction

Colorectal cancer stem cells (CSCs) expressing Lgr5 exhibit remarkable plasticity and are key drivers of tumor initiation, metastasis and therapy resistance. Recent studies suggest that Lgr5+ CSCs can establish themselves in a niche-independent manner during metastasis, indicating that these cells possess the intrinsic ability to sustain multipotency and self-renewal. However, the molecular mechanisms governing this plasticity remain poorly understood. Transfer RNAs (tRNAs) are essential for accurate mRNA translation and undergo extensive chemical modifications that regulate protein synthesis. While traditionally seen as passive translation molecules, growing evidence highlights their active role in cancer progression, including tumor initiation, invasion, and therapy resistance. Nonetheless, whether tRNA modifications influence CSC plasticity and survival remains unexplored.

Material and method

A conditional Apc knock-out mouse model was used to induce Wnt-driven transformation specifically in Lgr5+ intestinal stem cells, simulating colorectal cancer. Intestinal crypts were cultured as organoids, and Lgr5+ healthy and cancer stem cells were isolated using an Lgr5-GFP reporter. Multi-omics profiling (RNA sequencing, proteomics and tRNA analysis) was performed to characterize the differences between healthy and cancerous organoids (whole population) and healthy and cancer sorted stem cells. A CRISPR-Cas9 screen targeting genes involved in translation was then conducted on these organoids, and the role of a selected tRNA-modifying enzyme in CSCs was assessed through its depletion and chemical inhibition in organoid cultures, followed by proteome analysis and ribosome profiling.

Result and discussion

Our multi-omics analysis revealed an upregulation of protein synthesis in CSCs, independent of transcription. CSCs also showed enhanced tRNA adaptation, suggesting they rely on an optimized tRNA pool to support the increased translation observed, unlike healthy stem cells. Consistent with this, both tRNA availability and tRNA modifications were able to discriminate CSCs from healthy stem cells. Notably, the CRISPR-Cas9 screen identified tRNA aspartic acid methyltransferase 1 (Trdm1) as an essential tRNA-modifying enzyme for Lgr5+ CSC functionality, while being dispensable in normal stem cells. Further experiments showed that genetic depletion and chemical inhibition of Trdm1 resulted in the failure of CSC-derived intestinal organoid formation, which was linked to a disruption in the translation of key regulators of Lgr5+ CSC identity. This suggests that Trdm1-dependent translation regulation is vital for sustaining the plasticity and self-renewal of colorectal CSCs.

Conclusion

Together, these findings highlight the key role that tRNA biology plays in sustaining the intrinsic plasticity of Lgr5+ CSCs and pave the way for the development of targeted therapies against colorectal cancer stem cells.

AMPK as a regulator of glioblastoma invasion and cytoskeleton dynamics

S. Caamaño-Teixeira¹, V. González-Álvarez¹, A. Iglesias¹, J. Barbazán², R. Señarís¹

¹Center for Research in Molecular Medicine and Chronic Diseases (CiMUS), University of Santiago de Compostela, Neuroendocrinology, Metabolism, and Cancer, Santiago de Compostela, Spain

²Health Research Institute of Santiago de Compostela (IDIS), Translational Medical Oncology (Oncomet), Santiago de, Spain

Introduction

Glioblastoma is the most prevalent and aggressive primary brain tumor. AMP-activated kinase (AMPK), the main energy sensor of the cell, has been previously described by our group as a key factor in glioblastoma oncogenesis and proliferation and is known for taking part in tumoral metabolic transformation. Our lab has also formerly reported how AMPK regulates lipid

reliance of glioblastoma cells. Overall, this evidence positions AMPK inhibition as a promising antitumoural therapy for glioblastoma. Furthermore, AMPK has been reported to regulate cell invasion and migration, suggesting a potential role in orchestrating glioblastoma spreading in the brain.

Material and method

To study the role of AMPK in glioblastoma cytoskeleton dynamics, we used human glioblastoma cell lines U87 and U373 and suppressed AMPK activity by transfection with an siRNA for the catalytic subunits AMPK α 1/2. Cell migration was assessed by wound healing assays, and invasion was studied using spheroids in 2D and 3D experiments. Also, cytoskeleton morphology was studied by confocal microscopy, and cytoskeleton-associated protein levels were determined by western blot.

Result and discussion

Our data show that the silencing of AMPK reduces three-dimensional cell invasion. We also found that AMPK plays an important role in organizing the actin cytoskeleton and forming focal adhesions in the cell lines studied, probably through myosin regulation.

Conclusion

AMPK holds a relevant part in regulating glioblastoma cytoskeleton dynamics, affecting its invasion *in vitro*. This positions the inhibition of AMPK as a promising therapeutic strategy in glioblastoma, potentially decreasing or slowing down tumor expansion in the brain.

EACR25-2459

The Transcription Factor SNAI2 as a Novel Mediator of EWS-WT1 (+KTS) Oncogenic Activity in Desmoplastic Small Round Cell Tumour

L. Lobo Selma¹, J. Olmedo¹, C. Rodríguez Martín², J. Alonso², J. Díaz Martín¹, R. Rodríguez³, A. Amaral⁴, C. Salguero Aranda¹, E. de Álava¹

¹*Institute of Biomedicine of Seville, Department of Normal and Pathological Cytology and Histology, Seville, Spain*

²*Carlos III Health Institute, Madrid, Spain*

³*Institute for Health Research of the Principality of Asturias, Oviedo, Spain*

⁴*Center for Innovation in Biomedicine and Biotechnology, Coimbra, Portugal*

Introduction

Desmoplastic small round cell tumour (DSRCT) is a rare and aggressive sarcoma with a poor prognosis, highlighting the urgent need for improved therapeutic strategies. The driver of tumour malignancy is the chromosomal translocation between EWSR1 and WT1 genes. WT1 function is regulated by alternative splicing in exon 9, generating two isoforms depending on the presence of three amino acids (KTS), which alter the DNA-binding properties of EWS-WT1. The impact of both variants on tumour regulatory networks and their interactions with other transcription factors (TFs) remains poorly understood. This study identified SNAI2 as a potential target of EWS-WT1 +KTS.

Material and method

JN-DSRCT-1/Cas9-GFP cells were infected with a lentiviral gRNA library targeting 18479 TFs for CRISPR-based screening. NGS data were analysed using Galaxy platform. Transformed Human Mesenchymal Stem Cells (hMSC) were transfected with plasmids harbouring the two most prevalent gene fusion (GF) variants with KTS, fused to an HA-tag. RNA from these cells was used for a ClarionS expression array and analysed with TAC4.0 software. Integration of both models with a shRNA model targeting the GF (GSE180031) identified SNAI2 and its expression pattern was analysed in a set of public microarrays and validated at the protein level by IHC, in a subset of sarcomas samples including DSRCT. SNAI2 dependant expression of the GF was studied by targeting WT1 by siRNAs and analysed by qPCR and WB. Moreover, the binding of the GF to SNAI2 promoter was evaluated by a dual-luciferase reporter assay in JN, BER and SK-DSRCT cell lines. Finally, to investigate the dependence on the presence of KTS for the binding of the GF to SNAI2 promoter, a ChIP assay was developed in hMSC cells transfected with the GF with KTS. To assess the relevance of SNAI2 in the tumour biology, functional assays such as MTT assay, clonogenic, migration (wound healing), and invasion were conducted in the three DSRCT cell lines using siRNAs targeting SNAI2.

Result and discussion

Public microarray analysis revealed that DSRCT exhibits one of the highest expressions of SNAI2 among the studied sarcomas subtypes. These findings were validated by IHC, demonstrating moderate to high SNAI2 expression in DSRCT, compared to weak or absent expression in healthy tissues and other sarcomas. SNAI2 downregulation after the silencing of the GF verified its expression-dependency. Direct binding of EWS-WT1 +KTS to SNAI2 promoter was confirmed with dual-luciferase reporter assays, and validated by ChIP, showing significant binding of EWS-WT1 +KTS to the identified target sites. SNAI2 silencing significantly impaired cell proliferation, clonogenic capacity, migration, and invasion, underscoring its key role in DSRCT cell biology.

Conclusion

This study demonstrates that SNAI2 is a direct target of EWS-WT1 +KTS and a key driver of DSRCT malignancy, positioning it as a potential therapeutic target for further investigation.

EACR25-2460

Purine Synthesis as a Metabolic Bottleneck in TP53/KRAS Double-Mutant Lung Adenocarcinoma

J. Urgel i Solas¹, L. Ortet², A. Benito¹, S. Sdelci¹, A. Janic²

¹*Centre for Genomic Regulation, Barcelona, Spain*

²*Universitat Pompeu Fabra, Barcelona, Spain*

Introduction

Non-small cell lung cancers (NSCLC) harboring concurrent KRAS and TP53 mutations account for approximately 15% of all NSCLC cases and are associated with an aggressive clinical phenotype. While both TP53 and KRAS mutations are known to influence cancer metabolism, the specific metabolic adaptations in

KRAS/TP53 double-mutant tumors remain poorly understood. Given that metabolic reprogramming is a hallmark of cancer, we hypothesize that KRAS/TP53 double-mutant tumors undergo distinct metabolic remodeling to support their proliferative demands.

Material and method

We performed genomics screens, using human KRAS and KRAS/TP53 double-mutant lung adenocarcinoma cell lines with metabolism-focused CRISPR KO libraries targeting ~3,000 metabolic genes per species. To validate findings, we integrated TCGA and CCLE datasets, performed drug response assays, shRNA experiments, and analyzed DNA methylation and DNA damage. In preliminary *in vivo* studies, mice were injected with tumor cells expressing KRAS alone or KRAS/TP53 mutations, followed by treatment evaluation.

Metabolomics profiling and WGS were used to assess metabolic reprogramming and potential increases in mutational burden, respectively.

Result and discussion

Our functional genomics screening identified purine synthesis as a critical metabolic vulnerability in TP53/KRAS double-mutant lung adenocarcinoma. The metabolic essentiality of purine biosynthesis was further supported by data from the Cancer Cell Line Encyclopedia (CCLE), where cell lines with low p53 activity exhibited a similar dependency on purine metabolism. To validate these findings, we pharmacologically inhibited purine synthesis, revealing a higher sensitivity in TP53/KRAS double-mutant cell lines compared to their single-mutant or wild-type counterparts. Among purine metabolites, adenosine emerged as a key factor, as supplementation with adenosine rescued cell growth in both 2D and 3D models, suggesting that adenosine depletion plays a central role in the observed growth impairment upon purine inhibition. Furthermore, knockdown (KD) of key enzymes in the de novo purine synthesis pathway significantly increased sensitivity in TP53/KRAS double-mutant cells, reinforcing the notion that these tumors rely on purine biosynthesis for survival. Notably, inhibition of this pathway led to an accumulation of DNA damage and alterations in DNA methylation profiles, affecting specific epigenetic markers. These findings indicate that purine metabolism not only fuels tumor growth but also plays a role in maintaining genomic stability in TP53/KRAS double-mutant tumors.

Conclusion

Overall, our results highlight purine synthesis as a metabolic bottleneck in TP53/KRAS double-mutant lung adenocarcinoma, offering a potential therapeutic target for disrupting tumor progression while uncovering a link between purine metabolism and DNA integrity.

EACR25-2469

Asparagine-driven transsulfuration compensates for malate-aspartate shuttle deficiency in tumor growth

M. Milosevic¹, K. Dmytruk¹, A. Alghadi¹, P. Jakoube¹, J. Wong Soon¹, D. Tennant², M. Vander Heiden³, K. Rohlenova¹, J. Rohlena¹

¹Institute of Biotechnology of the Czech Academy of Sciences, Cellular Metabolism, Vestec, Prague-West, Czech Republic

²University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

³Massachusetts Institute of Technology, Koch Institute for Integrative Cancer Research, Cambridge, United States

Introduction

The malate-aspartate shuttle is a metabolic system with two major roles: (i) transferring reducing equivalents from the cytosol into the mitochondria to normalize the cytosolic NADH/NAD⁺ ratio and (ii) generating aspartate. Aspartate serves as a metabolic precursor for asparagine, arginine, and nucleotides. Both aspartate availability and a properly regulated cytoplasmic redox state are essential for biosynthesis and tumor progression. However, the combined effects of malate-aspartate shuttle disruption and aspartate synthesis deficiency on tumorigenesis remain unaddressed.

Material and method

We ablated GOT1 and GOT2, the malate-aspartate shuttle transaminases and the only two enzymes responsible for canonical aspartate synthesis in mammalian cells, in B16 mouse melanoma (GOT1/2 dKO) cells. Syngeneic subcutaneous tumors were generated in C57BL/6 mice for analysis by scRNA-seq and metabolomics. The substrate dependency of GOT1/2 dKO cells was assessed by measuring proliferation in culture media supplemented or depleted for specific nutrients. Metabolic tracing was performed to measure aspartate synthesis, and a loss-of-function CRISPR screen was used to identify dependencies in GOT1/2 dKO cells.

Result and discussion

Surprisingly, GOT1/2 dKO cells formed tumors normally. Integrated analysis revealed increased pyruvate utilization and decreased aspartate levels in GOT1/2 dKO tumors, consistent with disrupted aspartate synthesis and cytosolic redox imbalance. The growth of GOT1/2 dKO cells was constrained by an elevated cytosolic NADH/NAD⁺ ratio rather than by aspartate availability. CRISPR screening demonstrated that GOT1/2 dKO cells depend on the transsulfuration pathway. When transsulfuration is active, the redox imbalance in GOT1/2 dKO cells can be rescued by asparagine, which is exchanged for serine, a key substrate in transsulfuration.

Conclusion

We identified a new metabolic pathway wherein asparagine-stimulated transsulfuration corrects the cytoplasmic redox imbalance and supports tumor growth in the absence of functional malate-aspartate shuttle.

²Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Research Department, Microenvironment

Molecular Targets, Naples, Italy

³*University of Campania "L. Vanvitelli", Department of Environmental, Biological and Pharmaceutical Sciences and Technologies (DISTABiF), Caserta, Italy*

Introduction

Triple-negative breast cancer (TNBC) represents 15–20% of all breast cancer subtypes and is characterized by the lack of the three classical BC markers: estrogen receptor (ER), progesterone receptor (PR), and type-2 epidermal growth factor receptor (HER-2). To date, chemotherapy remains the mainstay of systemic treatment, since no relevant druggable targets have been identified. Many studies have tried to characterize TNBC to find new targetable proteins that can cure this BC subgroup. AR has gained a promising position during the past few years. This receptor is expressed in 20–50% of TNBCs and regulates different downstream pathways thus affecting the progression of this incurable disease.

Material and method

Using *in vitro* and *in vivo* experiments, we analyzed how AR and its partners, FLNA and CXCR4, promote TNBC cell proliferation and growth and influence the behavior of the tumor microenvironment (TME). In 2D and 3D models of TNBC-derived MDA MB 231 and 453 cell lines, and stroma NIH3T3 cell line, we analyzed androgen-induced cell proliferation by measuring 5-bromo2'-deoxyuridine incorporation and spheroid growth. We performed co-immunoprecipitation experiments, immunoblots, and immunofluorescence analysis to evaluate how and where AR interacts and co-works with FilA and CXCR4 and which pathways they control. Trans-well assays allow us to define how the androgen treatment of cancer cells conditions the stroma cells' activity. Using specific inhibitors in both *in vitro* experiments and MDA231-BALBc xenografts shows that AR, in collaboration with FilA and CXCR4, is responsible for TNBC progression. Immunohistochemical assays confirmed that AR action influences cancer cell proliferation and TME composition.

Result and discussion

Our results show that androgen treatment triggers cell proliferation in TNBC cells and, indirectly, in stroma cells. Furthermore, androgen-elicited cancer cells can influence TME. These effects are specifically due to the association between AR and Filamin A that controls, on one side, the chemokine receptor CXCR4 and on the other, the downstream activation of Ras and PKC. The use of the specific AR antagonist, the bicalutamide or Casodex (Cx), and of two peptides, the Rh2025u, specifically designed to mimic the AR sequences responsible for its interaction with Filamin A, and the R54, able to inhibit the CXCR4 activity, prevents cancer and stroma cell proliferation and strongly reduces cancer growth in MDA231-BALBc xenografts. In sum, our data demonstrates the pivotal role of AR in TNBC progression and how this protein can control cancer growth by acting directly on cancer cells and indirectly on TME.

Conclusion

These results give high importance to AR as a molecular target acting on cancer *in toto*. The use of combined therapy inhibiting AR and its partners in crime (FilA and CXCR4) can represent a winning proposal to develop effective therapies for fighting TNBC.

EACR25-2489

Divergent Effects of Tet2- and Dnmt3a-mutant Clonal Hematopoiesis on Breast Cancer Progression Upon Aging

N. Gönüllü¹, J. Fullin¹, S. Boettcher¹, F. Caiado¹, M. Manz¹

¹*University Hospital Zurich, Medical Oncology and Hematology, Zurich, Switzerland*

Introduction

Clonal hematopoiesis of indeterminate potential (CHIP) is a hematological condition defined by the presence of an expanded somatic blood cell clone harboring mutations in leukemia driver genes, most commonly DNMT3A and TET2, at a variant allele frequency more than 2% in the absence of other hematological abnormalities. CHIP incidence increases with age and is linked to higher risk of developing blood cancer, cardiovascular disease and all-cause mortality which associates mechanistically with increased pro-inflammatory responses by mutant myeloid cells. Recent findings suggest higher CHIP incidence in solid tumor patients, with carriers exhibiting a higher risk of developing breast cancer. However, whether hematopoietic cells carrying CHIP mutations directly impact solid tumor progression, and what are the underlying mechanisms, remain unclear. Thus, we hypothesize that Tet2/Dnmt3a-driven clonal hematopoiesis contributes to breast cancer incidence, growth, and/or metastasis by altering the inflammatory tumor microenvironment and immune compartments.

Material and method

To test our hypothesis, we established a transgenic mouse model of CHIP, where floxed Tet2 or Dnmt3a fl-R878H genes and a reporter gene are controlled by a hematopoietic-specific, tamoxifen-inducible CreER enzyme. Combining this CHIP model with a syngeneic, orthotopic and traceable breast cancer model using E0771 cell line, we aim to assess the contribution of CHIP-bearing hematopoietic cells to breast tumor progression in young (Y, 3–4 months old) and middle-aged (MA, 12–14 months) animal cohorts, carrying high (~70% of leukocytes) clonal fractions. Using longitudinal tumor size and metastasis quantification combined with histology, flow cytometry and scRNA-sequencing data, we further aim at revealing the potential underlying molecular mechanisms.

Result and discussion

We observe that Y Tet2^{+/−} CHIP mice showed comparable primary tumor growth, but increased lung metastasis burden compared to WT animals. In contrast, MA Tet2^{+/−} CHIP mice exhibited significantly enhanced tumor growth and elevated lung metastasis. Notably, we observed reduced numbers of Tet2^{+/−} tumor infiltrating T cells, particularly CD8+ and NKT populations, in MA animals. Conversely, both Y and MA Dnmt3a fl-R878H CHIP mice had slower breast tumor growth than WT littermates, with comparable metastatic burden in the lungs. Preliminary scRNA sequencing analysis of the tumor-infiltrating leukocytes revealed a suppressed T-cell response in MA Tet2^{+/−} CHIP animals, which contrast with increased type I interferon signatures in MA Dnmt3a fl-R878H CHIP mice.

Conclusion

These findings suggest that age and CHIP-mutations have a synergistic impact on breast cancer progression potentially by shaping the tumor infiltrating immune compartment. However, the precise molecular mechanisms linking CHIP and breast cancer, and its potential therapeutic implications remain to be explored.

Anti-Cancer Effects of *Haplophyllum tuberculatum* Extract Against Triple Negative Breast Cancer

Y. Al Dhaheri¹, A. Rahma¹, A. Wali², R. Iratni¹

¹*UAEU, Biology, Al Ain, United Arab Emirates*

²*RAK Medical & Health Sciences University, College of Pharmacy, RAK, United Arab Emirates*

Introduction

Breast cancer (BC) is the most commonly diagnosed cancer in women, with over 2 million new cases reported globally in 2020. In the United Arab Emirates (UAE), BC has the highest incidence rate among women, accounting for 32.16% of cases in UAE citizens and 41.41% in non-UAE citizens. Although several treatment options, including surgery, radiotherapy, and chemotherapy, are available for BC, these approaches often affect surrounding tissues and lead to various side effects. As a result, there is a growing interest in alternative treatments that offer high efficacy with reduced cytotoxicity. Medicinal plants present a promising alternative for cancer therapy due to their accessibility, efficacy, and lower toxicity. *Haplophyllum tuberculatum* is a widely recognized medicinal plant traditionally used by local communities to treat various ailments. This study aims to conduct a phytochemical screening of the ethanolic extract of *Haplophyllum tuberculatum* (HTEE) and its fractions to identify secondary metabolites, evaluate their antioxidant activity, and assess their anticancer potential on human breast cancer cell lines.

Material and method

MDA-MB-231 cell line was used in this study. CellTiter-Glo Luminescent cell viability assay was used to measure cell viability after the treatment following the manufacturer's protocol. Cell Morphology of treated and control MDA-MB-231 cells was examined using a light microscope with 40X magnification after 24 hours. Caspase 3/7 activity was examined using a luminescent Caspase-Glo® 3/7 assay kit following the manufacturer's procedures. The effect of HTEE on the migration of MDA-MB-231 cells was assessed using a wound-healing assay. Protein expression of the target proteins was measured using Western blotting.

Result and discussion

Our results demonstrated that HTEE inhibits the proliferation of MDA-MB-231 cells in a time- and concentration-dependent manner. Treatment with HTEE led to the downregulation of key proteins associated with cell proliferation, including cyclin D1, c-Myc, phospho-RB, and PCNA. The activation of caspase 3/7 and PARP cleavage indicated that HTEE induced apoptosis in MDA-MB-231 cells. Furthermore, the downregulation of p62 and accumulation of LC3II suggested the involvement of autophagic cell death in the observed cytotoxic effects. HTEE also effectively inhibited the migration of

MDA-MB-231 cells and decreased the protein expression of β-catenin, which is involved in both cell proliferation and migration. Additionally, HTEE increased phospho-H2A.X, a marker for DNA breaks, suggesting DNA damage induction.

Conclusion

Overall, our findings highlight the therapeutic potential of HTEE in targeting breast cancer cells.

Exploiting inhibitors of histone deacetylase and metabolism for pancreatic cancer therapy

D. Conde¹, M. Farma¹, N. Binti¹, L. Shiekh¹, C. Paul¹, A. Shiekh¹, M. Cheung¹, E. Zhou¹, C. Ezeh¹, Z. Nwosu²

¹*Cornell University, Ithaca, United States*

²*Cornell University, Molecular Biology and Genetics, Ithaca, United States*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a lethal cancer, largely driven by oncogenic KRAS and has limited therapeutic options. Although histone deacetylase inhibitors (HDACi) have been approved for various cancer treatment, these inhibitors showed limited efficacy in PDAC for unclear reasons.

Material and method

We used CRISPR/Cas9 gene editing to delete histone deacetylase in human and mouse pancreatic cancer cell lines, followed by metabolomics, molecular characterization, drug screening, and mouse subcutaneous xenograft studies. In addition, we performed bioinformatic analysis of human and mouse transcriptomics data of cells treated with HDACi.

Result and discussion

Here we show that, independent of KRAS activity, a subset of PDAC cell lines undergo cell death upon treatment with HDACi. Integrative metabolomics and transcriptomics analyses revealed that HDACi interfere with multiple metabolic pathways, notably disrupting nucleotide metabolism and amino acid pathways. These cataclysmic events are actively counteracted in the HDACi-resistant cells, which amplify de novo metabolism to sustain growth.

Conclusion

Our data identify new compensatory mechanisms enabling HDACi resistance and suggest that nucleotide biochemical axis is a major metabolic hub that could be exploited to improve response to HDACi in pancreatic cancer.

Seamless Capture Integration for Accurate NGS-Based Applications

K. Wiseman¹, B. J. Krajacic¹, R. Kempfer², Y. Liu², A. Willig², Z. Xu², J. Zhao¹, S. Lau¹, S. Celis³

¹*Element Biosciences, San Diego, United States*

²*SOPHiA GENETICS, Rolle, Switzerland*

³*Element Biosciences, Giessen, Germany*

Introduction

Capture-based NGS assays enable the identification of actionable biomarkers across hundreds of cancer-

associated genes in a single experiment. However, sample preparation for such assays can be time-consuming and technology demanding. The Trinity technology streamline the capture workflow by enabling directly library loading onto the sequencer after hybridization, eliminating the need for hands-on capture and wash steps. This study evaluates the compatibility of Trinity with established end-to-end solutions. The results suggest that the benefits of Trinity can be combined with the proven accuracy of the SOPHiA GENETICS™ applications.

Material and method

Reference samples were processed using the Trinity workflow on the AVITI™ sequencer with the target enrichment panels from two SOPHiA GENETICS™ applications; MSK-IMPACT® powered with SOPHiA DDM™ and SOPHiA DDM™ Whole Exome Solution v2. The same samples were processed in parallel using the end-to-end solutions from SOPHiA GENETICS, with sequencing on either the Illumina or Element instrument. Capture quality metrics and variants calling performance were assessed using the SOPHiA DDM™ Platform through its dedicated bioinformatics pipelines. The performance of the Trinity workflow with each target enrichment panel was compared to that of the corresponding end-to-end solution.

Result and discussion

Both capture assays displayed highly similar quality metrics, with 94% on-target rates and >99% coverage uniformity for traditional captures as well as Trinity captures. Whole exome sequencing using the Trinity workflow with SOPHiA GENETICS™ applications and pipelines showed excellent analytical performance with 99.3% sensitivity and 98.7% precision.

Conclusion

The findings demonstrate compatibility of the Trinity workflow that includes on-sequencer capture with existing end-to-end NGS solutions, such as MSK-IMPACT® powered with SOPHiA DDM™ and SOPHiA DDM™ Whole Exome Solution. The high accuracy of the SOPHiA GENETICS™ applications is preserved with the simplified workflow, indicating that solutions with a proven reliability can benefit from the technology. Further studies are planned to explore in more details the analytical performance and evaluate the utility in routine practice.

EACR25-2536

Dissecting the molecular mechanisms underlying the ERKi-Entrectinib combination in LKB1-mutated NSCLC

M. Colombo¹, A. Cerrone¹, A. Paffetti¹, S. Foroni¹, E. Caiola¹

¹Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Oncology, Milano, Italy

Introduction

LKB1-mutated NSCLCs represent a highly aggressive subtype lacking targeted therapeutic options. Previous preclinical studies demonstrated that these tumors are particularly sensitive to ERK inhibitors (ERKi). However, co-occurring alterations in the PI3K/Akt/mTOR pathway or other signaling networks may reduce ERKi efficacy. The project aimed to identify the most

effective ERKi-based drug combinations for LKB1-deficient NSCLCs using advanced preclinical models, including patient-derived xenografts (PDXs) and organoids (PDXOs).

Material and method

PDXs and PDXOs were generated from fresh tumor specimens and characterized histologically and molecularly. Their growth patterns and genetic profiles were analyzed by STR and Whole exome sequencing (WES) to confirm fidelity to the original tumor. A comprehensive drug screening of FDA-approved compounds was performed to identify candidates that enhance ERKi sensitivity. Key molecular mechanisms were investigated by western blot analyses and CRISPR/Cas9-mediated gene deletion to understand ERKi synthetic lethality in LKB1-mutated models. Drug efficacy was validated in 2D and 3D cultures by carrying out distinct cell viability and cell death assays, with selected combinations tested in vivo.

Result and discussion

From the drug-library screening, the ALK, NTRK, ROS1 inhibitor Entrectinib emerged as the best promising ERKi partner, showing the most significant impact in LKB1-deficient cells. This combination induced apoptosis, and demonstrated efficacy both in 2D and 3D models. To further clarify the specific mechanisms involved in Entrectinib activity, a pharmacological approach was applied by using Entrectinib analogues targeting only one or two receptors (ALK, NTRK, ROS1) and combined them with the ERK inhibitors. This approach revealed that inhibiting ALK is necessary, but probably not sufficient, to sensitize LKB1-mutated cells to ERKi. In vivo, the ERKi-Entrectinib combination reduced tumor growth, and improved survival rates, supporting its clinical potential. Further experiments are ongoing on patients-derived models to corroborate these results.

Conclusion

These findings highlight the therapeutic potential of ERKi-based combinations for LKB1-mutated NSCLCs, particularly with Entrectinib. The study provides a strong rationale for further preclinical and clinical evaluations to refine combination strategies, enhance efficacy, and minimize toxicity. This offers a new avenue for treating LKB1-deficient NSCLCs, a subtype with limited targeted therapies.

EACR25-2548

Mitochondrial dynamics control cancer cell migration

S. Dutta¹, J. Boix-Campos¹, P. Sáez¹

¹University Medical Center Hamburg-Eppendorf, Cell Communication and Migration Laboratory (CellComM), Institute of Biochemistry and Molecular Cell Biology, Center for Experimental Medicine, Hamburg, Germany

Introduction

Tumour metastasis remains the leading cause of mortality in breast cancer patients, with cell migration playing a pivotal role in this process. Our study reveals that mitochondria play a central role in orchestrating the directional migration of metastatic breast cancer cells.

Material and method

Utilizing high-resolution live cell imaging and micro patterns, we analysed the migratory behaviour of MDA-

MB-231, MDA-MB-468, and MCF7 cells, which have different metastatic potentials.

Result and discussion

We identified a distinct phenotype in MDA-MB-231 cells, which exhibited sustained actin cytoskeletal coordination that favoured directed migration in different levels of confinement. MDA-MB-231 cells presented a highly polarised distribution of mitochondria towards their leading edge as well as in protrusions where mitochondria maintained an elevated membrane potential ($\Delta\Psi_m$). In contrast, perinuclear mitochondria exhibited changes in the membrane potential. Multi-omics analyses revealed that the voltage-dependent anion channel (VDAC) family is overexpressed in the metastatic breast tumours from 1100 patient samples and more than 55 cell lines, with VDAC1 levels correlating with poor patient survival. Pharmacological disruption of mitochondrial function or inhibition of the VDAC1 channel significantly reduced migration speed and the number of actin stress fibres.

Conclusion

Together, these findings deepen our mechanistic understanding of how the precise spatiotemporal positioning of mitochondria-mediated by VDAC1 channel oligomerization contributes to the migratory behaviour of metastatic breast cancer cells. This insight encourages further exploration of mitochondrial dynamics as a potential component of future therapeutic strategies for aggressive breast cancer.

EACR25-2578

Type I interferons suppress pancreatic cancer initiation

I. Del Priore¹, B. Alagesan¹, J. Reyes¹, A. Chaikovsky¹, K. Tsanov¹, F. Barriga¹, Y. Ho¹, S. Lowe¹

¹Memorial Sloan Kettering, Cancer Biology and Genetics, New York, United States

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is characterized by a highly immunosuppressive tumor microenvironment (TME). The evolution of the TME during the early stages of PDAC development is poorly understood. Loss of chromosome 9p21.3 is the most common homozygous deletion across cancers; these deletions invariably affect the tumor suppressor genes CDKN2A/B and commonly extend to include a linked cluster of type I interferon (IFN) genes. Our laboratory recently found that IFN co-deletion contributed to an immunosuppressive TME and increased metastasis and resistance to immune checkpoint blockade in orthotopic mouse models of advanced PDAC. However, the role of type I IFN signaling in shaping the tumor immune microenvironment to suppress early stages of tumor initiation is not well characterized.

Material and method

In this study, we used autochthonous mouse models of PDAC driven by oncogenic Kras and a doxycycline-inducible shRNA targeting Trp53 restricted to the pancreatic epithelium. Mice were treated with an interferon alpha receptor 1 (IFNAR1) blocking antibody to induce systemic blockade of type I IFN signaling or an IgG control for six weeks. Tissue was collected for

histological analysis and Kras-mutant epithelial cells, immune cells, and stromal cells were isolated for single-cell RNA-seq.

Result and discussion

Using mouse models of PDAC driven by oncogenic Kras, we found that systemic blockade of type I IFN signaling increases the frequency of cancer initiating epithelial cells in a p53-dependent manner during tumor initiation. These changes in the epithelial compartment are coupled with an increased frequency of pro-inflammatory and pro-tumorigenic myeloid cell populations. We observed that type I IFNs are induced upon mutant Kras activation, and loss of type I IFN signaling also accelerated the progression of premalignant lesions to adenocarcinoma.

Conclusion

Our work implies that type I IFNs function as tumor suppressors during PDAC initiation through crosstalk with the immune microenvironment, and loss of this program accelerates tumor development.

EACR25-2579

IL-2/STAT5 signalling drives metabolic reprogramming to support cervical cancer cell proliferation

A. Valle-Mendiola¹, R. Fuentes-Pascacio², R. Rojas-Mercado², A. Gutiérrez-Hoya², B. Weiss-Steider², I. Soto-Cruz²

¹Universidad Nacional Autónoma de México, FEZ Zaragoza, Mexico City, Mexico

²Universidad Nacional Autónoma de México, FES Zaragoza, Mexico City, Mexico

Introduction

A relevant hallmark of human cancer is the ability to reprogram energy metabolism to fuel cell growth and proliferation. Cancer cells show enhanced glucose uptake and glycolysis and a decreased oxidative metabolism, mainly by upregulating glucose transporters and multiple enzymes of the glycolytic pathway. On the other hand, in normal T cells, this metabolic switch is maintained by continuous signalling of IL-2 through the JAK/STAT pathway. We have shown that the IL-2 receptor is present in cervical cancer cells and that the JAK/STAT pathway is constitutively active. However, little is known about the role of the IL-2/STAT signalling in metabolic reprogramming in cervical cancer cells.

Material and method

To elucidate the role of the IL-2/STAT5 signalling in metabolic reprogramming, cervical cancer cell lines HeLa and SiHa were treated with 10UI/mL of IL-2 to measure lactate secretion and the expression of HIF-1a, PDK1, GLUT1, and UQCRC1. The role of STAT5 was evaluated by using a shRNA to silence the STAT5 gene in cervical cancer cells. Cell proliferation was evaluated by Cristal violet.

Result and discussion

Our results show that the treatment with IL-2 induces an increase in lactate secretion and the expression of HIF1a, PDK1, GLUT1 and UQCRC1. When STAT5 was silenced, the lactate secretion decreased. Also, the expression of HIF1a, PDK1 and GLUT1 decreased, but the expression of UQCRC1 was not affected. Cervical

cancer cell proliferation was reduced by STAT5 silencing. These results indicate that STAT5 regulates metabolic reprogramming to enhance aerobic glycolysis by regulating genes related to energy metabolism which is important for cell proliferation.

Conclusion

These results suggest that IL-2 regulates glucose conversion into lactate to increase its concentration for intracellular acidification giving cervical cancer cells an advantage in proliferating and migrating. Also, STAT proteins modulate the metabolic switch in cervical cancer cells underlying the enhanced proliferation of these cells. A detailed understanding of the adaptations required downstream of the IL-2/STAT signalling could reveal targetable metabolic vulnerabilities.

EACR25-2587

Cancer associated fibroblasts regulate breast cancer migration through Laminin-511

M. Banerjee¹, R. Bhat¹

¹*Indian Institute of Science, Developmental Biology and Genetics, Bengaluru, India*

Introduction

Although under active investigation, alterations within the tumor microenvironment both causative to and a consequence of tumor progression are only beginning to be better appreciated. Within the tumor microenvironment, fibroblasts play complex multidimensional roles in modulating cancer cell migration (Sahai et al, Nat Rev Cancer, 2020; Labernadie et al, Nat Cell Biol, 2017; Barbazan et al, Nat Commun, 2023). In addition, computational and experimental studies suggest the requirement of a laminin-rich ECM in driving robust multimodal invasion of cancer cells rather than dispersed migration as seen in laminin-depleted setups (Pally et al, Front Physiol, 2019; Chang J et al, Nat Mater, 2024).

Material and method

This led us to hypothesize if cancer associated fibroblasts (CAFs) may remodel the tumor microenvironment through synthesizing an ECM that has biochemical and/or biophysical properties appropriate to facilitating more collective invasive migratory behaviors of cancer cells. To do so, we first standardized protocols for isolating CAFs from breast cancer patient tissues. We began by integrating immortalized and patient-derived primary fibroblasts within histopathologically complex 3D pathotypic models.

Result and discussion

demonstrated that CAFs enhance multimodal breast cancer migration through Collagen I-rich stromal-like spaces to a greater extent than non-cancerous fibroblasts (NFs). We further validated our results in a murine model. This was supported by our observations that the conditioned medium of CAFs could also spur the migration of cancer cells to a greater extent than the medium from normal fibroblasts (NFs). We performed a multilayered screen consisting of bioinformatics, immunocytochemistry and PCR to identify specific laminins that are expressed to greater extents in CAFs: laminin- β 1 and laminin- γ 1. Further investigations also

revealed an increase in breast cancer cells adhesion and migration on laminin-10 (α 5 β 1 γ 1) compared to laminin-1 (α 1 β 1 γ 1), laminin-2 (α 2 β 1 γ 1), and laminin-4 (α 2 β 2 γ 1). Furthermore, genetic perturbations and pharmacological screen revealed laminin-10 mediated cancer cell migration through Integrin α 6 β 1-FAK- Arp2/3 signaling axis.

Conclusion

Our findings reveal a specific correlation between CAFs secreted laminins and breast cancer migration, which we will investigate further for deciphering specific molecular mechanisms in the future.

EACR25-2589

PPP2R2B-derived circRNA in the suppression of ferroptosis in Pancreatic cancer cells

J. Pena Paladines¹, C. Wong¹, S. Wang¹, Y. Chen¹

¹*The Chinese University of Hong Kong, School of Biomedical Sciences, Hong Kong, Hong Kong, China*

Introduction

The limited availability of early-detection biomarkers and the poor response to current treatments have led to a low five-year survival rate of pancreatic ductal adenocarcinoma (PDAC) patients. Recent studies suggest that cancer cells can be susceptible to ferroptosis. However, the role of circular RNAs (circRNAs) in ferroptosis remains largely unexplored in PDAC. Hence, this project aims to identify circRNAs in ferroptosis to uncover further mechanisms and provide potentially effective targets for anti-cancer therapies.

Material and method

CircRNA-sequencing of pancreatic cancer cells after ferroptosis induction was performed, from which circPPP2R2B was selected for further analysis. Several ferroptosis markers were measured after circPPP2R2B knockdown. CircPPP2R2B expression was measured in PDAC cell lines, tumours, and adjacent tissue samples. The potential oncogenic activity was assessed by performing cell viability, migration, and invasion assays after knockdown and overexpression. CircPPP2R2B interacting proteins were investigated by performing mass spectrometry after a pull-down assay, while its downstream targets were identified by mRNA sequencing after its knockdown.

Result and discussion

The knockdown of circPPP2R2B showed higher levels of positive ferroptosis markers. CircPPP2R2B was up-regulated in PDAC cells and tumour tissues (p-value < 0.01), where patients with higher expression had a median overall survival (OS) of 7 months less than those with lower expression. Upregulation of circPPP2R2B was also observed in the serum of PDAC patients compared to healthy individuals. The loss of circPPP2R2B decreased the proliferation rate, migration, and invasiveness of PDAC cells, while its overexpression increased the IC50 of gemcitabine. The mRNA-sequencing data showed that PD-L1 was downregulated after circPPP2R2B knockdown and that circPPP2R2B interacts with proteins of the cohesin complex to potentially regulate PD-L1 expression.

Conclusion

CircPPP2R2B downregulation in pancreatic cancer cells undergoing ferroptosis indicates that its low levels are required for ferroptosis. The lower viability, migration, and invasion ability after circPPP2R2B knockdown shows it supports PDAC progression. Additionally, the increased IC₅₀ of gemcitabine after circPPP2R2B over-expression suggests its involvement in the resistance to this drug. By regulating the expression of PD-L1, a ligand suppressing the anti-cancer immune response, circPPP2R2B could be playing a critical role in the regulation of the tumour immune microenvironment.

EACR25-2598

Age-specific factors determine brain metastasis growth and immunotherapy response

C. Russell¹, S. Gurung¹, S. Sadoo¹, K. Simpson², C. Dive², C. Gaudy-Marqueste³, A. Viros¹

¹*Cancer Research UK Manchester Institute, Skin Cancer and Ageing, Manchester, United Kingdom*

²*Cancer Research UK Manchester Institute, National Biomarker Center, Manchester, United Kingdom*

³*Aix Marseille University, Dermatology, Marseille, France*

Introduction

Cutaneous melanoma is one of the most common cancers to metastasise to the brain. Melanoma cells that seed the brain and establish brain metastases (MBM) are characterised by a high OXPHOS metabolism and a highly invasive phenotype that destroys tissue locally and leads to mortality, primarily due to local symptoms and complications. One striking epidemiological hallmark is the median age of stage IV metastatic melanoma patients who develop MBM, which is 55 years. In contrast, the median age of patients with extracranial metastases is significantly higher at 78 years.

Material and method

We used metabolomics, lipidomics, bulk and spatial transcriptomics to discover key differences between young and aged brains that support distinct MBM behaviour and IT response by age.

Result and discussion

We studied whether factors in the primary cutaneous melanoma tumour microenvironment (TME) differ by age; and whether local cutaneous TME factors promote intracranial vs extracranial metastatic spread. We found ceramides, a lipid family that accumulates in aged skin, delayed brain metastatic seeding and promoted the rapid progression to liver metastasis. In contrast, lipids in young skin are permissive of MBM development. We next investigated whether brain-specific factors differ by age and contribute to greater melanoma cell growth. We used orthotopic brain melanoma models in immuno-competent animals to show that melanoma cells have distinct growth patterns in brains of different aged hosts. Melanoma cells that seed the young brain develop the classic hallmarks of MBM: a highly invasive phenotype, rapid growth, a switch to OXPHOS metabolism and activation of the PI3K/AKT signalling pathway. In contrast, the aged brain is less fertile for MBM to grow and presents a unique tumour immune cell landscape. Furthermore, we found the age of the brain impacts the

response to immunotherapy. Critically, we show that age-specific factors similarly impact the development and immunotherapy response of triple negative breast cancer and glioblastoma, which are also more likely to metastasise or develop in the brain of younger patients.

Conclusion

Our study shows the soil-specific brain factors that impact metastatic tumour growth and immunotherapy response by age.

Cancer Genomics

EACR25-0001

Genomic and single-cell characterization of patient-derived tumor organoid models of head and neck squamous cell carcinoma

Y. Park¹

¹*Yonsei University, Otorhinolaryngology, Seoul, Korea (Republic of)*

Introduction

Head and Neck Squamous Cell Carcinoma (HNSCC) remains a significant health burden due to tumor heterogeneity and treatment resistance, emphasizing the need for improved biological understanding and tailored therapies.

Material and method

While these recent important efforts in PDOs have greatly advanced the investigation of HNSCC precision medicine and predictive biomarker development, several key questions remain to be addressed: to what extent can PDOs model histopathology, drug responsiveness and mutational profiles of parental tumor specimens?

Relatedly, how does long term culture affect the biology and genomic stability of PDOs? Moreover, considering the high intratumor heterogeneity of HNSCC, single-cell transcriptomic profiling is required to further delineate gene regulatory network and cellular states within the PDOs. This study is designed to address these important questions by multi-omic, single-cell genomic and functional analyses of both primary tumors and matched PDO models maintained for various durations ex vivo

Result and discussion

This study enrolled 31 HNSCC patients for the establishment of patient-derived tumor organoids (PDOs), which faithfully maintained genomic features and histopathological traits of primary tumors. Long-term culture preserved key characteristics, affirming PDOs as robust representative models. PDOs demonstrated predictive capability for cisplatin treatment responses, correlating ex vivo drug sensitivity with patient outcomes. Bulk and single-cell RNA sequencing unveiled molecular subtypes and intratumor heterogeneity (ITH) in PDOs, paralleling patient tumors. We performed non-negative matrix factorization (NMF) to identify gene modules as described previously. This integrative computational approach attempts to alleviate the impact of both technical confounders (e.g., batch effects) and patient-specific characteristics, which often hinder the goal of

identifying common expression programs across different patient tumors. As a result, we identified eight clusters of recurrent gene modules across individual PDOs. Notably, a hybrid epithelial-mesenchymal transition (hEMT)-like ITH program is associated with cisplatin resistance and poor patient survival. Functional analyses identified amphiregulin (AREG) as a potential regulator of the hybrid epithelial/mesenchymal state. Moreover, AREG contributes to cisplatin resistance via EGFR pathway activation, corroborated by clinical samples.

Conclusion

In summary, HNSCC PDOs serve as reliable and versatile models, offer predictive insights into ITH programs and treatment responses, and uncover potential therapeutic targets for personalized medicine.

EACR25-0013

Genes that affect DNA repair and calcium metabolism predispose to Malignant Mesothelioma

F. Novelli¹, Y. Yoshikawa¹, V. Vitto², L. Modesti², S. Pastorino¹, E. Mitsuru¹, C. Giorgi², P. Pinton², H. Yang¹, M. Carbone¹

¹*University of Hawaii Cancer Center, Cancer Biology, Honolulu, United States*

²*University of Ferrara, Department of Medical Sciences, Laboratory for Technologies of Advanced Therapies, Ferrara, Italy*

Introduction

Mesothelioma, an aggressive cancer often caused by exposure to asbestos, is one of the malignancies currently seen with increasing frequency in younger patients. We have sequenced and analyzed the DNA of 61 patients who developed mesothelioma at young age (<55 y old) and who had no evidence of asbestos exposure. We discovered that ~1.8% of all mesothelioma patients and 4.9% of those younger than 55, carry rare pathogenic germline variants of the BRCA1 associated RING domain 1 (BARD1) gene.

Material and method

Cell cultures Human dermal skin fibroblasts from explants of skin biopsies were collected, as previously described (Bononi et al 2017) from BARD1WT and BARD1 mutant carriers. Fibroblasts were cultured in Dulbecco modified Eagle's medium (DMEM) (Corning Cellgro, #10-017-CV), supplemented with 10% fetal bovine serum (FBS) (Seradigm, #1500-500), and 1% penicillin-streptomycin (PS) (Life Technologies, #15140-163). Primary human mesothelial cells (HM) were derived from pleural fluids accumulated in individuals with congestive heart failure and cultured in DMEM with 20% FBS and 1% penicillin-streptomycin (PS). PBMCs were collected from BARD1WT and BARD1 mutant carriers. Gene Silencing with siRNA siRNA oligonucleotides were obtained from Qiagen. GeneSoluton siRNAs targeting four different BARD1 mRNAs were as follows: Hs_BARD1_2, (cat.no. 1027415, D: SI00010136); Hs_BARD1_3, (cat.no. 1027415, ID: SI00010143); Hs_BAP1_9, (cat.no. 1027415, ID: SI05103847); Hs_BAP1_10, (cat.no. 1027415, ID: SI0-5103854). A nonspecific control siRNA was used as a negative control (cat. no. 1027280). Transfection was performed with HiPerfect (Qiagen) for

24 hours. Western Blot: Total cell lysates were prepared in M-PER (Thermo Scientific, cat.no. 78501) reagent supplemented with proteases and phosphatases inhibitors (2mM Na3VO4, 2mM NaF, 50nM okadaic acid, 1mM PMSF and protease inhibitor cocktail) and 1mM DTT. 10 µg of protein were loaded and separated on NuPAGE Novex 4–12% Bis-Tris Gel (Life Technologies), and electron-transferred to PVDF according to standard procedures.

Result and discussion

We performed functional assays in primary fibroblasts obtained from a patient carrying a heterozygous BARD1 mutation. We found that these cells had genomic instability, reduced DNA repair, and impaired apoptosis. Studying underlying signaling pathways, we found that BARD1 interacts with p53 and SERCA2 modulating calcium signaling and apoptosis.

Conclusion

Our study elucidated mechanisms of BARD1 activity and revealed that heterozygous germline BARD1 mutations favor mesothelioma development in young patients and increase the susceptibility to asbestos carcinogenesis. These mesotheliomas are significantly less aggressive compared to asbestos-caused mesotheliomas. These patients experience significantly prolonged survival up to 20+ y and they require tailored screening and personalized therapeutic approaches.

EACR25-0024

The expression and clinical significance of serum exosomes miR-122 and miR-874 in patients with colorectal cancer

Y. Wang¹

¹*Chongqing Three Gorges Medical College Affiliated People's Hospital, Colorectal and anal surgery department, Chongqing, China*

Introduction

To investigate the expression levels of miR-122 and miR-874 in serum exosomes of patients with colorectal cancer (CRC) and their clinical significance.

Material and method

140 patients with colorectal cancer treated in our hospital from January 2020 to January 2022 were selected as observation group, and 90 healthy subjects were selected as control group. The expression of serum exosomes miR-122 and miR-874 was detected by qRT-PCR, and the relationship between the expression and clinicopathological features of CRC was analyzed. The optimal cut-off value of serum exosome miR-122 and miR-874 in predicting the prognosis of CRC was determined by receiver operating characteristic (ROC) curve. According to this value, patients in the observation group were divided into low expression group and high expression group. After 2 years of follow-up, Kaplan-Meier curves were drawn to analyze the relationship between the expression of serum exosomes miR-122 and miR-874 and overall survival (OS) and disease-free survival (DFS).

Result and discussion

The expression of miR-122 in serum exosomes in observation group was higher than that in control group, and the expression of miR-874 was lower than that in healthy group ($P < 0.05$). The expression of serum

exosome miR-122 was positively correlated with infiltration depth, TNM stage, lesion diameter, differentiation degree, and lymph node metastasis status in colorectal cancer patients ($r > 0$, $P < 0.05$), while the expression of miR-874 was negatively correlated with the above pathological characteristics ($r < 0$, $P < 0.05$). In the observation group, the 2-year OS was 72.86% and DFS was 61.43%. In the miR-122 overexpression group, the OS and DFS were 15.39 months (95% CI: 13.078-17.941) and 17.09 months (95% CI: 14.743-18.012) respectively. The results were lower than those in the low-expression group at 17.78 months (95% CI: 15.78-18.46) and 20.09 months (95% CI: 17.378-21.098) ($P < 0.05$). In the group with low expression of miR-874, the OS was 16.209 months (95% CI: 14.189-18.067) and DFS was 18.026 months (95% CI: 16.801-20.109). The results were lower than those in the highly expressed miR-874 group at 19.230 months (95% CI: 17.902-21.026) and 22.035 months (95% CI: 19.830-23.089), respectively ($P < 0.05$).

Conclusion

The expression of serum exosome miR-122 is high and miR-874 is low in patients with colorectal cancer, and the expression levels of both are related to the clinicopathological features and survival time of patients.

EACR25-0190

Expression of APOC3 in human colon cancer, the clinical and therapeutic value

C. Wang¹, A. Li¹, M. McKenna¹, Z. Xu¹, E. Khan², Q. Dou², J. Zeng¹, T. Martin¹, R. Hargest¹, W. Jiang¹

¹CCMRC, Cardiff University School of Medicine, Cardiff, United Kingdom

²Karmanos Cancer Institute, Wayne State University, Detroit, United States

Introduction

The APOC3 gene is located on 11q23.3 which is close to a region that frequently aberrant in breast cancer and encodes apolipoprotein-CIII (APOC3), a protein known to regulate the metabolism of triglycerides and involved in coronary heart diseases. APOC3 is highly expressed in the liver and in small intestines. Loss of heterozygosity (LOH) of the APOC3 gene has been found to have a possible association with disease progression in certain cancers including liver hepatocellular carcinoma. The present study aimed to determine the clinical value of the APOC3 gene transcript expression in human colon cancer.

Material and method

Expression of The APOC3 gene transcript was quantitatively analysed in a cohort of human colon cancer with matched normal colon tissues. Survival analysis was carried out using the Kaplan-Meier survival model for overall, disease free and distant metastasis outcomes. Comparisons were made against clinical and pathological factors and status of the ERBB family members.

Result and discussion

Colon cancer tissues expressed markedly higher levels of APOC3 transcript than normal tissues ($p < 0.00001$). High levels of APOC3 in colon cancer resulted in significantly shortened overall survival (OS) ($p = 0.031$, Hazard ratio (HR = 2.718 (95% CI 1.056-6.997)),

significantly shortened disease free survival (DFS) ($p = 0.011$, HR = 3.171 (95% CI. 1.243-8.086)). It was very interesting to note that the connection between APOC3 expression and OS and DFS largely existed in patients with Her2 positive tumours, namely DFS in Her2 negative ($p = 0.331$) and Her2 positive ($p = 0.012$) when comparing APOC3 high and low expressing groups. The same observation was seen when EGFR (ERBB1) and Her4 (ERBB4) were taken into consideration. In the multifactorial analysis against clinical factors including tumour grade, TNM staging, Dukes staging, ERBB family members and APOC3 expression, APOC3 was the only significant independent factor correlated with DFS. To further establish the clinical value of APOC3 in colon cancer, we also explored the TCGA database and found that APOC3 high levels were associated with resistance to chemotherapies ($p = 0.0016$ when comparing patients who were sensitive and who were resisted to the treatment). This connection was particularly strong for those receiving Capecitabine and Fluoropyrimidines, but not for 5-FU, Oxaliplatin nor Irinotecan.

Conclusion

The present study is the first report of the clinical connection between APOC3 and clinical colon cancer, which shows that high expression levels of APOC3 is an indicator for patient survival and response to chemotherapies. APOC3 thus has an important clinical and therapeutic value in colon cancer and constitutes a valuable therapeutic target.

EACR25-0193

Paired scRNA/TCRseq meta-analysis of T cells reveals clonal dynamics of response to checkpoint immunotherapy

O. Shorer¹, A. Pinhasi¹, K. Yizhak¹

¹Technion - Israel Institute of Technology, Department of Cell Biology and Cancer Science, Haifa, Israel

Introduction

T-cell clones play a crucial role in the anti-tumor activity of cancer patients treated with checkpoint immunotherapy. However, their characterization and association with clinical outcome remain insufficiently understood. Studying response mechanisms of T-cell clones could therefore reveal important factors driving therapy effectiveness or resistance.

Material and method

We performed a single-cell meta-analysis using paired RNA-sequencing/T-cell receptor sequencing of 767,606 T cells from 460 samples spanning 6 cancer types. This approach enabled us to analyze transcriptional and clonal dynamics in patients undergoing checkpoint immunotherapy.

Result and discussion

We identified a robust signature of expanded CD8+ clones that differentiates responders from non-responders. Analysis of persistent clones revealed therapy-induced transcriptional changes, suggesting an improved reinvigoration capacity in responding patients. A gene-trajectory analysis demonstrated changes in the pseudo-temporal state of de-novo clones that are associated with clinical outcome. Lastly, we found that clones shared between tumor and blood are more

abundant in non-responders and execute distinct transcriptional programs.

Conclusion

Our results highlight differences in clonal transcriptional states that are linked to patient response. They provide insights into cellular factors associated with effective anti-tumor immunity, suggesting biomarkers and potential therapeutic targets for monitoring and enhancing therapy efficacy.

EACR25-0241

Genome-wide CRISPR Screening in Embryonic Stem Cells Identifies Synthetic Lethality Interactions in MLH1 and TP53 Deficient Tumors

R. Cashman¹, G. Haim-Abadi², E. Lezmi², H. Philip¹, J. Nissenbaum¹, R. Viner-Breuer¹, T. Golan-Lev², A. Gadban², O. Kopper¹, N. Benvenisty²

¹NewStem LTD, NewStem LTD, Jerusalem, Israel

²The Hebrew University, Genetics, Jerusalem, Israel

Introduction

The genetic complexity and clonal heterogeneity of malignant tumors is a major challenge in the field of cancer therapeutics. A potentially useful tool in personalized oncology is synthetic lethality, a phenomenon where the combination of two genetic alterations leads to cell death, while each of them separately does not.

Material and method

We aimed to identify genetic mutations that have synthetic lethal interactions with either MLH1, involved in DNA mismatch-repair and is commonly mutated in certain types of cancers, or TP53, the most frequently mutated gene in cancer. We thus performed genome-wide CRISPR-Cas9 loss-of-function (LoF) screens in haploid human embryonic stem cells (hESCs) with or without a mutation in the MLH1 or TP53 genes. This screen, targeting all protein-coding genes, allowed us to identify genetic interactions that can lead to cell death in tumors harboring a mutation in MLH1 or TP53.

Result and discussion

The analysis revealed a list of potential hits with EXO1, NR5A2, and PLK2 genes for MLH1, and MYH10 gene for TP53 emerging as the most promising candidate genes. The synthetic lethality effects of these genes were validated either genetically or chemically using small molecule inhibitors. We further validated the effects of SR1848 (which inhibits NR5A2), ON1231320 or BI2536 (which inhibit PLK2), and blebbistatin (which inhibits MYH10) in cancer cell lines with and without LoF mutations in MLH1 or TP53. The selective effect of the small molecule BI2536 on MLH1-null tumors and of blebbistatin on TP53-mutated tumors was further validated in-vivo using animal studies with cancer cell lines xenografts.

Conclusion

Overall, our findings show the potential of genetic screening in haploid hESCs in identifying selective inhibitors and therefore advancing the realm of cancer precision medicine.

EACR25-0270

Characterizing Circulating Tumor Cell and containing Cancer Stem Cell Heterogeneity in Pancreatic Adenocarcinoma: A Single Cell Perspective

B. Sabanovic¹, S. Huang², L. Alessandri², C. Reina¹, C. Heeschen¹

¹Candiolo Cancer Institute - FPO - IRCCS, Pancreatic Cancer Heterogeneity, Candiolo, Italy

²University of Torino, Department of Molecular Biotechnology and Health Sciences, Turin, Italy

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer characterized by extensive inter and intratumoral heterogeneity, driving therapy resistance and metastasis. Among the key subpopulations contributing to tumor progression and relapse are circulating tumor cells (CTCs) and contained cancer stem cells (CSCs). CTCs, which detach from primary and metastatic lesions into the bloodstream, serve as a valuable liquid biopsy tool, providing real time insights into tumor diversity and evolution. As intact tumor derived cells, they offer a unique opportunity for comprehensive molecular profiling. CSCs, another rare but critical subpopulation, play a pivotal role in tumor initiation and metastasis, further contributing to PDAC's refractory nature. Recent advances in single cell transcriptomics and microfluidic technologies for isolation have enabled high resolution characterization of these rare cells, paving the way for novel biomarker discovery and targeted therapeutic strategies.

Material and method

CTCs and CSCs were isolated from PDAC patient blood samples using the Parsortix microfluidic platform. Cells were stained with antibodies against CAPRIN1 (cancer marker), CXCR4 (stemness marker), CD45 (leukocyte exclusion), and DAPI (nuclear stain). Single cells were selected via CellCeptor and subjected to transcriptomic profiling. Libraries were prepared using FLASHseq and sequenced on an Illumina NovaSeq X platform (150 bp paired end).

Result and discussion

Single cell transcriptomic analysis identified genes enriched in rare subpopulations with stemness features. Candidate genes were prioritized based on expression levels, public datasets, and literature evidence of involvement in PDAC progression, metastasis, and therapy resistance. qPCR validated candidate gene expression in CTC derived cultures under adherent and spheroid conditions. Functional characterization via siRNA mediated silencing revealed their impact on migration, invasiveness, and proliferation. The most promising candidates will undergo in vivo validation.

Conclusion

We established an effective approach for isolating and profiling of CTCs and CSCs at the single cell level, unveiling distinct molecular features associated with PDAC aggressiveness. Identified candidates may serve as novel biomarkers or therapeutic targets, paving the way for improved precision medicine strategies in PDAC.

EACR25-0314**Comparative analysis of genomic and clinicopathologic characteristics between multifocal and unifocal breast cancer patients by whole-exome sequencing***C. Kim¹, T. Jeon¹*¹*Korea University College of Medicine, Pathology, Seoul, Korea (Republic of)***Introduction**

Multifocal breast cancers (MFBCs) are associated with a higher risk of lymph node metastasis and poorer prognosis compared to unifocal breast cancers (UFBCs). However, there is a lack of comprehensive studies comparing their clinicopathologic and genomic characteristics. This study aims to analyze the differences between MFBCs and UFBCs using whole-exome sequencing (WES) to identify genetic mutations related to tumor invasiveness and progression.

Material and method

A total of 47 breast cancer patients (30 UFBC, 17 MFBC) who underwent surgery in 2018 were selected. Histologic and immunohistochemical characteristics (ER, PR, HER2, Ki-67) were compared between the two groups. WES was performed on tumor tissues, and genetic mutations were identified using variant calling and annotation tools. Clinicopathologic variables, including tumor grade, lymph node metastasis, and hormone receptor status, were statistically analyzed.

Result and discussion

MFBCs exhibited a higher histologic grade, increased HER2 positivity, and a higher proliferation rate than UFBCs. The average age at diagnosis was lower in MFBC patients, and they were more frequently associated with HER2 and triple-negative (TN) subtypes. WES analysis revealed that MFBCs had mutations commonly found in aggressive subtypes, including ERBB2, ERBB3, FGFR4, ZFHX3, and ROS1, which are associated with tumor proliferation and migration. In contrast, UFBCs showed mutations in PIK3CA, FOXA1, and NCOR2, which are more common in hormone receptor-positive tumors. Copy number alterations in MFBCs were more homogeneous within individual patients, suggesting a common clonal origin for multifocal lesions.

Conclusion

This study highlights the distinct clinicopathologic and genomic profiles of MFBCs compared to UFBCs. The findings suggest that MFBCs exhibit genetic alterations that contribute to aggressive tumor behavior and a higher risk of metastasis. The results emphasize the need for personalized treatment strategies that account for the unique molecular characteristics of MFBCs. Further studies with larger cohorts are necessary to validate these findings and improve clinical decision-making for breast cancer management.

EACR25-0317**The use of ultra-low-pass sequencing data to classify tumors' molecular deficiencies***S. Naky¹, Y. Maruvka¹, C. Hawkins², U. Tabori³, L. Negm⁴, R. Yuditskiy⁴*¹*Technion, Biotechnology and Food Engineering, Haifa, Israel*²*SickKids Research Institute, Laboratory Medicine and Pathobiology, Toronto, Canada*³*SickKids Research Institute, Haematology/Oncology, Toronto, Canada*⁴*SickKids Research Institute, Arthur and Sonia Labatt Brain Tumour Research Centre, Toronto, Canada***Introduction**

Genomic instability and hypermutation play a crucial role in tumor development and response to therapy. Two key drivers of these traits are Polymerase Proofreading Deficiency (PPD) and Homologous Recombination Deficiency (HRD), respectively. PPD arises from mutations in DNA polymerase genes, while HRD results from defects in DNA repair pathways, particularly in BRCA1/2 and associated genes. Detecting these deficiencies is essential for patient stratification and targeted treatment. The Low-Pass Genomic Instability Consortium (LOGIC) assembly was employed to develop a computational framework for identifying PPD and HRD from genomic data, leveraging mutational patterns and genome instability scores.

Material and method

To detect PPD, we analyzed somatic mutation profiles using whole-genome sequencing data. We looked into the known distinct mutational patterns associated with POLE/POLD1 deficiency. Our approach utilized meticulous noise filtration and normalization of each pattern by the frequency of each trinucleotide. For HRD detection, we implemented a workflow incorporating loss-of-heterozygosity (LOH), telomeric allelic imbalance (TAI), and large-scale state transitions (LST) scores. These features were derived from Sequenza-based copy number segmentation. The LOGIC assembly was optimized to compute these scores efficiently from low-pass sequencing data, ensuring applicability in clinical and research settings. We validated our approach using known BRCA-deficient tumor samples and compared the performance with existing HRD detection tools.

Result and discussion

Our analysis successfully identified PPD tumors exhibiting high mutational burden and distinct mutational patterns. Our method achieved high sensitivity and specificity in distinguishing PPD tumors from PPD normals and PP-proficient tumor/normal samples (AUROC = 0.9985). For HRD detection, our genome instability scores showed strong concordance with established HRD classifiers, effectively separating BRCA-mutant from BRCA-wildtype tumors (AUROC = 0.874). The integration of TAI, LOH, and LST provided a robust measure of HRD-associated genomic instability. Additionally, LOGIC's low-pass sequencing adaptation retained predictive power while reducing sequencing costs, making HRD testing more accessible.

Conclusion

We present a computational approach for detecting PPD and HRD using the LOGIC assembly. By leveraging mutational patterns and genome-wide instability metrics, our method provides a reliable framework for identifying these genomic deficiencies. The ability to infer HRD and

PPD from low-pass sequencing enhances their clinical applicability. Future work will focus on expanding validation datasets and refining models for lower quality samples (Formalin-Fixed, Paraffin-Embedded, or FFPE).

EACR25-0336

Spatiotemporal multi-omics uncover tumor ecosystem dynamics driving metastatic colonization

L. Wu¹

¹The Institute of Precision Health Research, BGI Research, Chongqing/Shenzhen, China

Introduction

The mechanisms underlying the interaction between disseminated tumor cells (DTCs) and their tissue microenvironment during metastasis colonization are poorly understood.

Material and method

We integrated multimodal single-cell and spatial profiling from liver cancer mouse models and human metastases to track the spatiotemporal dynamics of DTCs and their microenvironments across nine sequential time points from single-cell seeding until overt lung metastasis.

Result and discussion

We identified a residual population of quiescent Phgdhhigh DTCs that survive initial innate immune clearance and become transiently enriched in micro-metastases. These cells shape an immune-scarce microenvironment through PHGDH-dependent, H3K27me3-mediated epigenetic silencing of chemokine transcription, promoting metastatic expansion. Cx3cr1high interstitial macrophages were also found to be transiently enriched before DTCs expansion, creating an immune-privileged niche for metastatic outgrowth by recruiting immunosuppressive cells. Inactivating the Phgdh-H3K27me3 axis in DTCs or depleting interstitial macrophages restored immune surveillance and inhibited metastatic colonization. These findings provide new therapeutic concepts for developing micrometastasis-targeting regimens.

Conclusion

In summary, an integrated analysis of this atlas coupled with additional multi-omics data from human patients and *in vitro*, *ex vivo*, *in vivo* validation assays identified key cellular programs transiently activated in disseminated tumor cells (DTCs) or in immune cells that promote metastatic seeding by building an immune-compromised microenvironment. Our results shed light on the spatial and temporal complexity of metastatic colonization, laying a foundation for elucidation of the pathogenic mechanisms and therapeutic vulnerabilities of cancer metastases.

EACR25-0382

Machine learning-derived mutational signatures reveal distinct DNA repair pathway dysregulation and clinical outcomes in BRCA1/2 ovarian cancer

I. Funingana¹, J. Ambrose², P. Smith¹, T. Bradley¹, L. Porcu¹, M. Crispin-Ortuzar³, A. Sosinsky², J. Brenton⁴

¹University of Cambridge, CRUK Cambridge Institute, Cambridge, United Kingdom

²Genomics England, London, United Kingdom

³University of Cambridge, CRUK Cambridge Centre, Cambridge, United Kingdom

⁴University of Cambridge, CRUK Cambridge Institute, United Kingdom

Introduction

DNA signatures reflecting underlying mutational processes are key for precision medicine, especially in chromosomally unstable cancers (CIN). Cancers with homologous recombination deficiency (HRD) utilize diverse DNA double-strand break (DSB) repair pathways with specific genomic features, including micro-homologies (MH). However supervised methods (e.g. non-negative matrix factorisation) are insensitive to these patterns and may miss clinically important associations between mutation contexts and active DSB pathways and do not predict treatment. We reasoned that explainable cross-modal factor analysis (MOFA) could improve mechanistic associations from WGS data to develop improved clinical biomarkers.

Material and method

Cross-mutational process factor analysis was applied to 483 high-grade ovarian carcinoma (HGOC) deep whole-genome sequencing (WGS) samples from the National Research Genomic Library. Mutation contexts for single base substitutions (SBS), double base substitutions (DBS), small indels, structural variants (SVs) were extracted. A MOFA model with 15 factors was fitted. Factors were compared with clinical parameters (survival status, histotypes [high-grade serous carcinoma [HGSC], clear-cell carcinoma [OCCC], platinum response, sample type], key gene statuses and key COSMIC version 3.4 signatures.

Result and discussion

MOFA uncovered latent factors for multiple clinical and biological features. We identified a factor that distinguishes between Polθ-mediated end-joining (TMEJ) and classical non-homologous end-joining (NHEJ) based on deletion patterns with MH (positive weights for deletions with ≥ 2 bp MH). This factor strongly correlated with alterations in BRCA2, RB1, and MYC, moderately correlated with BRCA1 mutations, and significantly predicted improved survival outcomes ($HR < 1$, $p < 0.05$). In contrast, another factor identified samples with NHEJ/microhomology-mediated break-induced replication (MMBIR) activities and was the composite of small/medium tandem duplications with shorter MH lengths. It positively correlated with BRCA1 deficiency and negatively with BRCA2 deficiency, displaying a trend towards poorer overall survival ($HR > 1$, $p > 0.05$).

Conclusion

MOFA frameworks provide high resolving power for technical, biological, and clinical variability from clinically available WGS data. Cross-modal integration confirmed two distinct error-prone repair phenotypes in HGSC. TMEJ-like correlates with BRCA2 deficiency and better prognosis, whereas NHEJ/MMBIR-like is tied to BRCA1 deficiency and worse outcomes. We are now designing protocols to test how these findings predict treatment efficacy and outcomes in patients in the DENOVA trials framework.

EACR25-0388**Single-cell analysis reveals tumor-driven immune microenvironment reprogramming that promotes lung adenocarcinoma metastasis**

H. Zhang¹, A. Liu¹, P. Sun¹, W. Gong¹, L. Zhao¹, X. Li², T. Li², K. Mo²

¹*Department of Oncology, Yantai Yuhuangding Hospital of Qingdao University, Yan Tai, China*

²*Department of Basic Science, YuanDong International Academy Of Life Sciences, Hong Kong, China*

Introduction

As the leading cause of cancer-related mortality worldwide, the dismal prognosis of lung adenocarcinoma (LUAD) primarily stems from tumor metastasis and recurrence. To address this clinical challenge, our study systematically investigated the molecular mechanisms underlying LUAD invasion and metastasis through single-cell multiomics approaches, with particular emphasis on deciphering the composition and function of different cell populations in the tumor immune microenvironment.

Material and method

Based on data from the GEO database and the Human Cancer Atlas Network database, LUAD single-cell RNA sequencing data was downloaded and standardized for quality control. Various bioinformatics approaches, including cell clustering analysis, survival analysis, enrichment analysis, single-cell trajectory analysis, and cell-cell communication analysis, were employed to investigate how tumor cells in primary and metastatic LUAD lesions influence the tumor immune microenvironment. These analyses provide insights into the mechanisms by which tumor cells create a favorable niche for survival and progression during LUAD metastasis.

Result and discussion

This study constructs a comprehensive single-cell landscape of primary LUAD and metastatic LUAD primary lesions, identifying key cellular subsets involved in tumor progression. Notably, the IGF2BP1⁺ HOXA7⁺ double-positive LUAD subset was found to activate tight junction signaling pathways, promoting LUAD cell migration. Additionally, analysis of immune cell populations revealed that CD8⁺ T cell subsets exhibited an exhausted phenotype, characterized by the expression of exhaustion-related genes and a significant reduction in immunocytotoxic function. Furthermore, abnormal immunosuppressive phenotypes were observed in CD4⁺ T cells and natural killer T cell subsets. These findings suggest that LUAD cells actively reprogram the tumor immune microenvironment within the primary metastatic site, establishing conditions that facilitate tumor survival and metastatic progression.

Conclusion

This study offers a comprehensive perspective on LUAD and its immune landscape, uncovering novel mechanisms of LUAD progression from a unique standpoint. By providing a valuable resource for identifying actionable targets in LUAD research and treatment, this work lays a

strong theoretical foundation for the clinical diagnosis and therapeutic strategies of LUAD.

EACR25-0429**Whole-genome CRISPR-Cas9 screens identify SHOC2 as a genetic dependency in NRAS-mutant melanoma**

A. Gu^{1,2}, T. Lee^{1,3}, A. Khan¹, F. Hunter^{1,3,4}, D. Singleton^{1,3}, S. Jamieson^{1,5,6}

⁴*Janssen Research & Development, PA, United States*

⁵*Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand, University of Auckland*

⁶*Department of Pharmacology and Clinical Pharmacology, Auckland, New Zealand,*

Introduction

Melanoma is the most lethal form of skin cancer, with over 300,000 new cases worldwide every year. In particular, melanoma with NRAS mutations presents a significant clinical challenge due to its association with poor prognosis and the lack of specific treatment options. This highlights the urgent need for novel therapeutic strategies to address NRAS-mutant melanoma. A current approach to identify novel drug targets is based on the genetic concept of induced essentiality, where functional interactions that occur in response to oncogene addiction create a dependency on another gene.

Material and method

Whole-genome CRISPR-Cas9 knockout screens were conducted in 6 NRAS-mutant and 7 NRAS-wildtype melanoma cell lines that were derived from New Zealand melanoma (NZM) patients. These NZM cell lines were stably transduced with the whole-genome Brunello lentiviral single guide (sg) RNA library and screened for up to 35 days. In addition to the NZM whole-genome knockout screens, CRISPR-Cas9 screening data using the Avana sgRNA library from an additional 54 melanoma cell lines, available on the Cancer Cell Line Encyclopaedia (CCLE) database, were analysed using the BAGEL (Bayesian Analysis of Gene Essentiality) program.

Result and discussion

Comparative analysis between the NRAS-mutant and NRAS-wildtype cell lines revealed NRAS and SHOC2 as the top candidates which exhibit greater detrimental effects on the fitness of NRAS-mutant cell lines compared to the NRAS-wildtype cell lines. Further validation through in vitro individual gene knockout studies demonstrated that knockout of SHOC2, a scaffold protein essential for activation of the MAPK signalling pathway, results in the prevention of ERK phosphorylation and a more substantial reduction in cell proliferation in NRAS-mutant NZM cell lines when compared to NRAS-wildtype cell lines.

Conclusion

Our findings support previous studies that have identified SHOC2 as a potential therapeutic target for RAS-driven cancers and suggest that targeting of SHOC2 may have

utility in NRAS-mutant melanoma, where greater treatment options are urgently needed.

EACR25-0437

Molecular Evolution of Driver Mutations in Cancer with Microsatellite Instability and Their Impact on Tumor Progression: Implications for Precision Medicine in Patients with UCEC

J. Sheu¹, K. Sriramadasua¹, S. Ravichandran²,

T. Hwang¹

¹National Sun Yat-sen University, Institute of Biomedical Sciences, Kaohsiung, Taiwan

²University of Alabama at Birmingham, Department of Dermatology, Birmingham, United States

Introduction

Cancer development involves genetic alterations, particularly cancer driver mutations (CDMs), linked to aggressive phenotypes and shorter survival. In contrast, higher mutation loads from mismatch repair deficiency (MMRD) can enhance anti-cancer immunity, leading to tumor shrinkage and improved responses to checkpoint blockade therapies. However, understanding how CDMs and MMRD, influence cancer evolution remains limited.

Material and method

Datasets for ovarian serous cystadenocarcinoma (OVCA), cervical squamous cell carcinoma (CSCC), and uterine corpus endometrial carcinoma (UCEC) were sourced from The Cancer Genome Atlas (TCGA) and the Clinical Proteomic Tumor Analysis Consortium (CPTAC). As CSCC data was unavailable in CPTAC, its analysis relied solely on TCGA. From the OncoKB database, 682 genes were evaluated, of which 297 were identified as driver oncogenes. The analysis was restricted to oncogenes with mutation frequencies greater than 10% in OVCA, CSCC, and UCEC. Mutation counts per patient were calculated, and UCEC patients were categorized into two groups: those with mutation counts above 200 and those with fewer than 200. We selected a panel of UCEC cell lines with different microsatellite instability (MSI) statuses for drug efficacy testing using data from GDSC, CCLE, gCSI, and CTRPv2 databases. Drug efficacy metrics included Area Under the Curve (AAC), Half Maximal Inhibitory Concentration (IC50), and Drug Sensitivity Score (DSS1).

Result and discussion

We opted uterine corpus endometrial carcinoma (UCEC) due to its microsatellite instability (MSI) classification. Somatic mutation screening revealed that UCEC has a significantly higher rate of CDMs compared to ovarian cancer (OVCA) and cervical squamous cell carcinoma (CSCC), despite these cancers arising from histologically related organs in the reproductive tract. Interestingly, these CDMs did not necessarily drive progression. Using a mutation count (MC) cutoff of 200, we classified UCEC patients into two groups with distinct clinical features, genetic profiles, and drug sensitivities. Among the known CDMs, TP53 mutations and their functional networks emerged as key drivers in UCEC progression, while mutations in CTNNB1, PTEN, and ARID1A, may enhance anti-tumor immunity, correlating with longer overall survival. Drug screening using GDSC and

CTRPv2 databases suggested that GSK-3 inhibitor IX might be effective for aggressive UCEC patients with a non-MSI phenotype. Curcumin showed efficacy for MSI-UCEC patients, especially with immune checkpoint blockade therapy.

Conclusion

Our study highlights the importance of immune regulation and tolerance over CDMs in cancer development, particularly in those with an MSI phenotype. We propose that mutation count (MC) could serve as a valuable screening method alongside molecular and histopathological classifications to guide treatment strategies for UCEC patients.

⁶Oregon Health & Science University, 5 Department of Cell, Developmental & Cancer Biology, Portland, OR, United States

⁷Oslo University Hospital, Department of Oncology, Oslo, Norway

Introduction

Patients with large and aggressive ER-positive/HER2 negative breast tumors are currently treated with neoadjuvant chemotherapy, but the optimal therapeutic regimen is not known. The NeoAva clinical trial investigated the efficacy of combining anti-angiogenic treatment using bevacizumab with neoadjuvant chemotherapy in this patient group. The addition of bevacizumab significantly increased the response rate, but the impact of such treatment on the tumor microenvironment remains largely unknown. This study aimed to identify factors that are important for treatment response and resistance through analysis of the tumor landscape and interplay between cancer cells and surrounding immune and stromal cells using spatial proteomic profiling.

Material and method

Needle tumor biopsies from 13 patients collected at baseline ($n = 13$) and at week 12 ($n = 11$) in the NeoAva clinical trial were profiled using cyclic immunofluorescence (cycIF). Full tissue sections were stained in nine cycles, each with four antibodies and DAPI. The images were processed on the Galaxy platform [1] using the MCMICRO pipeline with Mesmer for single cell segmentation. Epithelial, stromal, endothelial and immune cells were phenotyped by hierarchical gating of functional markers. The immune cells were further

subtyped into CD8+ T-cells, CD4+ T-cells, T-regulatory cells, macrophages, and dendritic cells. A total of 1.1 million cells were identified for which downstream spatial statistics were performed using vector and raster-based analysis.

Result and discussion

At baseline, the dominant cell type across all samples was epithelial cells. Notably, there was no significant difference in CD8+ T-cell fraction or density between responders and non-responders. In responding patients, macrophages exhibited a higher overall fraction ($p = 0.014$) and density ($p = 0.022$), and average minimum distance (AMD) revealed higher co-localization with epithelial cells ($p = 0.035$) compared to those with a poor response. On-treatment samples revealed increased fractions of stromal, endothelial, and immune cells. The density of epithelial cells was significantly higher in non-responders than in responders among these samples ($p < 0.01$), although the treatment did not significantly affect the average density of stromal, endothelial, or immune cells. Furthermore, AMD indicated that CD8+ T-cells were highly co-localized with CD4+ T-cells, macrophages, and dendritic cells in responding patients, suggesting a link between spatial immune cell proximity and therapeutic efficacy.

Conclusion

This study shows that spatial proteomic profiling provides a valuable opportunity to study tumor ecosystem dynamics in the neoadjuvant setting. Our findings demonstrate that the tumor-immune cell spatial structure is an important factor for response to treatment with bevacizumab added to neoadjuvant chemotherapy.

³University of Cambridge, Early Cancer Institute, Cambridge, United Kingdom

⁴The Institute of Cancer Research, Breast Cancer Research Division, London, United Kingdom

⁵Imperial College London, Department of Chemistry, London, United Kingdom

⁶University of Reading, Biomedical Sciences, Reading, United Kingdom

Introduction

Mismatch repair deficiency (MMRD) occurs in ~15% of colorectal cancers (CRC). Its causes can be sporadic or familial (Lynch syndrome). MMRD results in a high burden of single nucleotide variants and indels and microsatellite instability (MSI). MMRD CRC demonstrate profound clonal complexity and evolvability under immune selection. High mutational load translates into elevated neoantigen numbers which is thought to be

the basis of their excellent response to immune checkpoint inhibitors (ICIs). However, for reasons yet unclear, ~50% of MMRD CRC do not respond to ICIs. Thus, improved biomarkers for patient stratification are required. The aim of my project is to understand genomic differences between MMRD genotypes that likely contribute to the variable clinical outcomes.

Material and method

CRISPR-Cas9 was used to knock out four genes implicated in MMR (MLH1, MSH6, MSH3, MBD4) in different combinations in a human colonic epithelium cell line (HCEC). The gene knockouts were validated through DNA sequencing (Sanger and Illumina MiSeq) and Western blotting. The cell lines were subjected to two rounds of subcloning and 3–4 weeks of mutation accumulation, followed by WGS at 30x. The cell doubling time was investigated using live-cell fluorescent imaging and flow cytometry. The WGS dataset was processed using an established bioinformatic pipeline for variant calling and mutational signature discovery. CUT & TAG to profile the distribution of H3K36me3 was conducted on select cell lines and analysed with a published protocol (Zheng Y et al (2020). Protocol.io).

Result and discussion

29 colonic epithelial cell lines were produced that model eight MMRD genotypes observed in clinical setting. Cell cycle profiles and cell doubling times were demonstrated to be similar, irrespective of the genotype. Evidence from Western blot experiments suggested that knockout of one MMR gene in cells does not significantly affect expression levels of other MMR genes. WGS data analysis (in progress) yielded reliable variant counts proving that the cell lines exhibit hypermutation, reproduced characteristic MMRD mutational signatures and provided novel insight into the mutational profile of MSH3. Preliminary CUT&TAG data processing revealed similar H3K36me3 distributions in WT and MSH6 -/- lines and identified peaks of marker abundance that will be used to assess mutations in transcribed genomic regions.

Conclusion

A suite of valuable cell models was established to study genomic impact of MMRD. Further analysis of the WGS dataset obtained through carefully planned rounds of cell line subcloning, as well as the complementary CUT&TAG data, will provide detailed insights into the burden, rate and types of mutation caused by various forms of MMRD. Overall, this work adds to the view of MMRD as a multifaceted genetic phenomenon and the catalogue of mutational signatures which carries potential as future biomarkers.

EACR25-0498

CRISPR-Cas9 knock-out screening of lncRNAs highlights new therapeutic targets for cancer treatment

²Human Technopole, Computational Biology Research

Centre, Milan, Italy

³*University of Naples Federico II, Department of Pharmacy, Naples, Italy*

Introduction

The genomic landscape of cancer hides numerous alterations in coding and non-coding genes. The molecular dissection of tumors revealed the key role of long-non coding RNAs (lncRNAs) in cancer progression and drug response. lncRNAs are non-coding transcripts longer than 200 nucleotides, which control gene expression at multi-omic levels. They are considered promising biomarkers and therapeutic targets but most of them remain unexplored.

Material and method

We i) performed a CRISPR-Cas9 screen to knock-out (KO) 671 lncRNAs in Multiple Myeloma (MM) cell lines sensitive and resistant to the conventional drug Bortezomib (BZB); ii) developed a bioinformatic prioritization pipeline able to integrate functional data from in vitro screens with patients-derived prognostic and genomics data from public datasets; iii) functionally validated the role of the most promising target RP11-350G8.5 via cellular and molecular studies in vitro and in vivo; iv) structurally characterized RP11-350G8.5 via biophysical assays including Thioflavin T, 1H-NMR spectroscopy and circular dichroism v) applied computational tools for predicting the putative binding regions of selective therapeutics vi) performed pan cancer bioinformatic analyses to identify biomarkers associated with the expression of our candidate lncRNA, and to evaluate its differential expression and prognostic value in other cancer types.

Result and discussion

Our CRISPR-screen revealed 8 lncRNAs whose KO reduced cell viability in MM cells, and that are associated with high expression and poor prognosis in MM patients'. Among them, RP11-350G8.5 emerged as the most promising target for MM also in BZB-resistant models. We highlighted that the loss of RP11-350G8.5 i) reduces tumour cell viability, proliferation and 3D colony-formation in vitro and impairs tumour growth in vivo, ii) induces apoptosis and sensitizes cells to BZB, iii) modulates the unfolded protein response system and triggers an Immunogenic Cell Death. We identified 2 G-quadruplex and 3 hairpin-forming regions and focused on specific 3D conformations for the development of selective drugs. In addition, we revealed RP11-350G8.5 overexpression and correlation with poor prognosis across different cancer types in addition to MM, including kidney renal papillary cell carcinoma, and predicted a genetic signature related to the expression of our candidate lncRNA that may help the choose of anti-tumoral therapeutic regimens.

Conclusion

Our study (Grillone K. et al., Blood 2024) highlighted novel genetic vulnerabilities never associated before to MM, among which the previously uncharacterized RP11-350G8.5 emerged as the most promising therapeutic target. We then moved forward the design of innovative anti-cancer compounds and to the investigation of the oncogenic role of our candidate lncRNA in a pan cancer setting.

⁶*BBMRI-ERIC, Finance & Project Management, Graz, Austria*

⁷*BBMRI-ERIC, Quality Management, Graz, Austria*

⁸*BBMRI-ERIC, Director General, Graz, Austria*

Introduction

BBMRI-ERIC is the European research infrastructure for biobanking and biomolecular resources in health and life sciences. BBMRI-ERIC encompasses 24 Members and Observer countries and IARC/WHO; comprising 25 National Nodes, 473 biobanks and affiliated partners. BBMRI-ERIC enables the development of innovative technology and processes as transnational European infrastructure that facilitates responsible access to high quality samples, data and biomolecular resources.

Material and method

This is facilitated through services and advancements in the areas of Ethical, Legal and Societal Issues (ELSI), Quality Management (QM), Information Technology (IT), Biobank Development (BBD), Public Affairs (PA), Outreach, Education & Communications (OEC), and Finance- and Project Management (FPM).

Result and discussion

Hereby, BBMRI-ERIC engages its community and partners in more than 23 active EU projects, including various projects for advancing cancer research that are strongly aligned with Cancer Mission and the EU Cancer beating plan namely, canSERV, EOSC4Cancer, EUCAIM, and the newly granted UNCAN projects. Our federated access and analysis platform has become a strong asset and reference point for major EU initiatives (e.g., EHDS, 1+Mio, GDI, EUCAIM) and helps scientists and clinicians to accelerate their personalised medicine research: BBMRI's fully GDPR-compliant pipeline enables access to samples and data of over 7 Mio. patients facilitated across 32 countries. The data comprise 7,834 distinct OMOP variables with biochemical measurements plus different types of OMICs data including e.g., over 150,000 genomes.

Conclusion

We will showcase how to access and make use of the richness of BBMRI-ERIC's resources and how to collaborate with our wider community on different topics through in-house or EU funding – locally, nationally or EU wide to foster cancer research.

Biomedical Sciences, Taoyuan, Taiwan

²*Department of Cell and Molecular Biology, Taoyuan,*

Taiwan, Chang Gung University

³*Molecular Medicine Research Center, Taoyuan, Taiwan,*

Introduction

Colorectal cancer (CRC) is the third most prevalent malignancy worldwide and holds the second highest mortality rate among cancers, as reported by the International Agency for Research on Cancer in 2022. Our laboratory has developed a comprehensive functional genomics database from 104 Taiwanese CRC patients using next-generation sequencing (NGS) technology. This database has facilitated the identification of a 13-gene signature that is predictive for both diagnostic and prognostic applications in CRC. Notably, one gene, DLG5, exhibited a positive correlation with tumor progression and distant metastasis. Elevated levels of DLG5 were associated with reduced survival and increased recurrence rates, suggesting its potential role as an oncogene and a biomarker for CRC prognosis and diagnosis. DLG5 is a member of the MAGUK family, which is crucial for maintaining cell polarity through the formation of the SCRIB-LGL-DLG complex. However, the role of DLG5 in CRC remains unexplored.

Material and method

Employed siRNA to downregulate DLG5 expression in HCT116 CRC cells. To perform proliferative test, we conduct colony formation assay. To perform cell migratory test, we conduct migration and invasion assay. Further investigations were conducted using NGS, quantitative PCR, and Western blot analyses to delve into the potential regulatory mechanisms.

Result and discussion

Downregulate DLG5 reduced the proliferative and migratory abilities, which supports its oncogenic function. Preliminary analyses suggest that DLG5 may influence several pathways including epithelial-mesenchymal transition (EMT), extracellular matrix organization, and immune-related pathways. These findings indicate a multifaceted role of DLG5 in CRC pathogenesis. Further experimental studies are necessary to elucidate the detailed mechanisms by which DLG5 contributes to CRC progression and to assess its viability as a therapeutic target. This study underscores the potential of DLG5 as an oncogenic factor in CRC and as a candidate for clinical biomarker development. By investigating its regulatory pathways, we aim to highlight new therapeutic avenues for CRC treatment.

Conclusion

1. Through the integration of functional genomic data and clinical analysis from a Taiwan-based CRC cohort, our study identifies DLG5 as a significant biomarker for poor prognosis and distant metastasis.
2. Inhibition of DLG5 expression significantly reduces the proliferative and migratory abilities of CRC cells.
3. Transcriptome profiling reveals that DLG5 may participate in several pathways, including EMT, extracellular matrix organization, and immune-related pathways.
4. Validation of DLG5's potential downstream targets was performed through Western blotting and quantitative

PCR.

5. Further experimental studies are necessary to elucidate the detailed mechanisms by which DLG5 contributes to CRC progression and to assess its viability as a therapeutic target.

Non-canonical ORF Translation in Neuroblastoma: A New Source of Therapeutic Targets?

M. Jovanceva¹, D. Hofman¹, A. Cornel¹, E. van der Werf¹, T. Luo¹, A. Pinheiro Lopes¹, S. Nierkens¹, J. Molenaar¹, J. Prensner², S. van Heesch¹

¹*Princess Maxima Center, Utrecht, Netherlands*

²*University of Michigan Medical School, Ann Arbor, USA*

Introduction

Neuroblastoma (NBL) remains one of the most devastating childhood cancers, with high-risk patients facing survival rates below 50% despite aggressive therapy. The biological complexity of NBL characterized by low mutation burden and frequent MYCN amplification severely limits conventional immunotherapy approaches. Despite advances with anti-GD2 antibody therapy, resistance mechanisms and toxicity concerns underscore the urgent need for alternative therapeutic targets. The translation of non-canonical open reading frames (ncORFs) represents an untapped reservoir of putative intracellular proteins that may play roles in neuroblastoma biology or may arise from cancer-specific translation mechanisms, offering unique advantages for targeted therapy.

Material and method

We conducted comprehensive transcriptomic and translational profiling across patient tumors, cell lines, and organoid models. Our integrated approach combining RNA-seq with Ribosome profiling (Ribo-seq) allowed us to distinguish actively translated regions from merely transcribed sequences. Differential expression analysis between NBL and normal tissue samples enabled the identification of NBL-enriched ncORFs, whereas separation of patient samples or models by driver mutations, such as MYCN, helped nominate ncORFs possibly important for specific NBL subtypes.

Result and discussion

Our analysis revealed substantial translation of non-canonical ORFs in neuroblastoma, nearly doubling the total number of ORFs presented in NBL-enriched genes. These might represent promising (immuno)therapeutic targets due to their tumor-specific expression patterns. The integration of RNA-seq and Ribo-seq highlighted that many non-canonical ORFs would remain undetected using conventional transcriptome analysis alone.

Conclusion

By expanding the targetable proteome beyond conventional protein-coding genes, this approach opens new avenues for therapy development against an unexplored class of coding sequences. Ongoing functional characterization of promising candidates is further validating their potential, potentially revolutionizing treatment strategies for children with this aggressive malignancy.

EACR25-0610

A Cost-Effective Droplet-Based Single-Cell Total RNA Sequencing Technology Reveals Transcriptional Heterogeneity in Drug-Tolerant Cancer Cells

X. Sun¹, S. Dadon¹, O. Ram¹

¹The Hebrew University, Department of Biological Chemistry, Jerusalem, Israel

Introduction

Drug resistance remains a major hurdle in non-small-cell lung cancer, driven by mechanisms such as cellular plasticity, transcriptional heterogeneity, and genetic mutations that enable tumor cells to evade targeted therapies. Recent studies highlight the importance of cell-to-cell transcriptional heterogeneity in drug-tolerant persistor (DTP) cells, yet conventional scRNA-seq methods capture only polyadenylated RNAs, overlooking crucial non-polyA transcripts. To address this, we developed sc-rDSeq, a cost-effective, droplet-based full-length total RNA sequencing method that profiles both polyA+ and polyA- RNAs, enabling a comprehensive view of transcriptomic changes in DTP cells.

Material and method

We applied sc-rDSeq to profile 7,051 PC9 cells, subjected to 9-day high-dosage (10X IC50) treatments with EGFR inhibitors Gefitinib or Osimertinib, or DMSO controls. Cells were co-encapsulated with barcoded hydrogel beads for strand-specific total RNA capture. Differential gene expression, cell cycle analysis, and alternative splicing events, chromosomal aberration (CNV) and single nucleotide variants (SNVs) were analyzed.

Result and discussion

In benchmarking against polyT-based inDrops, sc-rDSeq demonstrated a tenfold increase in unique molecules detected per cell, capturing polyA- RNAs. This enhanced sensitivity revealed four distinct clusters within naïve PC9 cells, usually considered homogeneous by conventional scRNAseq. sc-rDSeq of DTP cells showed G1 arrest, confirmed by cell cycle markers and elevated non-polyA histone mRNAs. Despite similar CNV backgrounds, we uncovered divergent resistance pathways in seven clusters, including metabolic reprogramming, epithelial-mesenchymal transition, and extracellular matrix remodeling. Differential expression of miRNA and enhancer RNA correlated with these clusters. Notably, sc-rDSeq detected isoform switching, such as MDK-204 (truncated midkine) linked to aggressive phenotypes. SNVs played a minor role in transcriptional heterogeneity, suggesting non-mutational mechanisms drive early drug persistence.

Conclusion

Our study highlights the power of sc-rDSeq in dissecting the full transcriptomic landscape of drug persistor cells, revealing novel non-polyA RNA signatures, alternative splicing and SNVs linked to drug resistance. These findings provide new insights into adaptive responses beyond genetic mutations, offering potential targets for combination therapies. The high-throughput scalability, high sensitivity and cost-effectiveness, with a library preparation cost of \$0.08 per cell, makes sc-rDSeq as a

valuable tool for basic cancer research and personalized cancer medicine.

EACR25-0617

Integrative Analysis Reveals RNF135 as a Prognostic and Immunological Biomarker in Glioblastoma

J. Chen¹, Q. Wu¹, A. Etame¹

¹H. Lee Moffitt Cancer Center and Research Institute, Department of Neuro-Oncology, Tampa, United States

Introduction

Glioblastoma (GBM) is among the most aggressive primary brain tumors, despite advances in surgical and adjuvant therapies, GBM patients often surviving less than two years after diagnosis. The exploration of new therapeutic targets and novel genes to alter the prognosis of GBM patients holds significant importance. Here, we identified RNF135, a ring-finger protein-encoding gene, as a potential immune-related biomarker and therapeutic target in GBM.

Material and method

We integrated high-throughput RNA-sequencing data from multiple public databases, including The Cancer Genome Atlas (TCGA), Chinese Glioma Genome Atlas (CGGA), and the IVY Glioblastoma Atlas Project. Bulk transcriptomic data were used for survival analyses and gene function analyses. Immune infiltration was assessed using MCP-counter, xCell and ssGSEA. Single-cell RNA-sequencing data from GSE131928 were utilized to provide cellular resolution of RNF135 expression among tumor-associated macrophage (TAM) subtypes, while bulk RNA-sequencing data from the IVY Glioblastoma Atlas were used to validate its spatial distribution within distinct anatomical regions of GBM. Drug sensitivity analysis was conducted to explore effective treatment options for the RNF135-high patient group.

Result and discussion

High RNF135 expression was strongly associated with poor overall survival. Immune deconvolution analyses revealed that RNF135-high tumors exhibit increased infiltration of T cells, NK cells, monocyte-derived macrophages, and myeloid-derived suppressor cells (MDSCs). Notably, single-cell RNA sequencing data showed that RNF135 is enriched in aggressive TAM subsets, specifically monocyte-derived TAM and proliferative TAM, suggesting a role in immuno-suppression and tumor angiogenesis. Validation using the IVY Glioblastoma Atlas confirmed that RNF135 is predominantly expressed in highly vascularized tumor niches, particularly in microvascular proliferation (CT.mvp) and highly vascularized (CT.hbv) regions. Gene set enrichment analysis (GSEA) demonstrated significant enrichment of inflammatory and oncogenic pathways, including KRAS, IL6-JAK-STAT3, and TNFalpha-NFKappaB, which support RNF135's involvement in tumor progression. Finally, drug sensitivity analyses indicated that RNF135-high tumors may be more responsive to MEK inhibition (e.g., selumetinib), aligning with the observed enrichment of KRAS-driven pathways.

Conclusion

Our study identifies high RNF135 expression in GBM is strongly associated with poor prognosis, increased

immune infiltration, and an immunosuppressive tumor microenvironment. RNF135 could serve as both prognostic marker and potential target for precision therapy. Further comprehensive experimental validation and clinical investigations are warranted to explore RNF135-targeted therapeutic strategies in GBM.

EACR25-0638

Spatial transcriptomics in precancerous lesions of the colorectum

M. Kerdreux¹, W. Rosenbaum¹, A. Ling¹, C. Holmlund¹, M. Landström¹, S. Edin¹, R. Palmqvist¹

¹*Umeå University, Department of Medical Biosciences, Umeå, Sweden*

Introduction

Colorectal cancer (CRC) develops through two main pathways: the traditional pathway, which contributes to 70% of colorectal cancers, and the serrated pathway, which accounts for 15% to 30% of CRCs. The lesions in the serrated pathway are mostly hyperplastic polyps (HP), followed by sessile serrated lesions (SSLs), and few traditional serrated adenomas (TSA). TSAs and SSLs have a higher risk of progressing to cancer.

Distinguishing the serrated lesions can be difficult, although very important to handle the patient in the most appropriate way. Another defy is the identification of dysplasia in SSL, which can be difficult to distinguish, yet of great diagnostic importance. A better understanding of the developmental processes in the serrated lesions of the colorectum is necessary to develop better clinically applicable diagnostic tools.

Material and method

Spatial transcriptomic analyses were performed on formalin-fixed paraffin-embedded tissue sections from selected lesions using the GeoMx® Digital Spatial Profiler from NanoString Technologies. Here, we analysed 8 SSLs, 3 TSAs, 2 HPs, 4 conventional adenomas and 2 normal tissues. Regions of interest were selected from both the base and surface of colonic crypts.

Result and discussion

When comparing gene expression between conventional and serrated lesions, the later showed significant higher expression of genes involved in colorectal epithelial cell differentiation, such as CLCA4, GUCA2A, GCG, CA1 and AQP8. In parallel, we found ADAM15 to be significantly overexpressed in the serrated lesions – independently of the presence of dysplasia, compared to the conventional lesions. ADAM15 – coding for an enzyme that is part of the disintegrin-like and metallo-proteinase family, has been shown to be overexpressed in colon cancer tissues and its overexpression led to a worse overall survival in CRC patients. We also found genes that were differently expressed between the different serrated lesions. We next focused on the SSLs, comparing lesions with and without dysplasia. Dysplastic SSLs were found associated with overexpression of genes involved in cell proliferation (e.g. TIMP1, S100A4, ID1, TM4SF4), and anti-microbial responses (e.g. LCN2, PI3, SLP1). Furthermore, we found differences in gene expression between the base and surface of the crypts.

Conclusion

Using spatial transcriptomics, we were able to identify unique genes that characterize different types of pre-cancerous serrated colorectal lesions. Further studies are needed to explore the potential of these candidate genes as clinical biomarkers.

EACR25-0673

Functional diversity of the TP53 mutational landscape revealed by saturating genome editing

⁸*Buchmann Institute for Molecular Life Sciences and Structural Genomics Consortium (SGC), Goethe University, 60438 Frankfurt am Main, Germany*

Introduction

The tumor suppressor gene TP53 is the most frequently mutated gene in cancer, with mutations present in approximately half of all tumors. Unlike other tumor suppressors, TP53 is primarily affected by missense mutations, leading to the production of a full-length protein with single amino acid substitutions. The mutational landscape is highly diverse, with over 2,000 distinct missense mutations with varying effects on the functionality of the protein identified in patients. This functional heterogeneity complicates precision oncology, where a detailed understanding of mutation-specific consequences is essential for patient stratification and targeted therapy.

Material and method

To systematically map the functional impact of TP53 mutations, we performed a deep mutational scan using saturation genome editing (SGE) with CRISPR-mediated homology-directed repair. This approach allowed the precise engineering of 9,225 variants in the endogenous TP53 locus of cancer cells, preserving native regulatory elements and physiological expression levels. We assessed variant abundance in response to specific p53-pathway stimulation, generating high-resolution functional activity maps covering approximately 94.5 % of all cancer-associated missense mutations.

Result and discussion

Our approach provides an unprecedented resolution in differentiating benign from pathogenic TP53 variants. By directly introducing mutations in the endogenous TP53 locus we identified previously misclassified loss-of-function variants with subtle phenotypic effects, some of which may be promising candidates for pharmacological reactivation. Additionally, we uncovered the roles of splicing alterations and nonsense-mediated mRNA decay in TP53 dysfunction, offering new insights into mutation-driven regulatory mechanisms.

Conclusion

The CRISPR-based SGE approach significantly improves the clinical interpretation of TP53 variants, enabling improved discrimination between benign and pathogenic mutations. By providing a comprehensive functional dataset with high predictive value, sensitivity, and specificity, this study supports the refinement of variant classification. These findings highlight the potential of SGE to advance genetic counseling and personalized cancer therapy by enabling more accurate TP53 variant assessment.

EACR25-0674

Cardiac metastasis: From spatial transcriptomics to targeted therapy

D. Lorizio¹, G. Ciucci², M. Chiesa³, G. Salina¹, M. Pinamonti⁴, R. Bussani⁵, S. Zucchigna¹

¹*Centro Cardiologico Monzino, Unit of Cardio-Oncology and Vascular Biology, Milan, Italy*

²*International Centre for Genetic Engineering and Biotechnology, Laboratory of Cardiovascular Biology, Trieste, Italy*

³*Centro Cardiologico Monzino, Bioinformatics and Artificial Intelligence facility, Milan, Italy*

⁴*Azienda sanitaria universitaria Giuliano Isontina (ASU GI), Anatomy and histopathology, Trieste, Italy*

⁵*University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy*

Introduction

Cardiac metastases are currently rare, but their incidence is expected to increase in the upcoming years due to improved survival of cancer patients. Unspecific cardiac symptoms and anatomical location prevent timely diagnosis and biopsy collection for molecular studies. Thus, cardiac metastases remain poorly characterized and current therapies are limited to surgery and adjuvant chemo- and radiotherapy.

Material and method

Spatial transcriptomics was performed on formalin-fixed paraffin-embedded sections from samples of primary tumor, cardiac metastasis and extra-cardiac metastasis, collected from three patients affected by different primary tumors. Candidate genes were silenced/over-expressed in human cancer cell lines for functional characterization, including mechanical stimulation with cell confiner and stretcher to mimic compressive and tensile cardiac forces. In addition, Engineered Heart Tissues (EHT) were used to reproduce the 3D structure of cardiac tissue, casting iPSC-derived cardiomyocytes together with tumor cells.

Result and discussion

Differentially expressed gene (DEG) analysis between tumor samples revealed 3095 dysregulated genes in

tumor cells of cardiac metastases. Unsupervised hierarchical clustering showed sample clusterization based on the tumor location (cardiac vs extra-cardiac tumors), regardless of the origin of the primary tumor, suggesting that various types of cancer cells share a common transcriptional signature once they have reached the cardiac tissue. Several of the upregulated genes encode for cytoskeletal proteins, including keratins, tubulin and actin subunits. Keratin-36 (KRT-36), a major constituent of intermediate filaments of hair and nails, stands out as one of the most upregulated genes. Lung and breast cancer cells overexpressing KRT-36 proliferate more than their wild-type control in basal conditions. Whereas wild-type cells display reduced proliferation in response to mechanical stimuli that mimic cardiac load, KRT-36-overexpressing cells retain their proliferative capability. This suggests that high levels of KRT-36 create a cytoskeletal shield that protects the nucleus and confers resistance to mechanical stimuli, eventually allowing tumor cell proliferation in the beating heart.

Conclusion

This study points to KRT-36 as a potential therapeutic target for cardiac metastases. In addition, we propose the repurposing of existing chemotherapies that target cytoskeletal filaments for tumor cell re-sensitization to the anti-proliferative effect of cardiac mechanical load, thus offering the first targeted therapy for cardiac metastasis.

EACR25-0742

Transcriptomic Signatures and Fusion Landscape in Relapsed B-ALL: Insights from RNA-Sequencing Analysis

G. Krishna Leons¹, S. Gupta¹, P. Sharma¹, R. Gupta¹, S. Bakhshi², R. Sahoo², V. Kumar Singh¹, A. Roy³, S. G¹, D. Pushpam²

¹*All India Institute of Medical Sciences (AIIMS), Laboratory Oncology Unit, New Delhi, India*

²*All India Institute of Medical Sciences (AIIMS), Department of Medical Oncology, New Delhi, India*

³*Indian Institute of Technology (IIT), Kusuma School of Biological Sciences, New Delhi, India*

Introduction

B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by various genetic aberrations including fusions, mutations, and gene expression profiles. Despite significant advancements in therapy, nearly 20% of B-ALL cases relapse or develop resistance, underscoring the need for novel biomarkers to refine risk stratification. Indian B-ALL patients exhibit an aggressive disease phenotype, with a higher prevalence of high-risk genetic features and a lower frequency of favorable-risk markers. This study aims to characterize differentially expressed genes (DEGs), pathway dysregulation, and fusion events associated with B-ALL relapse.

Material and method

RNA sequencing was performed on 56 B-ALL samples (21 relapsed, 35 non-relapsed). Differential expression analysis was conducted using DESeq2 ($|\log_{2}FC| > 1.5$, $FDR < 0.05$) to identify DEGs. Gene fusions were detected via STAR-Fusion and confirmed by RT-PCR followed by Sanger Sequencing. Functional enrichment

analysis was performed using clusterProfiler (KEGG database).

Result and discussion

We identified 197 differentially expressed (DE) RNAs (43 upregulated, 154 downregulated) in relapsed B-ALL. Key upregulated genes included PRAME ($\log_{2}FC = 3.1$, $FDR = 0.02$), a cancer/testis antigen linked to immune evasion, SPP1 ($\log_{2}FC = 3.1$, $FDR = 0.002$), involved in chemoresistance/tumor progression, LAMB4 ($\log_{2}FC = 3.5$, $FDR = 0.001$; extracellular matrix) and LMTK3 ($\log_{2}FC = 2$, $FDR = 0.02$), a kinase involved in tumor progression/chemoresistance. IFI27 (associated interferon response) and ESAM (angiogenesis) were also elevated. KEGG pathway analysis revealed enrichment in PI3K-Akt signaling and focal adhesion, implicating these pathways in relapse-driven mechanisms. A total of 61 long non-coding RNAs (lncRNAs) were differentially expressed, notably LINC00922 ($\log_{2}FC = 3.3$, $FDR = 0.014$), which is associated with cell proliferation and invasion and was observed to be significantly upregulated in relapsed cases. Additionally, three microRNAs (miRNAs) were downregulated, including miR-26a-2 ($\log_{2}FC = -1.7$, $FDR = 0.02$), a tumor suppressor implicated in cancer progression. Fusion analysis identified ETV6::RUNX1, KMT2A::AFF1, DUX4::IGH, FOCAD::EBF1 (novel fusion), IKZF1::CIITA, TCF3::ZNF384, and PAX5::ZNF521 in relapsed cases. In contrast, non-relapsed cases harbored BCR::ABL1, EPOR::IGH, and PAX5::ETV6 fusions.

Conclusion

Our study reveals distinct transcriptomic signatures and fusion landscapes in relapsed B-ALL. Upregulation of PRAME, SPP1, and LAMB4, alongside dysregulated PI3K-Akt and focal adhesion pathways, suggests potential mechanisms driving therapy resistance. The altered expression of lncRNAs and miRNAs further highlights regulation mechanisms in relapse. These findings underscore the need for transcriptome-based biomarkers, in addition to characteristic fusions, to enhance relapse prediction in B-ALL.

EACR25-0768

Identification of therapeutic targets and dependencies in ZNF703-amplified breast cancer

A. Lui¹, H. Bardwell¹, D. Georgopoulou¹, A. Shah², L. Nguyen³, D. Walter², J. Brenton¹, O. Rueda⁴, S. Chin¹, C. Caldas⁵

¹University of Cambridge, CRUK Cambridge Institute, Cambridge, United Kingdom

²AstraZeneca—Cancer Research Horizons Functional Genomics Centre, Cambridge, United Kingdom

³University of Toronto, Departments of Medicine and Medical Biophysics, Toronto, Canada

⁴University of Cambridge, MRC Biostatistics Unit, Cambridge, United Kingdom

⁵University of Cambridge, Department of Clinical Biochemistry, Cambridge, United Kingdom

Introduction

Focal amplifications of chromosome 8p11.23, likely precipitated by oestrogen-induced chromosomal instability, are recurrent in ~15% of breast cancer,

defines the IntClust6 subtype, and portends poor prognosis with high risk of late relapse and chemotherapy resistance. ZNF703 is the most frequently amplified gene and the putative driver oncogene within this locus, though mechanisms are poorly understood and targeted therapies are unavailable.

Material and method

To identify therapeutic vulnerabilities for ZNF703-amplified breast cancers, whole-genome CRISPR-Cas9 screens were performed in isogenic cell lines with modulated ZNF703 expression as well as ZNF703-amplified breast cancer cells. Top hits were further validated in targeted CRISPR-Cas9 competition assays using orthogonal guide RNAs. To further understand the mechanisms of ZNF703-driven growth, the ZNF703-dependent interactome and transcriptome were characterised using rapid immunoprecipitation mass spectrometry of endogenous proteins (RIME) and RNA sequencing of the aforementioned cell line models.

Result and discussion

We report that ZNF703 amplification is synthetic lethal with loss of OTUD5, a regulator of DNA double strand break repair and interferon signalling. Furthermore, ZNF703 overexpression favours error-free repair of CRISPR-Cas9-induced double strand breaks and confers increased dependency on homologous recombination. Interactomic and transcriptomic profiling suggests ZNF703 binds to transcriptional repressors and interferon-related transcription factors, resulting in down-regulation of interferon response. Notably, under-expression of interferon response genes is associated with dependency on OTUD5 and BRCA1 in a tumour agnostic dataset of 1066 cancer cell lines (DepMap 24Q2).

Conclusion

This is the most comprehensive study to date of ZNF703-driven tumorigenesis, where we report the first characterisation of the ZNF703 interactome and associated dependencies. Together, the findings propose that ZNF703 facilitates cell growth under chromosomal instability, and antagonism of this function by OTUD5 loss represents a promising therapeutic strategy.

EACR25-0803

Genetic Profiling of Homologous Recombination Repair Pathway Alterations in Ovarian Cancer patients' cohort from Serbia

K. Živić¹, I. Pantović¹, I. Boljević¹, M. Nedeljković¹, A. Krivokuća¹, M. Đordić¹, M. Tanić¹

¹Institute for Oncology and Radiology of Serbia, Experimental oncology, Belgrade, Serbia

Introduction

Among all gynecological cancers, ovarian cancer (OVCA) has the highest mortality rate. It develops and evolves as a result of acquiring genetic and epigenetic changes, and it is frequently identified when it is too late to receive an effective treatment. The vast majority of ovarian cancer cases is due to mutations in BRCA genes, involved in homologous recombination repair pathway. HR-deficient (HRD) cells usually rely on poly (ADP-ribose) polymerase (PARP) single-strand repair pathway.

The clinical usage of PARP inhibitors that cause synthetic lethality in HRD cancer cells has a significant impact on ovarian cancer therapy techniques. Therefore, identification of a predictive biomarker, other than BRCA mutation, is critical for the selection of patients who are most likely to benefit from these agents. The aim of this study was to obtain information about genetic alterations in genes involved in HRR pathway, beside BRCA, as it is thought that patients harbouring mutations in those genes can benefit from the same type of therapy.

Material and method

The study cohort included ovarian cancer patients who were tested on BRCA mutations at IORS from 2016 until June 2023., as a part of routine diagnostic procedure, as well as on BRCA promoter methylation status. One subgroup had a result of genetic screening from blood with panel that included other genes beside BRCA. Genetic material is extracted using commercial kits for isolation (QIAGENE®). For screening of HRR genes and library preparation we used QIASeq Targeted HRR Panel (QIAGENE®), we used 100-200ng of extracted DNA for library construction. Panel consisted of 2303 primers covering 15 HRR genes. Sequencing was carried out on Illumina NextSeq550Dx instrument using MidOutput sequencing kit in 150bp PE mode. We applied 10% Variant Allele Frequency and 500x coverage as cut-off.

Result and discussion

Tested cohort consisted of 38 newly diagnosed and 58 relapsed cases of OVCA. Of 96 tested samples, in 21 BRCA1/2 pathogenic mutations were found, 3 BRCA1/2 VUS alterations, and 72 were characterized as BRCA wild type. In germline testing, beside BRCA alterations, we found 3 ATM VUS, 1 CHEK2 likely pathogenic and 1 PALB2 pathogenic variant. Germline testing results were used as a control for Targeted HRR panel. Results of BRCA methylation status were used for potential discovering of co-existing epigenetic and genetic alterations that can possibly cause HRD when combined in cell. By testing other HRR genes we got additional information on OVCA etiology, needed for proper understanding of its origin and, in future, potential expanding of group of patients who can take PARPi treatment.

Conclusion

Genetic sequencing extended to other HRR genes, in combination of previously gained genetic and epigenetic screening, gave us additional picture about ovarian cancer etiology important for broadening the group of patients who can gain PARPi therapy.

EACR25-0832

Recurrent endocervical polyps harbor UBE2A p.(Arg6Trp) mutation

S. Reinikka¹, N. Sarvilinna², L. Katainen¹, A. Pasanen², R. Bützow², P. Vahteristo¹

¹*University of Helsinki, Helsinki, Finland*

²*Helsinki University Hospital and University of Helsinki, Helsinki, Finland*

Introduction

Endocervical polyps are overgrowths of cervical glands and stroma that protrude into the cervix. These common tumor-like-lesions affect 2-5% of adult women and exhibit 3-11% recurrence rate. Although endocervical polyps are generally benign, 0.1-1.4% may undergo

malignant transformation. Typically, these polyps are less than 20mm in size and often asymptomatic; however, they can cause intermenstrual, postcoital, and postmenopausal bleeding. Despite their high prevalence, the etiology of endocervical polyps remains poorly understood.

Material and method

In this study, we present a 43-year-old woman with recurrent endocervical polyps. Over a period of nine years, five endocervical polyps were removed from the patient during five separate gynecological visits. The histology of all five polyps was characteristic of endocervical polyps and no endometrioid components were present. As there are no known drivers in endocervical polyps, we analyzed the known endometrial polyp alterations: HMGA1 and HMGA2 expression levels were evaluated with immunohistochemistry, and alterations in KRAS and UBE2A with Sanger sequencing.

Result and discussion

Sanger sequencing revealed that all polyps harbored the same UBE2A c.16C>T, p.(Arg6Trp) missense mutation. Analysis of the blood sample confirmed the somatic origin of the mutations. While UBE2A mutations have not been reported in endocervical polyps previously, the same UBE2A p.(Arg6Trp) mutation has been identified recurrently in endometrial polyps. Mutation was predicted likely pathogenic based on REVEL (score 0.56) and CADD (score 24.4) assessments. The presence of the exact same mutation in both endometrial and endocervical polyps supports UBE2A as a novel driver gene in gynecological polyps. None of the polyp samples harbored KRAS or HMGA1/2 alterations.

Conclusion

We identified UBE2A c.16C>T, p.(Arg6Trp) mutation in five consecutive endocervical polyps. This finding suggests that UBE2A is a new driver gene in gynecological polyps. Further studies are required to determine the prevalence of UBE2A mutation in endocervical polyps, and to elucidate the tumorigenic mechanisms by which these mutations contribute to polyp development. Systematic, large-scale molecular analyses are needed to define the complete molecular background of endocervical polyps.

Core2Edge: A Human Glioblastoma Organoid and Brain Slice Co-Culture Model Capturing Tumor Infiltration and Transcriptional Heterogeneity from Core to Single-Cell Dispersion

A. Melhem¹, B. Pregler¹, J. Rodriguez-Gatica², M. Hözel³, H. Vatter¹, M. K. Schwarz⁴, U. Herrlinger⁵, U. Kubitscheck⁶, A. Potthoff⁴, M. Schneider¹

⁴*Institute for Experimental Epileptology and Cognition Research, Epileptology, Bonn, Germany*

⁵*Center for Neurology, Department of Neurooncology, Bonn, Germany*

⁶Institute of Physical and Theoretical Chemistry,
Biophysical Chemistry, Bonn, Germany

Introduction

Glioblastoma functions as intricate cellular networks that extend into the surrounding brain tissue enabling long distance communication. This malignant connectivity spans from the tumor core to remote infiltration zones, supporting the concept of glioblastoma as a whole-brain disease. With growing ethical considerations in biomedical research and the limitations inherent in cross-species comparisons between animal studies and human glioblastoma models, human tumor platforms remain constrained in their ability to replicate the full infiltration spectrum from the tumor core to single-cell dispersion.

Material and method

To address these challenges, we have developed Core2Edge, a three-dimensional, fully human ex vivo glioblastoma model that replicates extensive tumor infiltration while maintaining the intratumoral heterogeneity of patient-derived tumors. The model is established by implanting human glioblastoma organoids (GBOs) into organotypic human brain slices, preserving the genetic integrity and cytoarchitecture of both brain tissue and tumor. Once glioblastoma organoids are prepared, the protocol takes approximately 7–12 days. Key steps include brain slice preparation (~4–6 hours, depending on quantity), one day for initial culture before GBO staining and implanted, a variable culture period (up to ten days), and fixation (~2 hours). Additional time is required for downstream analyses, including imaging, sequencing, and proteomics.

Result and discussion

The Core2Edge model successfully recapitulates the full infiltration range of glioblastoma, from densely packed tumor regions to dispersed single-cell infiltration, addressing a critical limitation of previous human glioblastoma models. By preserving tumor heterogeneity, the model enables in-depth analysis of glioblastoma subpopulations, cell-cell interactions, and the role of the tumor microenvironment (TME) in supporting tumor invasion. The combining of light-sheet fluorescence and expansion microscopy allows for the visualization of tumor cell behavior, invasive front dynamics, and glioblastoma-stroma interactions in high detail.

Furthermore, this system serves as a drug screening and therapeutic testing platform, reducing the reliance on animal models while providing a human-relevant environment for preclinical investigations.

Conclusion

The Core2Edge model represents a significant advancement in glioblastoma research, bridging the gap between traditional *in vitro* models and *in vivo* studies. By maintaining the full spectrum of glioblastoma infiltration and preserving tumor heterogeneity, this model provides a powerful tool for studying tumor invasion, and micro-environment interactions. Additionally, the ability to conduct high-resolution imaging and molecular analyses makes Core2Edge a valuable platform for personalized medicine and drug development.

EACR25-0856

Deciphering the Timing of Somatic Driver Mutations in Early-Onset Breast Cancer

S. Lee¹, J. Bhin¹

¹Yonsei University, College of Medicine, Seoul, Korea
(Republic of)

Introduction

Breast cancer is a heterogeneous disease characterized by distinct molecular subtypes, genetic alterations, and varying clinical outcomes. Among these, early-onset breast cancer (EOBC), typically defined as breast cancer diagnosed before the age of 40, presents unique biological and clinical challenges compared to late-onset cases. EOBC is often associated with more aggressive tumor subtypes, higher genomic instability, and an increased likelihood of hereditary predisposition, particularly involving germline mutations in BRCA1 and BRCA2. However, beyond hereditary factors, the precise evolutionary trajectory of somatic driver mutations in EOBC remains poorly understood.

Material and method

We performed whole genome sequencing (WGS) analysis on 100 early-onset breast cancer (EOBC) patients and 76 conventional breast cancer (CBC) patients diagnosed after the age of 45. Somatic alterations, including single nucleotide variants, insertions/deletions, and structural variants, were identified using the Hartwig Medical Foundation WGS pipeline. Tumors were classified as whole genome duplication (WGD)-positive if more than 10 autosomes had a major allele copy number greater than 1.5. Sub-clonal tumor structures were analyzed using DPclust, and copy number (CN) segment timing was determined using GRITIC and AmplificationTimeR. Mutation timing analysis was conducted with MutationTimeR.

Result and discussion

We observed that the prevalence of whole-genome duplication (WGD) is significantly higher in CBC compared to EOBC, as supported by CN signature analysis. Additionally, EOBC exhibited a higher proportion of early clonal mutations. While differences in the somatic mutation spectrum were relatively minor, the timing of somatic driver mutations varied significantly between EOBC and CBC. Notably, key driver alterations in genes such as TP53, CCND1, ERBB2, and MYC occurred earlier in EOBC. Interestingly, we also found that WGD occurred earlier in EOBC. Finally, the time interval between the most recent common ancestor (MRCA) and WGD was significantly shorter in CBC (3.7 years) compared to EOBC (6.3 years), suggesting that WGD may play a role in promoting oncogenesis.

Conclusion

Our findings highlight distinct evolutionary trajectories between early-onset breast cancer (EOBC) and conventional breast cancer (CBC). EOBC is characterized by earlier acquisition of key driver mutations and WGD, whereas CBC exhibits a higher prevalence of WGD and a shorter interval between the most recent common ancestor (MRCA) and WGD. These differences suggest that WGD may contribute differently to tumor progression in EOBC and CBC, providing insights into

the underlying biology of breast cancer across age groups.

Single-Cell Multi-omics with InTraSeq Uncovers Novel Insights into Th17 Differentiation

M. Ariss¹, L. Huang², X. Ding², S. Sheth¹, M. Jacquet¹, P. Leung-Lee¹, S. Beausoleil¹, V. Kuchroo², R. Polakiewicz¹

¹Cell Signaling Technology, Danvers, United States

²Harvard Medical School, Boston, United States

Introduction

Single-cell RNA sequencing (scRNA-seq) has advanced our understanding of cellular heterogeneity, but it offers an incomplete view of function by focusing on mRNA. Cellular phenotypes are determined by biomolecule interplay, including proteins, which are often modified and crucial in signaling. We developed InTraSeqTM, a multimodal assay measuring mRNA and proteins in single cells. This integrated approach allows comprehensive characterization of cellular states and regulatory mechanisms.

Material and method

The InTraSeqTM 3' assay profiles the transcriptome and proteome in single cells. Using a buffer kit (CST #82906) and cocktail (CST #48167), InTraSeqTM processing requires one hour of benchwork over three days (Figure 1A, Supplementary Protocol 1). Briefly, cells are fixed in Methanol, stored at -20°C for up to seven days. Following fixation, cells are incubated with "scBlock" buffer and immunostained with antibody-oligo conjugates for 16 hours. On the third day, cells are washed before scRNA-seq using the 10X Genomics 3' assay. For this study, naïve CD4+ T cells from mouse spleens and lymph nodes were cultured under Th0, non-pathogenic Th17, pathogenic Th17, or stimulated with PMA and Ionomycin (PMA/IO). Cells were collected at 0 minutes (naïve), 10 minutes, 45 minutes, 6 hours, and 24 hours post-stimulation (Figure 3A). The InTraSeq Th17 dataset profiled RNA and protein in 83,772 cells across 16 samples.

Result and discussion

InTraSeqTM profiled mRNA and proteins, including surface markers, signaling molecules, and post-translational modifications, in single cells. Applying InTraSeqTM to Th17 cell differentiation revealed insights into this process. We identified regulatory factors and target genes, observed protein expression changes correlated with differentiation, and uncovered post-translational modifications associated with cell states. Our results demonstrate InTraSeqTM's power to dissect cellular processes and uncover regulatory mechanisms by providing a comprehensive view of cellular function compared to scRNA-seq.

Conclusion

InTraSeqTM is a multimodal assay that expands single-cell analysis by enabling simultaneous measurement of mRNA and proteins. This integrated approach provides a holistic understanding of cellular function and allows for the identification of regulatory mechanisms. By combining scRNA-seq with protein profiling, InTra-

SeqTM has the potential to advance our understanding of cellular heterogeneity and its role in health and disease.

Distinct Mutational Profiles in Primary Sclerosing Cholangitis-Associated Cholangiocarcinoma Compared to de novo Cholangiocarcinoma

S. Tian¹, F. Pinto e Vairo², A. Ali³, H. Yan⁴, E. Klee⁴, K. Lazaridis⁵

¹Mayo Clinic, Division of Computational Biology, Rochester, United States

²Mayo Clinic, Department of Clinical Genomics, Rochester, United States

³Mayo Clinic, Division of Gastroenterology and Hepatology, Rochester, United States

⁴Mayo Clinic, Division of Computational Biology, United States

⁵Mayo Clinic, Division of Gastroenterology and Hepatology, United States

Introduction

Cholangiocarcinoma (CCA) is a rare and aggressive malignancy characterized by etiologic heterogeneity and poor survival. Primary sclerosing cholangitis (PSC) is the most recognized risk factor for CCA in Western countries. PSC-associated CCA (PSC-CCA) is a leading cause of morbidity and mortality in PSC patients and exhibits distinct clinical features compared to those in de novo CCA. However, the molecular mechanisms driving these two subtypes of CCA remain largely unexplored. This study aimed to characterize the spectrum and prevalence of germline genetic variants in pathologically confirmed PSC-CCA, and de novo CCA as well as PSC patients without CCA (PSC-w/o CCA).

Material and method

This retrospective cross-sectional study included 301 patients with PSC-w/o CCA and 170 patients with CCA (PSC-CCA, n = 88; de novo CCA, n = 82) identified from two population genomics studies conducted at Mayo Clinic between 2016 and 2023. Their diagnoses, phenotypes, outcomes, as well as medical and family histories were obtained from electronic health records (EHRs) and self-reported questionnaires. Exome sequencing of these patients was conducted with genomic DNA, and genetic variants were identified using bio-informatics workflow following the Genome Analysis Toolkit (GATK) best practices. A comprehensive list of cancer susceptibility genes was compiled from prior cancer studies. Functional annotation and pathogenicity assessment of cancer-associated genetic variants were performed according to current American College of Medical Genetics and Genomics and the Association for Molecular Pathology (ACMG/AMP) guidelines.

Result and discussion

Analysis of exome sequencing data from 471 patients identified 53 pathogenic/likely pathogenic (P/LP) germline variants across 25 cancer susceptibility genes (CSGs) in 10.8% (51/471) of patients. The highest prevalence of P/LP germline variants was observed in PSC-CCA patients (13.6%, 12/88), followed by PSC-w/o CCA (10.0%, 31/301) and de novo CCA (9.76%, 8/82). Interestingly, PSC-CCA patients exhibited P/LP germline

variants mainly in moderate-, low-penetrance, and/or autosomal recessive genes, with significant enrichment in the Fanconi anemia DNA repair pathway. In contrast, patients with de novo CCA predominantly carried P/LP germline variants in the tumor suppressor genes that are key players in homologous recombination repair pathway. Similarly, germline variants led to differentially altered metabolic and signal pathways observed between PSC-CCA and de novo CCA patients.

Conclusion

These findings provide key insights into distinct CCA subtypes and call for an effort to systematically study germline testing of patients with PSC-CCA and de novo CCA as an approach to inform personalized approaches to screening, clinical management and targeted therapy of CCA in these patients.

³BioTechMed, Graz, Austria

⁴Medical University of Graz, Gottfried Schatz Research Center, Austria

⁵Medical University of Graz, Gottfried Schatz Research Center, Graz, Austria

Introduction

Several systemic treatments are approved for advanced stage hepatocellular carcinoma (HCC) (e.g., sorafenib, a multi kinase inhibitor) with limited improvement in disease outcome, thus making further treatment options urgently needed. By blocking two central energy-producing pathways, glycolysis and oxidative phosphorylation (OxPhos), in wild-type and p53 knockout (KO) models, we showed that adjacent nutrient deprivation (ND) improves the efficacy of sorafenib in HCC and is dependent on the p53 status. Six different human TP53 hotspot mutations are known to account for up to 25% of all TP53 missense or nonsense mutations in HCC. Here, we aim to address how three most common TP53 hotspot mutations in HCC (mut: R175H, R249S, and R273H) affect its response to combination therapy (sorafenib/ND) *in vitro*.

Material and method

To demonstrate the involvement of p53 in cell metabolism, we analysed gene expression profiling datasets (TargetGeneReg 2.0). RNAseq was performed in p53 knockout and wild type HepG2 cell line upon ND and sorafenib treatment. Vectors carrying TP53 hotspot mutations were overexpressed in p53-deficient HepG2 cells. We further created traceable isogenic Trp53-mutant models combined with wild type or knockout alleles utilizing a CRISPR/Cas9 knock-in strategy to analyse the metabolic phenotypes and potential metabolic vulnerabilities resulting from HCC-specific mutations in Trp53. Metabolic phenotyping was performed using a

Seahorse analyser and viability assays were performed to test response to treatment.

Result and discussion

The analysis of gene expression profiling datasets demonstrated that p53 binds to either transcription start sites and/or enhancers of metabolism-relevant genes. Also, p53 can have indirect effects on metabolic gene expression without occupying a direct binding site. Our RNAseq results in HepG2 p53KO cells, and upon p53 re-expression show p53-dependent regulation of metabolic genes after ND. Next, we overexpressed TP53 harbouring one of the three hotspot mutations in TP53KO HepG2 cells and then analysed the cells' metabolic capacity in energy-producing pathways. The cells expressing mutTP53 had different capacity for mitochondrial respiration and glycolytic function only upon ND, while no difference was observed in standard growth conditions. We observed loss of transactivation potential of canonical p53 targets CDKN1A and MDM2, as well as differential mutTP53 transactivation potential at metabolic gene loci under ND. The metabolic profiles and responses to ND and sorafenib treatment were dependent on the hotspot mutations and their combination with p53 knockout alleles.

Conclusion

We show that p53 with hotspot mutations modifies the metabolic phenotype of HCC-derived cells and subsequently their response to the combination therapy.

EACR25-0959

Massively scalable direct guide RNA capture for pooled CRISPR screening

V. Mishra¹, C. Conant², F. Kaper², C. Rogert², K. Fontanez², H. Rickner², R. Meltzer², Y. Xue², J. Ishibashi², M. Rahman²

¹Illumina, Marburg, Germany

²Illumina, San Diego, United States

Introduction

Single-cell direct capture CRISPR screens have the potential to uncover critical biological insight across a broad range of research fields such as oncology, immunology, and more. However, their utility to date has been limited by the availability of a truly high-throughput, economical, and accessible single-cell direct CRISPR capture technology. The number of cells processed per experiment scales with the number of perturbations; this can result in experiments requiring the processing of tens to hundreds of thousands of cells to ensure sufficient representation of each perturbation. In response to this challenge, we present a novel method enabling simultaneous capture of single-cell transcriptomes and CRISPR-Cas9 guide RNAs from individual cells facilitated by dual-oligo functionalized polymer particles called particle-templated instant partitions (PIPs).

Material and method

With the potential for multimodal profiling of up to one million cells in a single reaction, this method makes possible the profiling of pooled screens with tens of thousands of guides, a significant advance in direct capture CRISPR screening. To demonstrate the utility and scalability of this technology, millions of CRISPR-

Cas9 perturbed mammalian cells were combined with dual-oligo PIPs, emulsified by vortexing, and processed to distinct gene expression and guide libraries.

Result and discussion

We demonstrate the unique ability to archive cDNA on PIPs to enable segregated amplification of gene expression and sgRNA libraries, enhancing specificity and streamlining the workflow. We observed robust direct guide capture among a diversity of samples and confirmed that whole transcriptome mRNA sensitivity was comparable between uni-linker (mRNA only) and dual linker PIPs (mRNA and Cas9).

Conclusion

The combination of simple, high throughput single-cell analysis with emerging low cost high-capacity sequencing capabilities will enable routine genome-wide perturbational assays across many biological fields.

EACR25-0971

Different mutational patterns in primary colorectal cancer and its paired synchronous or metachronous metastasis and their association with patient outcomes

M. Rajtmajerova¹, F. Ambrozkiewicz¹, V. Hlavac², A. Trailin¹, L. Cervenka¹, J. Bruha³, P. Soucek², S. Susova², V. Liska³, K. Hemminki¹

¹*Charles University, Faculty of Medicine In Pilsen, Biomedical Center, Pilsen, Czech Republic*

²*National Institute of Public Health, Toxicogenomics Unit, Prague, Czech Republic*

³*Charles University, Faculty of Medicine In Pilsen, Department of Surgery, Pilsen, Czech Republic*

Introduction

Colorectal Cancer (CRC) is the second most deadly cancerous disease worldwide. Early diagnosis is vital for successful treatment as survival gradually drops from 90 % at stage I below 20% for stage IV. Most frequently CRC metastasizes to the liver, and it can be diagnosed simultaneously with primary tumor (synchronous metastasis) or after primary tumor (pCRC) removal (metachronous metastasis). We performed whole exome sequencing to depict genetic changes in primary tumors and their paired synchronous or metachronous liver metastases.

Material and method

Whole exome sequencing was performed on 87 samples of pCRC and its paired liver metastasis (LM) and 36 singletons (where only one tissue type was available). Firstly, we examined differential mutated genes and type of mutations and CNV. Secondly, we focused on the tumor mutation burden (TMB) in pCRC and LM. We evaluated its association with overall survival (OS) and disease-free survival (DFS) from colon and liver surgery by Cox regression and Kaplan-Meier method. For all analysis, different chronicity of metastases was considered.

Result and discussion

APC and TP53 were identified as the most commonly mutated genes in pCRC (both ~50%) and its metachronous metastasis (both 64%). For synchronous metastasis we observed much lower frequencies of

mutations in APC gene (40%). MPDZ gene mutations were characteristic to metachronous pCRC only, mutations in VCAN, MTCL1, MDN1, SHROOM2, SPEG and GLI2 were more prevalent in synchronous pCRC. FBN1 mutations were unique to synchronous LM. We observed significantly higher TMB ($p = 0.03$) in metachronous group when comparing pCRC and LM. On the other hand, in the synchronous group, we observed a significant positive correlation between TMB in pCRC and LM. We observed longer OS (HR = 0.3, $p = 0.01$) for patients with higher TMB in pCRC leading to synchronous metastasis. On the other hand, higher TMB in Metachronous metastasis was associated with shorter DFS (HR = 2.01, $p = 0.03$).

Conclusion

The results suggest that distinct tumor progression pathways account for different chronicity and may have ultimate impact on patient's prognosis.

Saturation mutagenesis of the FGFR kinase domains reveals all activating point mutations and their drug response

C. Tangermann¹, A. Ghosh¹, M. Ziegler², F. Facchinetto³, Y. Carus Sahin¹, L. Viardot¹, S. Loges², Y. Loriot³, A. Illert⁴, S. Diederichs¹

¹*Medical Center - University of Freiburg, Division of Cancer Research, Department of Thoracic Surgery, Freiburg, Germany*

²*German Cancer Research Center (DKFZ), Division of Personalized Medical Oncology (A420), Heidelberg, Germany*

³*Institut Gustave Roussy, Paris, France*

⁴*Internal Medicine III, Technical University Munich, München, Germany*

Introduction

To overcome the major challenge of variants of unknown significance in precision oncology, high-throughput functional genomics is essential. Only a comprehensive characterization of the vast landscape of cancer mutations enables optimized clinical treatment targeting molecular aberrations. Aberrant activation of fibroblast growth factor receptors (FGFRs) is a common oncogenic driver across multiple cancer types, with selective FGFR inhibitors (FGFRis) already approved for clinical use. However, the therapeutic potential of these inhibitors is constrained by the unknown characteristics of point mutations in FGFR1, FGFR2, FGFR3 and FGFR4, which can drive signaling and/or confer resistance. Here, we established a saturation mutagenesis scanning platform to assess all 11520 possible single nucleotide variants in the kinase domains of FGFR1-4 through pooled positive selection screens.

Material and method

We generated lentiviral libraries of all possible 11520 SNVs in the kinase domains of FGFR1-4 and tested their impact on FGFR activation as well as their capacity to mediate resistance to the FDA-approved FGFR inhibitors pemigatinib and futibatinib in positive selection screens. Selected activating and resistance mutations were individually cloned and their impact validated in a second cell line model.

Result and discussion

We classified 474 activating mutations and 738 resistance-conferring mutations to pemigatinib and/or futibatinib – many of which clustered within specific structural elements. Merging these two datasets we identified 301 targetable FGFR point mutations analogous to a strong PS3/BS3 evidence level. Notably, mutations at the same codon or the same mutations in different FGFRs could exhibit strikingly diverse effects, highlighting the necessity for a saturation mutagenesis approach. The screens also identified loss-of-function mutations and FGFR2-specific activating nonsense mutations. Importantly, the functional screens detected 97% of acquired resistance mutations in a clinical trial. To enhance experimental robustness and universality, the screening protocol was also established using a urothelial cancer cell line - a common FGFR-altered cancer entity. This approach revealed a significant overlap in identified resistance mutations, contributing to a more comprehensive understanding of the utility of model cell systems in saturation mutagenesis screening.

Conclusion

In summary, we present a thorough and clinically valuable catalog of all druggable point mutations within the FGFR kinase domains which is readily accessible for clinical decision making to select the optimal cancer therapy and expanding the potential application of the approved inhibitors.

³*Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Unit of Bio-imaging, Department of Molecular Biochemistry and Pharmacology, Milano, Italy*

⁴*Azienda USL-IRCCS di Reggio Emilia, Pathology Unit, Reggio Emilia, Italy*

Introduction

Lung cancer is the leading cause of cancer-related deaths worldwide. KRAS mutations, present in ~30% of lung adenocarcinomas, are associated with poor prognosis and limited treatment options. We identified EGLN1 as a novel druggable dependency in KRAS- mutated lung cancer. EGLN1 encodes PHD2 prolyl-hydroxylase, known for degrading HIF1α under normoxia. We previously showed that EGLN1 supports tumor progression via HIF1α-dependent and independent mechanisms.

Material and method

Using CRISPR/Cas9 system we silenced EGLN1 in several NSCLC cell lines. On these cells, we performed functional assays, including proliferation, migration and invasion. In order to investigate the HIF1alpha independent role of EGLN1, we have generated knockout (KO) cell

lines for EGLN1, HIF1alpha or both genes and performed proteomic and transcriptomic profiling. To characterize EGLN1 role in regulating mitochondria biology, we performed seahorse mitostress test, confocal microscopy analysis and TEM analysis.

Result and discussion

We identified and validated EGLN1 as a novel druggable dependency gene, associated with KRAS- mutated lung cancer. EGLN1 is overexpressed in tumor tissue and its high expression correlates with worse prognosis in lung cancer patients. In lung cancer cell lines, EGLN1 supports proliferation, migration, colony formation and 3D growth. Pharmacological inhibition of EGLN1 exerts anti-proliferative effects both in cell lines and patient-derived organoids. EGLN1 acts at least through two different molecular mechanisms, one HIF1α dependent and one HIF1α independent. Through integrative analysis of transcriptomic and proteomic profiles of EGLN1 KO, HIF1α KO and double KO cells, we identified a panel of mitochondrial genes deregulated independently on HIF1α transcriptional activity. Strikingly, EGLN1 KO leads to aberrant mitochondria morphology and profound impairment of mitochondrial respiration.

Conclusion

Overall, we identified EGLN1 as a novel therapeutic target in KRAS-mutated lung cancer. EGLN1 has a pro-oncogenic function in lung cancer, in part because of its capacity to control mitochondria through an HIF-independent mechanism.

Introduction

Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related mortality worldwide, with surgery remaining the only curative option due to limited effectiveness of alternative treatments. Two key hallmarks of HCC, intra-tumoral heterogeneity (ITH) and a complex tumor microenvironment (TME), play crucial roles in tumor progression and therapeutic resistance, yet their molecular features remain poorly understood.

Material and method

To address this gap, single-cell RNA sequencing was performed on 15 samples (13 treatment-naïve HCC patients and 2 normal livers) to map the transcriptional

landscape of HCC tumors and their surrounding TME. Copy-number analysis inferred the clonal architecture of the tumor cells. By applying the non-negative matrix factorization, heterogeneous cancer cells were classified into distinct functional metaprograms (MPs). Spatial transcriptomics, combined with cell-cell interaction analysis, provided insights into the dynamic interactions between malignant cells and TME components.

Result and discussion

We identified seven distinct transcriptional metaprograms, along with their potential master regulators, within malignant hepatocytes, reflecting a broad spectrum of biological processes, including stress responses, metabolism, and epithelial-to-mesenchymal transition (EMT). By examining the genetic regulation of these inferred MPs, we found most HCCs are polyclonal at the copy number level. Some tumors exhibited homogeneous expression patterns across all CNV-defined malignant subclones, while others displayed multiple distinct transcriptional states, highlighting how clonal diversity contributes to the complex transcriptional landscape of HCC, yet only partially accounts for its functional heterogeneity. Moreover, integrating spatial transcriptomics with ligand-receptor analysis, we uncovered specific tumor-stroma interactions involving angiogenic endothelial cells, mediated by type IV collagen (COL4A1/2) and fibronectin (FN1), which engage integrins (ITGA1/B1) and syndecans (SDC1/4) on tumor cells. We also observed that some tumor subclones in distinct spatial regions exhibit different interaction patterns with the TME, suggesting their location may influence cell communication and contribute to functional heterogeneity.

Conclusion

Our study offers a high-resolution spatial map of ITH in HCC. We identified distinct tumoral cell states showing that transcriptional diversity extends beyond genetic variability and may result from tumor plasticity. Spatial interactions between tumor and angiogenic endothelial cells suggest mechanisms reshaping the TME and influencing tumor behavior. These findings provide new insights into the complex relationship between subclonal structure and the TME, highlighting potential therapeutic targets for HCC.

Introduction

High mortality of colorectal cancer is usually due to the development of distant metastases, the most common site of which is the liver. Unlike in primary tumors, there are no known molecular markers predicting relapse in the metachronous metastatic setting, in which a metastasis develops more than 6 months after primary tumor diagnosis, is then surgically resected, but a recurrence/relapse soon occurs in more than half of patients, while in others it does not for many years. Markers for risk of metastasis relapse could help optimize treatment strategies and minimize over/undertreatment of patients.

Material and method

We selected a cohort of patients with differing time to relapse after resection, treated at the University Hospital in Pilsen ($n = 41$), and analyzed matched pairs of fresh frozen metachronous colorectal cancer liver metastasis (mCLM) and adjacent non-tumor liver ($n = 41$) by whole exome sequencing and mRNA sequencing ($n = 38$, overlap $n = 34$). Detailed clinical data were collected, including relapse-free survival after mCLM resection (RFS) and complete blood work. Associations of somatic short mutations, as well as copy number alterations and gene expression profiles with all available clinical data were tested using a range of statistical methods. Data were also compared to those from primary tumors from TCGA ($n = 613$).

Result and discussion

While short SNV and indel and gene-level CNA analysis observed features known from primary tumors, no individual genes were associated with RFS. However, arm-level loss of chr3p, chr5q and gain of chr16p were associated with poor RFS (FDR-adjusted P values 0.029, 0.017 and 0.042, resp.). TCGA samples showed a similar association of loss of chr3p and chr5q with progression-free interval (unadjusted $p = 0.015$ and $p = 0.0015$, resp.), but not for gain of chr16p. The frequencies of these CNAs were approx. 2x higher in early relapse mCLMs than in the rest of mCLMs and TCGA, despite the overall CNA load not being significantly different. Gene set enrichment analyses showed that these CNAs led to expected changes in mRNA levels for their respective arms, but the dysregulated pathways differed between mCLMs and primary tumors with the same alterations, depending on the subset of the TCGA cohort. The general pathway signature of early relapse mCLMs was similar to that of more advanced primary tumors and less advanced tumors with early progression.

Conclusion

Arm-level CNAs in chr3p, chr5q (contain major tumor suppressor genes), and chr16p (host to several oncogenes) should be the subject for further study as potential predictors of early relapse in mCLMs. In general, early relapse mCLMs show transcriptomic signatures similar to those of more aggressive/advanced primary tumors.

Genomic instability and mitochondrial dysfunction drive high grade serous ovarian cancer

A. Ewing¹, A. Meynert¹, R. Silk¹, M. Churchman², S. Herrington³, B. Dougherty⁴, P. Roxburgh⁵, C. Gourley², C. Semple¹

¹University of Edinburgh, MRC Human Genetics Unit, Edinburgh, United Kingdom

³University of Edinburgh, Edinburgh, United Kingdom

⁴AstraZeneca, Translational Medicine, Waltham, United States

⁵University of Glasgow, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom

Introduction

Deciphering the complex somatic variation present in tumour genomes is crucial to determine the events that drive tumour progression and fully understand the evolution of tumours. High grade serous ovarian cancer (HGSOC) is often considered an archetypal example of a tumour type that is driven by frequent structural variants and genomic instability, while the roles of somatic mtDNA variants in this tumour type are poorly studied. We have comprehensively studied the mutational landscape driving HGSOC, exploiting a large, deeply whole genome sequenced dataset with matched RNA-seq expression data.

Material and method

We constructed a combined WGS cohort ($N = 324$) of primary HGSOC tumours, to generate a harmonised dataset of consensus somatic mutation calls and gene expression for five HGSOC WGS sub-cohorts, including our own cohort ($N = 115$) and four previously published WGS cohorts. We also used state-of-the-art algorithms to predict complex structural variants, which are prevalent in this tumour type, including chromoplexy (55% of samples), chromothripsis (31%), pyrgo (28%) and breakage-fusion-bridge events (BFB) (27%) and ecDNA (16%).

Result and discussion

We show that the genomic chaos seen in these tumours obscures meaningful underlying patterns, namely two divergent evolutionary trajectories, affecting patient survival and causing different genomic aberrations. One involves homologous recombination repair deficiency while the other is dominated by whole genome duplication with frequent chromothripsis, breakage-fusion-bridges and ecDNA. Remarkably, these heavily

disrupted nuclear genomes are also frequently accompanied by alterations to the mitochondrial genome, impacting patient survival. The magnitude of the impact on survival is directly related to the types and frequencies of the mtDNA variants involved. There is also evidence that mtDNA mutation loads interact with some structural alterations in the nuclear genome to affect survival.

Conclusion

These new layers of driver mutations, mediated by genomic instability and mitochondrial dysfunction, suggests new directions for research into tumour biology and potential therapeutic targets.

EACR25-1076

Single-cell sequencing analysis highlights the transdifferentiation potential of cancer cells in a neuroblastoma cell line

M. Tomanelli¹, J. Hoti¹, D. Ceresa¹, P. Malatesta¹, P. Modesto², T. Florio³, A. Pagano⁴

¹University of Genoa, Department of Experimental Medicine (DIMES), Genoa, Italy

²Ospedale San Martino IRCCS, Genoa, Italy

³University of Genoa, Department of Internal Medicine (DIMI), Genoa, Italy

⁴University of Genoa, Department of Experimental Medicine, Genoa, Italy

Introduction

Neuroblastoma is the most commonly diagnosed extracranial tumor in infants and originates from neural crest cells during development. Our laboratory identified in the past a chromosomal region encoding a long non-coding RNA, (namely 29A) within the first intron of ASCL3 gene. Several studies characterized the role of this 29A nc-RNA in neuroblastoma, showing that its expression leads to tumor differentiation, thereby reducing malignancy. Genetically modified cell clones over-expressing this non-coding RNA were generated from the SK-N-BE(2) neuroblastoma cell line. High levels of 29A lead to neuronal differentiation of the culture, as evidenced by the expression of specific neuronal markers and the generation of action potentials and specific currents by these cells. Alongside these observations, molecular markers and microscopical analyses showed the presence of different cell types within the culture. This finding was particularly intriguing because these clones originated from a single cell, thus suggesting that the observed heterogeneity is reached by trans-differentiation processes occurring within the culture, a key aspect to be investigated in tumor biology.

Material and method

These findings were further validated through a single-cell RNA sequencing analysis which identified nine distinct cell populations within the culture. The single-cell RNA sequencing analysis allowed us to identify specific membrane markers expressed by individual subpopulations, thus enabling us to attempt their separation via Fluorescence-Activated Cell Sorting (FACS) for further subpopulation-specific studies.

Result and discussion

The study aimed to investigate these nine NB cell subpopulations by analyzing the gene expression of specific pathways relevant to tumorigenesis. In particular,

we identified subpopulations producing vascular endothelial growth factor (VEGF), as well as a single population capable of receiving this signal expressing VEGFR. This suggests the relevance of this cell-to-cell communication in coordinating angiogenesis. Additional gene expression analyses were conducted to examine pathways involved in DNA repair, cell cycle regulation, invasion and metastasis, and the epithelial-mesenchymal transition process in order to better characterize the behavior of these subpopulations.

Conclusion

In conclusion, we report that the presence of specific subpopulations within the NB tumor mass might be consequent to specific transdifferentiation processes whose appropriate understanding could lead to more targeted therapies. The use of specific antibody panels to assess the presence identify specific cell subpopulations within the tumor nodule might help to increase the accuracy of therapies.

⁴*Akershus University Hospital, Department of oncology, Lørenskog, Norway*

⁵*University of Oslo, Institute of Clinical Medicine, Faculty of Medicine, Oslo, Norway*

Introduction

Ductal carcinoma in situ (DCIS) is an early form of breast cancer where cancer cells grow within the milk ducts, separated from the surrounding stroma by the myoepithelium and the basement membrane. DCIS itself is indolent, and as many as 50% of DCIS will never progress to invasive breast cancer (IBC), even if untreated. However, there exist no reliable diagnostic tools to stratify DCIS lesions according to risk of progression. The escape of cancer cells from the milk ducts is influenced by the cancer cells themselves, the microenvironment surrounding the ducts and the interplay between the two. Exploring this interplay could help us increase our understanding of the invasive potential of DCIS.

Material and method

We performed GeoMx spatial transcriptomics of 16 cases of pure DCIS (Luminal A: n = 8, Triple Negative (TN): n = 8) to characterize cancer cell and stromal cell compartments separately. Differential gene expression analyses and gene set enrichment analyses were used to compare cancer cell expression profiles between the subtypes. To characterize the stromal immune cell composition, we performed *in silico* immune cell deconvolution and multiplex immunofluorescence for immune cell protein

markers. For validation, we utilized a gene expression dataset from bulk tumor tissue comprising pure DCIS (n = 57) and IBC (n = 131).

Result and discussion

Compared to Luminal A, we found enrichment of genes involved in energy metabolism in TN DCIS cancer cells with enhanced glucose metabolism, increased pentose phosphate pathway activity, increased glutamine uptake, altered mitochondrial metabolism and increased iron uptake, indicating extensive metabolic reprogramming in TN DCIS. In addition, we found higher expression of genes encoding secreted proteins involved in extracellular matrix reorganization in Luminal A DCIS. The relative composition of immune cells surrounding ducts with DCIS cancer cells was similar between the subtypes, however, the immune cell abundance was much higher in TN DCIS compared to Luminal A. In TN DCIS, immune cells were commonly organized as immune cell clusters, while in Luminal A DCIS, immune cells were more often dispersed throughout the periductal stroma. Validation performed in a bulk gene expression dataset confirmed metabolic differences between the TN and Luminal A subtypes in DCIS. These subtype differences were also found in IBC.

Conclusion

This study revealed a correlation between cancer cell metabolic reprogramming and immune cell abundance in DCIS which was linked to subtype. These findings provide insights into the breast cancer invasion process, potentially contributing to improved understanding of DCIS progression and future treatment strategies.

Investigating the molecular diversity of luminal breast cancer arising in young women

L. Musco¹, G. Di Giustino¹, A. Dall'Acqua¹, I. Segatto¹, C. Gava¹, M. Mattevi¹, G. Rampioni Vinciguerra², G. Baldassarre¹, B. Belletti¹

¹*Centro di Riferimento oncologico, Molecular Oncology, Aviano, Italy*

²*Faculty of Medicine and Psychology, University of Rome, Clinical and Molecular Medicine, Rome, Italy*

Introduction

Breast cancer (BC) arising in young women (Y) is uncommon, yet clinically relevant. Even when corrected for tumor stage, grade and subtype, BC in Y display worse response to standard therapies, higher risk of relapse and lower overall survival compared to older patients (nY), particularly evident in the Luminal subtype (LBC). LBC biology in Y remains poorly understood and models that accurately reflect its molecular characteristics are still lacking. Therefore, this study aims to uncover the genetic, molecular and biological bases of LBC in Y, in order to identify mutational signatures, novel biomarkers and, possibly, therapeutic targets for LBC Y patients.

Material and method

Next-Generation Sequencing (NGS) approaches were used to perform a comprehensive mutational profiling analysis on a cohort of LBC samples from Y (<45 y) (n = 119) and nY (>55 y) (n = 92) patients. Samples were first sequenced using a custom-made amplicon-based panel,

targeting the most frequently mutated genes in LBC (PIK3CA, AKT1, TP53, GATA3) at high coverage, then by whole exome sequencing (WES). Next, using lentiviral approaches, we generated primary luminal breast epithelial (BPE) cells carrying PIK3CAE545K, PIK3CAH1047H, TP53R175H mutants, either alone or in combination, and tested them in proliferation, survival, 3D-morphogenesis and response to therapies.

Result and discussion

Targeted NGS analyses revealed that mutations in PIK3CA/AKT1 and GATA3 were significantly enriched in Y, who also harboured higher frequency of PIK3CA/AKT1 co-mutations with GATA3 or TP53, especially in the luminal B subtype. WES analyses confirmed these results revealing also other gene mutations enriched in Y (ERBB2, FAT3, CBFB and MAP3K1) and in nY (LRP1B, EPHA3 and CSMD3). Copy number variation analysis also revealed that Y women displayed TP53 deletions and GATA3 amplification at higher frequency compared to nY ones. To test the biological implications of these alterations, we characterized BPE cells carrying these mutants. As expected, PIK3CA mutations, especially in combination with TP53 mutations, altered the growth and led these normal cells to a transformed phenotype. More interestingly, combining PIK3CA and TP53 mutations made these cells resistant to endocrine therapy and CDK4/6 inhibitors. Synthetic lethality approach revealed vulnerability by inhibiting EZH2.

Conclusion

Overall, our results provide new insights into the molecular fingerprint of LBC patients supporting the hypothesis that BC arise in Y may represent a unique biological entity. Moreover, we shed new light on the biological impact of PIK3CA and TP53 co-mutations on tumorigenesis and drug resistance in LBC context, suggesting that they might represent novel predictive biomarkers for epigenetic therapies, such as EZH2i, possibly not just in Y but across all LBC patients carrying these mutations.

EACR25-1164

Same-cell spatial transcriptomics and proteomics expression at single-cell resolution to decipher melanoma cell state heterogeneity and relationships with the inflammatory microenvironment in metastasis

M. Andhari¹, A. Antoranz¹, J. Chui¹, J. Pey², N. Dubroja¹, A. Arnould¹, G. Shankar¹, K. Nowak¹, F. De Smet¹, F. Bosisio¹

¹KU Leuven, Department of imaging and pathology, Leuven, Belgium

²Intelligent Biodata, Basque Country, Spain

Introduction

Melanoma exhibits significant tumoral heterogeneity, with several melanoma cell states (mCS) identified through single-cell RNA sequencing (scRNA-seq). Although some mCS have been linked to poor immunotherapy response, their role in metastasis is still hypothetical. Immunohistochemistry, the most widely used diagnostic technique, identifies cellular phenotypes

affecting diagnosis and treatment. However, since mCS signatures were discovered at the transcriptomic level, validating their protein expression is crucial. Moreover, while most early stage melanomas (ESM) cases have favorable prognoses and are not followed after excision, 10% of patients develop metastatic disease. Identifying biomarkers to predict progression is therefore essential. This study aims to (1) validate RNA-protein correlation at the single-cell level using an innovative spatial technology enabling simultaneous RNA and protein detection in the same cell; (2) investigate the presence of mCS in ESM; (3) compare mCS enrichment and spatial distribution in metastasising (M+) vs. non-metastasising (M-) ESM.

Material and method

We assembled a cohort of 10 ESM cases (5 M+ vs. 5 M-), matched for key clinicopathological prognostic factors to minimize bias. A single tissue section per case was analyzed using the hyperplex multiomics technology on Lunaphore's COMET instrument. A panel of 24 proteins (MITF, MelanA, AQP1, S100B, SOX10, SOX9, NGFR, TCF4, PDGFRb, BRAF, FAP, CD3, CD4, CD8, CD20, FOXP3, CD68, CD163, podoplanin, MECA79/pNA, α SMA, CK, CD31, and CD45) and 12 RNAs (THY1, MLANA, S100A1, S100B, SOX10, TCF4, ID3, PRAME, TYR, COL5A1, COL1A1, and PMEPA1) was selected to assess RNA-protein correlation for mCS markers and explore their spatial relationship with the inflammatory microenvironment. RNAs were chosen based on minimal signatures from relevant studies. Evaluating protein and RNA markers simultaneously was also evaluated. For data processing and integration, we developed a novel bioinformatics software, DISCOVERY, specifically designed for the integrated analysis of high-dimensional multiplex IF and spatial transcriptomics data.

Result and discussion

MelanA showed strong RNA-protein correlation, whereas SOX10, S100A1, and TCF4 protein expression did not align with their RNA levels. Significant heterogeneity in mCS was observed across samples. Trajectory analyses were performed using protein, RNA, and hybrid approaches. M+ ESM showed enrichment in undifferentiated mCS subtypes, whereas M- cases, despite heterogeneous melanoma marker expression, had minimal undifferentiated mCS content.

Conclusion

This study underscores the importance of multiomics approaches in translating RNA-based signatures into protein-level markers. Unique melanoma cell subtypes identified in this study may serve as potential prognostic markers for high-risk ESM.

EACR25-1195

KRAS mutation derived PSMB8 activates MEK/ERK signaling to promote chemoresistance in pancreatic adenocarcinoma

S. Xue¹, T. Mao¹, Y. Wang¹, J. Ma¹, W. Lu¹, S. Wu¹, J. Cui¹, L. Wang¹, H. Xu¹

¹State Key Laboratory of Systems Medicine for Cancer of Oncology Department and Shanghai Cancer Institute, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Introduction

Pancreatic adenocarcinoma (PAAD) harbors KRAS mutations in >90% of cases, yet KRAS-targeted therapies face limited efficacy and rapid resistance. The ubiquitin-proteasome system (UPS), a master regulator of proteostasis, is frequently hijacked in tumors to drive progression and therapy resistance. Here, we interrogated the clinical and mechanistic roles of KRAS mutation-associated UPS-related genes (KMUPSGs) in PAAD, with a focus on their potential as predictive biomarkers and therapeutic targets to overcome chemoresistance.

Material and method

KMUPSGs were systematically identified via univariate Cox regression and LASSO-penalized regression to construct a prognostic risk signature. Independent prognostic value was validated using multivariate Cox models. Survival differences were assessed by log-rank tests, while Spearman correlation and t-tests evaluated associations with immune infiltration, tumor mutational burden (TMB), and pathway activity. Functional validation included PSMB8 knockdown (siRNA) and pharmacological inhibition (oprozomib) in PAAD cell lines, with proliferation (CCK-8), metastasis (transwell), apoptosis (flow cytometry), and drug sensitivity assays (IC50). Mechanistic studies focused on MEK/ERK pathway activation (Western blot). Experiment in vivo was performed using a cell line-derived xenograft (CDX) model.

Result and discussion

A 7-gene KMUPSG signature stratified PAAD patients into high- and low-risk groups, with high-risk patients exhibiting shorter overall survival, immunosuppressive microenvironments, elevated TMB, and gemcitabine resistance. PSMB8, the top-ranked KMUPSG, was overexpressed in KRAS-mutant tumors and correlated with advanced stages. PSMB8 silencing suppressed proliferation and invasion, and enhanced sensitivity to gemcitabine treatment. Oprozomib, a PSMB8 inhibitor, also exhibited favorable anti-tumor effect.

Mechanistically, PSMB8 drove chemoresistance via MEK/ERK hyperactivation, evidenced by MEK1/2 and ERK1/2 phosphorylation and rescued sensitivity upon its silence. Finally, the PSMB8 knockdown CDX models illustrated better response to gemcitabine treatment.

Conclusion

We established a robust KMUPSG signature for prognostic stratification and chemotherapy response prediction in PAAD. PSMB8 emerged as a central effector of KRAS-mediated chemoresistance, operating through MEK/ERK signaling. Targeting PSMB8 represents a promising strategy to overcome gemcitabine resistance, offering actionable insights for precision therapy in KRAS-mutant PAAD.

Integrated multi-omics analysis identifies sex differences in muscle-invasive bladder cancer

J. Sung^{1,2}, H. Cho^{1,2,3}, S. Cho^{1,2}, D. Yeo^{3,2}, M. Kwon^{3,2}, M. Kim^{3,2}, J. Choi^{3,2}, B. Jo^{3,2}, I. Cha^{3,2}, S. Oh^{3,2}

¹Kyungpook National University, Department of Advanced Bioconvergence, Daegu, Korea (Republic of)

²Kyungpook National University, Cell and Matrix Research Institute, Daegu, Korea (Republic of)

³Kyungpook National University, Department of Biomedical Convergence Science and Technology, Daegu, Korea (Republic of)

Introduction

Bladder cancer (BC) exhibits distinct sex disparities, with men having a fourfold higher incidence rate than women, while women are more likely to present with aggressive tumors and worse outcomes. Despite these disparities, research on sex-based differences in BC remains limited, and sex-specific therapeutic strategies are lacking. Studies in other cancers, such as non-small cell lung cancer (NSCLC), have demonstrated sex-based differences in oncogene expression, mutation profiles, and treatment response, underscoring the importance of investigating sex-based differences in cancer research. In this study, we aim to elucidate sex-based molecular differences in muscle-invasive bladder cancer (MIBC) through a multi-omics analysis, identifying potential biomarkers and therapeutic targets to facilitate precision medicine approaches.

Material and method

We analyzed the MIBC cohort from publicly available dataset, by integrating genomic, transcriptomic, and proteomic data. In genomics, somatic mutations and copy number variations (CNV) were identified from whole-exome sequencing (WES) data. Differential gene expression was analyzed using mRNA sequencing data, while protein abundance was assessed with reverse-phase protein array (RPPA) data. Statistical analyses and data visualization were conducted using R.

Result and discussion

Our analysis revealed significant sex-based differences in BC at multiple molecular levels. Genomic analysis identified distinct mutational profiles between sexes, with specific oncogenic alterations enriched in each group. Transcriptomic profiling uncovered differentially expressed genes related to immune response and cell cycle regulation, which may contribute to the observed disparities in tumor progression and patient outcomes. By performing consensus clustering using immune-related genes, we identified distinct immune microenvironment differences between sexes and uncovered key genes contributing to these variations. Proteomic analysis further supported these findings, revealing sex-specific variations in protein expression patterns and identifying key signaling pathways associated with tumor aggressiveness and therapy response. By integrating multi-omics data, we identified key molecular interactions that contribute to sex-based disparities in BC progression.

Conclusion

This study provides a comprehensive molecular characterization of sex-based differences in BC through an integrative multi-omics approach. By delineating distinct molecular signatures, we identify potential biomarkers and therapeutic targets that could inform the development of sex-specific precision medicine strategies for BC. These findings provide an approach for

personalized patient management and survival prediction in future clinical studies.

EACR25-1254

Comprehensive genomic profiling and RNA-seq analysis reveal distinct genomic and transcriptomic signatures associated with treatment response in metastatic colorectal cancer (mCRC) patients (pts) enrolled in the NIVACOR trial

R. Esposito Abate¹, A. Damato², S. Tessitore¹, F. Bergamo³, L. Antonuzzo⁴, G. Nasti⁵, E. Maiello⁶, A. De Luca¹, C. Pinto², N. Normanno⁷

¹Istituto Nazionale Tumori Fondazione G. Pascale – IRCCS, Cell Biology and Biotherapy Unit, Naples, Italy

³Veneto Institute of Oncology IOV - IRCCS, Medical Oncology I, Padua, Italy

⁴University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

⁵Istituto Nazionale Tumori Fondazione G. Pascale – IRCCS, Abdominal Oncology Division, Naples, Italy

⁶Foundation IRCCS, Casa Sollievo della Sofferenza, Oncology Unit, San Giovanni Rotondo, Italy

⁷IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST), Scientific Directorate, Meldola, Italy

Introduction

In the phase II NIVACOR trial, pts with RAS/BRAF mutated (mut) mCRC received FOLFOXIRI/bevacizumab (bev) combined with nivolumab (niv) as first-line therapy. An objective response rate (ORR) of 76.7% and a median progression-free survival (mPFS) of 10.1 months was reached. Here, we describe data from comprehensive genomic profiling (CGP) and RNA-seq of tumor samples from NIVACOR pts, focusing on the microsatellite stable (MSS) cohort.

Material and method

Pts with untreated RAS/BRAF mut mCRC received FOLFOXIRI for 8 cycles followed by bev and niv as maintenance. DNA and RNA were obtained from formalin fixed paraffin embedded (FFPE) specimens of primary tumor samples. Translational analyses were performed by the Oncomine Comprehensive Assay Plus® and the Ion AmpliSeq™ Transcriptome Human Gene Expression® assays.

Result and discussion

CGP on DNA was successful for 49 MSS tumors. The tumor mutation burden (TMB) was >10.4 mutations/Mb in 9 pts with a mPFS of 18 months, while the 40 TMB-low showed a mPFS of 9 months ($p = 0.06$). In order to identify a genomic signature, we compared the mutational landscape exclusively present in the 25th or 75th PFS percentile MSS cases. We identified two distinct signatures: a poor prognosis signature (RES) of 53 genes and a good prognosis signature (SENS) of 98 genes. When the two signatures were applied to the MSS cohort, pts with at least one genomic alteration (GA) in RES showed a statistically significant shorter mPFS ($p < 0.0001$), while pts carrying at least one GA in SENS showed a longer mPFS ($p = 0.0003$). Furthermore,

RNAseq analysis between the 75th vs 25th percentile cohorts revealed 219 differentially expressed genes involved in immune system, PI3K cascade and DNA Replication-Dependent Chromatin Assembly.

Interestingly, from both DNA and RNA analysis we found an involvement of the PI3K/AKT pathway (PIKpath). For this reason, we performed a survival analysis considering as mut pts with at least one GA in this pathway. The results showed a mPFS of 10 months for the mutant versus 8 months for the wild type cases in the MSS subgroup ($p = 0.12$). Remarkably, the fraction TMB-high patients was higher in pts mut in PIKpath in the MSS cohort (25% vs 5,5%).

Conclusion

The NIVACOR trial demonstrates the potential of combining ICIs with intensive chemotherapy and anti-angiogenic therapy in a challenging mCRC population, and suggests the utility of molecular profiling that might improve patients' selection and optimize treatment efficacy. These results are particularly relevant because they were obtained in the subgroup of RAS/BRAF mut mCRC with worst prognosis.

EACR25-1261

Analysis and machine-learning based prediction of cellular adaptation during ovarian cancer treatment

J. Wong Ramirez¹, J. Jäntti¹, J. Dai¹, M. Falco¹, Y. Wang¹, A. Vähärautio¹

¹University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland

Introduction

In cancer, the inherent diversity in cell states lays the ground for evolutionary selection. Furthermore, plasticity allows for adaptation during treatment. Recently, the lab identified a stress-related cellular state that contributes to both inherent and acquired resistance in high-grade serous ovarian cancer (HGSC) metastases, suggesting that prior stress exposure enhances cancer cell resilience during chemotherapy. To address the role of stress in pre-existing and adaptive resistance, we are developing a single-cell stress recording system combined with lineage tracing methodology, in addition to a data-analysis pipeline to process the integrated information. The unique generated data will then be used to build a machine learning model that predicts past and future stress responses from gene expression profiles alone, allowing stress history estimation from existing scRNA-seq data to reveal how adaptive stress is associated with cancer cell resilience.

Material and method

The experimental design of the project is based on two particular methodologies, which lately are analyzed by a collection of in-house scripts, combined with public software. We use a (1) CRISPR-based recording system (Cassiopeia, by Jones et al. 2020.) to study the stress activity in individual cells at the level of transcription factors (TFs). Briefly, the stress activity is measured by a system of "scars" (indels), that will be used to reconstruct cellular evolution to explore treatment adaptation at the level of cells and clones. To determine the sisterhood relationship between cells, we use a (2) barcode-labeling

system, performing pairwise comparisons of similarity and determining the “strength” of the connection by analyzing the evidence supporting the barcodes. After testing our pipeline and validating our data, in the future, we aim to test neural network models, to predict future and past adaptations.

Result and discussion

For the sisterhood-relation pipeline, recent in-house results suggest recovering a couple of thousands of cells, allowing us to use them to study their transcriptomic profiles. Preliminary conclusions on the stress recording system show consistent results compared with the literature, suggesting a successful induction of the CRISPR scarring machinery.

Conclusion

Our preliminary results support that our experimental methodology in combination with custom data analyses enables us to explore the programs driving inherent and acquired resistance, using sister cells. We now intend to refine our approach by testing variations in our parameters during the analysis, to then integrate the whole pipeline, experimental validation, and laying the foundation for our deep learning prediction.

EACR25-1262

Novel replication stress signature predicts non-homologous end-joining association mediated by the MutS α complex

P. Jung¹, M. Kschischko¹

¹University of Koblenz, Institute for Computer Science, Koblenz, Germany

Introduction

Cancer development is closely linked to genomic instability, with chromosomal instability (CIN), characterized by the continuous gain of aneuploidies, as its most common form. One major contributor to CIN is replication stress (RS), which refers to disruptions in DNA replication leading to chromosomal missegregation. The impact of CIN and RS on cancer cell proliferation is complex and context-dependent. While some studies suggest that the increased intra-tumor heterogeneity as a result of RS and CIN provides a mechanism for adaptability, others have observed genomic instability to be a cellular burden. Existing signatures aiming to quantify the level of RS are derived by overexpressing oncogenes like MYC, likely introducing a bias toward proliferation.

Material and method

We gathered RNA-sequencing data from five independent studies, using six gene targets to induce replication stress: three methods used oncogene over-expression and the other three relied on gene knockouts disrupting replication integrity. Using these labeled samples, we identified genes consistently deregulated in RS samples. By leveraging large-scale cancer databases, we explored pan-cancer processes associated with the RS signature.

Result and discussion

Our RS signature was the only one that reliably distinguished RS from non-RS samples in unseen samples. Applying the signature to large cancer databases

revealed distinct differences between primary tumors and cancer cell lines. In tumors, RS was associated with an enrichment of cell cycle gene sets, while the expression of their leading-edge genes suggested accelerated cell cycle progression. Conversely, in cell lines, RS samples displayed a slight reduction in cell cycle activity. Additionally, we identified links between the RS signature, the mismatch-sensing MutS α complex, and non-homologous end-joining (NHEJ) repair pathway activity. Interestingly, the RS-NHEJ association was removed when controlling for protein expression of MutS α components, indicating a potential role for mismatch sensing in modulating the double-strand break response upon replication stress.

Conclusion

By reducing bias toward oncogene-related RS, this new RS signature might capture the complex association of genomic instability with proliferation more accurately. The signature may also facilitate the identification of novel processes associated with tumorigenic RS and uncover new potential targets for cancer treatment.

EACR25-1281

Single-Cell Analysis Reveals U1 snRNA Mutation-Driven Tumor Micro-environment Remodeling in Chronic Lymphocytic Leukemia via CD44 Signaling

S. López-Tamargo¹, J. Fernández-Mateos¹, P. Bousquets-Muñoz², C. Olivari-Fernández¹, A. Fuente-González¹, E. Campo³, D. Colomer³, A. Gutiérrez-Fernández¹, X. Puente¹

¹University of Oviedo, Spain

²The Institute of Cancer Research, London, United Kingdom

³Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain

Introduction

Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of monoclonal mature B lymphocytes in peripheral blood, bone marrow, lymphoid tissues, and extranodal sites. Genes involved in RNA splicing such as SF3B1 and U1 are frequently mutated in CLL, leading to altered splicing and generation of tumor neoepitopes.

Material and method

To investigate how these mutations shape the tumor microenvironment (TME), we performed an in-depth characterization of CLL using multiple single-cell sequencing technologies, including 5'GEX, single-cell TCR, and CITE-seq. Our study analyzed 26 tumor samples from the bone marrow or lymph nodes of 23 U-CLL patients, with 7 carrying U1 mutations, 8 carrying SF3B1 mutations, and 10 lacking splicing gene mutations.

Result and discussion

We have developed the most comprehensive single-cell atlas of unmutated CLL, encompassing the largest number of cells and patients while integrating multi-layered information. We observed significant intra-tumor heterogeneity, discerning 12 distinct transcriptional programs, one associated with the U1 g.A3>C mutation and characterized by hyperactivation of NF-κB signaling.

The T-cell and NK compartments exhibited site-specific and mutation-specific enrichment, characterized by elevated CD4+ regulatory T cells (Tregs) and CD8+ exhausted cells within lymph nodes. Conversely, U1-mutant tumors showed enhanced CD8+ cytotoxic activity, predominantly mediated by effector-like CD8+ cells. Single-cell T-cell receptor sequencing revealed clonotype expansion in U1-mutated tumors, particularly within CD8+ effector and exhausted cells, indicative of a neoantigen-driven immune response. Cell-to-cell interaction analyses identified CD44 as a key mediator in U1-mutated tumors, highlighting pro-B survival interactions such as those involving the MIF-CD44-CD74 axis. Furthermore, tumorigenic CD44 isoforms characterized by the inclusion of alternative exons were found to be upregulated in U1-mutant tumors. In addition, enhanced interactions between CD80 on CLL cells and CTLA4 on Tregs and CD8+ exhausted cells underscored an immunosuppressive phenotype associated with U1-mutated CLL.

Conclusion

These findings underscore the intricate crosstalk between CLL mutations and the TME, revealing potential therapeutic avenues for U-CLL with U1 mutations. Notably, CD44, a key mediator of microenvironmental communication and intracellular signaling, was upregulated and alternatively spliced in U1-mutant CLL, positioning it as a promising target for therapies such as anti-CD44v6 treatment. Additionally, the heightened CD8+ effector response in U1-mutant tumors suggests neoantigen recognition, highlighting a potential opportunity for immunotherapeutic interventions.

Glucocorticoid receptor as a prognostic factor in triple-negative breast cancer correlates with migratory signature at a single-cell level

H. Butz¹, L. Pongor², L. Bársznyi¹, F. Fekete¹, E. Tóth¹, R. Gyebrovszki³, B. Budai¹, V. Vereczki¹, A. Patócs¹

²HUN-REN-OOI-TTK-HCEMM Oncogenomics Research Group, Budapest, Hungary

³Semmelweis University, Budapest, Hungary

Introduction

Introduction. The glucocorticoid receptor (GR) plays a highly context-dependent role in tumorigenesis. The GR agonist dexamethasone is routinely administered as supportive therapy alongside chemotherapy to reduce anaphylactic reactions and nausea. However, recent RNA-based and preclinical studies have suggested caution when using glucocorticoids in patients with breast cancer, as GR activation has been shown to promote metastasis in mouse models. Our aim was to investigate GR mRNA and protein expression at the single-cell level and to correlate it with patient survival.

Material and method

Materials and Methods. GR expression was analyzed at the single-cell level using the following approaches:

- i) First, confocal immunostaining was performed to examine GR expression in different cell types within triple-negative breast cancer (TNBC).
- ii) Findings were validated using single-cell sequencing of TNBC samples and conventional immunohistochemistry on 161 TNBC tissue samples.
- iii) Finally, the effect of GR activation on tumor cell migration was assessed through time-lapse imaging of single-cell tracking in vitro using MDA-MB231 and Hs578T TNBC cell lines treated with dexamethasone.

Result and discussion

Results and Discussion. Confocal staining revealed heterogeneous, medium-to-low GR expression in TNBC tumor cells compared to cells in the tumor microenvironment (TME). High GR expression was detected in immune cells, including infiltrating T cells and macrophages. In our TNBC cohort, cytoplasmic GR staining positively correlated with Ki67 expression. Additionally, patients with high nuclear GR staining had significantly shorter progression-free survival (HR = 0.35 [0.08–1.50]; p = 0.0185). Single-cell tracking time-lapse migration experiments demonstrated that GR activation increased cell motility in a time-dependent manner. Single-cell sequencing showed a significant positive correlation between the GR signature and migration signature ($R = 0.61$, $p < 2.2e-16$). Tumor cells with higher GR encoding NR3C1 expression exhibited an increased migration signature. Fast-migrating cells displayed significantly higher expression levels of NR3C1 and its targets SGK1 and TSC22D3 compared to clusters of slow-migrating cells.

Conclusion

Conclusion. Glucocorticoids are essential supportive therapy in routine chemotherapy. However, our findings suggest that high nuclear GR expression is a negative prognostic marker in TNBC patients. GR activation enhances tumor cell migratory potential, which may contribute to poorer outcomes. Therefore, careful monitoring of TNBC patients with high nuclear GR expression is warranted.

Investigating Topoisomerase IIβ Binding Protein 1 as a Potential Prognostic Biomarker and Therapeutic Target in Bladder Cancer

*A. Yehya^{1,2}, A. Al Kurdi³, F. Ghamlouche², J. Basbous^{*1}, W. Abou-kheir^{*2}*

¹University of Montpellier, Institute of Human Genetics, Montpellier, France

²American University of Beirut, Department of Anatomy, Cell Biology and Physiological Sciences, Beirut, Lebanon

³American University of Beirut, Molecular And Cellular Biology Unit, Beirut, Lebanon

Introduction

Bladder cancer (BC) is a major global health concern, ranking among the most prevalent cancers worldwide.

Lebanon has one of the highest BC incidence rates, ranking first in 2018 according to the American Institute for Cancer Research (AICR). Despite advances in molecular biology and treatment strategies, BC management remains challenging due to significant side effects and a high rate of recurrence. This is largely attributed to the heterogeneous nature of the tumor and reduced treatment efficacy. Thus, identifying novel targets to improve diagnostic and treatment effectiveness is essential for enhancing patient outcomes. Topoisomerase II β binding protein 1 (TOPBP1) is a key mediator in the DNA damage response (DDR) and genomic integrity. Research has shown that TOPBP1 is overexpressed in several solid tumors and is associated with poor prognosis in cancer patients. However, its role in BC has not yet been investigated. This study aims to evaluate the potential role of TOPBP1 as a prognostic biomarker and therapeutic target in BC.

Material and method

We will assess the expression levels of TOPBP1 in BC tissues and correlate them with clinical outcomes. Additionally, we will assess the therapeutic potential of targeting TOPBP1 in both two-dimensional (2D) and three-dimensional (3D) culture systems using *in vitro* and *ex vivo* BC models. Finally, we will investigate the disrupted protein functions and interactions caused by TOPBP1 aberrant expression in BC.

Result and discussion

Our preliminary analysis of the Cancer Genome Atlas (TCGA) database indicates that TOPBP1 expression is significantly elevated in BC tissues compared to normal tissues. Moreover, patients with high TOPBP1 expression levels exhibit poor overall and progression-free survival probabilities compared to those with low TOPBP1 expression.

Conclusion

This study may identify TOPBP1 as a novel therapeutic and prognostic marker, with the goal of improving BC management and overcoming tumor resistance and recurrence.

EACR25-1323

Origin of chromosomal instability during acinar to ductal metaplasia in pancreatic cancer

F. Mendoza León¹, L. López Noriega¹, D. Rico², V. Comaills¹

¹*University of Seville, Department of Cell Biology. Cellular Plasticity and Chromosomal Instability in Cancer, Seville, Spain*

²*CSIC/CABIMER, Computational Epigenomics and Cell Identity, Seville, Spain*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is among the cancers with the highest mortality rates, with an overall 5-year survival rate of approximately 5%. Similarly to other cancers, PDAC exhibits a wide variety of genetic insults, ranging from point mutations to more intricate events, primarily copy number variations (CNVs) and complex chromosomal rearrangements. However, the mechanisms underlying the generation of this widespread genomic heterogeneity during PDAC tumorigenesis have not yet been elucidated. A proposed pathway originates

from precursor lesions of Pancreatic Intraepithelial Neoplasia (PanIN), characterised by a disruption in the typical architecture of acinar cells. In response to stressors such as inflammation, pancreatic acinar cells transdifferentiate into ductal cells through a reversible process known as acinar to ductal metaplasia (ADM). When sustained, this transformation can result in PanIN lesions and lead to a gradual progression toward PDAC. The present study focuses on the initial phases of PDAC progression and investigates whether ADM constitutes the origin of genomic instability, mainly through ploidy variation in acinar cells, and promoting early tumorigenesis.

Material and method

The study employed an integrative approach combining single-cell RNA sequencing (scRNA-seq) data analysis with experimental validation. Publicly available scRNA-seq datasets were analysed to investigate CNV alterations and differential gene expression in ADM cells. Immunofluorescence staining (IHC) was performed to assess DNA damage and nuclear envelope integrity in samples from PDAC and PanIN mouse models.

Result and discussion

Early bioinformatics analyses revealed variations in CNV profiles across acinar and ADM cells, suggesting potential subpopulations that exhibited distinct patterns of chromosomal alterations. Additionally, functional enrichment analysis of differentially expressed genes indicated a downregulation of genes associated with the nuclear envelope (NE) in ADM cells. These findings were supported by IHC, which identified multiple indicators of genomic instability, such as double-strand DNA breaks, chromatin bridges, micronuclei and NE alterations.

Conclusion

This study provides preliminary evidence suggesting that ADM may play a key role in driving genomic instability during the initial stages of PDAC development. The observed accumulation of genomic damage and ploidy variations, along with potential NE vulnerabilities, highlights potential fragilities in cells undergoing ADM that could contribute to early tumorigenesis. These findings seem to underscore the importance of targeting ADM and its associated mechanisms as potential targets for preventive strategies in PDAC. Further research is required.

EACR25-1328

Spatial profiling of matched adnexal and omental tumors in high-grade serous carcinoma

N. Aho¹, F. Niemeyer², A. Laury¹, O. Youssef¹, A. Erickson², O. Carpén¹

¹*University of Helsinki, Pathology, Helsinki, Finland*

²*University of Helsinki, Helsinki, Finland*

Introduction

High-grade serous tubo-ovarian carcinoma (HGSC) is the most common and most lethal ovarian cancer subtype. HGSC is often diagnosed at late stage when it has already metastasised to the abdominal lining. Although the majority of the patients do respond to chemotherapy initially, a relapse is likely to occur shortly after, with eventual treatment resistance. Hence to better treat and

understand HGSC it is essential to investigate both adnexal and extra-pelvic tumours. Moreover, the lack of clinically relevant biomarkers for HGSC remains as a challenge.

Material and method

We collected a retrospective cohort of nine patients which all underwent a primary debulking surgery and received at least six rounds of standard chemotherapy. The cohort consisted of three patients with a long (≥ 18 months) progression-free interval (PFI), two with medium (6–18 months) and four with short (≤ 6 months) PFI. From each patient we used matched adnexal and omental tumor samples. Moreover, all utilized tumor samples were fixed with Paxgene, an alcohol based, preservative. We constructed four tissue microarrays which were used for spatial transcriptomics (10x Genomics Visium Spatial Gene Expression for FFPE). To analyse the data, we applied computational methods including pathway enrichment analysis, spot-wise expression analysis and inferCNV to resolve copy-number alterations.

Result and discussion

We discovered several differences between PFI groups and found also consistently pathways up-regulated in the short PFI groups independent of tumor site when compared to medium- and long PFI group. Interestingly, in tumor epithelium, interferon-related pathways were among the most up-regulated in short PFI group while stromal cell expression was enriched for epithelial-mesenchymal transition. Further, we were able to show that several genes possessing a higher expression levels within the interferon pathway can be explained by copy number gains in tumor cells.

Conclusion

Here we show that spatial transcriptomics can be used as a tool to identify biologically relevant differences between PFI groups as well as tumor sites in treatment-naïve patients. Identifying differentially expressed pathways and copy-number alterations is important as they are recognized to contribute to genomic instability facilitating metastasis and chemotherapy resistance. Therefore, uncovering these alterations may help in the development of better treatments and/or predictive biomarkers for HGSC.

EACR25-1334

Phenotypic and genomic characterisation of single micronuclei

J. Maharaj¹, I. McNeill², M. Guscott¹, T. Singer³, S. Hauch³, S. McClelland¹

¹Barts Cancer Institute, Centre for Cancer Evolution, London, United Kingdom

²Barts Cancer Institute, Single Cell Genomics Facility, London, United Kingdom

³Qiagen, Hilden, Germany

Introduction

Chromosomal instability (CIN) is an ongoing process involving the gain and loss of whole, or parts of, chromosomes in many cancers. CIN causes structural and numerical abnormalities both within and without the nucleus, the latter of which is exemplified by micronuclei (MN). MN contain either whole lagging chromosomes or

acentric chromosome fragments which were excluded from the main nucleus and encapsulated in their own membrane after an erroneous mitosis. MN initially cause unequal inheritance of genetic material and may be a source of further significant genetic change through accumulation of DNA damage from dysfunctional replication and repair, as well as chromosome shattering and re-ligation events such as chromothripsis. We aim to better understand the contents of micronuclei, their behaviour, and their impact on genomic evolution.

Material and method

Immunofluorescent microscopy was used to characterize frequency of micronuclei, and whether they were actively transcribing or replicating as well as their propensity to rupture. Micronucleus purification was achieved utilizing Qiagen's QProteome Nuclear Protein Kit, and a combination of filtration and centrifugation steps. MN were size-selected using the cellenONE microfluidics platform and a tagmentase-based "single-cell" DNA library protocol was used to sequence micronuclei.

Result and discussion

We have characterised micronuclear behaviour in both a diploid, chromosomally stable cell line with pharmacologically induced CIN and a panel of cancer cell lines to provide a more comprehensive view of MN behaviour, including rupture, DNA damage levels, and their ability to replicate and transcribe their DNA. We demonstrate that, the frequency of rupture and subsequent likelihood of DNA damage varies across cell lines, and that replication of MN DNA occurs at low levels while transcription is more common. To directly examine MN contents, we developed a novel purification method and applied it to both a model of induced MN (confirming known biases in MN content), and to a cancer cell line. We validated this method by single and bulk sequencing of purified micronuclei derived from our induced system. The sequencing data allowed us to clearly distinguish between whole nuclei and micronuclei based on the representation of read counts across chromosome and to estimate copy numbers of chromosomes and chromosome fragments present in MN.

Conclusion

For the first time we have sequenced both single and bulk micronuclei induced by DNA replication stress and by mitotic defects in normal, chromosomally stable cell lines, and are able to apply this method to cancer cell lines. We aim to establish a more holistic view of micronuclei utilizing induced MN in diploid cell lines and spontaneous MN in chromosomally unstable cancer cell lines to establish their contributions to ongoing CIN and tumour evolution.

EACR25-1335

Method Development of Single Cell Readable Stress Signal Recording System

J. Jäntti¹, R. Wong-Ramirez¹, Y. Wang¹, J. Dai¹, M. Falco¹, A. Vähärautio¹

¹University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland

Introduction

High-grade serous carcinoma (HGSC) is the most common and lethal subtype of ovarian cancer. Although

initially responsive to treatment, most HGSC patients experience recurrence with chemotherapy resistance, leading to poor survival outcomes. This resistance, which develops over time, has been linked to transcription factors (TFs) induced by stress signals. However, the specific stress pathways activated and their role in helping cancer cells adapt and survive chemotherapy remain unclear. To address this, we are developing a single cell-based recording method to track the activation of various stress-related transcription factors. This method employs CRISPR-Cas based editing to introduce genomic scars (insertions and deletions) that can be analyzed using single cell RNA sequencing.

Material and method

This method employs CRISPR-Cas based editing to introduce genomic scars (insertions and deletions) that can be analyzed using single cell RNA sequencing. Our approach involves the integration of single-cell transcriptomics with advanced lineage tracing techniques to map the dynamic transcriptional responses to chemotherapy.

Result and discussion

By capturing the temporal activation patterns of adaptive signaling pathways in individual cells, we hope to discover how pre-existing cellular states influence the emergence of resistance. This will be extended to patient-derived HGSC organoids, providing a clinically relevant model to validate our findings and explore the therapeutic potential of targeting specific stress pathways.

Ultimately, this research aims to uncover novel insights into the mechanisms driving chemoresistance in ovarian cancer, with the potential to identify new therapeutic targets and improve treatment outcomes for patients.

Conclusion

The development of this single-cell readable stress signal recording system represents a significant advancement in our ability to study cellular adaptation mechanisms and could have broad applications in cancer research.

³Universitat Pompeu Fabra (UPF), Department of Medicine and Life Sciences, Barcelona, Spain

⁴Universitat Pompeu Fabra (UPF) and Institució Catalana de Recerca i Estudis Avançats (ICREA), Department of Medicine and Life Sciences, Barcelona, Spain

Introduction

Clear cell renal cell carcinoma (ccRCC) is the most prevalent and deadliest form of kidney cancer, with more than 434,800 new cases and 155,900 deaths recorded worldwide in 2022, according to the Global Cancer Observatory latest statistics. The incidence of ccRCC

shows wide geographical variation, with Baltic and Eastern European countries, such as Lithuania and the Czech Republic, exhibiting the highest rates (Hsieh et al., 2017, *Nature Reviews Disease Primers*). This has been attributed to differences in exposure to risk factors. Known risk factors for renal cancer include obesity, tobacco smoking and hypertension, although the mechanistic link with tumorigenesis remains unknown. While some risk factors, such as exposure to aristolochic acid, are mutagenic, a recent study (Senkin et al., 2024, *Nature*) concluded that differences in the mutational patterns across geographical regions cannot fully explain the global differences in renal cancer incidence. We therefore asked whether the exposure to some of these risk factors, and the observed regional variation in incidence, are associated with distinct patterns of tumor evolution, such as the age at which key tumorigenic genomic events occur, the types of driver mutations acquired or different degrees of genomic instability.

Material and method

To address this question, we analysed the somatic mutations from whole-genome sequencing and epidemiological data obtained from a cohort of 962 patients diagnosed with primary ccRCC from eleven geographical areas with widely varying risk. This dataset was generated by the Cancer Grand Challenges Kidney Mutograph's project (Senkin et al., 2024, *Nature*).

Result and discussion

By analyzing the clock-like accumulation of mutations that result from mutational processes associated with aging, we estimated the age at which chromosome 3p loss occurred in the cell lineage where the tumor originated. Chromosome 3p loss is a canonical early driver event described in more than 90% of the ccRCC cases (Mitchell et al., 2018, *Cell*). We also estimated the age at which the most recent common ancestor cell of the tumour emerged. Additionally, we examined the landscape of driver events using state-of-the-art driver discovery methods, such as IntOGen, as well as methods to profile the genomic instability of these tumours. With all these genetic evolutionary features, we carried out an association study to uncover potential links with lifestyle ccRCC risk factors.

Conclusion

With this analysis we hope to gain a deeper understanding of how risk factors influence tumour evolution. This is essential to gain a more comprehensive understanding of the global cancer burden, intending to improve prevention strategies and reduce the incidence in the future.

Introduction

Tumor microenvironment (TME) in breast cancer is a heterogeneous landscape with multiple cell types, each modulating the tumor progression and the disease prognosis. Each cell type in the TME influences clinical outcomes for patients in a good or bad way, depending on the interaction with tumor cells. Our recent study showed that a higher proportion of Indian TNBC patients had intra-tumoral TILs compared to Western cohorts, and these are predictive of better response to NACT and longer disease-free survival in patients, making it a distinct finding from western reports. In the follow-up study, infiltrating immune cells subtypes and the signaling cross-talk are characterized using multiplex IF, GeoMx spatial transcriptomics and whole transcriptomics on FFPE tumor samples comparing responders vs non-responders.

Material and method

A retrospective cohort TNBC patients from a single onco-surgeon breast cancer clinic with a uniform treatment strategy was evaluated for this study. 24 FFPE primary tissue samples with variable TILs scores, taken from patients with a response and no response groups post-NACT, were stained for various immune cell panel; Pan-B cells, Pan-T cells, Pan-macrophages, and CD4+, CD8+, FOXP+, tumor (PanCK) and counterstained with DAPI. Multispectral images of whole slide scans were obtained using the Leica Aperio Versa system.

Parameters such as individual cell types and spatial proximity to tumor cells are determined by HALO Indica software. Total RNA was extracted from the same 24 FFPE samples and was analysed for whole transcriptome. TMA was prepared for a set of responder and non-responder samples and were run through GeoMX for ROI specific transcriptomics between responders and non-responders.

Result and discussion

TNBC samples were stained for immune and T-cells subtypes panel to determine the TiME. Around 50000-300000 cells were evaluated across all samples. Our preliminary analysis shows a higher proportion of T and B cells in stroma of the tissue in patients who show complete response compared to that of macrophages. The cross-talk of the immune infiltrates with each other and with epithelial cells is being evaluated using RNA-seq analysis and GeoMX platform. The analysis results will be presented at the congress.

Conclusion

Immune cell profiles are distinct among responding and non-responding TNBC patients in an Indian cohort. And not just the numbers of different cell types, but the proportions thereof could be influencing tumor response to the treatment. The inter-association of various immune cell types will need to be factored in while determining the clinical relevance of these profiles to identify distinct

prognostic immune subgroups in TNBC in the Indian cohort of breast cancer patients.

EACR25-1392

Investigating the impact of PRUNE2 deregulation on prostate cancer

M. Cardoso¹, M. Corado¹, P. Paulo¹, R. Henrique¹, B. Orr¹, M. Teixeira¹, A. Brandão¹

¹Portuguese Oncology Institute of Porto, Porto, Portugal

Introduction

Prostate cancer (PrCa) remains one of the leading causes of cancer-related morbidity and mortality among men worldwide, with familial susceptibility playing a significant role. Despite this, the underlying genetic mechanisms contributing to PrCa predisposition remain poorly understood. Our research group previously performed whole-exome sequencing in 96 PrCa patients from 45 families and reported, for the first time, pathogenic/likely pathogenic germline variants in the tumor suppressor gene PRUNE2 in patients with hereditary and/or early-onset PrCa. These findings led to the proposal of PRUNE2 as a novel biomarker for PrCa predisposition. Building on these findings, we aimed to further investigate its functional role as a tumor suppressor gene in PrCa.

Material and method

Whole transcriptome sequencing was performed on 12 prostate tissues (tumor and adjacent normal) from two PRUNE2 variant carriers and four non-carriers.

Differential gene expression analysis was conducted to identify deregulated genes and pathways associated with PRUNE2 variants. Additionally, to assess the impact of PRUNE2 depletion on cell viability and apoptosis, we performed siRNA-mediated knockdown in PNT1A cells and evaluated its impacts using Calcein AM and propidium iodide assays.

Result and discussion

Transcriptomic analysis identified 86 differentially expressed genes in PRUNE2 variant carriers (40 upregulated and 46 downregulated), with significant enrichment in extracellular matrix-associated pathways. Key deregulated genes, including LAMC2, IGFBP7, and THBS4, were linked to the PI3K/Akt pathway, a major driver of tumorigenesis. Knockdown of PRUNE2 in PNT1A cells led to increased cell viability and reduced apoptosis, supporting its role in suppressing oncogenic phenotypes.

Conclusion

Our findings provide new insights into PRUNE2's role as a tumor suppressor in PrCa, demonstrating its association with key oncogenic pathways and phenotypic changes upon depletion. These results reinforce PRUNE2's potential as a biomarker for PrCa predisposition and as a target for further functional studies.

⁴School of Nutrition and Translational Research in Metabolism, Department of Complex Genetics and Epidemiology, Maastricht, Netherlands

⁵Institute of Applied Health Research, Birmingham, United Kingdom

⁶Institute of Cancer Research, The Royal Marsden NHS Foundation Trust, London, United Kingdom

⁷School of Biomedical Sciences, Birmingham, United Kingdom

Introduction

Isoform switching refers to differential usage of isoforms of certain genes in different conditions and may play an important role in cancer pathogenesis. Even when total gene expression remains unchanged, changes in isoform composition can significantly impact protein function, influencing cancer initiation and progression. Therefore, identifying and characterizing isoform switching events in non-muscle invasive bladder cancer (NMIBC) is crucial for understanding disease biology. Here, we investigate isoform switching in NMIBC progression, with a focus on the Uracil-DNA Glycosylase (UNG) gene, to determine its potential functional consequences. We also extend our analysis to an independent dataset from UROMOL, a large-scale transcriptomics study of NMIBC, to validate our findings.

Material and method

Bladder tumour samples from the Bladder Cancer Prognosis Program (BCPP) were analyzed [1]. RNA-seq data from 17 G1pTa and 48 G3pT1 tumours were processed using 3D RNA-seq and IsoformSwitch-AnalyzeR tools in R to identify significant isoform switching events. APOBEC mutational activity was quantified using the R package deconstructSigs (v1.8.0) for each sample. To functionally validate key findings, we designed isoform-specific PCR assays to assess the expression levels of the different UNG isoforms across NMIBC samples. Additionally, UROMOL RNA-seq data was analysed to determine whether the observed isoform switching patterns were reproducible in an independent NMIBC cohort.

Result and discussion

Five genes exhibited significant isoform switching events in both computational tools, including UNG, a critical gene in DNA repair and uracil removal from DNA. While total UNG gene expression did not significantly differ between tumour grades, isoform-level analysis revealed a striking switch: ENST00000242576 was highly expressed in G3pT1 tumours but low in G1pTa. ENST00000336865 exhibited the opposite pattern. Structurally, ENST00000242576 harbors both an Intrinsically Disordered Region (IDR) and a Uracil-DNA Glycosylase (UDG) domain, whereas ENST00000-336865 contains only the UDG domain. Our ongoing isoform-specific PCR experiments will further confirm these expression patterns at the RNA level. Additionally, preliminary UROMOL data analysis suggests a similar

isoform switch in an independent NMIBC cohort, supporting the robustness of our findings.

Conclusion

Isoform switching is a key molecular event in NMIBC progression, potentially altering protein function without changes in gene expression levels. In the case of UNG, the presence of an IDR in ENST00000242576 may confer a functional advantage in high-grade tumours (G3pT1) by enhancing DNA repair activity, which we are actively investigating through functional validation. UROMOL cohort and isoform-specific PCR validation will help determine whether UNG isoform switching could serve as a diagnostic and prognostic biomarker in NMIBC.

³INCLIVA Biomedical Research Institute, Pathology, Valencia, Suriname

⁴INCLIVA Biomedical Research Institute, Pathology, Valencia, Spain

⁵INCLIVA Biomedical Research Institute, Biostatistics Unit, Valencia, Spain

Introduction

Microsatellite stability (MSS) tumors represent 80–85% of colon cancer patients, which are poorly infiltrated by lymphocytes and show limited response to immunotherapy. Recent evidence suggests that MSS primary tumors can be classified into high or low evolution subtypes based on the degree of plasma cell infiltration. Tumors with higher plasma cell infiltration exhibit greater genomic diversity, promoting immune-driven tumor adaptation. However, the cross-talk between tumor and plasma cells and their spatial distribution in the tumor microenvironment remain unclear. Unraveling these interactions could reveal new strategies to enhance immune infiltration and improve MSS patients' outcomes.

Material and method

A cohort of 8 MSS colon cancer patients, 3 high and 5 low evolution, classified upon genomic similarity between primary and relapse tumors, was selected. FFPE primary tumor samples underwent spatial transcriptomics at single-cell resolution using Visium HD. Data pre-processing was performed using Spaceranger and Spacexr for cell-type deconvolution with a CRC scRNA-seq reference. Log-normalized counts were tested for differential expression ($|log2FC| > 2$) and functional enrichment with Seurat and clusterProfiler, respectively.

Result and discussion

Spatial transcriptomics data revealed an average of 14,783 normalized spots representing tumor epithelial

cells. Analogously, mean normalized plasma cell spots detected were 3 times higher in high than low evolution samples (718 vs 224). Differential gene expression analysis between high vs low evolution primary samples indicated amplified cytokine/chemokine activity as CXCL10, overexpression of Pattern Recognition Receptors signaling pathways as Nod-like receptors, and activation of JAK/STAT and TNF α signaling via NF κ B pathways ($p < 0.001$) in tumor cells of high evolution samples. This pro-inflammatory microenvironment attracts plasma cells, enhancing their antigen presentation pathways, positively correlating with increased neoepitope presentation by tumor cells ($p = 0.015$). In contrast, tumor cells in low evolution samples over-express mucins as MUC4 or MUC12, creating a barrier for immune cell infiltration. Moreover, spatial analysis exposed that tumor epithelial cells in direct contact with plasma cells undergo epithelial-mesenchymal transition (EMT), trigger an inflammatory response, and secrete extracellular matrix-modifying factors such as metalloproteinases ($p < 0.001$) compared to more distant tumor cells.

Conclusion

High evolution MSS tumors with increased neoepitope presentation foster a pro-inflammatory environment that recruits plasma cells. This positive feedback loop triggers EMT in tumors and stimulates the immune system. These insights suggest that combining plasma cell attractants with immunotherapy could improve immune responses in these patients.

Introduction

Spatial Multiomics allows for context-based study of the tumor microenvironment (TME). TME consists of diverse cells that collectively influence tumor progression, therapeutic response, and immune activation. CD8 T-cells, essential for antitumor immunity, often become exhausted in the TME. Recent studies show that PD1+ TCF1+ stem-like CD8 T-cells retain differentiation potential and can be rejuvenated through cytokine signaling and immune checkpoint modulation. This detailed spatial profiling of RNA and protein expression in the TME is crucial to understanding immune cell function, activation, and differentiation.

Material and method

Here we introduce a protease-free workflow for RNAscopeTM Multiplex Fluorescent v2 assay combining RNA in-situ hybridization (ISH) and protein immunofluorescence to study cell marker proteins (CD8, PD1) with RNA targets (TNFA, TCF7, IFNG) in a tumor microarray (TMA). The Manual Multiplex Protease-Free workflow enables simultaneous RNA and protein visualization without enzymatic disruption, preserving antigen integrity and tissue morphology.

Result and discussion

Using this Multiomics assay we can study CD8 T-cell differentiation and activation. Co-detection of TNFA, TCF7, and IFNG transcripts with CD8 and PD1 proteins provides insights into specific T cell phenotypes and their activation/exhaustion status. Data reveal robust co-expression patterns of these targets, particularly in the tumor-cell neighboring stromal and immune cells in breast, cervical and stomach cancers, reflecting immune activation and exhaustion across distinct TME niches

Conclusion

This methodology lays a foundation for refining immunotherapeutic strategies targeting PD1+ TCF7+ CD8 T-cells, enhancing effector functions, and advancing precision oncology interventions.

EACR25-1447

Identifying immune cell phenotypes and their function by using high throughput spatial multiomics

I. Rodriguez Carrascosa¹, D. Wakhloo², J. Yu², S. Deshpande³, D. Allen⁴, A. Hellebust⁴, A. Dikshi⁴

¹Biotechne SLU, Technical Support, Madrid, Spain

²Biotechne SLU, Technical Support, California, United States

³Biotechne, Technical Support, California, United States

⁴IndicaLab, Technical Support, California, United States

Introduction

Advances in our understanding of the tumor microenvironment (TME) will help inform the development of next generation immunotherapies and engineered immune-cell therapies. Spatially characterizing immune cells with cell marker protein and activation marker RNAs is crucial to determine therapeutic efficacy and potential therapeutic toxicity. To address this, we have developed a high throughput RNAscopeTM assay on the BOND RX to spatially visualize RNA and protein markers on the same slide

Material and method

We utilized the new RNAscopeTM Multiomic LS assay that can detect up to 6 RNA and protein targets on the same slide. The TSA-based amplification strategy offers signal boost for both RNA and protein targets. To optimize protein detection, the workflow is completely protease-free thereby preserving antigen integrity and tissue morphology. The assay can be customized to include any target RNA and proteins of interest. Here, we demonstrate the use of our pre-conjugated antibody panel which includes CD8, CD4, FoxP3 and PanCK to visualize tumor infiltrating lymphocytes (TILs). We also utilized unconjugated primary antibodies for CD68 and CD163 to detect tumor macrophages in multiple tumor tissues. Using the HALO[®] image analysis software from Indica Labs, we performed RNA and protein quantification as well as cell phenotyping and spatial analysis

Result and discussion

Infiltrating Cytotoxic T cell lymphocytes were detected using CD8, GZMB and IFNG co-expression. Regulatory T cells were detected using CD4, FOXP3 co-expression. PanCK was used as a tumor marker to delineate tumor from stroma. Similarly, tumor associated macrophages

were detected using CD163, CD68, IL10 and IL-1B expression. We were also able to identify distinct M1 and M2 macrophage populations in the tumor samples.

Conclusion

The protease-free RNAscope Multiomic LS assay was successfully able to interrogate different subpopulation of immune cells with high fidelity RNA and protein signal while maintaining tissue morphology. The higher plex capability provides detection of more markers simultaneously, in turn enabling immune phenotype profiling while maintaining the sensitivity and specificity. Finally, the assay affords a very high throughput on the BOND Rx allowing large-scale pre-clinical and patient sample analysis.

EACR25-1515

Genome-scale screenings identify determinants of sensitivity of cancer cells and tumors to NFYA inhibition

C. Vitali¹, G. Graziano¹, A. Canevotti¹, G. Pagani¹, P. Gandellini¹

¹*University of Milan, Department of Biosciences, Milan, Italy*

Introduction

Oncogene addiction, the dependency of certain tumors on specific genes, now extends to transcriptional dependencies, highlighting transcription factors as potential therapeutic targets in cancer. The nuclear factor Y (NFY) is a heterotrimeric transcription factor composed of NFYA, NFYB and NFYC. NFY and its targets are upregulated in cancer, with NFYA, the regulatory subunit, particularly overexpressed in human tumors. However, NFYA therapeutic potential remains unexplored.

Material and method

To study vulnerability to NFYA inhibition, we analyzed genome-scale dependency maps from CRISPR and RNAi screens conducted in over 1,000 cell lines (DepMap). A combined scoring method (60 CRISPR:40 RNAi) integrating both approaches was applied. To identify determinants of vulnerability and resistance, gene correlation and enrichment analyses were performed. Finally, we derived a single score based on gene expression to estimate NFYA dependency across all cell lines and TCGA.

Result and discussion

The combined score revealed that ~30% of cancer cell lines are dependent on NFYA. Notably, NFYA inhibition is more selective than other NFY subunits, suggesting a better therapeutic window. Vulnerability to NFYA inhibition is not related to NFY subunits' mRNA, protein levels or copy number. To identify determinants of NFYA dependency, we focused on genes whose expression correlates with combined score. Resistance genes, whose higher expression is linked to lower dependency, are enriched in interferon response pathways. Vulnerability genes, whose higher expression is associated to higher dependency, are involved in estrogen response pathways. Indeed, among breast cancer subtypes, luminal cell lines are also the most NFYA-dependent. To infer NFYA dependency in non-screened cell lines and patient tissues, we computed a single score based on the expression of determinants. Fibroblasts are

among the least dependent, suggesting lower sensitivity of non-neoplastic cells to NFYA inhibition. In TCGA, normal tissues have higher score than matched tumors, further supporting lower sensitivity. This is promising for therapy, as it may help limit offside effects and toxicity in normal tissues. Consistent with the enrichment of resistance genes in interferon pathways, the single score positively correlated with immune infiltration, indicating that immune-cold cancers may benefit from NFYA inhibition.

Conclusion

Our findings establish NFYA as a selective cancer vulnerability, particularly in tumors with high estrogen response gene expression and low immune infiltration. By identifying resistance and vulnerability determinants, we provide a foundation for predictive biomarkers and patient stratification. More broadly, we illustrate how transcriptional dependencies can be identified from genome-scale screenings and translated to patient tumors.

EACR25-1519

Putative Novel Breast Cancer Genetic Drivers in Ghana: Insights from a Cohort Study

C. Anyigba¹, L. Paemka²

¹*C. K. Tedam University of Technology and Applied Sciences, Biochemistry and Forensic Sciences, Navrongo, Ghana*

²*University of Ghana, Accra, Ghana*

Introduction

A growing number of young Ghanaian women are diagnosed with breast cancer, yet its genetic basis remains largely unexplored. The only existing study used a Eurocentric panel of 34 breast cancer susceptibility genes, identifying some novel variants but lacking the ability to uncover genes and gene variants unique to Ghanaians. Given the high genetic diversity in African populations and rising breast cancer cases, this study utilized whole exome sequencing as a more comprehensive approach to profile germline and somatic breast cancer genetic risk factors in Ghanaian women.

Material and method

Breast cancer patients scheduled for surgery were recruited from four health centers in Ghana after providing written informed consent. Saliva samples were collected from all patients; breast tissues were obtained only from neoadjuvant-naïve patients. Whole-exome sequencing was performed on 86 patient samples and the germline and somatic variants analyzed using established bioinformatics pipelines. Additionally, whole-exome data from 44 Ghanaians in a Ghanaian hearing impairment cohort served as controls.

Result and discussion

Analysis revealed 20 pathogenic germline variants across 20 genes, including novel variants in BRCA2, CHRNG, CEP83, MAN1B1, and CYP4F22, as well as a previously reported BRCA1 variant (rs80357708). Nine of these genes have been linked to breast cancer metastasis, proliferation, and immune evasion, with FUS, BRCA1, and BRCA2 being key components of the DNA damage repair network. While further high-powered and functional studies are needed for validation, existing data suggest these genes may influence breast cancer

prognosis. Additionally, 20 putative somatic drivers were identified, with interaction analysis revealing 12 co-occurring and 2 mutually exclusive somatic interactions. The most significant co-occurrence was between SCUBE2 and UGT2A1 in eight cases. SCUBE2 was identified as a novel breast tumor suppressor gene and a key predictor of taxane-based neoadjuvant chemo-resistance. With the emerging link between UGTs, cancer, and drug resistance, this co-occurrence may indicate potential drug resistance in the study cohort. Somatic mutations were predominantly single-base substitutions, driven by defective DNA double-strand break (DSB) repair via homologous recombination, spontaneous 5-methylcytosine deamination, and APOBEC cytidine deaminase activity. Among these, spontaneous 5mC deamination was the most enriched mutational signature, underscoring the need for further investigation into epigenetic predispositions to breast cancer in Ghanaian women.

Conclusion

Once validated, the identified germline drivers will expand the biomarker repertoire, enhancing breast cancer detection, prognosis, and genetic counseling in the Ghanaian population. The somatic drivers will provide further insights into sporadic tumorigenesis.

EACR25-1584

Decoding the Complexity of Prostate Cancer Evolution: Uncovering Heterogeneous Cell States by Integrative Approaches

G. Cassanmagnago^{1,2}, M. Bolis^{1,2}

¹*Institute of Oncology Research, Bioinformatics Core Unit, Bellinzona, Switzerland*

²*Istituto di Ricerche Farmacologiche 'Mario Negri' - IRCCS, Computational Oncology Unit, Milano, Italy*

Introduction

Prostate cancer (PC) frequently acquires therapy resistance via lineage plasticity, enabling tumor cells to adapt to androgen deprivation (AD) by activating alternative transcriptional programs. While scRNA-Seq can capture diverse cellular states at high resolution, its use in clinical settings is constrained by cost, limited sample size, and lack of extended patient follow-up. By contrast, bulk RNA-Seq is widely available and accompanied by robust clinical data, yet lacks the cellular granularity provided by scRNA-Seq. To bridge these gaps, we propose a combined approach that integrates scRNA-Seq with customized deconvolution of large-scale bulk datasets to reveal subclonal architectures in both clinical samples and preclinical models.

Material and method

We integrated scRNA-Seq profiles from normal prostate, primary and castration-resistant (CR) tumors in two stages: first using scVI for unsupervised integration, then scANVI to incorporate cell-type annotations, preserving biological signals and enabling incremental updates to our reference with new data. Our atlas was also enriched with PDXs and in vitro cultures to track tumor evolution under AD and other pharmacologic pressures. We then applied a deconvolution method tailored to prostate

populations-specific signatures, allowing bulk RNA-Seq data to be broken down into pseudo-cells, that were mapped back to the single-cell reference.

Result and discussion

Our strategy captured a spectrum of tumor phenotypes, including AR-driven, neuroendocrine, WNT-dependent, or immune-modulated states, and additionally revealed novel subtypes, underscoring the deeper complexity of PC plasticity. Embedding bulk data provided the clinical context, such as prognosis and treatment response, to link transcriptional states with patient outcomes. We identified multiple coexisting clones within single tumors, mapping to distinct clusters and exposing pre-existing clonal heterogeneity in primary disease as well as clonal evolution under AD, thus enabling classification of primary and metastatic tumors by transcriptional profiling and specific genomic alterations. Notably, a subset of CR tumors with heightened immune infiltration emerged, pointing to a distinctive tumor micro-environment interplay and potential immunotherapeutic sensitivity. Moreover, applying literature-derived PC signatures onto PDXs uncovered distinct subclones within uniform model systems, clarifying their representativeness of specific clinical phenotypes and emphasizing the heterogeneity of late-stage disease.

Conclusion

By coupling single-cell and bulk transcriptome data, our framework delivers both the resolution to identify emergent subclones and the large-scale clinical perspective essential for translational insights. Our resource maps PC progression, aligns *in vitro* and *in vivo* models with patient subtypes, and ultimately can guide more precise therapeutic strategies.

EACR25-1669

Decoding atypical teratoid rhabdoid tumor subtype-specificity: single cell aspect of differentiation trajectories and potential maturation therapy

J. He¹, E. Blanco-Carmona², I. Paassen¹, J. DeMartino¹, A. Büllesbach², M. Kool², J. Drost¹

¹*Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands*

²*Hopp Children's Cancer Center (KiTZ), Division of Pediatric Neurooncology, Heidelberg, Germany*

Introduction

Atypical teratoid rhabdoid tumors (ATRTs) are among the most lethal pediatric central nervous system (CNS) tumors, which only harbor one single genetic driver mutation, the bi-allelic loss of the BRG1/BRM-associated factors (BAF) complex member SMARCB1. Based on DNA methylation profiles, three molecular subtypes have been further identified: ATRT-SHH, ATRT-MYC, ATRT-TYR. Each subtype has their own molecular and clinical features. Due to the very low occurrence rate (1–2 cases per million children per year), there are currently no subtype-specific treatments available, highlighting the necessity to better understand inter- and intra-subtype heterogeneity. Because paediatric cancers are often caused by block of developmental maturation, this knowledge will also be crucial for

development of maturation therapy (inducing cancer cells towards more mature, less aggressive state).

Material and method

We generated an unique single-nucleus transcriptome atlas of 19x ATRTs covering all three subtypes, validated by single-nucleus ATAC-seq and spatial transcriptomics, to study subtype-specific differentiation trajectories. Patient-derived-tumoroid models were used to validate potential maturation-including drugs.

Result and discussion

We discovered brain progenitor-like expression profiles within unique subtype-specific differentiation lineages. A shared cycling, progenitor-like cell population, interspersed throughout tumors, was observed across all ATRT samples. Additionally, top hits for maturation therapies, e.g., HDAC inhibitor Entinostat and PKC inhibitor Ro31-8220 were tested in our ATRT tumoroids, pointing that subtype-specific differentiation trajectories can be induced pharmacologically to push tumor cells towards a more mature and less-proliferative state.

Conclusion

Our study decodes ATRT subtype-specificity at single cell level and reveals that each ATRT subtype is enriched for distinct signaling trajectories mirroring normal fetal brain development, enabling the development of maturation therapies tailored towards ATRTs.

EACR25-1672

Inhibition of the heat shock response enhances modulated electrohyperthermia effects in triple negative breast cancer mouse model

C. Schvarcz¹, P. Leroy Vianna¹, T. Krenács², D. Bócsi¹, J. Kun³, P. Hamar¹

¹Semmelweis University, Institute of Translational Medicine, Budapest, Hungary

²Semmelweis University, Institute of Pathology, Budapest, Hungary

³University of Pécs, Genomics and Bioinformatics Core Facility, János Szentágóthai Research Centre, Pécs, Hungary

Introduction

Modulated electro-hyperthermia (mEHT) is a selective cancer treatment used in human oncology complementing other therapies. During mEHT, a focused electromagnetic field (EMF) is generated within the tumor inducing cell death by thermal and nonthermal effects.

Material and method

Here we investigated molecular changes elicited by mEHT using multiplex methods in an aggressive, therapy-resistant triple negative breast cancer (TNBC) model. 4T1/4T07 isografts inoculated orthotopically into female BALB/c mice were treated with mEHT three to five times.

Result and discussion

mEHT induced the upregulation of the stress-related Hsp70 and cleaved caspase-3 proteins, resulting in effective inhibition of tumor growth and proliferation. Several acute stress response proteins, including protease inhibitors, coagulation and heat shock factors, and complement family members, were among the most upregulated treatment-related genes/proteins as revealed

by next-generation sequencing (NGS), Nanostring and mass spectrometry (MS). pathway analysis demonstrated that several of these proteins belong to the response to stimulus pathway. Cell culture treatments confirmed that the source of these proteins was the tumor cells. The heat-shock factor inhibitor KRIBB11 reduced mEHT-induced complement factor 4 (C4) mRNA increase.

Conclusion

mEHT monotherapy induced tumor growth inhibition and a complex stress response. Inhibition of this stress response is likely to enhance the effectiveness of mEHT and other cancer treatments.

²Olivia Newton-John Cancer Research Institute, Blood Cancer and Immunotherapy Lab, Melbourne, Australia

³Genentech, Department of Molecular Biology, California, United States

⁴Genentech, Computational Sciences, California, United States

Introduction

CRISPR-Cas9 technology has revolutionized genetic research, particularly in the discovery of novel tumour drivers and resistance factors through CRISPR screens. Cas12a (Cpf1) distinguishes itself from Cas9 by short crRNAs and a unique PAM site. Additionally, intrinsic RNase activity simplify multiplexed gene targeting via the processing of individual crRNAs from a pre-crRNA-encoding RNA.

Material and method

Here, we present a mouse model that constitutively expresses enhanced Acidaminococcus sp.Cas12a (enAsCas12a) linked to an mCherry fluorescent reporter. We generated compact, genome-wide Cas12a knockout libraries targeting each gene with four crRNAs encoded across one (Scherzo) or two (Menuetto) vectors, and performed multiple screens.

Result and discussion

We validated robust expression of Cas12a in our mouse model across multiple tissues, with a particular focus on hematopoietic organs, a key facet of our research. We demonstrate efficient single and multiplexed gene-editing in vitro, using primary and transformed cells from enAsCas12a mice. We further demonstrate successful in vivo gene-editing, using normal and cancer-prone enAsCas12a stem cells to reconstitute the hematopoietic system of wild-type mice. We demonstrated the utility of genome-wide Cas12a libraries across multiple screens: in vitro enrichment screening in lymphoma cells, in vitro drop-out screening in immortalised MDFs, and in vivo enrichment screening in the hematopoietic lineage of mice to identify lymphoma-driving events. The consistency and robustness of the data extracted from each of our screens underscore the high effectiveness and broad potential of these new tools. Finally, we demonstrate CRISPR multi-

plexing via simultaneous gene knockout (via Cas12a) and activation (via dCas-SAM) using primary T cells and mouse dermal fibroblasts (MDFs). This highlights the compatibility of our enAsCas12a mouse model with other CRISPR technologies.

Conclusion

Collectively, our enAsCas12a mouse model and accompanying crRNA expression libraries enhance genome engineering capabilities and complement current CRISPR technologies.

EACR25-1693

The computational strategy, popmax, decreases misclassification of germline variants

N. Lee¹, M. Hum¹, M. Wong¹, P. Ong², S. Lee², A. Lee¹

¹*National Cancer Centre Singapore, Singapore, Singapore*

²*National University Cancer Institute, Singapore, Singapore*

Introduction

Classifying variants accurately is challenging for underrepresented populations. Here, we have utilized a computational strategy, popmax, to determine if the misclassification of germline variants can be decreased.

Material and method

Germline variants from Singapore and the United States were used to represent two ancestrally diverse populations. From Singapore, we had early-onset or familial colorectal cancer (CRC) cases ($n = 132$) and population-matched controls from the SG10K_Health cohort ($n = 9,740$). From the United States, 100 early-onset CRC patients and population-matched controls from gnomAD ($n = 134,187$) were used. The effect of using the popmax computational strategy was explored by comparing matched and mismatched (swapped) control cohorts, with and without popmax.

Result and discussion

In both CRC cohorts, population-matched classifications identified 62 pathogenic or likely pathogenic (P/LP) variants in 34 genes. The use of population-mismatched control cohorts resulted in an increase in the misclassification of non-P/LP variants as P/LP variants. However, these misclassifications were partially alleviated with the use of popmax.

Conclusion

Popmax decreased the number of misclassified variants in our cohorts, and can potentially be applied to studies of underrepresented populations with limited variant data of control cohorts.

EACR25-1694

Prevalence of Chromosomal Alterations in Acute Leukemias: A Descriptive Analysis in the Colombian Population

N. Poveda-Garavito¹, A. Romero², G. Cárdenas-Montoya³, R. Parra-Medina⁴, C. Orozco Castaño⁵, A. Combita⁶, Y. Torres-Llanos⁷, J. Riaño⁸

⁶*Universidad Nacional de Colombia, Doctorado en Oncología, Bogo, Colombia*

⁷*Versiti Blood Research Institute, Stem cell, Milwaukee, United States*

⁸*Instituto Nacional de Cancerología, Departamento de Genética, Bogot, Colombia*

Introduction

Acute leukemia encompasses a heterogeneous group of hematologic malignancies characterized by diverse chromosomal alterations that significantly influence prognosis, treatment response, and survival outcomes. Understanding the distribution and frequency of these alterations is crucial for refining diagnostic and therapeutic strategies. In Colombia, there is a limited understanding of the prevalence of these genetic abnormalities due to the scarcity of comprehensive studies. This descriptive study aims to identify and compare the chromosomal alterations present in adult and pediatric patients with acute leukemia in the Colombian population, providing valuable insights into the genetic landscape of these malignancies.

Material and method

Bone marrow samples were collected from 48 patients de novo diagnosed with acute leukemia, including 27 adults (≥ 18 years) and 21 children (≤ 17 years). Chromosomal alterations were detected using RT-PCR, assessing 28 different genetic alterations, including translocations and inversions associated with leukemia. Statistical analyses were performed using chi-square tests, considering a p-value < 0.05 as significant to determine differences between the groups.

Result and discussion

Acute myeloid leukemia (AML) was more frequent in adults (74.07%) compared to children (23.81%) ($p = 0.001541$), while acute lymphoblastic leukemia (ALL) predominated in children (76.19%). The Hemavision test was positive in 37.04% of adults and 19.05% of children ($p = 0.298243$). Among the chromosomal alterations detected, inv(16) (CBFB-MYH11) was present only in adults (14.81%) and absent in children ($p = 0.188206$). Similarly, t(15;17) (PML-RARA) was exclusive to adults (7.41%) ($p = 0.585053$). In contrast, t(12;21) (ETV6-RUNX1) was detected only in children (14.29%) ($p = 0.153473$), and t(4;11) (KMT2A-AFF1) was present exclusively in children (4.76%) ($p = 0.898686$). The alterations t(9;22) (BCR-ABL1), t(6;11) (KMT2A-AFDN), and t(8;21) (RUNX1-RUNX1T1) were rare and showed no clear differences between age groups. These findings highlight the distinct patterns of chromosomal alterations between adults and children, emphasizing the heterogeneity of acute leukemias.

Conclusion

This is the first study to describe the prevalence and distribution of chromosomal alterations in de novo acute leukemia patients in Colombia. The exclusive presence of

inv(16) and t(15;17) in adults and t(12;21) and t(4;11) in children highlights the importance of implementing age-specific diagnostic strategies. It is important to note that these data are preliminary, and we plan to expand the number of patients included in the study to increase the robustness of the findings.

EACR25-1713

Comprehensive analysis of somatic structural variations in Malignant pleural mesothelioma (MPM) using long-read sequencing

M. Alhazmi¹, A. Dawson², A. Nakas³, C. Poile², J. Dzialo², A. Bzura², K. Kutywayo^{2,3}, C. Tufarelli¹, D. Fennell^{2,3}, E. Hollox¹

¹*University of Leicester, Department of Genetics, Genomics and Cancer Sciences, Leicester, United Kingdom*

²*University of Leicester, Leicester Cancer Research Centre, Leicester, United Kingdom*

³*University Hospitals of Leicester NHS Trust, Leicester, United Kingdom*

Introduction

Malignant pleural mesotheliomas (MPMs) harbour extensive somatic genome structural variations. Molecular targeted therapy is lacking. Identifying somatic driver mutations in MPM is critical in understanding the development of mesothelioma and developing new therapy strategies. Long-read DNA sequencing using Oxford Nanopore Technology (ONT) can detect chromosomal rearrangements, shorter insertion/deletions, collectively known as structural variants (SVs) compared with short-read whole exome sequencing. ONT also directly profiles the methylome, allowing assessment of epigenetic silencing. In this proof-of-principle study, we aim to identify and validate somatic structural variants using long read sequencing in three MPMs using matched blood samples as a reference, and comparing with matched WGS short-read DNA sequencing. We also examine the matched transcriptomes data.

Material and method

Three MPM tumours with matched blood DNA samples were sequenced at high coverage using ONT PromethION. Structural variants were identified using minimap2 and Severus, then compared to variants identified by Illumina whole genome sequencing using BWA and Manta. The segmentation copy number alteration was detected by CNVkit. The gene expression was detected by using Salmon. Finally, the affected genes were examined their impact on survival time using TCGA data.

Result and discussion

The three MPM tumours were sequenced to between 38x and 42x coverage, with a median read length between 20 kb and 28 kb, and a maximum read length between 580 kb and 248 kb. The most common SV type was translocation (35.7%), followed by deletion (27.8%), insertion (21.1%), inversion (0.11%), and duplication (0.11%). We identified the double hits of MPM driver genes such as NF2, LATS2, BAP1 using both whole genome sequencing Illumina and whole genome sequencing

ONT. On the other hand, Severus identified between 61–156 novel SVs not reported by whole genome sequencing Illumina. These SVs affected multiple COSMIC cancer-associated genes including LRP1B, BIRC6, EXT1, NBEA, GPC5, LPP, ROBO2, JAZF1, CDH1, FLCN, SPECC1, and EPHA7. Additional, potential cancer genes were previously reported in other cancers such as GPC6 and PRKN. Furthermore, some of these SVs were involved in complex rearrangement on same haplotype. Gene expression levels of GPC6 and PRNK were associated with survival time.

Conclusion

Long read sequencing using Oxford nanopore technology identifies novel structural variants in MPM, missed by short-read sequencing, including potential complex events such as chromoplexy. For future studies, the ONT could be applied to larger cohorts of MPM patients to identify the double hit and complex rearrangements during MPM evolution, and to support new precision medicine strategies.

EACR25-1740

Targeting Aurora Kinase A in Breast Cancer Brain Metastasis

A. Powell¹, S. Prekovic², A. Dowd¹, L. Young³, D. Vareslija¹

¹*RCSI University of Medicine and Health Sciences, School of Pharmacy and Biomolecular Science, Dublin, Ireland*

²*University Medical Centre Utrecht, Center for Molecular Medicine, Utrecht, Netherlands*

³*RCSI University of Medicine and Health Sciences, Department of Surgery, Dublin, Ireland*

Introduction

Breast cancer brain metastasis (BCBM) affects 10–38% of metastatic patients, particularly those with HER2-positive and triple-negative subtypes. BCBM is highly aggressive, with a poor prognosis and an average survival rate of less than two years. BCBM diverge from their primary breast tumours both genetically and clinically and decoding mechanisms allowing drug-tolerant metastatic tumour cells to persist therapy and proliferate in the brain remains a challenge.

Material and method

In this study, we performed DNA exome sequencing ($N = 38$), RNA sequencing ($N = 63$), and DNA methylation analysis ($N = 18$) of patient-matched primary and BCBM sample pairs to identify genomic and transcriptomic vulnerabilities. This approach in combination with a high-throughput drug screening in five BCBM cell lines (LY2-MET [ER+], T347 [ER+HER2+], SUM190-BR [HER2+], MDA-MB-231-BR [TNBC], and JIMT1-BR [HER2+]) revealed significant sensitivity to AURKA pathway inhibitors.

Result and discussion

Our analyses identified aberrant activation of AURKA in BCBM patient samples, with high AURKA mRNA levels correlating with poorer overall and post-metastasis survival. Both genetic and pharmacological inhibition of AURKA yielded significant anti-tumor effects across cell lines, patient-derived organoids, and brain organotypic cultures. *In vivo*, alisertib substantially reduced brain metastasis growth. Furthermore, transcriptomic and

phosphoproteomic analysis revealed that targeting AURKA modulated Notch signaling, which appears to enhance tumor proliferation. Elevated expression levels of AURKA and MAML1 were linked to worse post BCBM survival outcomes in patient samples.

Conclusion

Our findings establish AURKA as a critical vulnerability in BCBM. Targeting both its kinase-dependent and kinase-independent functions may offer new therapeutic strategies to improve patient outcomes.

EACR25-1768

Unraveling the role of LKB1 mutations in Non-Small Cell Lung Cancer brain metastasis formation

L. Goodman^{1,2}, S. Sisoudiya³, B. Kaplan³, S. Sivakumar³, E. Sokol³, D. Fishman⁴, T. Rubinek^{1,2}, I. Wolf^{1,2}

¹Tel Aviv Sourasky Medical Center, Department of Oncology, Tel Aviv, Israel

²Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel

³Foundation Medicine Inc., Cambridge, MA, United States

⁴Ben-Gurion University of the Negev, Department of Physiology and Cell Biology, Faculty of Health Sciences, Beer Sheva, Israel

Introduction

Non-small cell lung cancer (NSCLC) is a prevalent form of lung cancer that presents significant challenges due to its propensity to metastasize to distant organs, with brain metastases (BMs) being a frequent and severe complication. NSCLC cells may exploit specific molecular interactions and signaling pathways to cross the blood-brain barrier and form tumors in the brain's microenvironment, characterized by low oxygen, limited nutrients, and a unique immune landscape. Based on our analysis of a large genomic database, we aimed to investigate the impact of STK11 mutations in the formation of NSCLC BMs, focusing on the mTOR signaling pathway and its effects on cell survival under brain-mimicking conditions. STK11 encodes liver kinase B1 (LKB1), a highly conserved serine/threonine kinase that regulates essential cellular processes such as metabolism and growth.

Material and method

The study cohort included 58,101 patients with NSCLC who underwent comprehensive genomic profiling of at least 300 genes (Foundation Medicine, Inc. (FMI)). Samples from both primary and metastatic sites were analyzed to identify common genomic alterations in BMs. An in vitro model using A549 cells was employed to assess the effects of LKB1 overexpression on NSCLC cell viability. Cells were cultured under hypoxic conditions, glucose deprivation, and in astrocyte-conditioned medium (a-CM) to mimic the brain microenvironment. Additionally, in an ex vivo model, A549 cells were cultured on brain slices from mice. mTOR pathway activity was assessed through Western blot analysis. Viability assays were conducted to evaluate the impact of LKB1 expression on cell survival.

Result and discussion

Analysis of N = 2,815 BMs and N = 9,793 non-BMs in FMI's genomic database revealed a higher incidence of STK11 loss-of-function mutations in BMs (24%) compared to non-BMs (19.2%) ($P < 0.001$). LKB1 over-expression in A549 cells decreased cell viability under hypoxic and glucose-deprived conditions, highlighting its role in cellular stress responses. Similarly, LKB1 over-expression reduced cell viability in a-CM. Additionally, we observed a reduction in the proliferation of A549 cells overexpressing LKB1 when cultured on brain slices, further supporting its role in inhibiting cell growth within the brain microenvironment. Moreover, LKB1 over-expression reduced mTOR pathway activity in brain-like conditions, suggesting a potential mechanism for decreased cancer cell survival. Analysis of a-CM revealed elevated levels of hepatocyte growth factor (HGF), which also decreased the viability of NSCLC cells overexpressing LKB1 and downregulated mTOR pathway activity.

Conclusion

Our findings suggest that STK11 mutations contribute to NSCLC BMs by enhancing cell survival in the brain microenvironment through the mTOR pathway. This research highlights the potential of targeting mTOR signaling in patients with NSCLC BMs as a therapeutic strategy to improve treatment outcomes.

Introduction

Genomic profiling of cancer with next-generation sequencing (NGS) is widely studied for cancer diagnosis, monitoring, and prognosis. Two main sources of tumour DNA for genomic analysis are: standard biopsy of primary or metastatic tumour and liquid biopsy-derived circulating tumour DNA (ctDNA). The first provides a greater amount of tumour DNA, while the other is low-invasive and accessible for longitudinal tumour DNA analysis. Here we present the results of targeted NGS performed on 126 melanoma samples, including 32 patient-matched tumour and liquid biopsies.

Material and method

Tumour DNA (standard biopsy, n = 45) and cfDNA (cell-free DNA, liquid biopsy, n=81) derived from 81 patients with stage IV or III melanoma were used. CfDNA was isolated with the QIAamp Circulating Nucleic Acid Kit (Qiagen). DNA libraries were prepared with a custom panel (30 genes) and the Ion AmpliSeq HD library kit. Sequencing and data analysis were performed using the Ion Torrent NGS platform, dedicated software, and the Alamut Visual Plus programme. The copy number variation analysis was performed using the ONCOCNV 7.0, CNVkit 0.9.10, and ExomeDepth 1.1.15 programmes. Statistical analysis evaluated the predictive power of the gene panel. Genetic profiles were analyzed using hierarchical clustering, multiple correspondence analysis (MCA), and univariate logistic regression in R (v4.4.1). Pairwise comparisons between patient subgroups were made using Fisher's exact test [1].

Result and discussion

The analysis detected approximately 180 variants in 62 patients (76.5%) that covered all genes in the panel with allele frequency (VAF) ranging from 0.1% to 86%. They were divided into pathogenic (mutations) and likely pathogenic variants of unknown significance (VUS-LP). The genes that were the most frequently mutated were BRAF, NRAS, NF1, ARID2, TP53, and the TERT promoter. The concordance analysis revealed a 64% overlap of all variants between liquid and a tumour biopsy and 70% concordance for pathogenic variants. Statistical analysis showed no genomic clustering for the immunotherapy response. For targeted therapy, some clustering patterns suggested potential genetic associations. For 7 patients, two or more LB samples were profiled before therapy and at the time of progression/start of a new therapy showing an increased, or decreased VAF of altered genes or the appearance of new variants.

Conclusion

Genomic profiling of tumour and liquid biopsy melanoma samples is a useful tool for the identification of mutated genes in melanoma and, in some cases, for the monitoring of genomic evolution during treatment. The usefulness of our 30-gene NGS panel in predicting response to therapies needs further investigation in larger patient cohorts.

STAG2 mutations in the normal colon induce upregulation of oncogenic pathways in neighbouring wildtype cells

D. Chan¹, Y. Wei Ni¹

¹National University of Singapore, Surgery, Singapore, Singapore

Introduction

There has been recent interest in the role of somatic driver mutations in phenotypically normal organs, particularly in relation to oncogenesis. One such driver mutation is STAG2, a critical component of the cohesin complex involved in mitosis. Here, we sought to characterise the role of STAG2 mutants in the normal colon in relation to oncogenesis.

Material and method

We performed this study using patient-derived human colonic organoids, in which the STAG2 mutation was introduced using CRISPR-Cas9 gene editing. We performed single-cell RNA sequencing (scRNAseq) to determine transcriptomic changes in co-cultured wildtype and STAG2 mutant organoids.

Result and discussion

Co-cultured cells on scRNAseq clustered into four clusters. There was a higher proportion of STAG2 mutant cells in Cluster 3, while there was a higher proportion of wildtype cells in Clusters 0 and 2. Cluster 1 appeared to have equal proportions of STAG2 mutant and wildtype cells. Comparing between STAG2 mutant and wildtype cells, only GPS2, SPTSSA, H4C3, and HNRNPA0 had average log2FC >1 and were statistically significantly different. Analysis of STAG2 wildtype and mutant cells using Gene Set Enrichment Analysis (GSEA) for "Hallmark" gene sets (50 genes sets) revealed that only the "HALLMARK_TNFA_SIGNALING_VIA_NFKB" gene set was upregulated in wildtype compared to mutant at an FDR of <25%. Intriguingly, no gene sets were upregulated in STAG2 mutant relative to wildtype. Further analysis was conducted within clusters. In Cluster 0 and 2, we observed that the "HALLMARK_TNFA_SIGNALING_VIA_NFKB" which had been upregulated in wildtype cells was also upregulated in both clusters with FDR < 25% and nominal p-value < 5%. In Cluster 0, other gene sets which were upregulated included "HALLMARK_ANGIOGENESIS" and "HALLMARK_EPITHELIAL_MESENCHYMAL_TRANSITION". In Cluster 2, other gene sets which were upregulated included "HALLMARK_EPITHELIAL_MESENCHYMAL_TRANSITION", "HALLMARK_KRAS_SIGNALING_UP", and "HALLMARK_P53_PATHWAY". Notably, in Cluster 3, none of the Hallmark gene sets were observed to have been upregulated or downregulated at FDR < 25%.

Conclusion

These observations confirm that oncogenic pathways are upregulated in co-cultured wildtype cells while oncogenic pathways in STAG2 mutant cells themselves remain relatively quiescent, suggesting a novel cell-cell interactive modality of oncogenesis hitherto undescribed.

EACR25-1840

Genome-wide CRISPR screen identifies RAB14 as a new target for gastric cancer treatment

A. Nunes¹, C. Oliveira^{1,2,3}, J. Neto^{1,4}

¹*i3S – Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal*

²*IPATIMUP – Instituto de Patologia e Imunologia Molecular da Universidade do Porto, Porto, Portugal*

³*Faculdade de Medicina, Universidade do Porto, Porto, Portugal*

⁴*Division of Molecular Carcinogenesis, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Introduction

About 20% of gastric cancers (GC) exhibit HER2 overexpression. HER2-positive GC patients can be treated with HER2 inhibitors like trastuzumab. Due to HER2 expression heterogeneity in tumours, only ~47% of patients respond to this targeted treatment, and even those who do, eventually develop resistance to it. This project aims to explore the biology of HER2-GC and to uncover additional targets and modifiers of response to anti-HER2 therapies.

Material and method

We performed a pilot genome-wide CRISPR screen, in a HER2-positive GC cell line, to identify genes which lead to increase in sensitivity or resistance to HER2 small molecule inhibitor lapatinib. Validation was performed with target knock-out (KO) of the top hits in multiple GC cells lines using CRISPR/Cas9.

Result and discussion

KO of the top hit, RAB14, sensitized five different GC cell lines to multiple HER2 inhibitors. Unexpectedly, we found that loss of RAB14 was synergistic with HER2 inhibition, not only in HER2-positive, but also in HER2-negative cell lines. Rab14 was found overexpressed in GC. Our current data supports that RIC8A may have a similar effect to RAB14 in HER2-positive cells.

Conclusion

In summary, we identified two modifiers of response to HER2 inhibition, RAB14 (overexpressed in GC) and RIC8A, each synergizing with lapatinib to reduce cell viability. The notable synergistic effect of RAB14 depletion and lapatinib in HER2-negative cells, likely reflects lapatinib pleiotropy, providing an opportunity to treat HER2-negative GC, which accounts for 80% of GC cases and currently lacks targeted treatment strategies.

EACR25-1869

Dependency-Shock transcriptomic footprints as predictive tools in early anti-cancer drug discovery

L. Projetti¹, G. Vozza¹, O. Croci¹, V. Spagnolo¹, A. Oikonomou¹, N. Radic¹, G. Frera¹, M. Garnett², F. Iorio¹

¹*Human Technopole, Computational Biology Research Centre, Milan, Italy*

²*Wellcome Sanger Institute, Cambridge, United Kingdom*

Introduction

The oncogenic shock model has been proposed to describe the interplay between pro-survival and pro-

apoptotic signals that follow an oncogene's inactivation and lead to cancer cell death. Building on this model, we call cancer dependency shock (DepSHOCK) the signal dynamics' interplay that follows the ablation of any gene essential for cancer survival, i.e., cancer dependency gene. Any DepSHOCK triggers the sudden inactivation of pro-survival pathways and activates death-inducing signals, with both events impacting down-streaming transcription factors, leaving a measurable gene expression footprint. Each DepSHOCK footprint can be deconvoluted to infer transcriptional markers of signals that emanate from a dependency gene and drive cancer cell survival through the constitutive activity of specific biological pathways. Our goal is to investigate this hypothesis across tissues, canonical oncogenic addictions, and novel candidate cancer therapeutic targets.

Material and method

We have established an experimental/computational platform for the generation and the analysis of transcriptional data generated upon drug and genetic perturbation of a selected panel of cancer cell lines and therapeutically relevant dependency genes. We generated a first post-perturbational dataset profiling 10 cancer cell lines with 9 drugs, such that each drug targets at least a cell line-specific cancer driver gene and for each drug there is at least one very sensitive cell lines (harbouring a driver mutation in the targeted gene). We are applying a variety of unsupervised machine learning methods to this data to identify genetic signatures that can be used to sense the presence of specific pro-survival signals, thus drug sensitivity and genetic dependencies in independent cancer samples.

Result and discussion

Our preliminary results show that the basal expression of specific dependency-shock signatures is predictive of drug response and genetic dependency in independent cancer samples comparably to pathway/gene-addiction signatures derived with much more complex supervised machine learning methods applied to much larger datasets of clinical and multiomic datasets.

Conclusion

Our main goal is to study the information content of the DepSHOCK footprints and their potential use as computational tools in early anti-cancer drug discovery through new statistical and machine-learning methods delivering mechanistically grounded therapeutic markers and hints for the design of combinatorial therapies.

Introduction

Missing heritability in hereditary diffuse gastric cancer (HDGC) ranges from 60 to 90%. HDGC-like families, despite fulfilling HDGC clinical criteria, lack actionable variants in adhesion molecules CDH1 and CTNNA1, and are not offered HDGC-targeted life-saving disease preventive measures. Thus, we hypothesized that novel inherited mechanisms within CDH1-regulatory elements (REs) contribute to HDGC predisposition.

Material and method

We called single-nucleotide/copy-number variants (SNV/CNV) from 19 HDGC probands whole-genome sequencing data, performed gene-ontology analysis, 4C-seq and ATAC-seq in healthy stomach epithelia, CRISPR-Cas9, RT-PCR and flow cytometry in cell lines, immunohistochemistry and microsatellite instability analysis in tumours and enhancer assays in mouse embryos.

Result and discussion

We show novel mechanisms affecting the CDH1-regulatory network, predisposing HDGC-like families to cancer in 16% of HDGC-like families. We found a family carrying a germline deletion of two hypomorphic tissue-specific REs within CDH3, and another with a germline RE deletion downstream of CDH1, both triggering CDH1 mRNA/protein downregulation. The same effect was triggered by a MLH1 germline deletion overlapping a stomach-specific RE in a family with gastric but no colorectal cancer. Tumour of CDH3 and MLH1 probands showed CDH1 reduced expression and presence of signet ring cells, a cell adhesion loss phenotype. Co-occurring deletions of stomach-associated REs and truncating variants, affecting mucin and immune-related genes were found in additional 9/19 (47%) families. In one patient, recurrent deletions were confirmed by long-read sequencing.

Conclusion

This pioneer study identifies monogenic-like heritability through REs deletions in the CDH1 locus or stomach-specific REs, and raises the hypothesis of polygenic heritability mechanisms involving co-occurring variants

favouring cancer predisposition via immune-deficient phenotypes in HDGC-like families.

Introduction

BRAF is a critical oncogene driving tumorigenesis in multiple cancer types, including melanoma, colorectal cancer, and non-small cell lung cancer. Advances in comprehensive genome profiling reveals a growing number of alterations whose clinical significance remains undefined due to the lack of functional testing. The clinical interpretation of these variants of unknown significance in BRAF pose significant challenges for personalized treatment, particularly non-V600 variants such as CRAF-dependent class-III BRAF variants. By focusing on the functional impact of these lesser-known BRAF alterations, this study aims to elucidate their role in MAPK pathway activation and assess their potential as actionable targets in cancer therapy.

Material and method

We collected BRAF variants detected in cancer patients analyzed at our center between 2021 and 2025. The cohort consists of 3520 and 972 samples for DNA and RNA, respectively. For functional testing, we selected a previously uncharacterized FNBP1::BRAF fusion and several uncharacterized non-V600 BRAF variants (E510K, G466A, E549Q, E695Q), which were introduced into plasmids via Golden Gate cloning or site-directed mutagenesis, respectively. HEK-293T cells were transfected with wild-type or mutant BRAF plasmids alone or co-transfected with CRAF. After 48 hours, proteins were isolated, and p-ERK levels analyzed by western blot. Cells transfected with FNBP1::BRAF were treated with MEK and RAF inhibitors for two hours to assess p-ERK inhibition.

Result and discussion

BRAF variants were processed to remove artefacts, low quality variants and intronic/synonymous variants,

yielding a total of 247 variants. Of those, 20% are of unknown significance, with 27% located in the kinase domain, 5% in the cysteine-rich domain, and 16% in the Ras-binding domain. Functionally, cells expressing FNBP1::BRAF, identified in a glioma patient, exhibited elevated ERK activation, with p-ERK levels similar to BRAF p.V600E-transfected cells. Treatment with RAF inhibitor Dabrafenib or MEK inhibitor Trametinib and their combination successfully reduced p-ERK levels. BRAF p.E501K and BRAF p.E549Q showed kinase impairment when mono-transfected, but CRAF presence triggered ERK hyperactivation, suggesting a class-III BRAF variant. In contrast, BRAF p.G466A led to elevated p-ERK signals, regardless of CRAF presence. BRAF p.E695Q did not cause pathway overactivation, regardless of CRAF-presence.

Conclusion

This study identifies FNBP1::BRAF as a previously uncharacterized potential driver of glioma. Trametinib and Dabrafenib effectively reversed its constitutive ERK phosphorylation. Additionally, BRAF p.E501K and BRAF p.E549Q are likely pathogenic class-III BRAF variant, as it exhibits CRAF dependent ERK hyperactivation. In contrast, BRAF p.G466A is a likely pathogenic BRAF variant that induces ERK hyperactivation independent of CRAF.

⁷*Institute of Molecular and Cell Biology, A*STAR, Singapore, Singapore*

⁸*Department of Anatomical Pathology, Singapore General Hospital, Singapore, Singapore*

Introduction

High-resolution study of the tumour microenvironment is made possible by spatial transcriptomics, which captures interactions between stromal, immune, and tumour cells. This work used a PolyA capture-based spatial transcriptomic technique to evaluate intra-tumour heterogeneity in three tumour regions and the normal adjacent skin from a patient with cutaneous squamous cell carcinoma (SCC). The tumour regions displayed diverse morphologies under a microscope, including big nests displaying squamous differentiation, medium-sized nests, and smaller nests within the desmoplastic stroma.

Material and method

Prior to RNA sequencing, four cryosectioned tissue samples were placed onto a Visium® slide and subjected to the Visium Spatial Gene Expression V1® protocol. Further downstream analyses, including normalization, clustering, and cell annotation were conducted using the Seurat package in R. Regulatory network inference was performed using SCENIC to identify key transcription factors and gene regulatory modules in each different tumour region. The intercellular communication networks within the tumour microenvironment were inferred using CellChat.

Result and discussion

In tumour regions, the Visium® protocol yielded 78,344 mean reads per spot and 2,026 median genes per spot. Two tumour regions exhibited diverse SCC cell subtypes, including typical epithelial SCC, basal-like SCC, and SCC with epithelial-mesenchymal characteristics. Myofibroblastic cancer-associated fibroblast (myCAF) demonstrated the highest transcription factor enrichment among stromal cells, which was primarily regulated by NR2F1. Significant interactions were observed between myCAF and SCC clusters, potentially sharing similar CXCL signalling pathways. The third tumour region, which displayed smaller nests in the desmoplastic stroma, predominantly exhibited basal-like SCC. Vascular cancer-associated fibroblast (vCAF) demonstrated the highest transcription factor enrichment, which was primarily regulated by KLF2 and NR2F2. Concurrently, vCAF, myCAF, and basal-like SCC exhibited the strongest interactions exclusively through GALECTIN, SELE, PTPR, Netrin and PDGF signalling pathways.

Conclusion

We showed that spatial transcriptomics analysis on frozen tissue samples is an effective method to study intra-tumour heterogeneity and potential molecular interactions within cutaneous SCC. The three tumour regions exhibited marked differences in tumour morphologies, which were associated with distinct cell composition, gene regulatory module, and cell interactions.

EACR25-1919

BUB1-Mediated G2/M Checkpoint Control and Mitotic Integrity: A Targetable Vulnerability in MPM

E. Cakiroglu^{1,2}, S. Eris^{2,2}, S. Senturk^{1,2}

¹*Dokuz Eylul University, Izmir International Biomedicine and Genome Institute, Izmir, Turkey*

²*Izmir Biomedicine and Genome Center, Izmir, Turkey*

Introduction

Malignant pleural mesothelioma (MPM) is a rare but highly aggressive malignancy with limited treatment options, a severe prognosis, and poor survival rates, necessitating the identification of novel therapeutic targets. BUB1, a mitotic checkpoint serine-threonine kinase, plays a pivotal role in the spindle assembly checkpoint (SAC) function and accurate chromosome segregation. Elevated BUB1 expression has been correlated with poor prognosis in multiple cancers. Here, we demonstrate the role of BUB1 as an emerging cancer-

essential gene and a potential druggable vulnerability in MPM.

Material and method

BUB1 was identified as a vulnerability for MPM cells by a whole-genome CRISPR screen and this role was validated by knockout and pharmacological inhibition (BAY-1816032). RNA sequencing was conducted to analyze transcriptomic profiles of BUB1-depleted MPM cells. Affected pathways and regulatory networks were defined by gene set enrichment analysis (GSEA). To explore BUB1's functional role in mitotic regulation, localization of key mitotic checkpoint proteins and BUB1 interaction partners MAD1, MAD2, and Shugoshin (SGO1) was assessed by immunofluorescence (IF) staining and the expression of BUB1 local network genes (CDC20, Cyclin A, Cyclin B, and p21) was measured by western blot. Additionally, time-lapse live-cell imaging was conducted to track mitotic progression and cytokinesis dynamics in real time.

Result and discussion

MPM cell survival and growth were significantly impaired by genetic depletion or pharmacological inhibition of BUB1, which also caused G2/M cell cycle arrest, cellular senescence, apoptosis, and a reduction in aggressive cancer cell traits. RNA-seq analysis of BUB1 knockout cells revealed widespread transcriptional changes associated with cell cycle regulation, G2/M checkpoint control, and mitotic reprogramming.

Mechanistically, BUB1 is essential for the proper localization of MAD1, MAD2, and SGO1, ensuring the integrity of the spindle assembly checkpoint (SAC). The loss of BUB1 impaired SAC integrity, leading to mitotic errors. These defects were accompanied by significant downregulation of CDC20, Cyclin A, and Cyclin B, alongside an upregulation of p21, as well as G2/M cell cycle arrest reinforcing the role of BUB1 in G2/M checkpoint control. Live-cell imaging further confirmed that BUB1 KO cells exhibited prolonged mitosis, frequent cytokinesis failure, and multinucleation, underscoring the essential function of BUB1 in maintaining mitotic fidelity.

Conclusion

Our findings establish BUB1 as a critical regulator of mitosis by modulating the G2/M checkpoint in MPM. The observed mitotic defects and altered transcriptional programs reinforce the role of BUB1 in MPM pathophysiology. These results highlight BUB1 as a key dependency in MPM and provide a strong rationale for targeting BUB1 in preclinical models of MPM therapy.

EACR25-1925

Illumina based ex situ whole transcriptome workflow providing large area capture substrate, up to 7.5 cm² active area, and a scalable end-to-end software solution

K. Ahmad¹, C. Allen¹, J. Sher¹, R. Riahi¹, E. Sarocco¹, D. Segale¹, M. Wang¹, C. Rogert¹, E. Parker¹, V. Mishra¹

¹Illumina, San Diego, United States

Introduction

Spatial Omics, by preserving the architecture of the tissue, enables new insight into the biological processes

within their native micro-environments. A large capture area can allow for large tissues to be studied on a single substrate, without the need to break tissues up into multiple separate runs. However, the ability to study large tissues is challenging, as it requires a large capture area and the capability to process the correspondingly large amount of data. Illumina spatial technology is built for scalability and efficiency by leveraging Illumina's best-in-class software ecosystem, enabling an end-to-end spatial analysis workflow. Powered by DRAGEN™ and Partek™ Illumina Spatial Technology (IST) provides a scalable system for researchers to analyze large datasets, with user-friendly interfaces for image processing, secondary analysis, spatial visualization and tertiary analysis. Combining with tissue imaging, IST has automated cell-based binning through nuclei identification and cell border expansion, yielding improved cell typing and marker gene identification. In addition, IST gives the flexibility for users to export data for use with third-party spatial analysis tools.

Material and method

To demonstrate this large capture area and end-to-end analysis capability, we present kidney on a single IST spatial substrate and processed the data with IST. From the data, we get ~3 million cells being captured. We were able to process the entire dataset, including secondary and tertiary analysis, within 14 hours.

Result and discussion

Additionally, using 1 NovaSeqX 25B 200 cycle kit we detected a median of 1964 molecules and 991 genes per cell. Using 3 NovaSeqX 25B 200 kits, we detected a median of 3100 molecules and 1365 genes per cell. Further, Illumina Connected Multomics (ICM) provides accelerated discovery of biological insights via an intuitive interface and scalable tertiary analysis functionality.

Conclusion

This shows the ability of IST end-to-end solution to analyze large tissue samples and accelerate discoveries with scalable analysis software.

EACR25-1942

The landscape of copy number intra-tumour heterogeneity in breast cancer and its impact on the tumour ecosystem

M. Callari^{1,2}, B. Sandey², W. Cope³, H. Bardwell², T. Baslan⁴, O. Rueda⁵, S. Chin², C. Caldas⁶

¹Fondazione Michelangelo, Milan, Italy

²University of Cambridge, CRUK Cambridge Institute, Cambridge, United Kingdom

³Cambridge University Hospital foundation trust, Department of Histopathology, Cambridge, United Kingdom

⁴University of Pennsylvania, Department of Biomedical Sciences, School of Veterinary Medicine, Philadelphia, United States

⁵University of Cambridge, MRC Biostatistics Unit, Cambridge, United Kingdom

⁶University of Cambridge, Department of Clinical Biochemistry, Cambridge, United Kingdom

Introduction

The genomic landscapes of breast cancer are dominated by copy number aberrations (CNAs). High-throughput

bulk sequencing has revealed the extent of intra-tumour genetic heterogeneity (ITH) in breast cancer genomes and advanced our understanding of tumour progression and treatment response. However, the identification of sub-clonal CNAs from bulk data is challenging due to limitation in inferential statistics. Single nuclei-based copy number aberration (snCNA) profiling overcomes such limitations by providing direct quantification of ITH. The impact of CNA ITH on the tumour micro-environment has not been systematically investigated.

Material and method

We generated snCNA profiles through shallow whole genome sequencing for nearly 40,000 single nuclei isolated from primary breast cancers (METABRIC cohort, n = 142). After alignment and quality control, a per-nucleus absolute copy number profile was generated using an optimised computational pipeline. snCNA profiles were used as input for per-tumour clustering, phylogenetic analysis, ITH metrics computation and extraction of snCNA signatures. snCNA data were integrated with multi-omics data available for the same tumours: SNP6, targeted sequencing, mRNA and miRNA expression, methylation and imaging mass cytometry data using unsupervised and supervised statistical methods.

Result and discussion

snCNA profiles matched the bulk tissue CNA profile, particularly for clonal events, validating the snCNA profiling method. The CNA events driving each IntCluster subtype (e.g. ERBB2 amplification in IC5) were mostly clonal. The extent of ITH was highly variable, from tumours showing no evidence of heterogeneity to highly heterogeneous tumours by both ploidy and number of distinct CNA subpopulations. snCNA signatures capturing high ITH associated with presence of TP53 mutations, higher tumour grade and higher tumour ploidy. Phylogenetic analysis highlighted distinct patterns of tumour evolution. Significant associations with patients survival and multiple tumour micro-environment features were found. Further integration with multi-omic data is ongoing and results will be presented.

Conclusion

snCNA profiling in a well annotated cohort provides an unprecedented insight into the extent and patterns of copy number ITH in breast cancer.

A defined genomics approach for delineating the cellular states during pancreatic cancer initiation

L. Fei¹, S. Cancellieri², K. Zhang³, S. Hautaniemi⁴, B. Sahu⁵

¹*Oslo University Hospital, Department of Cancer Genetics, Oslo, Norway*

²*University of Oslo, Centre for Molecular Medicine Norway, Oslo, Norway*

³*University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland*

⁴*University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland*

⁵*University of Oslo, Centre for Molecular Medicine Norway, Norway*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers. Patients seldom exhibit specific symptoms at the beginning, thereby usually diagnosed at advanced stage. The molecular mechanisms of PDAC initiation are still elusive, especially the cellular states that are conducive for the oncogenic drivers to hijack necessary for malignant transformation.

Material and method

To understand the cellular states critical for cancer initiation, we established a human PDAC model through novel cancer modelling approach that combines cell-fate reprogramming using defined transcription factors (TFs) and expression of PDAC-specific oncogenes for pancreatic cell transformation to delineate the early molecular events during PDAC carcinogenesis. The distinct cellular states are characterized by modern cutting-edge functional genomic methods such as RNA-seq, ATAC-seq and CUT&RUN in addition to in vivo functional analysis.

Result and discussion

We show that in collaboration with pancreatic ductal-specific TFs, mutant KRAS together with overexpression of MYC oncogene and loss of TP53 are sufficient and necessary for inducing cellular transformation.

Conclusion

Our data provide high-resolution profiling of the epigenome and transcriptome changes that contribute to cancer initiation. Importantly, analysis of the regulatory events by defined TFs elucidated critical signalling pathways that are activated for the oncogenic drivers to hijack during exocrine pancreatic cell fate determination, highlighting the strength of this dynamic cancer modelling approach for further dissection of the early events of pancreatic tumorigenesis.

⁴*Romanian Academy of Medical Sciences, Romania*

Introduction

Anaplastic thyroid carcinoma (ATC) is a highly aggressive malignancy with limited treatment options and poor prognosis. Identifying new therapeutic targets is crucial for improving patient outcomes. In this study, we

utilized microarray analysis to establish differential gene expression profiles in ATC cells, providing a molecular basis for drug discovery. This approach allowed us to identify dysregulated pathways and potential targets for therapeutic intervention.

Material and method

Microarray analysis compared gene expression profiles between ATC cell lines (C643 and CAL-62) and human primary thyroid epithelial cells (HPTE), identifying key dysregulated genes and pathways. Based on these findings, we screened the Small Molecule Immuno-Oncology Compound Library (Selleckchem library No. L4800) for potential therapeutic agents. Selected compounds were evaluated for cytotoxicity using cell viability assays, including the MTT assay, to determine their selective effects on ATC cells while preserving normal thyroid cell viability.

Result and discussion

Microarray analysis revealed significant alterations in gene expression patterns associated with cell proliferation, apoptosis, and immune modulation in ATC cells. We found 2164 overexpressed and 2425 down-regulated genes. The analysis has been done using Feature Extraction and Agilent GeneSpring GX program (Agilent Technologies). An unpaired t-test with Benjamini-Hochberg correction was applied, with a fold-change cutoff of 2.0 and a corrected p-value threshold of 0.05, utilizing Agilent single-color technology. Guided by these results, we identified candidate compounds with potential therapeutic efficacy. Among them, fludarabine phosphate exhibited the most potent cytotoxic effect, significantly reducing ATC cell viability time-dependently, while exerting minimal impact on normal thyroid cells. Further pathway analysis indicated that fludarabine's mechanism of action involves the inhibition of proliferative and survival signaling pathways in ATC cells. Cellular and molecular testing was performed at different time points establishing the best framework to use several compounds as potential therapeutics for ATC.

Conclusion

Our findings highlight the utility of microarray analysis on ATC cell lines in identifying potential candidates and therapeutic targets and guiding drug discovery efforts for ATC. Fludarabine phosphate emerged as a promising candidate for further preclinical evaluation. Future studies will focus on validating its molecular mechanisms and assessing its efficacy in vivo models to explore its potential as a targeted therapy for ATC.

EACR25-2024

Microhomology-Driven Genomic Alterations in Ovarian Cancer

D. Kostka¹, P. Szstromwasser², R. Jaksik¹

¹Silesian University of Technology, Department of Systems Biology and Engineering, Gliwice, Poland

²Gordian Bioscience Inc., Cambridge, MA 02142, United States

Introduction

Microhomology-mediated end joining (MMEJ) is an error-prone DNA repair mechanism that utilizes short homologous sequences to mediate double-strand break (DSB) repair. This process can lead to complex genomic rearrangements, including insertions, deletions, and

multinucleotide variants (MNVs). Understanding MMEJ activity is particularly relevant in tumors with homologous recombination deficiency (HRD), where alternative repair pathways may significantly contribute to genomic instability. Since ovarian cancer frequently exhibits HRD-related deficiencies, it serves as a key model for investigating MMEJ's role.

Material and method

We developed an algorithm to classify indels (insertions, deletions, and MNVs) as MMEJ-dependent. The analysis incorporated whole-genome sequencing (WGS) and whole-exome sequencing (WES) data, processed using bioinformatics tools including Strelka2, MuTect2, Pindel, and VarScan2. Statistical analyses focused on the frequency and characteristics of MMEJ-mediated indels, with a primary emphasis on ovarian cancer due to its well-established HRD deficiency. Additionally, a pan-cancer analysis across 33 cancer types was conducted to assess whether MMEJ is also involved in other malignancies.

Result and discussion

Our results demonstrated the influence of mutation detection algorithms and sequencing type (WES/WGS) on the statistics of microhomology-associated deletions. We examined the impact of the classification algorithm parameter (N) on the identification of MMEJ-dependent indels and determined that the optimal threshold is N = 4. This parameter represents the minimum number of matching nucleotides required between the mutation fragment and the adjacent sequence to classify it as MMEJ-dependent. We observed variations in the frequency of MMEJ-mediated deletions across different cancer types, with the highest proportions detected in testicular germ cell tumors, pancreatic adenocarcinoma, diffuse large B-cell lymphoma and ovarian cancer. Importantly, our analysis demonstrated that increased MMEJ dependency results not only from BRCA1/2 mutations but can also be driven by alterations in the RB1 gene. Furthermore, survival analysis revealed that a higher number of microhomology-mediated deletions is associated with improved patient survival, even in the absence of PARP inhibitor treatment.

Conclusion

We developed a novel method for detecting MMEJ-dependent indels and optimizing classification parameters, providing a robust approach to studying microhomology-mediated deletions. Our findings highlight the potential of these deletions as predictive markers for treatment response and patient prognosis. By elucidating the role of MMEJ in genomic instability, particularly in HRD-related cancers, this study paves the way for more precise diagnostic and therapeutic strategies in oncology.

²*University of Medicine and Pharmacy, Genomics Department, MEDFUTURE - Institute for Biomedical Research, Cluj-Napoca, Romania*

³*Medical Sciences Academy, Bucharest, Romania*

Introduction

Lung squamous carcinoma (LUSC), a subtype of non-small cell lung cancer (NSCLC), poses a significant therapeutic challenge due to the lack of reliable biomarkers and the high resistance to conventional therapies. Immuno-Oncology compounds that target key pathways such as angiogenesis, cell cycle regulation, and DNA damage and repair (DDR) offer promising therapeutic strategies. This study employs microarray analysis to establish a gene expression profile in lung squamous cell carcinoma (LUSC) cell lines, aiming to identify cytotoxic Immuno-Oncology compounds and evaluate their cellular and molecular effects.

Material and method

Gene expression profiling was conducted on two untreated LUSC cell lines (H1703 and SK-MES1) using Agilent's microarray technology. An integrated bioinformatics approach compared microarray data from these LUSC cell lines with publicly available TCGA datasets from LUSC patient samples to refine candidate compound selection. This analysis identified 233 commonly altered genes across all three datasets, emphasizing dysregulated cellular pathways. Based on these insights, 27 compounds from the commercially available Immuno-Oncology Compound Library (Catalog No. L4800, Selleck Chemicals) were screened for cytotoxic effects on the two cell lines. Active compounds were further assessed using the RealTime-Glo™ MT Cell Viability Assay to determine IC₅₀ values. Additional functional assays, including cell cycle, apoptosis, and colony formation assay were performed to characterize their cellular effects.

Result and discussion

Five compounds showed significant cytotoxic effects on LUSC cell lines, impacting key oncogenic pathways like angiogenesis, DDR, and cell cycle regulation. The cell cycle assay demonstrated phase-specific arrest, while apoptosis assays confirmed heightened apoptotic activity. The colony formation assay indicated reduced clonogenic potential, suggesting long-term inhibitory effects. The observed cellular responses correspond with the known mechanisms of action of these compounds, reinforcing their therapeutic potential in LUSC.

Conclusion

This study highlights the utility of molecular profiling in identifying dysregulated pathways in LUSC and guiding the selection of potential therapeutic compounds. The identified Immuno-Oncology compounds demonstrated promising cytotoxic effects, supporting their further evaluation as potential candidates for LUSC treatment. Future studies will focus on validating these findings in preclinical models to advance therapeutic development.

⁴*The University of Tokyo, Laboratory of Sequence Analysis, Tokyo, Japan*

⁵*Kyoto University, Department of Pathology and Tumor Biology, Kyoto, Japan*

⁶*Kyoto University, Institute for the Advanced Study of Human Biology, Kyoto, Japan*

Introduction

Upper urinary tract urothelial carcinoma (UTUC) is a poor-prognosis cancer of the renal pelvis and ureters. Due to its rarity, previous large-scale genomic studies of urothelial carcinomas have focused on bladder cancer, which is the commonest malignancy of the urinary tract. Recently, our study identified five molecular subtypes of UTUC with different outcomes. To further understand the molecular pathogenesis of UTUC, we performed whole-genome sequencing (WGS) of UTUCs.

Material and method

We studied a total of 122 UTUCs which were surgically resected at the University of Tokyo hospital from 2000 to 2020. Matched germline control samples were also obtained from the normal renal cortex or peripheral blood samples. WGS was performed using NovaSeq at 120x and 30x depth for tumor and normal samples respectively. G-CAT, GRIDSS, and FACETS were used to identify single nucleotide variants/insertion-deletions, structural variants (SVs), and copy number variants. Amplicon-suite was used to identify extrachromosomal DNA (ecDNA).

Result and discussion

The median 11,000 mutations were detected per sample (range 2,700–780,000). Ten samples (8.1%) were hypermutated (>100,000 mutations), all of which had mutations in mismatch repair genes (MSH2, MSH6 and MLH1). dN/dS analysis identified 16 driver genes, of which the most frequently mutated driver gene was KMT2D in 54 samples (44.3%), followed by TP53 (33.6%), FGFR3 (32%), and ARID1A (23%). Recurrent non-coding mutations were also investigated, which identified known driver mutations in the promoter and 5' UTR regions of TERT. Comparing the frequency of mutations in the ureter and renal pelvis, TERT promoter and HRAS mutations were significantly more common in the ureter, while KMT2D and TP53 mutations were more frequently mutated in the renal pelvis. Mutational signature analysis using SigProfiler identified SBS1 and SBS5, which are clock-like signatures and increase with age, and SBS2/13 caused by APOBEC mutagenesis. Mutations caused by APOBEC were identified in 87 cases and hotspot mutations in the non-coding regions accumulated on target motifs of APOBEC. SV analysis identified driver SVs, such as SVs involving FGFR3 (N = 10), which included 7 FGFR3-TACC3 translocations. In addition, KLF5 duplications and AHR deletions were observed in 9 and 7 samples, respectively. L1 retro-

transpositions originating from TTC28 and PHACTR1 loci were also frequently detected as SVs. ecDNA was found in 58 samples (52%), including those containing oncogenes such as CCND1 and MDM2.

Conclusion

UTUCs were strongly affected by APOBEC mutagenesis, generating the hotspot mutations in non-coding regions. WGS identified non-coding driver mutations, driver SVs and ecDNAs, which have not been identified by the previous study. These data could contribute to the refined UTUC classification and further understanding of its pathogenesis.

EACR25-2106

Exposing G2/M Checkpoint Vulnerabilities: BUB1B and BUB3 as Essential Dependencies in Malignant Pleural Mesothelioma

E. Kirmiziy¹, E. Cakiroglu¹, S. Eris¹, S. Sentürk¹

¹Dokuz Eylül University, Izmir International Biomedicine and Genom Institute, Genomics and Molecular Biotechnology, Izmir, Turkey

Introduction:

The G2/M checkpoint is a critical regulatory mechanism ensuring proper DNA replication and repair before mitosis preventing genomic instability and aneuploidy. Its dysfunction is implicated in various cancers, including Malignant Pleural Mesothelioma (MPM), a rare and aggressive cancer with poor prognosis. The BUB gene family, particularly BUB1 and its interaction partners BUB1B and BUB3, plays a key role in both the G2/M checkpoint and Spindle Assembly Checkpoint (SAC), ensuring accurate chromosome segregation. Whole-genome CRISPR/Cas9 screening in MPM cell lines identified BUB1B and BUB3 as essential genes, suggesting their involvement in MPM progression. This study aims to investigate the molecular effects of BUB1B and BUB3 in MPM, assessing their role in cell proliferation and survival to explore their therapeutic potential.

Material and method

Recently we conducted genome-wide CRISPR screening in H2052, H2452, and H28 MPM cell lines, identifying the BUB gene family (BUB1, BUB1B, and BUB3) as having a significant impact on MPM cell survival and proliferation. Following CRISPR/Cas9-mediated gene knockout, the dependency of MPM cells on BUB1B and BUB3 and their roles in aggressive phenotypes were assessed through functional assays such as BrdU incorporation, cell cycle, and 2D and 3D colony formation. Ongoing functional analyses aim to test the molecular and cellular implications of BUB1B and BUB3 in MPM.

Result and discussion

Genetic silencing of BUB1B and BUB3 individually profoundly impaired MPM cell proliferation and survival. Cell cycle analysis revealed significant accumulation in the G2 phase. Elevated expression of BUB1B or BUB3 was strongly associated with poor overall survival, as predicted based on their expression levels in publicly available datasets. Critically, DepMap analyses conducted in MPM cell lines revealed a

significant depletion of BUB1B and BUB3, supporting their impact on MPM survival. Interestingly, G2/M checkpoint molecules with high interaction scores in StringDB annotation have generally exhibited a depletion trend, highlighting that MPM cells are functionally dependent on proper G2/M modulation. Our ongoing studies aim to provide a deeper understanding of the functional and molecular effects of these genes on the G2/M checkpoint and their role in MPM pathobiology.

Conclusion

Findings highlight the critical role of BUB1B and BUB3 in the proliferation and survival of MPM cells, emphasizing their potential as both biomarkers and therapeutic targets. Silencing of these genes disrupted the cell cycle, particularly by inducing arrest in the G2 phase, pointing to their essential function in regulating the G2/M checkpoint. Further functional and molecular studies will be essential to fully understand the mechanisms by which BUB1B and BUB3 contribute to MPM pathogenesis. These investigations may offer valuable insights into novel therapeutic strategies targeting the G2/M checkpoint in MPM treatment.

EACR25-2186

Deciphering oncogenic gene regulatory mechanisms at nucleotide resolution using precision genome editing

J. Hietarinne¹, A. Dyas¹, S. Vanharanta¹

¹University of Helsinki, Faculty of Medicine, Helsinki, Finland

Introduction

Understanding oncogenic signaling and its regulation is critical for uncovering the mechanisms of tumorigenesis and tissue-specificity in cancer. However, the complexity of oncogenic transcriptional pathways and the limitations of currently used CRISPR-based technologies pose a significant challenge for studying signaling at the gene regulatory level. To overcome this, we have optimized and adapted a genome editing method to study the essentiality of oncogenic transcription factors by directly modifying their binding motifs at candidate regulatory loci of oncogenic driver genes.

Material and method

The genome editing method is based on homology-directed recombination (HDR) and it enables the editing of specific genomic regions precisely, simultaneously minimizing the confounding effects previously linked to other CRISPR-based approaches. To model oncogenic signaling in clear cell renal cell carcinoma (ccRCC), we used HIF2A-dependent cells with HIF-knockout cells as controls. Cells were transfected with ribonucleoprotein complexes and HDR templates, together with HDR enhancers or oligonucleotide modifications. The repair templates introduced either original or modified transcription factor binding motifs along with sequence tags, providing internal controls and increasing statistical power. The candidate regulatory regions were derived from CRISPR screens, and the essentiality of specific motifs was established by conducting *in vitro* and *in vivo* competition assays for edited alleles.

Result and discussion

By modifying repair templates and manipulating endogenous double-strand break repair pathways, we

optimized a precision CRISPR editing method, improving editing efficiencies. Using competition assays, we were able to demonstrate the effect of specific transcription factor binding motifs located in candidate regulatory regions on cell fitness in vitro and in vivo.

Conclusion

Using an optimized precision editing method, we were able to showcase the functional essentiality of specific transcription factor motifs in candidate regulatory regions of cancer-related genes downstream of the HIF2A pathway, thereby elucidating gene regulatory mechanisms in tissue-specific oncogenic pathways.

EACR25-2252

Common Genetic Dependencies of Sonic Hedgehog Medulloblastoma (SHH-MB) variants are Regulated by the Non-Malignant Microenvironment

M. van Essen¹, E. Becker¹, J. Jacob¹

¹*University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom*

Introduction

Medulloblastoma, of which SHH-MB is a major subtype, is the commonest malignant childhood brain tumour. Analysis of the genetic landscape of these tumours has uncovered further subdivisions of SHH-MB, which has led to the view that their optimal treatment will require uniquely tailored therapies [1]. Superimposed on this classification scheme are key oncogenic mutations, for example affecting TP53 which have a profound effect on prognosis. We showed that SHH-MB cell states can mirror in vivo tumour cell states in a manner that is determined by the cerebellar microenvironment [2]. To determine whether there are shared cell-intrinsic determinants across SHH-MB variants, we sought to identify the key upstream regulators in the gene regulatory network and their direct targets (regulons) through computational approaches. Identifying these regulons could inform targeted therapies applicable across SHH-MB subtypes.

Material and method

The SHH-MB cell line, DAOY which harbours a TP53 mutation, was grown as monocultures or in co-culture with non-malignant human iPSC-derived cerebellar organoids, to simulate the microenvironment, for 25 days. Cells were processed for scRNA-seq then analysed using the three-step SCENIC pipeline [3]. First, candidate regulatory modules are inferred from gene co-expression patterns. Next, co-expression modules are pruned by eliminating indirect targets using transcription factor motif discovery, to define regulons for each transcription factor. Last, the activity of these regulons is measured in individual cells and used for clustering.

Result and discussion

There was a striking shift in the combinatorial pattern of regulons expressed by tumour cells in co-culture. Indeed, one of the top regulons, ELK1 in co-cultured tumour cells matched the second highest ranked regulon in a batch of four single cell sequenced TP53 wildtype ($n = 2$) and mutant ($n = 2$) patient tumours. Furthermore, another top regulon in DAOY cells in co-culture, CREB5 was a

homologue of the highest ranked factor, ATF4 (also called CREB2) in these patient tumours. Unexpectedly, high-risk TP53 mutant tumours shared identical top ranked regulons with TP53 wild-type tumours.

Conclusion

Our in silico analysis suggests common genetic dependencies across SHH-MB tumour subtypes which is regulated by the cerebellar microenvironment, and that could be exploited therapeutically.

Introduction

Serrated adenocarcinoma (SAC) is a rare CRC subtype, which differs from conventional adenocarcinoma in morphology and expression of genes associated with extracellular matrix remodeling and epithelial-mesenchymal transition, presenting a worse prognosis. However, it is unknown at which stage this serrated phenotype is developed and how it is regulated by procarcinogenic factors at primary and metastatic sites.

Material and method

In this work, the prometastatic transcriptional pattern of conventional and serrated CRC was compared by studying expression levels and interrelations of a broad family of 72 CRC genes known to be regulated by *E. coli* endotoxins and soluble factors of tumor-activated hepatocytes and hepatic sinusoidal myofibroblasts, mimicking the colorectal cancer cell response to soluble factors from the HPMR promoting the hepatic metastasis disease.

Result and discussion

We identified a gene signature whose overexpression (>3 -fold change) was associated to serrated pathway carcinogenesis (DPEP1, PRDX4, SEM1, CLDN4, G6PD, PGK1, YWHAZ, PKM, HMGB1, NME1) and hepatic

metastasis development (CFTR, PRDX4, TIMP1, SEM1, CLDN4, SPP1, G6PD, PGK1, YWHAZ, PKM, HMGB1 and NME1), compared to their expression changes in conventional CRC versus normal mucosa. In addition, both unsupervised clustering and principal component analyses remarkably segregated normal and tumor tissue biopsies, primary tumors and metachronic (but not synchronous) metastases. Finally, a Pearson correlation matrix showed that around 50% prometastatic genes inversely correlated between serrated and conventional primary CRCs, and that this mainly occurred in serrated versus conventional CRCs.

Conclusion

These results demonstrate distinct prometastatic gene signatures for conventional and serrated colorectal carcinomas and suggest different transcriptional response patterns by effect of the same prometastatic micro-environmental factors at primary colonic mucosa and hepatic sites.

EACR25-2348

GEM-X Flex: Scalable and cost-effective whole transcriptome single cell analysis for cancer marker detection from FFPE tissue section slides

J. Aleksejeva¹, T. Drennon², J. Abousoud², R. Stott², J. Romero², P. Lund², N. Sponer², S. Taylor², P. Smibert², A. Kohlway²

¹10x Genomics, Vienna, Austria

²10x Genomics, R&D, Pleasanton, United States

Introduction

Formalin-fixed paraffin-embedded (FFPE) tissue blocks are the most widely used sample type in clinical research for preserving tissue morphology and supporting long-term storage. These samples can be particularly valuable for studying rare cancers or when sample procurement is challenging. The growing demand for comprehensive single cell gene profiling calls for methods that require less sample input, reduce costs and enable high-throughput analysis for large clinical studies.

Material and method

Large-cohort studies are often limited by financial constraints. To overcome this challenge, we performed a cost-effective, high-throughput experiment with eight different FFPE blocks (glioblastoma, colorectal, lung, breast, skin, endocervical cancers, normal kidney, and reactive lymph node), with two replicates per sample. Using the 16-barcode multiplexing approach of GEM-X Flex, we processed 320,000 cells pooled from all 16 samples in a single lane (20,000 cells per sample). The distinct barcodes allowed us to obtain high quality single cell sequencing data from each individual sample with $\sim 8\%$ undetected multiplets.

Result and discussion

We identified tumor markers specific to each cancer, including PROM1 (glioblastoma), BRCA1 (colorectal), KRT19 (lung), MUC1 (breast), GPC3 (breast), and MUC16 (endocervical). This method allows processing up to 2.56 million cells per chip across 8 lanes, reducing the cost per sample to just one cent per cell, making large-scale studies more cost-efficient. We also extended this approach to tissue sections already mounted on slides

and subjected to histological analysis, enabling the extraction of the most information from precious clinical samples. Using the GEM-X Flex assay, we generated whole transcriptome profiles from as few as 25,000 nuclei isolated from 5 μm FFPE tissue sections on standard superfrost slides. Gene expression profiles, cell type proportions, and assay sensitivity from these thin sections were comparable to those from 25 μm tissue scrolls from the same FFPE block, demonstrating that high-quality single cell RNA sequencing is achievable with minimal sample input. The ability to work with 5 μm tissue sections expands options for universal sample preparation across various assays. It also broadens sample procurement opportunities by using tissue sections instead of whole FFPE blocks, significantly lowering costs.

Conclusion

As a conclusion, the GEM-X Flex assay enables whole-transcriptome gene profiling at single cell resolution from 5 μm FFPE tissue sections. By combining H&E image analysis with RNA sequencing data from sequential sections of the same cancer block, pathologists can achieve more precise diagnostics. The assay's multiplexing capability significantly lowers costs and supports high-throughput studies, enabling large-scale tumor marker screening for early detection, progression monitoring, and therapeutic target development.

EACR25-2363

Long-Read Resequencing of Acute Myeloid Leukaemia Single-Cell RNA Sequencing Samples Improves Detection of Malignant Genomic Alterations

M. Ó Dálaigh¹, J. Umberto Verga¹, P. Ó Broin¹, P. Nicholson², E. Szegezdi¹

¹Ollscoil na Gaillimhe - University of Galway, Research Ireland Centre for Research Training in Genomics Data Science, Galway, Ireland

²University of Bern, Next Generation Sequencing Platform, Bern, Switzerland

Introduction

Acute myeloid leukaemia (AML) is an aggressive blood cancer, resulting in the accumulation of poorly differentiated white blood cells in the bone marrow. Normal and malignant haematopoiesis occur simultaneously in AML, requiring methods to separate these cell populations in bone marrow aspirate samples. Single cell transcriptomics (scRNA-seq) data have been used in recent years to infer the presence of genomic alterations (single-nucleotide variants, insertions/deletions, fusion genes) which allows cells with cancer-relevant alterations to be identified. One of the most popular scRNA-seq platforms, 10x Genomics®, typically uses Illumina® short-read sequencing, ultimately biasing transcript coverage towards the mRNA capture site. This limits detection of genomic alterations in regions distal to the capture site, complicating efforts to use these as markers of malignancy in cancers with a low mutational burden such as normal karyotype AML. Emerging single-cell technologies such as PacBio® Kinnex scRNA-seq utilises long-read sequencing to cover the whole transcript and is compatible with existing 10x cDNA

libraries. Here, we investigate the ability of Kinnex to identify the malignant cell population in primary, patient-derived AML samples previously sequenced with the 10x 3' workflow by identifying genomic alterations linked to malignant transformation.

Material and method

4 patient samples harbouring a range of different genomic alterations relevant to AML (e.g. TET2/DNMT3A point mutations, an NPM1 insertion, and a DEK::NUP214 fusion) were resequenced with the Kinnex scRNA-seq kit and processed with the single-cell Iso-Seq analysis pipeline. CTAT-Mutations and pbfusion were used for variant calling and fusion gene identification respectively. VarTrix was used to assign identified CTAT-Mutations variants to individual cells.

Result and discussion

Kinnex recovered 29% fewer cells than 10x across the 4 samples. For cells which were sequenced with both technologies, CTAT-Mutations identified approximately 63% more single-nucleotide cancer-relevant variants in the Kinnex data than the 10x. On average, the Kinnex data covered AML mutation hotspot sites in NRAS, TET2, FLT3, DNMT3A, and NPM1 in 1.84x more cells; e.g. in an NPM1 mutated sample, Kinnex data revealed ~3x more (1000 vs. 280) mutant NPM1 cells than 10x. The Kinnex data also identified the DEK::NUP214 fusion which was not detectable in the corresponding 10x data.

Conclusion

Despite the lower number of cells recovered, the Kinnex data identified more malignant cells with a higher confidence by improving coverage of AML mutation hotspots located distal to the 3' of relevant transcripts. Kinnex scRNA-seq data display a superior ability to detect multiple genomic alterations, highlighting the benefits of using long-read sequencing to characterise cancer samples in single-cell studies.

Extensive spatial heterogeneity of transcript variants in localised prostate cancer

S. Kidd¹, B. Johannessen¹, A. Bakken¹, A. Stranger¹, M. Bogaard^{1,2}, X. Zhang¹, U. Axcrona^{1,2}, R. Lothe^{1,3}, K. Axcrona^{1,4}, R. Skotheim^{1,5}

¹Institute for Cancer Research, Oslo University Hospital–Radiumhospitalet, Department of Molecular Oncology, Oslo, Norway

²Oslo University Hospital–Radiumhospitalet, Department of Pathology, Oslo, Norway

³Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway

⁴Akershus University Hospital, Department of Urology, Lørenskog, Norway

⁵Faculty of Mathematics and Natural Sciences, University of Oslo, Department of Informatics, Oslo, Norway

Introduction

Prostate cancer is the second most frequently diagnosed cancer in males worldwide. The majority of patients are diagnosed with multiple prostate-confined tumours with extensive spatial heterogeneity. While localised disease generally harbours few recurrent somatic point

mutations, gene fusions are a characteristic trait. These predominantly involve genes in the ETS family of transcription factors fused with androgen-regulated genes, causing overexpression of the ETS gene. TMPRSS2::ERG is the most prevalent, occurring in approximately 50% of cases. Our previous findings indicate that ERG overexpression is associated with a poor prognosis, but the topic is still debated. Moreover, the diversity in transcript variants has often been overlooked. Here, we aim to characterise the fusion transcript variants and explore intrapatient heterogeneity.

Material and method

We analysed a cohort of treatment-naïve, radical prostatectomy cases from Oslo University Hospital–Radiumhospitalet (2010–2012) using long-read RNA sequencing (Oxford Nanopore Technologies). The study included 110 fresh-frozen tissue samples (82 malignant, 28 benign) from 31 patients. Technical validation was performed using short-read RNA sequencing and real-time RT-PCR.

Result and discussion

In total, 92 samples from 28 patients passed the quality control of >200,000 reads, and were included in further analyses. The long-read sequencing data showed a high level of concordance with both short-read sequencing and real-time RT-PCR. TMPRSS2::ERG was the most common fusion transcript (found in at least one sample from 61% of patients), whereas TMPRSS2::ETV1 was observed in 4%. In fusion-positive samples, distinct ERG and ETV1 transcript variants were identified. These reflect the part of the ETS gene included in the fusion; however, the differences in transcript structures are not solely attributed to the truncated gene length. Intra- and interfocal heterogeneity in ERG transcript variant expression was found in 93% and 92% of patients, respectively. For ETV1, all patients exhibited both intra- and interfocal heterogeneity. Specific transcript variants, such as ETV1-207, appear to be associated with a more aggressive disease and poor prognosis. This finding, together with the spatial heterogeneity of transcript variants, may have implications for the prognostic utility of ETS genes. Additionally, non-ETS fusions were identified, such as AZGP1::GJC3 (50% of patients) and the novel ENSG00000284512::CMC2 (found in 14%).

Conclusion

A distinct expression pattern of ERG or ETV1 transcript variants exists in samples with TMPRSS2::ERG or TMPRSS2::ETV1 fusions. The extensive intrapatient heterogeneity in transcript variant expression should be considered during further development of ERG and ETV1 as prognostic biomarkers in localised prostate cancer. More research is warranted to explore the link between specific transcript variants and aggressive disease.

³*D'Or Research Institute, Salvador, Brazil*

⁴*University of Sheffield, Sheffield, United Kingdom*

Introduction

Oral squamous cell carcinoma (OSCC) presents high mortality and therapeutic resistance, influenced mainly by the complex tumor microenvironment, particularly cancer-associated fibroblasts (CAFs). CAFs actively remodel the extracellular matrix (ECM) and mediate signaling that may enhance tumor progression and invasion. Additionally, cell-in-cell (CIC) structures have been identified as markers of tumor aggressiveness in OSCC, yet the association between CAFs and these phenomena is still unclear. This study aims to clarify the interaction between CAFs, ECM remodeling, and tumor invasiveness in OSCC using advanced *in silico* and 3D spatial transcriptomic approaches.

Material and method

We conducted a combined *in silico* and experimental study. Initially, *in silico* analyses of publicly available transcriptomic data of OSCC were performed, focusing on genes related to ECM remodeling, epithelial-mesenchymal transition (EMT), invasion, and metabolic processes. Experimentally, OSCC cell lines representing metastatic (SCC04) and non-metastatic (H357) phenotypes, as well as dysplastic cell lines (DOK), were cultured alone or co-cultured in 3D spheroids with normal (NHOF), activated (MYO), or senescent (SEN) fibroblasts. Spatial transcriptomics analysis was performed after 6h, 24h, and 48h of co-culture. Data normalization utilized TPM (Transcripts Per Million), and differentially expressed genes (DEGs) were identified ($p < 0.05$). Functional enrichment analysis identified impacted biological pathways.

Result and discussion

In silico analysis showed significant upregulation of genes involved in ECM remodeling and EMT (e.g., MMP9, SNAI2) in metastatic compared to non-metastatic OSCC cells. Spatial transcriptomics of 3D spheroids confirmed that metastatic SCC04 spheroids exhibited statistically significant upregulation of genes involved in ECM degradation (MMP9), cell adhesion, and EMT (CAV1, SNAI2) compared to non-metastatic H357. Co-culture with normal or activated CAFs did not show significant immediate transcriptional alterations, though minor changes related to ECM organization were observed. Importantly, co-culture with senescent fibroblasts significantly influenced metabolic and inflammatory pathway activation in dysplastic cell spheroids, highlighting their early and critical role in tumor progression and CIC formation, suggesting a potential mechanistic link to enhanced invasiveness, though this requires further investigation.

Conclusion

Our results demonstrate that CAFs are significantly associated with transcriptomic alterations linked to ECM remodeling, EMT, and tumor invasion in OSCC spheroids. These insights underscore the importance of the CAF-tumor cell interplay in cancer progression, providing potential targets for future therapeutic interventions.

EACR25-2435

Transforming AI-Driven Drug Discovery with a 100 Million Single-Cell Dataset

G. Demirkan¹, C. Curca¹, B. Hariadi¹, O. Sanderson¹, E. Papalex¹, S. Marryjo¹, A. Rosenberg¹, H. Nguyen¹, C. Roco¹, J. Pangello¹

¹*Parse Biosciences, Seattle, United States*

Introduction

Single-cell RNA sequencing (scRNA-seq) has become a powerful tool for studying complex biological systems, offering transcriptome-wide insights at single-cell resolution. AI-driven drug discovery requires large, high-quality datasets covering a broad range of experimental conditions to train and refine predictive models. Recent advancements in single-cell combinatorial barcoding have enabled profiling of transcriptomes from 10s to 100s of millions of cells in a single experiment. This presents an opportunity for combinatorial barcoding to provide over 100 million cells as training data and set a new standard for a more robust and comprehensive system for modeling drug perturbations in diverse cellular systems.

Material and method

A heterogeneous model system comprising over 50 cell lines was treated with ~300 cancer drugs at three concentrations for 24 hours. Cells were subsequently fixed to enable large-scale combinatorial barcoding in batches exceeding 10 million cells each. The Parse Biosciences GigaLab platform was employed for single-cell barcoding, which enables high-throughput while maintaining high transcript detection. Library preparation, including cDNA capture, PCR amplification, and clean-up, was automated in a 96-well format to ensure efficiency. The entire workflow, from treatment to sequencing-ready libraries, was completed within five weeks. Sequencing was performed on the UG 100™ (Ultima Genomics), and data were processed through the Parse Biosciences pipeline. Cell line identity was resolved using Demuxlet for downstream analysis.

Result and discussion

This study successfully generated transcriptomic data from over 100 million single cells across 60,000 experimental conditions, demonstrating the feasibility of scaling single-cell sequencing for large-scale AI applications. Automated workflows minimize batch effect while significantly accelerating processing time. The resulting dataset provides a powerful resource for AI-driven drug discovery, allowing researchers to model drug perturbations across diverse cellular backgrounds. These findings highlight the feasibility and impact of large-scale single-cell sequencing for AI applications in biomedical research.

Conclusion

By establishing a scalable and efficient single-cell sequencing workflow, this study sets a new benchmark for high-throughput transcriptomics in drug discovery. The ability to generate high-resolution data from 100 million cells provides unprecedented opportunities for modeling complex biological responses at scale. This approach will enable more accuracy and efficiency in future AI-driven studies in disease modeling, drug screening, and precision medicine, accelerating the development of novel therapeutics.

EACR25-2446**Optimizing low input and high-throughput cell fixation for single-cell RNA sequencing with combinatorial barcoding**

O. Kaplan¹, S. Schroeder¹, V. Tran¹, A. Salvino¹, A. Sapre¹, S. Marrujo¹, A. Rosenberg¹, G. Demirkan¹, C. Roco¹, A. Sinclair¹

¹Parse Biosciences, Seattle, United States

Introduction

Single-cell analysis is a critical approach for extracting nuanced biological insights. Combinatorial barcoding is a highly efficient method for scRNA-seq at scale, offering both sensitivity in gene detection and flexibility in sample input. However, this approach becomes challenging when working with sample inputs of fewer than 100,000 cells. To address this limitation, we have developed a modified fixation and cell capture method optimized for low-input samples while maintaining compatibility with combinatorial barcoding. This advancement allows researchers to fix, store, and barcode cells efficiently without requiring costly or specialized instruments.

Material and method

The Low Input Fixation method enables the fixation and profiling of up to 384 samples in parallel, significantly reducing workflow duration while ensuring consistent handling. This minimizes both experimental variability and the burden of scaling. Fixed samples remain stable at -80°C, and capture efficiency remains consistently high for inputs as low as 10,000 cells. The workflow is designed to maximize sample recovery while providing accurate and comprehensive transcriptional profiling. To validate this approach, we applied it to a cancer drug screening panel, utilizing cell input amounts ranging from 10,000 to 20,000 cells per treatment.

Result and discussion

Robust cell capture minimizes cell loss during drug perturbations, leading to consistent gene detection. Whole transcriptome analysis using Evercode WTK identifies gene expression changes associated with each drug class and cell type. The results validate putative drug targets within the panel and demonstrate that panel-based perturbation allows for the scalable detection of off-target effects. The stability and efficiency of this method make it a powerful tool for studying transcriptional responses in low-input single-cell experiments.

Conclusion

This work demonstrates that combining low-input fixation with combinatorial barcoding enables high-throughput cancer drug and compound screening. By facilitating the efficient processing of low-input samples, this method expands the applicability of single-cell transcriptomics to a broader range of biological and clinical studies.

EACR25-2451**Towards a Quantitative Phenotypic Progression Model of Prostate Cancer**

F. Inaba¹, W. Wu¹, M. Keyes², C. MacAulay¹, M. Guillaud¹

¹BC Cancer, Integrative Oncology, Vancouver, Canada

²BC Cancer, Radiation Oncology, Vancouver, Canada

Introduction

Prostate cancer (PCa) is the most prevalent cancer among men, with significant global health implications. Among the three factors in the D'Amico classification system, Gleason Score (GS) remains the gold-standard for diagnosis but lack prognostic value. There is still need to develop better marker of Prostate cancer aggressiveness. We propose an Quantitative Phenotypic Progression Model of Prostate Cancer, leveraging tissue architecture (TissArch) features AND features measuring changing in the nuclei DNA organisation to provide a more reproducible and objective method that could complement the current PCa grading system.

Material and method

A total of 250 PCa patients were included in this study from the Prostate Cancer Centre. We identified 3 cohorts: cohort 1 composed of patients with GS 6 with no sign of progression and patients with GS 9 (n = 60); Cohort 2 composed of patients with GS6 under active surveillance that progressed (n = 42); Cohort 3 composed of 148 patients followed for PSA recurrence after brachytherapy. Cohort 2 and 3 are used for validation of the model. For training purpose, we randomly assigned 75% of GS6 patients (n = 31) form and 75% GS9 patients (n = 15) from the cohort 1, with the remaining samples used for testing (n = 14). Biopsies were stained by Feulgen, a DNA-stoichiometric dye. Scanned imaged were analysed by our in-house Hyperspectral Cell Sociology Imaging Pipeline (HCS), powered by Deep learning abased segmentation techniques. More than 100 Large scale DNA organisation (features were calculated for each segmented nucleus and about 50 TissArch features were extracted from Voronoi diagrams and other triangulations constructs.

Result and discussion

Using Linear Discriminant analysis, an overall accuracy of 97% on the training set and 90% on the test were achieved by Tissue Architecture analysis. Using Random Forest algorithms, LDO analysis reached a balanced accuracy of 85% for the training set and 86% for the test set. An LDO Score and a TissArch Score was then calculated for the remaining patients in the validation cohorts. We will analyze and discuss the potential of this parametric phenotypic canonical space to characterize the phenotypic progression "signature" of the patients and its correlation with the degree of aggressiveness of these lesions

Conclusion

This Quantitative Phenotypic Parametric model of Prostate Cancer progression could give additional insight into PCa biological dynamics and help in the clinical management of PCa patients.

EACR25-2452**Heterogenous fusion transcript landscape in multifocal primary prostate cancer**

A. Stranger¹, B. Johannessen¹, S. Kidd¹, U. Axcrona^{1,2}, R. Lothe^{1,3}, K. Axcrona^{1,4}, R. Skotheim^{1,5}

¹Institute for Cancer Research, Oslo Univeristy Hospital-Radiumhospitalet, Oslo, Norway

²Department of Pathology, Oslo University Hospital–Radiumhospitalet, Oslo, Norway

³Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway

⁴Department of Urology, Akershus University Hospital, Lørenskog, Norway

⁵Department of Informatics, Faculty of Mathematics and Natural Sciences, University of Oslo, Oslo, Norway

Introduction

Prostate cancer is the second most commonly diagnosed cancer in men globally, and is characterised by significant clinical and molecular heterogeneity. Most patients present with multiple primary tumour foci, each displaying distinct molecular profiles, with recurrent fusion genes playing a pivotal role in pathogenesis. These fusions typically involve ETS transcription factors such as ERG, ETV1, ETV4, and FLI1, with the TMPRSS2::ERG fusion observed in approximately 50% of cases. However, studies often rely on single focal sampling, thereby overlooking the considerable interfocal heterogeneity present within patients.

Material and method

In our study, multiple samples per patient were included to capture both interfocal and intrafocal heterogeneity. We analysed samples from 43 prostate cancer patients, including 2–3 malignant samples from 1–3 tumour foci and 1 benign sample per patient. High throughput RNA sequencing was performed on the 159 samples, followed by computational analysis using the fusion detection tools STAR-Fusion and Arriba to identify fusion transcripts. High-confidence fusions were prioritised based on detection by both tools, presence of multiple isoforms, breakpoints located at splice sites, and expression above 0.1 fusion fragments per million mapped fragments.

Result and discussion

We identified 3414 distinct fusion transcripts, with a median of 55 fusions per malignant sample. All known prostate cancer-related fusions displayed interfocal, or both intra- and interfocal expression variance, suggesting complex heterogeneity within and across tumour foci. TMPRSS2::ERG and SLC45A2::AMACR were the most frequently expressed fusions, present in 43% and 48% of samples, respectively, with approximately half of these samples expressing both fusions. The stringent filtering process yielded 16 high-confidence fusion candidates with evidence of pathogenic relevance; most of which were novel. Many involved genes with established cancer roles, such as IGF1R::CSPP1, MTUS1::OTOG, CTNND1::ETV1, and PDZRN3::CMTM8, and exhibited notable intrapatient heterogeneity. Most fusion transcripts were expressed at low frequencies, present in less than 5% of patients.

Conclusion

This study reveals a complex landscape of fusion transcript heterogeneity in multifocal primary prostate cancer, marked by substantial inter- and intrafocal variation. The discovery of novel fusion transcripts opens opportunities for future research into their functional roles in oncogenesis and offers promise for their potential as biomarkers and therapeutic targets.

EACR25-2468

Unraveling chemoresistance in breast cancer through circulating miRNAs in liquid biopsy

S. Romero-Cordoba¹, A. Perez-Moreno¹, Y. Chavarri-Guerra², A. Tenorio-Torres³, E. Ruvalcaba-Limon³, G. Consentino⁴, M. Iorio⁴

¹Institute of Biomedical Research, UNAM-INCIMNSZ, Department of Genomic Medicine and Environmental Toxicology, Mexico, Mexico

²National Institute of Medical Sciences and Nutrition Salvador Zubiran, Hematology and oncology, Mexico, Mexico

³Institute of Breast Diseases FUCAM, Medical Direction, Mexico, Mexico

⁴Fondazione IRCCS Istituto Nazionale dei Tumori, U12, Milan, Italy

Introduction

Neoadjuvant chemotherapy (AdjCh) is essential for breast cancer treatment, but resistance remains a major challenge. Circulating molecules, particularly extracellular vesicles (EVs) and microRNAs (miRNAs), are promising biomarkers. EV cargo exchange and circulating transcripts may drive resistance by altering gene expression and tumor behavior. Thus, this study explores the role of circulating RNAs as markers of chemoresistance.

Material and method

EVs were isolated from the culture media of breast cancer cell lines (MDA-MB-468, MDA-MB-231, and BT-549) with varying drug responses using PEG precipitation and differential ultracentrifugation (dUC). Small EVs (sEVs) were physically and biochemically characterized. Sensitive cells were exposed to 10,000 sEVs per cell from resistant cells. Transcriptomic analysis of EV cargo and recipient cells via microarrays was correlated with public TNBC datasets, identifying four key RNA transcripts linked to EV-mediated chemoresistance. Their functional roles were validated in vitro using siRNA and miRNA mimic transfections, assessing their impact on drug response and tumor aggressiveness. Circulating RNA was isolated from blood using Norgen kits, and miR-574-5p and miR-7977 expression was quantified via Qiagen digital PCR with TaqMan probes. miRNAnome was sequenced on an Illumina platform with Takara enrichment achieved 20 million reads of coverage.

Result and discussion

Given their stability and enrichment in circulation, miRNAs are promising biomarkers. We identified and functionally characterized miR-574-5p and miR-7977, secreted via small vesicles in chemotherapy-resistant cells. Their upregulation increased proliferation, viability, and motility, while transcriptomic analysis linked them to key cancer-related metabolic processes. Public datasets confirmed their enrichment in breast tissues resistant to neoadjuvant chemotherapy. As an initial approach, we assessed miR-574-5p and miR-7977 circulating expression in blood samples from 69 breast cancer patients treated with neoadjuvant chemotherapy using digital PCR. Their predictive performance for poor response, no response, or disease progression, quantified by the area under the curve (AUC) and optimized using

bootstrap analysis, reached 0.774. Furthermore, we evaluated the transcriptional landscape of circulating miRNAs in a liquid biopsy approach from 60 baseline samples of patients undergoing AdjCh, uncovering distinct expression patterns associated with treatment response.

Conclusion

This proof-of-concept study demonstrates how plasma miRNA profiles can reveal treatment resistance-associated miRNAs and provide biologically and clinically actionable insights, with potential implications for therapeutic decision-making.

EACR25-2487

Molecular Profiling of Brain Metastases from Distinct Primary Tumors Identifies Subtypes with Implications for Therapy and Biomarker Development

I. Weissberg¹, R. Paes de Araujo¹, C. Contieiro¹, P. Reis¹

¹São Paulo State University, Botucatu, Brazil

Introduction

Brain metastases (BM) are the most prevalent tumors of the central nervous system (CNS), affecting up to 40% of cancer patients, occurring ten times more frequently than primary CNS tumors. Despite their prevalence, BM remains highly heterogeneous, shaped by both their primary tumor origin and the brain microenvironment. Evidence suggests that BM retain distinct gene expression patterns from their primary tumor, influencing tumor progression, therapeutic response, and biological pathways. Understanding transcriptomic changes associated with BM from distinct primary tumor sites is crucial for biomarker discovery and precision medicine.

Material and method

This study analyzed 43 BM samples from primary tumors from nine distinct primary sites. Patient samples were obtained from our local clinical hospital at Unesp. Total RNA sequencing was performed using the Illumina NovaSeq X platform, with gene expression quantified in transcripts per million (TPM) and normalized using DESeq2. Principal component analysis (PCA) and K-means clustering identified five molecular sample subgroups. Differential expression analysis was conducted using ANOVA ($p < 0.05$), followed by Tukey's post-hoc test. Biomarker selection focused on genes with the highest expression differences, prioritizing those with consistent expression patterns within subgroups for further validation.

Result and discussion

16,782 genes were assigned to the five molecular clusters based on transcriptomic profiling. Each cluster exhibited distinct pathway enrichment, influencing tumor behavior and treatment response. Clusters 1 and 4 were enriched in RNA processing, DNA repair, and protein degradation, suggesting stress responses and genomic instability. Clusters 2 and 5 were dominated by synaptic function and neurotransmitter regulation, highlighting potential interactions with the brain microenvironment. Cluster 3 was enriched in extracellular matrix (ECM) interactions, focal adhesion, and cancer pathways, emphasizing its role in tumor invasion and metastasis. Immune-related

pathways were underrepresented, likely reflecting immune evasion mechanisms in BM.

Conclusion

This study identifies distinct molecular subtypes in BM, each characterized by unique biological processes affecting tumor behavior and therapeutic response. Clusters enriched in RNA processing and DNA repair indicate genomic instability, while clusters with synaptic function suggest interactions with the brain microenvironment. ECM remodeling and adhesion pathways highlight mechanisms of tumor invasion and metastasis. The absence of immune pathway enrichment suggests immune evasion may play a critical role in BM progression, with implications for immunotherapy. These findings establish a foundation for biomarker discovery and targeted therapies, driving advancements in precision oncology to benefit patients with BM.

EACR25-249

The TP53:AHR genetic interaction regulates MAGE:TRIM28 activity to prevent cellular transformation

K. Mueller¹, D. Maneta¹, M. Wegner¹, S. Nikte^{1,2}, N. Tolay¹, A. Bremm¹, R. Bhaskara^{1,2}, M. Looso^{3,4,5}, M. Kaulich^{1,6,5}

³Max Planck Institute for Heart and Lung Research, Bioinformatics Core Unit, Bad Nauheim, Germany

⁴German Center for Cardiovascular Research, Frankfurt, Germany

⁵CardioPulmonary Institute, Frankfurt, Germany

⁶Frankfurt Cancer Institute, Frankfurt, Germany

Introduction

Within an organism, transformed cellular physiology is the concerted effect of intracellular alterations, interactions with other cells, hypoxia and nutrient-shortage tolerance, as well as the ability to grow in an anchorage-independent manner.

Material and method

To better mimic these physiological conditions, we developed a 3D soft-agar system with non-transformed human cells. We then analyzed global transcriptional changes of single and combinatorial gene knockout cell lines with bulk RNA-sequencing and publicly available TCGA LUAC patient data.

Result and discussion

We discovered a previously unknown genetic interaction between TP53 and the AHR/ARNT genes. Analysis of RNA-seq data originating from gene knockout cell lines revealed an increased expression of Type I Melanoma Antigen Gene (MAGE) family genes upon the synergistic loss of TP53 and AHR. Type I MAGE proteins have been shown to bind the E3-ligase TRIM28 which redirects its substrate specificity. On the same line, TCGA LUAC patient data show that expression of MAGEC2 correlates with shorter survival times, an effect which is even more pronounced when expression of ARNT and TP53 is low. While mechanistic studies are

ongoing, we also employed structural bioinformatics to model the TRIM28 dimer and its binding to MAGEC2.

Conclusion

Our findings point to a clinically relevant model in which the loss-of-function of TP53 and AHR/ARNT leads to the expression of type I MAGE genes, which causes an altered TRIM28 substrate specificity and the degradation of one or multiple anti-transformative factors.

EACR25-2496

Sex-Dependent Transcriptional Gene Expression in Urothelial Bladder Cancer

A. Myumyun¹, A. Saeed^{1,2}, E. Yuksek Tekben¹, D. Ward³, R. Arnold³, R. Bryan³

¹University of Birmingham, Institute of Cancer and Genomics, Birmingham, United Kingdom

²Anatomy and Pathology Department, College of Veterinary Medicine, Sulaimani University, Iraq

³University of Birmingham, Cancer and Genomic Sciences, Birmingham, United Kingdom

Introduction

The incidence of bladder cancer is three times higher in men than in women. While the underlying causes of this disparity remain unclear, potential contributing factors such as smoking, hormonal effects, X chromosome inactivation, and anatomical differences cannot fully explain the significantly higher prevalence in males. More research is needed on the sex-specific biological mechanisms that cause this disparity. Aim: This study investigates sex-specific transcriptional differences in bladder cancer by analysing gene expression patterns. By identifying differentially expressed genes between male and female patients, I aim to uncover molecular mechanisms underlying sex-based disparities, particularly in the early stages of the bladder cancer.

Material and method

Bulk RNA sequencing data from the UROMOL2021 study were used for the analysis. This dataset includes NMIBC samples from 535 patients (121 females and 414 males) and 7 non-cancerous bladder tissues from the GTEx database. Differentially expressed genes (DEGs), gene set enrichment (GSE), progression-free survival (PFS), and tumour microenvironment (TME) analyses were performed to identify differences between male and female tumour tissues.

Result and discussion

DEG analysis revealed 94 genes with differential expression between male and female NMIBC patients, including 19 X-chromosome, 22 autosomal, and 53 Y-chromosome genes. In normal bladder tissues, only 16 genes exhibited differential expression between the sexes. Seven X-chromosome genes were significantly associated with PFS in male patients, compared to only two in female patients (log-rank test, $p < 0.05$). For autosomal genes, six were significantly associated with PFS in male patients not in female. In male patients, cancer-related pathways were significantly upregulated in tumour tissues, while no significant pathways were observed in female tumour tissues. However, in normal bladder tissues, up-regulation of cancer pathways was exhibited in male patients, while immune-related pathways were upregulated in females. Furthermore, gene ontology analysis of biological processes has

revealed that epigenetic regulation, X chromosome inactivation, and miRNA metabolic processes play a critical role in the sex-specific differences observed in NMIBC.

Conclusion

Comprehensive sex-specific data analysis of NMIBC patients indicates that most transcriptional differences are linked to X and Y chromosome genes. Notably, my findings highlight XIST expression and its regulatory mechanisms as key contributors to these differences, particularly in relation to PFS outcomes. The PFS analysis revealed that XIST expression affects males and females in opposite ways. These findings suggest that XIST and its associated mechanisms may provide a crucial explanation for sex-based differences in NMIBC.

EACR25-2553

Exploring Alternative Splicing in Breast Cancer: Direct RNA Nanopore Sequencing for Transcriptome Profiling

L. Claudino¹, C. Silva², L. Vieira², A. Rodrigues¹, B. Costa Gomes¹, S. Nunes Silva¹

¹Comprehensive Health Research Centre (CHRC), NOVA Medical School, Universidade NOVA de Lisboa, Lisboa, Portugal

²Instituto Nacional de Saúde Doutor Ricardo Jorge, Departamento de Genética Humana, Lisboa, Portugal

Introduction

Breast cancer (BC) remains one of the most widespread diseases globally, profoundly affecting millions each year, particularly women. This study investigates the feasibility of utilizing direct RNA nanopore sequencing protocols from Oxford Nanopore Technologies (ONT) for transcriptome profiling in BC-related cell lines, including nontumoral MCF-10A cells, luminal A MCF-7 cells, and triple-negative MDA-MB-231 cells.

Material and method

The selected cell lines were cultured, RNA was extracted and sequenced, and the resulting data underwent processing through the bioinformatics pipeline FLAIR. This approach enabled the identification of alternative splicing (AS) events in various genes associated with tumorigenesis. Given the substantial volume of data obtained, the genes analyzed for AS events were chosen based on their roles in mRNA splicing and translation initiation pathways.

Result and discussion

Multiple AS events were identified in genes encoding RNA polymerase II subunits – POLR2G and POLR2H – as well as in the splicing factor gene SRSF2. Furthermore, EIF3A and EIF3E, which encode subunits of the eukaryotic initiation factor 3 (eIF3) complex essential for translation, exhibited novel isoforms and distinct expression patterns across the analyzed cell lines. The identification of novel isoforms in these genes suggests potential functional implications in BC development and progression. For example, intron retention in POLR2G and exon skipping in POLR2H may disrupt co-transcriptional splicing, thereby impairing RNA processing regulation. Additionally, nonsense-mediated decay (NMD)-sensitive isoforms detected in SRSF2 could influence its autoregulation, impacting cell survival. The discovery of a novel EIF3A isoform predominantly

expressed in MDA-MB-231 cells suggests potential alterations contributing to BC progression. Likewise, protein modeling of various EIF3E isoforms using AlphaFold revealed the possibility of distinct functional properties.

Conclusion

These results might be an essential step for further biologically significant discoveries in cancer transcriptomics, potentially advancing clinical management, diagnosis, and therapeutic strategies for BC patients.

EACR25-2557

Integrative analysis of epigenetic and transcriptional interrelations identifies histotype-specific biomarkers in early-stage ovarian carcinoma

H. Swenson¹, E. Ittner¹, L. Werner¹, T. Parris¹, K. Helou¹, S. Nemes², E. Werner Rönneman¹, C. Claudia Mateoiu³, P. Dahm-Kähler⁴, P. Karlsson⁵

¹*Institute of Clinical Sciences, Department of Oncology, University of Gothenburg, Göteborg, Sweden*

²*AstraZeneca, Göteborg, Sweden*

³*Sahlgrenska University Hospital, Department of Clinical Pathology, Göteborg, Sweden*

⁴*Institute of Clinical Sciences, Department of Obstetrics and Gynecology, Göteborg, Sweden*

⁵*Institute of Clinical Sciences, Department of Laboratory Medicine, Göteborg, Sweden*

Introduction

Ovarian carcinoma (OC) is a deadly and heterogeneous disease comprising five major histotypes: clear cell carcinoma (CCC), endometrioid carcinoma (EC), low- and high-grade serous carcinoma (LGSC, HGSC), and mucinous carcinoma (MC). Despite this heterogeneity, OC is often treated as a homogenous disease, and reliable screening tests are lacking. Although progress has been made, there is a pressing need for biomarkers to refine patient stratification, guide treatment, and improve outcomes. Here, we elucidated the relationship between DNA methylation and gene expression patterns in OC to identify histotype-specific biomarkers.

Material and method

Differential DNA methylation and gene expression analyses were performed for 86 early-stage OC samples after histopathological reclassification stratified by histotype. The correlation between DNA methylation and gene expression was examined, and histotype-specific biomarkers were identified. Hierarchical clustering and predictive machine learning modeling were employed to assess the performance of the histotype-specific biomarkers using four external cohorts.

Result and discussion

OC histotypes exhibited distinct epigenetic, transcriptional, and functional profiles, with candidate histotype-specific biomarkers such as CTSE and VCAN effectively distinguishing CCC, HGSC, and MC on the transcriptional level. Gene expression for the candidate biomarkers was found to be reproducible across external cohorts, with histotype-specific differences remaining homogenous.

Conclusion

This study identified promising histotype-specific biomarkers for OC using integrative transcriptomic and epigenomic analysis. Furthermore, these findings indicate that additional stratification or potential reclassification of the EC histotype is warranted in future studies.

EACR25-2563

Molecular Characterisation of Trophoblast Tumours

H. Crook¹, E. Hayes², E. Ghorani², G. Maher², L. Zapata³

¹*Institute of Cancer Research, Department of Cancer Biology, London, United Kingdom*

²*Imperial College London, London, United Kingdom*

³*Institute of Cancer Research, London, United Kingdom*

Introduction

Placental site trophoblastic tumors (PSTT) and epithelioid trophoblastic tumors (ETT) are rare malignancies arising from trophoblast cells post-pregnancy. Despite their aggressive cellular origins, these tumors exhibit slow progression and remain poorly characterized at the molecular level. This study employs a multi-omic approach to elucidate the molecular mechanisms underlying PSTT and ETT, with the aim of improving diagnostic and therapeutic strategies and informing broader cancer evolution models.

Material and method

Archival formalin-fixed paraffin-embedded (FFPE) samples of PSTT and ETT were analyzed using whole-genome sequencing (WGS), whole-exome sequencing (WES), RNA sequencing (RNA-seq), and shallow whole-genome sequencing (sWGS). A Nextflow-based bioinformatics pipeline processed sequencing data, identifying genomic alterations, copy number aberrations, and immune evasion mechanisms. HLA-typing was performed using WGS/WES data and validated via RNA-seq. Tumor mutational burden and immune selection pressure were assessed through variant analysis and immune dN/dS calculations.

Result and discussion

A significant correlation between the time since causative pregnancy and genomic instability was identified, with higher percent genome altered (PGA) in tumors arising more than four years post-pregnancy. HLA-typing revealed that immune evasion in PSTT/ETT mirrors their trophoblastic origin, with loss of HLA-A/B expression and retained HLA-C expression. Immune dN/dS analysis showed a lack of immunoediting, reinforcing the hypothesis that trophoblast tumors inherently evade immune detection rather than acquiring this ability.

Conclusion

This study provides novel insights into PSTT/ETT molecular evolution and immune evasion. The development of a time-dependent tumor progression model may enhance patient stratification and guide therapeutic interventions, with potential applications to other malignancies beyond PSTT and ETT.

EACR25-2564**Spatial Transcriptomics for characterising pathologic response to FOLFOX regimen in colorectal Liver Metastases**

N. Molina¹, M. Bañuls², N. Ruiz³, E. Aranda⁴, K. Mils³, L. Lladó³, R. Sanz⁴, A. Antolin¹, V. Moreno², D. García Molleví²

¹*Bellvitge Biomedical Research Institute (IDIBELL), Hospitalet de Llobregat, Spain*

²*Catalan Institute of Oncology, Hospitalet de Llobregat, Spain*

³*Hospital of Bellvitge, Hospitalet de Llobregat, Spain*

⁴*ISS Aragón, Zaragoza, Spain*

Introduction

Liver metastases are major cause of cancer deaths. Surgery is a potential cure, but recurrence is common, and only 20% are initially surgical candidates. Pre-operative FOLFOX chemotherapy is frequently used. As postoperative chemotherapy benefits are unclear, understanding preoperative response could improve treatment and relapse management. This study utilizes spatial transcriptomics to identify biomarkers predictive of FOLFOX response, enabling personalized adjuvant strategies based on hepatic growth patterns (HGP) of liver metastases.

Material and method

TMA of CRCLM, categorized by FOLFOX response and HGP, were created. Spatial transcriptomics (GeoMx) analyzed gene expression in tumor cells, CAFs, and immune cells. Data analysis used linear mixed models, GSEA, and cell deconvolution. Lasso regression and cross-validation were used to develop a predictive gene classifier.

Result and discussion

Analysis revealed distinct gene expression profiles between encapsulating and infiltrative hepatic gland patterns (HGP) within both tumor cells and cancer-associated fibroblasts (CAF). Gene candidates differentiating these HGPs are currently undergoing validation. In terms of pathological response, tumor cells from responders exhibited enrichment in inflammatory pathways, notably IL6-JAK/STAT3 signaling, while non-responders showed upregulation of DNA repair, chromatin remodeling, and proliferation-associated pathways. Notably, despite rigorous statistical analysis, no significant differential gene expression was detected in CAFs between responders and non-responders, regardless of HGP. However, non-responding areas, and non-encapsulating metastases, displayed a higher presence of contractile CAFs, despite ECM-producing CAFs being the most abundant subtype in both groups. Immune cell composition showed no major changes, except for increased neutrophils in non-responding areas and non-encapsulating metastases. Further immune cell characterization is ongoing, combining transcriptomic and proteomic data. Lasso regression identified four genes with high predictive value for treatment response, withheld due to patent concerns. Drug screening identified a transmembrane protein ligand (methanobenzazocine derivative) and a PROTAC.

Conclusion

Spatial transcriptomics revealed molecular differences in FOLFOX response and HGP biomarkers in CRCLM,

enabling biomarker-driven personalized post-hepatectomy treatment and relapse management. 4-plex staining validation is ongoing.

EACR25-2581**Clinical and Genetic Heterogeneity in Early-Onset Colorectal Cancer: Unclosing Distinct Molecular Entities**

³*Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE, Clínica de Risco Familiar, Lisboa, Portugal*

⁴*Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE, Anatomia Patológica, Lisboa, Portugal*

Introduction

The incidence of early-onset colorectal cancer (EO-CRC) has been increasing dramatically over the last few decades. The younger affected population tends to have more advanced stages, poor response to therapy and a worse prognosis among treated patients with metastatic CRC, thus emerging the need to investigate novel susceptibility genetic variants responsible for increased EO-CRC risk and to support therapeutic decisions.

Material and method

With the aim of identifying inherited variants underlying increased susceptibility for EO-CRC, 202 patients (≤ 50 years) who had previously undergone Next-Generation Sequencing-based germline genetic diagnosis using a custom multigene panel (Agilent) were analyzed, in a retrospective study, for germline genetic variants in selected cancer susceptibility genes and selected genes coding for components of relevant cancer mechanisms. The genetic variants of interest were selected based on their ClinVar classification, population frequency and predictive damaging in silico software.

Result and discussion

At the clinical level, women presented distal tumors ($p = 0.049$) and a family history (FH) of cancer ($p = 0.006$) more often than men. Patients under 30 mostly have no FH of cancer ($p = 0.014$). Moreover, metastatic disease was positively linked to a cancer FH in non-1st-degree relatives ($p = 0.013$) and inversely correlated with history of polyps ($p = 0.000$). Pathogenic/likely pathogenic variants (PVs) were identified in 20/182 (11%) patients, with 19/20 variants being identified in genes involved in different DNA repair mechanisms (ATM, MUTYH, FANCD2, ...). Furthermore, 105 putative damaging (PDVs) according the above mentioned criteria were identified in 84/182 (46%) patients. Among these PDVs, 57% are associated to DNA repair pathways and the remaining to other cellular mechanisms. Besides, 27/84 (32%) patients carried 2 or more PDVs and these presented less frequently FH of CRC ($p = 0.043$). Most DNA repair gene variants were related to homologous recombination DNA repair ($p = 0.013$) and PVs seemed to be associated with rectal cancer ($p = 0.043$) and

inversely related to a personal history of polys ($p = 0.041$). Lastly, since ATM showed the highest mutation rate in the entire cohort, with 4/20 (20%) of the patients with PVs presenting alterations in this gene ($p = 0.015$), we analyzed an additional validation cohort of 1652 patients with increased risk of CRC and identified 13 PVs and 23 PDVs in ATM gene, which appeared to be differentially distributed throughout the protein according to specific phenotypes.

Conclusion

EO-CRC population revealed heterogeneous features, defining specific clinical and genetic subgroups, with a subset associated to deficiency in distinct DNA repair mechanism, thus shedding light to the distinct etiologies of EO-CRC and the identification of specific traits that may be associated with greater tumor aggressiveness and to distinct responses to chemotherapy and PARP inhibitors.

EACR25-2592

Genomic Analysis of PARP Inhibitor Response in High-Grade Serous Ovarian Cancer: Insights from Whole Genome Sequencing

Y. Kim¹, O. Kang¹, H. Eum¹, S. Kang¹, S. Lee¹

¹*Asan Medical Center, University of Ulsan College of Medicine, Department of Obstetrics & Gynecology, Seoul, Korea (Republic of)*

Introduction

To evaluate the clinical utility of whole-genome sequencing (WGS)-based HRDetect in identifying homologous recombination deficiency (HRD) and its association with clinical outcomes in high-grade serous ovarian cancer (HGSOC) patients treated with PARP inhibitors (PARPi).

Material and method

This single-center study analyzed patients with stage III-IV high-grade serous ovarian or fallopian tube cancer treated at Asan Medical Center from 2017 to 2022.

Participants underwent surgery followed by adjuvant or neoadjuvant chemotherapy and maintenance therapy with olaparib or niraparib. Patients were stratified into four groups by BRCA status and progression-free survival (PFS). Retrospective data collection included demographics, treatments, and outcomes. Tumor and normal samples underwent WGS, and HRD was evaluated using HRDetect and Myriad genomic instability scores (GIS). Genomic features, including mutational signatures, structural variations, and copy number alterations, were analyzed.

Result and discussion

Among 37 patients, ScarHRD identified 30 as HRD-positive and 7 as HRD-negative, while HRDetect classified 17 as HRD-positive and 20 as HRD-negative. Discordant cases arose only when HRDetect labeled tumors as HRD-negative but ScarHRD classified them as HRD-positive. Tumors with key HRD-associated features, such as SBS3, ID6, RS3, and RS5, were consistently identified as HRD-positive by both methods. In contrast, tumors lacking SBS3 and displaying ambiguous characteristics, including age-related

mutational signatures or microsatellite instability, were classified as HRD-negative by HRDetect, even when ScarHRD deemed some of these HRD-positive.

Conclusion

This study suggests that WGS-based HRDetect can complement existing HRD assessment methods in HGSOC, offering a more comprehensive approach to identifying patients for targeted therapies.

EACR25-2603

Multimodal analysis of spatial transcriptomics data uncovers novel invasive lobular carcinoma subtypes

M. Serra¹, M. Rediti², L. Collet¹, F. Lifrange³, D. Venet¹, D. Vincent¹, G. Rouas¹, F. Rothé¹, C. Sotiriou¹

¹*Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium*

²*6IFOM ETS, the AIRC Institut of Molecular Oncology, Milan, Italy*

³*Department of Pathology, Centre hospitalier universitaire de Liège (CHU de Liège), Liege, Belgium*

Introduction

Invasive lobular carcinoma (ILC) is the second most common histological subtype of breast cancer. This study integrates morphological, spatial, and molecular data from spatial transcriptomics (ST) to analyze the ILC tumor microenvironment (TME), leading to a novel classification based on TME heterogeneity.

Material and method

ST (Visium 10X) was performed on 43 HR+/HER2- ILC frozen tumors and relative H&E slides were morphologically annotated. To improve resolution, ST spots were deconvoluted using external RNA sequencing data. Imaging and sequencing data were independently analyzed and then integrated using intNMF, leading to the identification of ILC4TME, a novel ILC classification. This classification was validated in external bulk RNA-seq using a surrogate gene signature-based classifier.

Result and discussion

Morphological and molecular analysis revealed distinct immune cell compartmentalization: adaptive immune cells (B and T cells) clustered near epithelial cells, while innate immune cells (macrophages and monocytes) associated with adipose tissue. In situ/normal glands correlated with better outcomes, while proliferative and metabolic-enriched tumor cells indicated worse outcomes. Multimodal integration of ST data identified four ILC subtypes (ILC4TME): proliferative (P, enriched in tumor cells and proliferation-related pathways), normal-stroma enriched (NSE, enriched in fibroblasts, carcinoma in situ, and EMT-related pathways), androgen receptor-enriched (ARE, enriched in AR expression, endothelial cells, and metabolic pathways), and metabolic-immune enriched (MIE, enriched in adipocytes, macrophages, endothelial cells, and metabolic pathways). Our classifier identified the same subtypes in METABRIC and SCAN-B ILC samples, where survival differences emerged: NSE and P subtypes were significantly associated with longer and shorter relapse-free intervals, respectively. Notably, the P subtype correlated with higher copy number aberrations in METABRIC and was linked to

larger tumors, higher grade, lymph node involvement, and high Ki67.

Conclusion

Multimodal integration of spatial transcriptomics (ST) data led to the identification of four distinct invasive lobular carcinoma (ILC) subtypes, each characterized by unique biological features and associated with different survival outcomes. This classification not only provides insights into the tumor microenvironment and disease progression but also highlights potential therapeutic targets. Importantly, these subtypes were also identified in more accessible bulk RNA sequencing data using surrogate gene signatures, facilitating their broader clinical applicability and potential for integration into routine diagnostic and prognostic assessments.

Unravelling the role of AP-1 transcription factor in DNA damage signalling and response (DDR), platinum and PARP inhibitor resistance in ovarian cancers

S. AlOahtani¹, R. Mahmoud¹, M. Algethami¹, A. Ibrahim¹, A. Shoaifi¹, J. Jeyapalan¹, N. Mongan¹, E. Rakha¹, A. McIntyre¹, S. Madhusudan¹

¹University of Nottingham, School of Medicine, Nottingham, United Kingdom

Introduction

Hypoxia is a characteristic of the microenvironment in high-grade serous ovarian cancer (HGSOC) and plays a role in resistance to platinum-based treatments and PARP inhibitors. It activates the activity of the AP-1 transcription factor, which promotes continuous cell proliferation, invasion, metastasis, and angiogenesis. However, the involvement of AP-1 in DNA damage signalling and repair, as well as its contribution to platinum and PARP resistance in HGSOC, remains uncertain.

Material and method

The activity of 48 different transcription factors (TFs) were assessed in PARP-sensitive and resistant high-grade serous ovarian cancer (HGSOC) cells (PEO1, PEO1R, and OVCAR4) using a luciferase-based reporter assay. The protein expression of AP-1 subunits, including c-JUN, JUND, JUNB, cFOS, and FOSL2, was analyzed under both normoxic and hypoxic (1% O₂) conditions. Immunohistochemical evaluations for JUNB, FOSL2, MRE11, CA-9, and CD-31 expression were conducted on tumor xenografts from PEO1 and PEO1R. CRISPR knockouts (KOs) of JUNB and FOSL2 were created and studied for their effect on DNA repair gene expression using DNA repair profiler PCR arrays, whole genome RNA sequencing, as well as proliferation, invasion, and sensitivity to cisplatin through clonogenic and 3D spheroid assays. Functional assays were performed to evaluate the accumulation of DNA double-strand breaks (DSBs), cell cycle progression, apoptosis, along with immunofluorescence, protein stability assays, and co-immunoprecipitation. Additionally, the clinical and

pathological significance of FOSL2, JUNB, and MRE11 expression was explored in a cohort of 331 patients with epithelial ovarian cancer.

Result and discussion

In platinum/PARP-resistant PEO1R cells, AP-1 transcription activity was significantly elevated compared to PEO1 cells, with JUNB and FOSL2 proteins being overexpressed under both normoxic and hypoxic (1% O₂) conditions. Tumor xenografts of PEO1 and PEO1R exhibited high JUNB and FOSL2 levels in hypoxic tumor regions. JUNB and FOSL2 knockout (KO) cells demonstrated reduced proliferation and increased sensitivity to cisplatin and the PARP inhibitor olaparib compared to controls, which was linked to increased double-strand breaks (DSBs), G2/M cell cycle arrest, and apoptosis. DNA repair profiling in KO cells showed downregulation of multiple DNA repair genes, including MRE11, a critical factor in the DNA damage response. JUNB and FOSL2 physically interacted with MRE11, enhancing its stability. RNA sequencing revealed enrichment of pathways related to platinum response, oxidative phosphorylation, and translation in KO cells relative to controls. Clinically, elevated expression of FOSL2, JUNB, and MRE11 correlated with significantly shorter progression-free survival (PFS) and poorer overall survival (OS).

Conclusion

Our findings suggest that JUNB and FOSL2 play a role at the intersection of hypoxia and the DNA damage response (DDR) in high-grade serous ovarian cancer (HGSOC). Beyond their predictive and prognostic value, JUNB and FOSL2 could serve as promising therapeutic targets, particularly in platinum/PARP-resistant HGSOC.

EACR25-0044

Targeting Replication Protein A (RPA) heterotrimeric complex to enhance platinum sensitivity and reverse PARP inhibitor resistance in ovarian cancers

M. Algethami¹, S. Alqahtani¹, M. Toss¹, N. Singhania¹, A. Shoaifi¹, A. Lashen¹, J. Jeyapalan¹, N. Mongan¹, E. Rakha¹, S. Madhusudan¹

¹Naaz-Coker Ovarian Cancer Research Centre, Biodiscovery Institute, School of Medicine, Nottingham, United Kingdom

Introduction

Resistance to platinum-based chemotherapy poses a significant challenge in treating epithelial ovarian cancers, making the development of novel biomarkers and therapeutic targets essential. Replication Protein A (RPA), a heterotrimeric complex made up of RPA1, RPA2, and RPA3 subunits, functions as a single-stranded DNA (ssDNA)-binding protein that plays a crucial role in DNA replication, checkpoint regulation, and DNA repair.

Material and method

In this study, we assessed the clinicopathological significance of RPA1, RPA2, and RPA3 protein expression in a cohort of 331 ovarian tumors. We analyzed RPA1, RPA2, and RPA3 transcripts using publicly available datasets (n = 1287) and conducted detailed bioinformatics analyses in the ovarian TCGA cohort (n = 379). Preclinical experiments involved

depleting RPA1 or RPA2 in platinum-resistant ovarian cancer cells, followed by testing their sensitivity to cisplatin and PARP inhibitors (Olaparib, Talazoparib). Additionally, we evaluated the effects of HAMNO, a prototypical 70N-PPI inhibitor, in both PARPi-resistant and sensitive cells.

Result and discussion

Our findings revealed that high levels of RPA1 and RPA2 protein and transcripts were associated with platinum resistance and poor survival outcomes in human tumors. Furthermore, depleting RPA1 or RPA2 not only resensitized the cells to platinum therapy but also reversed resistance to talazoparib and olaparib. Treatment with HAMNO selectively enhanced the cytotoxicity of PARPi-sensitive compared to PARPi-resistant.

Conclusion

In conclusion, an RPA-directed precision oncology strategy holds promise as a potential approach for ovarian cancer treatment

Translational control in ovarian cancer: role of the glutaminyl-tRNA synthetase (QARS) in DNA damage response

M. Serafini¹, Y. Kieffer¹, L. Djerroudi²,

F. Mechta-Grigoriou¹, V. Mieuler³

¹*Institut Curie, Research, Paris, France*

²*Institut Curie, Hospital, Paris, France*

³*Infinity, Research, Toulouse, France*

Introduction

High-grade serous ovarian cancer (HGSOC) is one of the deadliest gynecologic cancers. Treatment options have seen limited progress, despite the development of anti-angiogenic drugs and PARP inhibitors. While the latter are effective in homologous recombination-deficient (HRD) patients, resistance remains a challenge, highlighting the need for new therapeutic targets. We found that 50% of HGSOC patients exhibit MAP3K8 accumulation, activating the MEK/ERK pathway independently of KRAS/BRAF mutations. MAP3K8/MEK regulates the translation of specific mRNAs, with QARS (glutaminyl-tRNA synthetase) as the top target. QARS, like many ARSs (aminoacyl-tRNA synthetases), regulates substrates, not only via translation but also through aminoacylation, controlling various cellular processes. Here, we discovered a novel role for QARS in the DNA damage response (DDR).

Material and method

Polysome profiling investigated MAP3K8/MEK-mediated QARS translational regulation in ovarian cancer cell lines (OCCL), validated by immunohistochemistry with HGSOC tissue. Data from two patient cohorts highlighted QARS role in DDR. QARS function was examined in cell lines through overexpression of wild-type and catalytically inactive forms, analyzing DDR markers (DNA breaks via Comet assay, γH2AX, RAD51, and 53BP1 foci by immunofluorescence). Co-immunoprecipitation and *in vitro* glutaminylation assays were used to assess QARS involvement in DDR mechanisms.

Result and discussion

Inhibition of MAP3K8/MEK in OCCL decreased QARS protein levels without affecting mRNA expression, supported by human HGSOC tissue analysis showing a significant correlation between MAP3K8 and QARS protein levels. This indicates MAP3K8 regulates QARS translation without affecting transcription. QARS accumulation is associated with increased DDR; tumors sensitive to cisplatin-based chemotherapy exhibited elevated QARS expression. In line with patient observations, we provided evidence that QARS plays a role in DDR *in vitro*. Wild-type QARS overexpression reduces DNA damage and promotes double-strand break repair via homologous recombination, as shown by decreased γH2AX and increased RAD51 foci. In contrast, the catalytically inactive QARS mutant reversed these effects, highlighting the importance of its enzymatic activity in DDR. These results suggest QARS may accumulate in HRD patients sensitive to chemotherapy, to compensate and favour HR. This accumulation may enhance the DDR response in tumors, ultimately aiding their survival and chemotherapy response. We are currently investigating the molecular mechanisms by which QARS regulates DDR, identifying two potential QARS targets for translational regulation and/or glutaminylation.

Conclusion

MAP3K8 regulates QARS at the translational level in HGSOC, and QARS plays a critical role in promoting DNA repair. This study aims to identify new targetable pathways for HGSOC, a major clinical challenge.

Introduction

Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma (NHL), representing approximately 30% to 40% of all newly diagnosed lymphomas. In 2017, the WHO confirmed a previous provisional entity, EBV+DLBCL, NOS. It has

been hypothesized that Epstein Barr virus (EBV) may act as an alternative or complementary mechanism to the genetic alterations involved in DLBCL development. Since traces of EBV infection were described by sensitive methods in cases considered negative by conventional techniques, the involvement of EBV infection in DLBCL pathogenesis is still under discussion. For that purpose, our aim was to analyze the genetic alterations, classify them according to their pathogenicity, and correlate these with the presence of the virus and its traces, detected using both conventional and high-sensitivity methods.

Material and method

A cohort of 35 patients with DLBCL was analyzed. EBV+DLBCL was defined by EBERs *in situ* hybridization (ISH), with 20% of EBERs⁺ tumor cells as cut-off. The presence of viral traces was explored by ViewRNA assay that detected LMP1 and EBNA2 transcripts. Genetic variants were evaluated using a custom-designed next-generation sequencing (NGS) panel (Qiagen), focusing on pathogenic and non-pathogenic variants and pathways enrichment analyses. Comparative analyses were conducted between three groups: EBV+ DLBCL, EBV-DLBCL with viral traces, and EBV- DLBCL without traces. Statistical analyses assessed the associations between genetic variants and the presence of EBV presence or its traces.

Result and discussion

NGS analysis identified pathogenic variants predominantly in ATM, TP53, PTEN, ARID1B, and KMT2A genes across all groups, suggesting shared mechanisms of DNA repair dysfunction and cell cycle regulation. No significant association was found between EBV presence or traces and the frequency of pathogenic variants when they were analyzed as a whole ($p > 0.05$, Fisher's test). However, EBV+ DLBCL exhibited unique alterations in BTK, HAX1, PAFAH1B1, and NAGLU genes, implicated in immune regulation, apoptosis, and mitochondrial dynamics, while 75% of EBV+ DLBCL displayed variations in C11orf65 gene. Notably, variants at the NOTCH signaling pathway were exclusively enriched in EBV+ DLBCL.

Conclusion

Our findings reveal no significant impact of EBV or its viral traces on the frequency of pathogenic genetic variants as a whole in DLBCL. This aligns with previous studies suggesting EBV contributes to lymphomagenesis through epigenetic or immunomodulatory mechanisms rather than specific genetic alterations. The high prevalence of mutations in ATM, TP53, and PTEN across all groups underscores the importance of genomic instability in DLBCL pathogenesis. In EBV+ DLBCL exclusive genetic alterations and NOTCH pathway enrichment indicate virus-specific mechanisms that may promote tumorigenesis. Further studies, are needed to validate these findings.

EACR25-0503

Late effect of radiotherapy: impairment of DNA double-strand break repair mechanisms in skin and lung fibroblast of previously irradiated sheep

L. Bodgi¹, C. Feghaly¹, H. B. Hadir², R. Challita³, J. Al Choboq¹, J. Bou-Gharios¹, J. Azzi⁴, A. Jurjus³, W. Abou-Kheir³, B. Youssef¹

¹*American University of Beirut Medical Center, Radiation Oncology, Beirut, Lebanon*

²*Radiation Oncology, Beirut, Lebanon**

³*American University of Beirut, Anatomy, Cell Biology and Physiological Sciences, Beirut, Lebanon*

⁴*American American University of Beirut Medical Center of Beirut, Radiation Oncology, Beirut, Lebanon*

Introduction

Children who undergo radiotherapy (RT) for cancer at an early age face a significant risk of developing long-term complications. One of the most concerning late effects is the increased likelihood of developing radiation-induced cancer. This occurs because radiation exposure to normal tissues can lead to genetic mutations affecting DNA damage repair pathways, proto-oncogenes, and tumor suppressor genes. To simulate pediatric craniospinal irradiation, a sheep model was utilized, where five sheep received radiation treatment to the thecal sac, while four served as controls. However, surrounding tissues were also exposed. The goal of this study is to investigate how prior RT influences DNA double-strand break (DSB) repair kinetics. Three years post-treatment, lung and skin biopsies from areas exposed to both low and high doses of X-rays were collected and analyzed to compare the effects of radiation in previously treated versus untreated sheep.

Material and method

This study included a total of nine sheep, with five receiving radiation treatment and four serving as controls. The treated sheep underwent eight sessions of radiation therapy, receiving a total dose of 28 Gy targeted at the spinal thecal sac. The treatment areas were categorized into high-dose (HD, >17 Gy) and low-dose (LD, <2 Gy) regions. Three years post-treatment, lung and skin biopsies were collected from HD, LD regions, and untreated control sheep. Primary lung and skin fibroblast cells were isolated and cultured, yielding a total of 23 cell lines: nine control (five lung and four skin), six LD (Four lung and two skin), and eight HD (four lung and four skin) primary fibroblast cell lines. Cultured cells were irradiated with 2 Gy, and DSB repair kinetics were evaluated using anti- γ H2AX and anti-pATM immunofluorescence assays. The clonogenic and micronuclei assays were also performed.

Result and discussion

In lung cells, under baseline conditions, both LD ($p < 0.05$) and HD ($p < 0.01$) cells exhibited a significantly higher number of spontaneous γ H2AX foci compared to the control group. Ten minutes after a 2 Gy re-irradiation, only LD lung cells showed a significantly lower number of foci than the control. No significant differences were observed at these time point for skin cells. Interestingly, 24 hours post-irradiation, the number of residual γ H2AX foci remained higher in cells derived from previously irradiated sheep compared to those from non-irradiated sheep, for both lung and skin fibroblasts ($p < 0.01$). Finally, LD and HD cells displayed a significantly lower number of pATM foci 10 minutes after 2 Gy irradiation ($p < 0.01$) compared to the control cell line, in both skin and lung fibroblasts.

Conclusion

Our findings indicate that, in the long term, prior irradiation of normal tissues can lead to (1) increased genomic instability, (2) reduced efficiency of DNA double-strand break (DSB) signaling, and (3) impaired DSB repair in primary ovine lung and skin fibroblast cells.

EACR25-0802

Fibronectin leucine-rich transmembrane protein 3 is a potential driver of intrahepatic cholangiocarcinoma

L. Prates¹, F. Manzano-Nuñez¹, A. Lapitz², S. Cordi¹, J. Bandales², C. Sempoux³, F. Lemaigne¹

¹Université catholique de Louvain, De Duve Institute, Brussels, Belgium

²University of the Basque Country, Biogipuzkoa Health Research Institute, San Sebastian, Spain

³University of Lausanne, Institute of Pathology, Lausanne, Switzerland

Introduction

Extensive research has identified oncogenic mutations, such as IDH mutations and FGFR fusions, as drivers of cholangiocarcinoma (CCA). However, these mutations are found in a limited subset of intrahepatic CCA (iCCA) cases, and resistance may develop. Thus, a comprehensive understanding of iCCA pathogenesis is crucial for developing effective therapies by elucidating mechanisms that drive tumor initiation and progression. Our study aims to identify molecular drivers of tumor progression using *in vitro* and *in vivo* models.

Material and method

We generated intrahepatic cholangiocyte organoids (ICOs) from mouse cholangiocytes carrying the KrasG12D mutation. These organoids were studied *in vitro* and *in vivo* after subcutaneous injection into immunodeficient mice. Human EGI-1 and Mz-Cha-1 CCA lines were used for molecular studies. Immunolabeling of human pathological samples was performed to investigate gene expression in iCCA. Mining of human transcriptome data further determined the expression of genes in human CCA.

Result and discussion

KrasG12D ICOs did not show morphological changes *in vitro* but induced subcutaneous tumors *in vivo* in immunodeficient mice, whereas wild-type ICOs did not. The resulting tumors displayed key features of human biliary lesions evolving into CCA, with desmoplastic stroma and cystic structures lined by cholangiocyte marker-expressing epithelial cells. RNA sequencing of KrasG12D and wild-type organoids identified candidate genes involved in tumorigenesis. Among these, fibronectin leucine-rich transmembrane protein 3 (FLRT3) emerged as a possible driver of iCCA progression. FLRT3 protein and mRNA expression was detected in a subset of human iCCA tumor cells. Functional inhibition of FLRT3 using shRNA significantly reduced organoid-derived tumor growth, as well as *in vitro* migration and invasion of human EGI-1 and MZ-Cha-1 cells.

Conclusion

In conclusion, we developed a versatile ICO-based model that closely mimics human iCCA and enables the identification of tumorigenic drivers. Our findings

suggest that FLRT3 stimulates iCCA progression. Further studies will clarify FLRT3-mediated tumor progression *in vivo* *in situ*, and explore how FLRT3 drives the progression of CCA.

EACR25-1000

The inter-relationship between arsenic exposure and oxidative stress biomarkers on the risk of cancer occurrence - A population-based cohort study

P. Liao¹, K. Hsu²

¹Chang Gung University, Master Degree Program in Health and Long-term Care Industry, Taoyuan, Taiwan

²Chang Gung University, Department of Health Care Management, Taoyuan, Taiwan

Introduction

Arsenic exposure has been known as a risk factor for various cancers. However, the inter-relationship between arsenic exposure and cellular oxidative stress on cancer occurrence is still imperfectly understood. This study investigated the association between urinary arsenic metabolites and all cancer occurrence while examining the effects of oxidative stress biomarkers with a population-based cohort.

Material and method

This study conducted a 9-year follow-up on 6,402 residents aged over 40 years from the southwestern coast of Taiwan, and identified 305 all-cancer cases. The urinary arsenic metabolites were determined by inductively coupled plasma mass spectrometry, and oxidative stress biomarkers were assessed through urinary 8-hydroxy-2-deoxyguanosine (8-OHdG) and urinary malondialdehyde (MDA). Cox proportional hazards model was performed to calculate the multi-variate-adjusted hazard ratio (HR) of cancer occurrence.

Result and discussion

The analyses revealed a significant dose-response relationship between urinary arsenic and cancer occurrence. Participant's urinary arsenic in the highest tertile was at 1.45 folds (95% CI = 1.05-2.02) of developing cancers as opposed to ones in the lowest tertile. The results showed that the interactions of urinary arsenic and 8-OHdG or MDA were statistically significant. Participants with relatively higher urinary arsenic and higher urinary 8-OHdG were at the highest risk of developing cancers (HR = 1.44; 95% CI = 1.03-2.00) among four combination groups. Participants with relatively higher urinary arsenic and higher urinary 8-OHdG but lower MDA were at the highest risk of developing cancers (HR = 2.43; 95% CI = 1.37-4.31) than those with relatively lower levels of the three biomarkers.

Conclusion

Oxidative stress is considered an important pathway for cancer occurrence. However, the biomarkers of DNA damage and lipid damage moderate differently when considering the association between arsenic exposure and cancer occurrence. DNA damages and arsenic exposure play a synergistic role in the long-term arsenic carcinogenesis.

EACR25-1013**Secreted clusterin promotes the migration and invasion of triple-negative breast cancer cells***A. Ciringione¹, M. Marozzi², S. Belletti¹, F. Rizzi¹*¹*University of Parma, Department of Medicine and Surgery, Parma, Italy*²*University of Parma, Parma, Italy***Introduction**

Treatment of metastatic breast cancer (BC) remains a major problem. Thus, understanding the molecular processes that favor the acquisition of a motile phenotype, may help to find new “druggable” targets to block BC cells escape. Clusterin (CLU) is a secreted glycoprotein up regulated in BC that plays a role in cell adhesion, lipid metabolism, and membrane transporter recycling. We investigated the effects of CLU silencing on the migratory and invasive capacity of BC cells focusing our attention on the mechanisms that support extracellular matrix (ECM) remodeling and cytoskeleton fibers rearrangements.

Material and method

We abrogated CLU expression (siRNA transfection) in two BC cell lines at different stages of malignancy, MCF-7 and MDA-MB-231. We used transwell migration and invasion assays to study cell motility and molecular biology techniques, i.e., RT-PCR, Western Blot, immunocytochemistry, and Rho/GTP pull-down assay, to explore the mechanisms underlying the observed phenotypes.

Result and discussion

In the aggressive triple-negative breast cancer (TNBC) cell line, MDA-MB-231, CLU knock-down reduced both migration and invasion. This phenotype was accompanied by a dramatic change in the cell shape and an impressive reduction of F-actin-enriched (filopodia-like) cell membrane protrusions. Consistently, we observed a decreased activation of AKT and RhoA GTPase, both involved in the regulation of cytoskeletal dynamics and cell motility. Finally, we found a reduction of the activated form of NF- κ B and a coherent transcriptional down-regulation of MMP9. Conversely, CLU silencing had none of these effects on luminal-like MCF-7 cells. We also observed that CD44 and LRP1 receptors, which are involved in lamellipodia formation and cell motility, are more expressed in MDA-MB-231 than in MCF-7 cells.

Conclusion

Our work suggests that CLU contributes to the migratory phenotype of TNBC cells affecting the transduction of cell signalings that modulate the dynamics of the cytoskeleton and promote the ECM degradation through a mechanism that may involve the CD44/LRP1 axis. Of note, CLU is a known ligand of LRP1. Although our study needs to be extended *in vivo*, we are confident that it may have relevant translational implications, including the possibility of limiting the disease progression towards a metastatic stage in specific subpopulations of BC patients that may benefit from CLU antisense oligonucleotides (already available) in combination with chemotherapy.

EACR25-1051**Biological relevance of the long non-coding RNA NEAT1 in Squamous Cell Carcinoma progression***S. De Domenico¹, V. La Banca², A. Peschiaroli²,**S. Nicolai², S. D'amico²*¹*Tor Vergata, Experimental Medicine, Rome, Italy*²*CNR, IFT, Rome, Italy***Introduction**

Different Squamous Cell Carcinomas share genetic alterations, including Tp53 mutations and Tp63 modifications. Δ Np63, a truncated Tp63 isoform, is essential for stratified epithelial tissue integrity. We identified the lncRNA NEAT1 as a Δ Np63 target, showing its repression by Δ Np63 via HDAC recruitment is critical for epidermal differentiation. NEAT1 has also been recognized as a p53 target, important for transformation suppression, but its role in SCC pathophysiology is unclear. This study explores NEAT1 dysregulation and the influence of p53 mutations and Δ Np63 amplification on the NEAT1-dependent response to genotoxic stress in SCC and normal cell lines.

Material and method

We analyzed how Δ Np63 and p53 regulate NEAT1 expression under genotoxic stresses. We treated p53-positive and p53-negative/mutant SCC and normal cell lines with UVB radiation and Doxorubicin to induce DNA damage. NEAT1 isoform expression, p53 target gene activity, and apoptosis were analyzed using RT-PCR and Western blot. We repeated the same experiments while silencing Δ Np63 and p53 using siRNA. We assessed DNA damage after silencing NEAT1 before UVB exposure. Lastly, we evaluated if NEAT1 targeting could enhance HDACI cytotoxic effects, such as Givinostat, in human and murine SCC cell lines.

Result and discussion

NEAT1 was upregulated rapidly after genotoxic stresses, independently of apoptosis. Its induction correlated with cell cycle arrest genes, indicating its role in DNA repair and cell survival. Notably, NEAT1 upregulation was p53-dependent. Interestingly, silencing Δ Np63 further enhanced NEAT1 induction after genotoxic stress, indicating that p53 and Δ Np63 have opposing roles (p53 promotes, while Δ Np63 represses NEAT1 expression). This pattern was consistent in both normal and SCC cells. NEAT1 expression was downregulated in primary basal cell carcinoma (BCC), cutaneous SCC, and TCGA datasets, supporting its tumor-suppressive role.

Moreover, NEAT1 depletion increased DNA damage, indicating its importance in genomic stability. HDACI (Givinostat) treatment increased NEAT1 expression in a p53-independent manner. Our findings highlight a critical regulatory axis involving p53, Δ Np63, and NEAT1 in SCCs. p53 promotes NEAT1 expression in response to DNA damage, while Δ Np63 represses it. Disruption of this balance, with frequent TP53 mutations and Δ Np63 overexpression, may impair genomic stability, contributing to SCC tumorigenesis. NEAT1 functions as a tumor suppressor in SCCs by facilitating DNA repair. HDAC inhibition upregulates NEAT1 in a p53-independent manner, providing a potential therapeutic approach for SCCs.

Conclusion

This study establishes NEAT1 as a regulator of the DNA damage response in normal cell and in SCCs. Its down-regulation in SCCs may lead to genomic instability, thereby promoting tumorigenesis. Importantly, targeting NEAT1 enhances the cytotoxic effects of HDACIs, offering a promising therapeutic strategy.

EACR25-1075

The landscape of somatic mutations in Hepatitis B virus-infected livers and its role in the origins of liver carcinogenesis

P. Otero¹, T. Leonel², N. Espasandin¹, S. Pérez-del-Pulgar², J. Tubio¹

¹*Mobile Genomes, Centre for Research in Molecular Medicine and Chronic Diseases, CiMUS, Universidad de Santiago de Compostela, Santiago de Compostela, Spain*

²*Viral Hepatitis Lab, IDIBAPS, Barcelona, Spain*

Introduction

More than 3.5% of the global population lives with chronic hepatitis B virus (HBV) infection. Over time, 15 to 40% of these individuals will develop cirrhosis, hepatocellular carcinoma (HCC), or liver failure, leading to ~800,000 deaths annually. In recent years, numerous initiatives have focused on studying cancer genomes and timing analyses have shown that many cancer-driving mutations arise years before diagnosis. As a result, research has increasingly shifted toward investigating genomic alterations in normal tissues. In the liver, the mutations that drive the early clonal expansions are still unknown. Additionally, although HBV insertions have been detected in HCC, the precise role in tumour initiation and progression is not yet understood. Here, we carried out a comprehensive analysis of somatic mutation in HBV-infected cirrhotic liver with unprecedented resolution, using whole-genome sequencing, cyto-histological techniques, and cytogenetics.

Material and method

We performed low-input DNA sequencing from >100 laser capture microdissections from different HBV-infected livers. We then performed computation analyses to call different types of somatic variation, to identify different clones, putative drivers of clonal expansion, identify mutational signatures, and reconstruct clonal evolution in regenerative nodules.

Result and discussion

We find that while microdissections from different nodules share very few somatic variants, distinct clones can be detected within individual nodules, indicating that clonal expansions are restricted to the nodular area. Notably, some clones carry variants affecting genes involved in cell proliferation and apoptosis. HBV-infected livers exhibit a patchy pattern, with nodules that either strongly express the HBV surface antigen (HBsAg) or appear negative. Interestingly, we identified cases where antigen-positive nodules accumulate distinct mutational signatures compared to antigen-negative nodules. This suggests that, the mutational processes active in HBV-positive nodules differ from those in HBV-negative nodules. Furthermore, while human hepatocytes are typically tetraploid, we observe that

positive nodules can be either tetraploid or octaploid, suggesting that viral infection may drive this transformation. The analysis of DNA insertions identified clonal HBV integrations and rearrangements, confirming that it represents an early event in cancer development. Finally, we found a positive association between clonal integrations and higher HBsAg levels, suggesting HBsAg expression from integrated HBV copies.

Conclusion

Clonal expansions in HBV-infected cirrhotic livers are restricted to regenerative nodules and often involve mutations in key oncogenic pathways. Infection promotes specific signatures in HBsAg-positive versus HBsAg-negative nodules, illuminating new biological insights into the mutational mechanisms of early liver carcinogenesis.

PD-L1 Expression by Macrophages and Myeloid-Derived Suppressor Cells in the Tumor Microenvironment of Epstein-Barr Virus-Associated Pediatric Hodgkin Lymphoma

K. Lindl¹, A. Moyano¹, S. Colli², M. Preciado³, E. De Matteo¹, P. Chabay¹

¹*Multidisciplinary Institute for Investigation in Pediatric Pathologies (IMIPP), CONICET-GCBA, Buenos Aires, Argentina*

²*Ricardo Gutierrez Children Hospital, Pathology Department, Buenos Aires, Argentina*

³*Multidisciplinary Institute for Investigation in Pediatric Pathologies (IMIPP), CONICET-GCBA, Argentina*

Introduction

In Argentina, EBV is associated with more than 70% of Hodgkin lymphoma (HL) cases in children under 10 years. PD-L1, a ligand expressed by HRS and micro-environment cells, plays a key role in promoting protumoral conditions immune escape. Our group described PD-L1 overexpression in the microenvironment of EBV+ HL in children, but the specific cell types involved remain unclear. PD-L1 expression by macrophages and Myeloid-derived suppressor cells (MDSCs) were described in adult HL at the tumor microenvironment, to contribute to immunosuppression. Our aim was to investigate whether MDSCs and macrophages express PD-L1 in pediatric EBV+ HL and compare its expression in EBV-infected tonsils.

Material and method

This study included 22 cHL and 36 tonsil formalin-fixed paraffin-embedded (FFPE) biopsies from pediatric patients. EBER in situ hybridization (ISH) was performed to assess EBV presence. Expression of CD33 (MDSC marker), CD68, and CD163 (macrophage markers), as well as PD-L1 expression, were analyzed by immunohistochemistry (IHC), and results were expressed as positive cells/mm².

Result and discussion

Thirteen cHL patients were EBV- and nine were EBV+. PD-L1+ cells were significantly higher in EBV+ patients ($p=0.0009$). No significant differences were found for CD33+, CD68+, or CD163+ cells, nor for CD33+/PD-

L1+, CD68+/PD-L1+, or CD163+/PD-L1+ between EBV- and EBV+ patients ($p > 0.05$). For tonsil analysis, 11 primary infected (PI), 10 carriers (C), 10 reactivated (R), and 4 non-infected (NI) patients were compared. CD33+/PD-L1+ expression was significantly higher in C compared to PI, R, and NI ($p = 0.0005$, $p = 0.0164$, $p = 0.0039$). No significant differences were found for CD68+ or CD68+/PD-L1+ between groups ($p > 0.05$). Similarly, no significant differences were observed for CD163+ or CD163+/PD-L1+ ($p > 0.05$, Mann Whitney test). Significant correlations were found between CD68+/PD-L1+ and PD-L1+ ($p < 0.0001$, $r = 0.5870$) and PD-L1+/CD163+ and PD-L1+ ($p < 0.0001$, $r = 0.9292$) in EBV+ tonsils. A significant difference in PD-L1 and PD-L1/CD163 expression was observed between primary infected and reactivated groups ($p = 0.0274$, $p = 0.0131$).

Conclusion

This study provides evidence that MDSCs and CD68+ and CD163+ macrophages may not be directly related to the overexpression of PD-L1 that characterizes the tumor microenvironment in HL. Remarkably, in children with persistent EBV infection, PD-L1 expression may be upregulated in MDSCs, suggesting a mechanism for immune response regulation.

EACR25-1547

Notch signaling during G2 Damage Checkpoint: a multifaced node to overcome drug resistance in T-cell acute lymphoblastic leukemia (T-ALL)

A. Simeone¹, A. Zonfrilli¹, G. Ferrera¹, S. Cialfi¹, C. Talora¹

¹Dept. of Molecular Medicine, Rome, Italy

Introduction

Drug resistance remains an important challenge in cancer treatment, and understanding the molecular mechanisms behind it is crucial. Among the many players, Notch signaling has emerged as a key regulator, not only in cancer progression but also in the development of resistance to conventional therapies. Its multifaceted role in both promoting and sustaining tumorigenesis makes it a critical target for oncologic intervention.

Material and method

In our previous work, we uncovered a crucial interaction between Notch1 and PLK1 kinase during the G2/M transition in squamous cell carcinoma. This interaction is vital for the DNA damage response, with PLK1 inhibition preserving Notch1 expression. To extend these findings, we explored T-cell acute lymphoblastic leukemia (T-ALL), an aggressive malignancy where Notch1 serves an oncogenic role. Using human leukemic T-cell lymphoblasts as an in vitro model, we investigated the dynamic regulation of Notch1 signaling in response to DNA damage.

Result and discussion

Our results suggest a complex network in cancer cells, where Notch1 signaling is both upregulated and downregulated during the DNA damage-induced G2 checkpoint. Notably, in T-ALL cells, we observed that Notch1 expression is sustained, allowing some cells to survive checkpoint-mediated arrest and evade apoptosis.

Remarkably, we found that while there is variability in the intrinsic ability of T-ALL cells to exhibit resistance to Notch1 inhibition under basal conditions, exposure to DNA damage triggers a fascinating adaptation at the G2 checkpoint, where Notch1 plays a crucial role in promoting resistance to chemotherapeutic agents, regardless of the cells' initial sensitivity to Notch1 inhibition.

Conclusion

These findings highlight a critical temporal window during which Notch1 signaling plays a pivotal role in the acquisition of therapy resistance, offering new opportunities to identify strategies to overcome Notch1 inhibitor resistance.

Alterations in laminin alpha2-chain impact melanoma progression

V. Ribeiro¹, A. Lopes², A. Conceição¹, I. Fonseca¹, J. Ferreira¹, É. Mocho¹, S. Martins¹, S. Ramos³, R. Zilhão¹, A. Carlos¹

¹CE3C & CHANGE – Faculdade de Ciências da Universidade de Lisboa, Lisbon, Portugal, Lisbon, Portugal

²CE3C & CHANGE – Faculdade de Ciências da Universidade de Lisboa, Lisbon, Portugal, Unidade Local de Saúde de Lisboa Ocidental (ULSLO), Lisbon, Portugal, Lisbon, Portugal

³Unidade Local de Saúde de Lisboa Ocidental (ULSLO), Lisbon, Portugal, Lisbon, Portugal

Introduction

Extracellular matrix (ECM) remodeling has been described to directly impact the modulation of cancer hallmarks, particularly through the regulation of epithelial-mesenchymal transition (EMT), promoting metastatic spread. Laminins are ECM components, more specifically are part of the basement membrane, a specialized type of ECM that links cell membrane to ECM and promotes cell-ECM communication. Previous studies have shown that laminin remodeling alters cancer cell proliferation and migration, facilitating metastasis. However, whether changes in gene expression or mutations in laminins are per se key steps during cancer progression, remains largely unexplored.

Material and method

This study involved a comprehensive approach, including in silico analysis, the examination of patient samples, and in vitro experiments, to better understand the role of LAMA2 in melanoma progression.

Result and discussion

Considering that the ECM is an important component of the skin, we analyzed the frequency of genomic alterations in the five laminin alpha-chains(LAMA1 to 5) in melanoma samples, using cBioportal platform. Results showed that LAMA2 gene, encoding laminin alpha2-chain, crucial for the connection of the ECM to cell cytoskeleton, has the highest percentage of alterations in cutaneous melanoma. Also, within all types of cancer reported in cBioportal, cutaneous melanoma is the one where LAMA2 is most frequently altered. Moreover, our immunohistochemistry analysis of patient samples showed that laminin alpha2-chain levels were significantly lower in melanoma when compared to

melanocytic nevus. Similar results were obtained for collagen type IV, another basement membrane component, collectively suggesting a disruption of this structure in melanoma. To understand the impact of LAMA2-deficiency at cell level, we established LAMA2-knockout (KO) melanoma cells and explored proliferation, cell death, migration and DNA damage. Results showed that LAMA2-KO cells have reduced cell proliferation and migration and increased cell death and DNA damage. To better mimic the *in vivo* environment, melanoma WT and LAMA2-KO spheroids were also established to explore alterations in ECM proteins, EMT markers, proliferation and DNA damage. The absence of LAMA2 also prevented the detection of collagen IV, pointing towards the lack of basement membrane in these spheroids. To gain further insights into how laminin alpha2-chain impacts tumor progression, LAMA2 overexpressing cell lines were established and cellular processes were validated. Results show a significant recovery in DNA damage compared to LAMA2-KO cell lines, further confirming the importance of maintaining laminin alpha2-chain to prevent DNA damage.

Conclusion

This study will contribute to understand the role of the ECM in melanoma, particularly how LAMA2-deficiency may affect ECM structure resulting in cellular changes that may contribute for tumorigenesis.

Weaponizing the CRISPR/Cas9 technology

S. Tavella¹, F. Iannelli², V. Matti², A. di Lillo², F. d'Adda di Fagagna³

¹*IGM-CNR / IFOM, Milan, Italy*

²*IFOM, Milan, Italy*

³*IFOM / IGM-CNR, Milan, Italy*

Introduction

Most of current therapies against cancer can cause non-specific toxicity on healthy tissues because of their impact on important cellular mechanisms shared, to different extents, between cancer and healthy cells. For this reason, there is an urgent need for more specific and more effective therapies. To address this challenge, we developed a potentially therapeutic strategy to induce sequence-specific DNA double-strand breaks (DSBs) with the CRISPR/Cas9 technology. This approach can selectively target genomic sequences present only in cells to be eliminated. Possible applications include cancer cells harbouring genomic mutations or chromosomal rearrangements. Importantly, the effectiveness of this approach is independent of whether the aberrant genome sequences are expressed or not.

Material and method

As a proof of principle, an isogenic pair of cell lines with a healthy and a diseased counterpart was generated in two distinct cell systems. HeLa and RKO cells were infected with a lentiviral vector containing a promoterless Green Fluorescent Protein (GFP) construct to simulate genomic alterations present in cancer cells. The Cas9 endonuclease with the RNA guide targeting the integrated GFP sequences was retrovirally transduced in these cells. As a negative control, a Cas9 loaded with a

scramble guide that does not recognize any sequence in the human genome was used.

Result and discussion

DSBs generated by Cas9 within the GFP sequence reduce cell viability and increase mortality. This is associated with the activation of the DNA damage response (DDR), increased cell size, multinucleation, cGAS-positive micronuclei accumulation and the activation of an inflammatory response. However, since cells can survive to DNA damage insults thanks to DNA repair mechanisms, we investigated the combined effects of sequence-specific DSBs generation and DNA repair inhibition on cells viability. Impairment of the non-homologous end-joining (NHEJ) repair pathway – achieved by pharmacologically inhibiting the DNA-dependent protein kinase (DNA-PK) – further kill target cells when combined with Cas9-induced DSBs.

Conclusion

These results suggest the possibility to “weaponize” the CRISPR/Cas9 system for the elimination of cells with an aberrant genome.

²*Institut Català d’Oncologia (ICO), Badalona, Spain*

³*Hospital Germans Trias i Pujol, Badalona, Spain*

⁴*Institut Germans Trias i Pujol (IGTP), Badalona, Spain*

Introduction

Glioblastoma (GB) is the most undifferentiated and aggressive central nervous system tumor, and its pathogenic mechanisms remain poorly understood. In our previous study, YWHAG gene overexpression was postulated as biomarker of bad prognosis using human GB tissue samples. YWHAG encodes for the γ member of the 14-3-3 family of intracellular dimeric phosphoserine-binding proteins that regulate signal transduction, cell cycle, metabolic cascades and antagonize apoptotic cell death in response to a triggering stimuli. This work aims to elucidate the mechanisms through YWHAG impacts in GB prognosis, to assess its potentiality as a therapeutic target.

Material and method

YWHAG gene expression was silenced by siRNA in two IDH-wt GB cell lines, U251MG and LN229. YWHAG-silencing level was determined by western blot (WB) and RTqPCR. Cell proliferation and two-dimensional cell migration was measured by trypan blue exclusion and wound-healing assays respectively. Based on these findings, YWHAG expression was further silenced by a doxycycline-induced shRNA with an RFP reporter in U251MG. Transfection efficiency was evaluated by fluorescence using a LEICA DMI6000B microscope and LAS X software. YWHAG-silencing level was

determined by RTqPCR. All experiments were performed at different time-points. Results were obtained by comparing non-target cells versus siRNA or shRNA - transfected cells in at least three independent experiments. Data was analyzed using GraphPad Prism 8 software.

Result and discussion

In U251MG cells, the highest siRNA-YWHAG silencing rates were obtained at 72 h by RTqPCR (93.8%) and 96 h by WB (63.7%), and at 96 h by RTqPCR (84.3%) and WB (37%) in LN229. A statistically significant reduction of proliferation rate of U251MG siRNA-YWHAG was observed at 96 h after transfection (p -value = 0.0079). A trend to a reduction in cell migration was also observed at 96 h after transfection. Regarding LN229, despite the reduction of cell migration 120 h after transfection (p -value = 0.0001), no effect in proliferation was observed. Finally, U251MG cell line was selected for the establishment of the stable and inducible sh-YWHAG-silencing model. Suitable transfection rate by fluorescence signal was observed at 48 h after doxycycline treatment, with a promising 78% of gene silencing at RNA level in the sh-YWHAG cells.

Conclusion

YWHAG gene silencing causes a reduction in cell proliferation and migration in GB in-vitro models. To be deeply explored, a stable YWHAG inducible knocking-down model has been generated to confirm these results in preclinical advanced models, hence elucidating its potential role as biomarker and putative therapeutic target in GB.

Partial inactivation of VPS34 combined with oncogenic KRAS accelerates pancreatic cancer initiation and mimics early metastasis dissemination

C. Guyon¹, H. Shalhoub¹, F. Ramos Delgado¹, E. Baurens-Tran¹, N. Therville¹, E. Boutet-Robinet², B. Thibault¹, J. Guillermet-Guibert¹

¹*CRCT, Toulouse, France*

²*Toxalim, Toulouse, France*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease with a poor prognosis. To improve the diagnosis and management of this disease, we need to understand the effectors responsible for the development of these tumours. The importance of the KRAS mutation (95% of cases), in cancer initiation is well known, but not sufficient to explain cancer development. Autophagy is a mechanism for degrading and recycling cellular components via lysosomes. Autophagy machinery proteins participate in pancreatic homeostasis and cancer progression. However, the role of VPS34, a PI3K that promotes autophagic flux, is unknown. We therefore investigated the role of VPS34 in pancreatic cancer development.

Material and method

To mimic low VPS34 protein activity found in patients with poorer prognosis, we developed a mouse model combining KRAS mutation with heterozygous inactivation of VPS34 (KCV34), using Cre recombinase

under the control of the Pdx1 promoter. KCV34 mice histological phenotype was quantified and compared to that of KRAS mutant mice (KC). We compared a panel of circulating markers present in the mice's plasma using Olink® technology. Cell lines obtained from a mouse in each of the KC and KCV34 groups were used to explain these histological analyses by studying their genome expression, autophagy flux and invasive capacities.

Result and discussion

We have observed a decrease in VPS34 levels in human precancerous lesion cells. An partial inactivation of VPS34 in murine model KCV34 showed a significantly decreased prognosis compared to KC mice. Histological analysis of HE staining revealed earlier and more aggressive lesions than in the KC cohort. We observed KCV34 tumours in mice of 4 to 6 months of age, some associated with metastases, whereas KC mice showed only few high-grade precancerous lesions at these ages. Analyses on derived cell lines showed a reduced autophagy flux in KCV34 compared with KC cells. However, migratory and invasive capacities did not appear to be increased. Acceleration of the tumorigenesis could be partly the results of a change in inflammatory context observed with VPS34 partial inactivation. Plasma of KCV34 mice showed decrease in IL23r level implicated in Th17 lymphocytes recruitment. Further analysis to understand the cellular mechanisms underlying this phenotype is required to fully understand the involvement of VPS34 in pancreatic carcinogenesis.

Conclusion

VPS34 partial inactivation induce a reduced autophagy flux that leads to an acceleration of pancreas carcinogenesis. This knowledge will help to decipher novel means of early diagnostic and treatment.

EACR25-1790

Development of an ex vivo model to determine early transcriptional changes in breast cancer

H. Barnes¹, A. Gilmore¹, S. Howell¹, A. Ucar², K. Brennan¹

¹*The University of Manchester, Manchester, United Kingdom*

²*Brunel University London, London, United Kingdom*

Introduction

The early transcriptional events pre-disposing the mammary gland to transformation are poorly characterised. Mammographic density is an established risk factor for breast cancer and is associated with increased stiffness of the periductal stroma. However, the precise molecular mechanisms remain unknown. A major reason for this is the deficiency of physiologically relevant models of healthy tissue to study early transformation events.

Material and method

Intact mammary ducts were isolated from mice at 10-12 weeks of age and seeded ex vivo into 3D reconstituted basement membrane gels at different stiffnesses. Different methods were tested to induce oncogene activation and RNA sequencing was used to investigate mechanosensitive changes in signalling pathways downstream of oncogenic insults.

Result and discussion

Mammary ducts with luminal-basal polarity and an intact basement membrane can be isolated and co-cultured ex vivo with endothelial cell populations in a 3D mechanically tuneable system. Oncogenic Her2 over-expression can be induced in ducts using a doxycycline inducible promoter and protein and RNA can be extracted from these structures to examine immediate downstream signalling changes.

Conclusion

This model provides a novel approach to studying early events pre-disposing healthy tissue to tumourigenesis. By identifying transcriptional changes driving predisposition of the mammary duct to breast cancer, we can better characterise the events which are crucial for improvement of early detection and preventative therapies.

²CIBERONC, Madrid, Spain

³UPF, MELIS, Barcelona, Spain

⁴International Agency for Research on Cancer (IARC/WHO), Genomic Epidemiology Branch, Lyon, France

⁵UPF and ICREA, Barcelona, Spain

Introduction

Cancer appears when mutated cells with a proliferative advantage expand, invading the surrounding tissue and forming a tumor. However, several studies have shown that potential cancer driver mutations are present in healthy tissues, implying that these mutations alone are not sufficient for tumor formation. Recent evidence also shows that many carcinogens are not mutagenic. These observations lead to a reconsideration of cancer as a multistage process, in which pre-existing mutated clones acquire a growth advantage upon the exposure to a promoter. Understanding the differences in the clonal architecture of normal tissues from donors with different lifelong exposures to cancer risk factors is key to understanding their potential role as tumor promoters and their relation to cancer risk. For clear cell renal cell carcinoma (ccRCC), with widely varying incidence worldwide, sex, hypertension and obesity are amongst the highest risk factors and none of them is known to be mutagenic.

Material and method

Duplex sequencing allows for the detection of somatic mutations present in very few cells in a tissue. We used this technology to sequence DNA from normal kidneys of 40 donors who suffered ccRCC, to a depth of 25,000x targeting 9 ccRCC driver genes. Furthermore, we sequenced DNA samples from tissue obtained via laser capture microdissection of normal kidney tubules – as the origin of the disease resides in the proximal tubules – from 90 different donors who suffered from ccRCC, targeting 192 genes to a depth of 2,000x. Samples were

obtained from the Mutographs biorepository, with rich clinical data for all donors. Cases from 8 different countries with varying incidence were selected considering relevant risk factors and using age and sex to balance groups. We developed two end-to-end pipelines that facilitated the mutation calling from duplex sequencing data, and then computed metrics to characterize the clonal structure of the normal kidney epithelial tissue.

Result and discussion

We detected a consistent increased presence of STAG2 mutant cells across all samples. Other genes such as CDKN1A or PTEN are positively selected but only in specific clinical groups, suggesting the presence of interindividual variability that we are currently investigating. The overall size of clones driven by mutations in these and other genes appear smaller than in other tissues. Interestingly, our analysis provides evidence that mutations in some genes may be under negative selection in normal kidney tubules.

Conclusion

This is the first characterization of the clonal landscape in normal kidney tubules. We identify some genes that when mutated provide a selective advantage in this epithelium. The degree of interindividual variability related to differences in certain risk factors could reveal how these factors tune the selection constraints favouring some mutated clones versus others. This would be the first step towards investigating how these affect cancer initiation.

EACR25-1796

A synergistic effect of RNF43 and BRAF mutations on colorectal carcinogenesis

A. Bauche¹, T. Groll², K. Steiger², M. Vieth³, K. Janssen⁴, M. Gerhard¹, R. Mejías-Luque¹

¹Institute for Medical Microbiology, Immunology and Hygiene, Technical University of Munich, TUM School of Medicine and Health, Department Preclinical Medicine, Munich, Germany

³Institute of Pathology, Friedrich-Alexander-University Erlangen-Nuremberg, Klinikum Bayreuth, Pathology, Bayreuth, Germany

⁴Department of Surgery, Technical University of Munich, School of Medicine and Health, Hospital Rechts der Isar, Department of Surgery, Munich, Germany

Introduction

Up to 30 percent of all colorectal cancer (CRC) cases develop from the serrated pathway. In this subtype of tumors, an association between mutations of the tumor suppressor RNF43 and mutations of the oncogene BRAF has been reported. In addition, recent studies uncovered RNF43 mutations as a predictive marker for better treatment response and survival outcomes in patients harboring the BRAF-V600E mutation and receiving anti-EGFR/BRAF therapy. However, the underlying molecular mechanisms explaining how RNF43 mutations may affect development and response of the mCRC BRAF-V600E patients have not yet been understood.

Material and method

We generated a novel mouse model by crossing Rnf43-ΔEx8 to Braf-V637E mice. These mice were monitored over time and sacrificed at specified time points with subsequent macroscopic examination, histopathological evaluation and immunohistochemistry staining.

Result and discussion

Rnf43-ΔEx8/Braf-V637E mice showed a more severe phenotype and increased tumor burden than single mutated Rnf43-ΔEx8 and Braf-V637E mice. The prominent tumorigenic phenotype of the double mutant mice was already macroscopically apparent after six weeks. Pathological evaluation of old mice confirmed a higher proportion of the Rnf43-ΔEx8/Braf-V637E mice presenting pathological alterations characteristic of serrated tumors as well as adenomas compared to the single mutated mice.

Conclusion

These results support a synergistic effect of RNF43 and BRAF mutations on CRC tumorigenesis.

EACR25-2011

VPS34-driven autophagy permits cell plasticity and cancer initiation

F. Ramos-Delgado¹, H. Shalhoub¹, C. Guyon¹, C. Handschin², N. Therville¹, C. Joffre¹, H. De-Oliveira², M. Dufresne¹, B. Thibault¹, J. Guillermet-Guibert¹

¹Cancer Research Centre of Toulouse, Université de Toulouse, Inserm, CNRS, Toulouse, France

²ART BioPrint, INSERM U1026, Bordeaux, France

Introduction

Autophagy, a self-digestive process, is a protective mechanism for tissue homeostasis. However, its importance during cell plasticity is not fully understood. Numerous human diseases are caused by epithelial cell plasticity, and animal models of pancreatic diseases are recognised as study models. Therefore, we developed a unique model in which VPS34, the highly conserved class III PI3K that promotes the autophagic flux, was inactivated in pancreatic exocrine epithelial acinar cells.

Material and method

Models that reconstitute early pancreatic cancer are recognised models to study cell plasticity. We hence generated a murine model of inducible VPS34 inactivation specifically in pancreatic acinar cells (ElasCreER/VPS34flx/flx), combined or not with KRAS mutation (KC/VPS34flx/flx). Phenotypic, histopathologic and single cell RNA sequencing analysis (scRNAseq) were realized. We used lentiviral vectors to overexpress VPS34 and demonstrate causative roles of VPS34.

Results were validated in Human samples.

Result and discussion

VPS34 inactivation (ElasCreER/VPS34flx/flx) induced a heterogeneous increase of lipids and markers of autophagy in the pancreas compared to control mice. The scRNAseq highlighted that VPS34 inhibition triggered the loss of an acinar subpopulation with a high mitochondrial activity for the benefit of 3 subpopulations expressing REG mRNAs, linked with pancreas regeneration. These cells had an altered expression of genes related to canonical autophagy and expressed embryonic markers. Those populations of cells were identified in Human pancreas associated with decreased

autophagy gene expression. VPS34-inactivated cells presented reduced protein levels of REG3A, due to an increased lysosomal activity. An overexpression of VPS34 was responsible for an increase of REG3A level and of AKT phosphorylation. A pharmacological activator of PI3K increased REG3A levels. Reversely, the PI3Kα pharmacological inhibition reduced the level of REG3A. The total inactivation of VPS34 in the pancreas protected from cell plasticity induced by inflammation and/or oncogenic KRAS alterations (KC/VPS34flx/flx).

Conclusion

VPS34 is a key protein for pancreatic cell plasticity, through positive control of autophagy, activation of class I PI3K and reduced selective degradation of REG3A by lysosome, which can be prevented solely with PI3Kα inactivation. Our unexpected findings transform the once unattainable goal of preventing environmentally-induced cancer initiation into a tangible possibility, paving the way for new protective strategies.

⁴Sahlgrenska University Hospital, Clinical chemistry, Gothenburg, Sweden

⁵Sahlgrenska University Hospital, Oncology, Gothenburg, Sweden

Introduction

The treatment with lutetium-177-DOTATATE (¹⁷⁷Lu-DOTATATE) improves survival in patients with metastatic neuroendocrine tumors but is limited by bone marrow toxicity. Individualized dose planning is challenging due to uncertainty in absorbed dose estimates and patient sensitivity to radiation. Here, we investigated the in vitro sensitivity of patient T cells to ¹⁷⁷Lu-DOTATATE as a tool in individualized dose optimization.

Material and method

Blood samples were collected from healthy individuals. Peripheral blood mononuclear cells were prepared and treated with different concentrations of ¹⁷⁷Lu-DOTATATE, corresponding to specific absorbed doses. Cells were also exposed to external beam radiation as a comparison. Cell survival and DNA damage was then analyzed using our in-house developed CDA and γH2AX assays.

Result and discussion

Our data indicate a dose dependent, but non-linear in vitro T cell sensitivity to ¹⁷⁷Lu-DOTATATE at treatment relevant doses. We detected an unexpected

hypersensitivity at very low (0.15–0.25) radiation doses. The ¹⁷⁷Lu-DOTATATE individual cell sensitivity correlated with EBR sensitivity. However, the kinetic of ¹⁷⁷Lu-DOTATATE double-strand break induction in T cells was different to EBR as indicated by γ H2AX staining.

Conclusion

The CDA could measure the in vitro sensitivity of T cells to ¹⁷⁷Lu-DOTATATE and may be a useful tool for evaluating individualized hematological toxicity.

Introduction

Xeroderma Pigmentosum (XP) is a rare autosomal recessive disorder characterized by defects in Nucleotide Excision Repair (NER) or translesion synthesis. XP patients have an extremely high risk of skin cancer (1,000-fold increase) and an elevated incidence of internal tumors, including leukemia and gynecological and brain cancers (34-fold increase). However, the somatic mutagenesis mechanisms underlying this cancer predisposition remain incompletely understood from a genomic perspective.

Material and method

We assembled a unique cohort of skin tumors ($n = 39$) from five XP subgroups with the highest cancer susceptibility (XP-A, XP-C, XP-D, XP-E, XP-V) and internal cancers ($n = 23$) from XP-C patients, including leukemia, ovarian, pancreatic, thyroid tumors, and others. Whole-genome sequencing and detailed bioinformatic analyses were performed to characterize their mutational landscapes in comparison with sporadic cancers. In vitro (XP-C, XP-V) and in vivo (XP-C) mutation accumulation models were developed to investigate mechanisms mutagenesis in XP.

Result and discussion

An ultra-mutated tumor phenotype was observed in skin tumors with impaired GG-NER (XP-E: 350 mut/Mb, XP-C: 162 mut/Mb) and TLS (XP-V: 248 mut/Mb).

Mutational profiles of XP skin tumors with NER defects were dominated by C>T mutations, with each XP group exhibiting distinct trinucleotide context features. XP-A and XP-D tumors, with combined GG-NER and TC-NER defects, showed a uniform mutation distribution across chromatin compartments, indicating that NER modulates genome-wide mutation rate heterogeneity. XP-V skin tumors, characterized by TLS polymerase eta deficiency,

exhibited a unique mutational profile with a high frequency of TG>TT mutations (28%), absent in sporadic skin cancers. These mutations likely arise from error-prone bypass of rare photolesions in TpA and TpG contexts in the absence of polymerase eta. In internal tumors, XP-C cancers displayed a 21-fold increase in mutation rates compared to sporadic, tissue-matched counterparts. The mutational signature of XP-C internal tumors was consistent across different cancer types but markedly distinct from sporadic cancers. Mutations showed strong transcriptional bias, suggesting an association with unidentified endogenous bulky purine DNA lesions. To validate our findings, we sequenced hematopoietic stem cells from XPC knockout (KO) mice and observed a significant age-dependent increase in mutagenesis. The mutational signature in XPC KO mice resembled that of XP-C internal cancers, reinforcing our hypothesis.

Conclusion

The increased cancer susceptibility in XP patients is driven by an excess of unrepaired DNA lesions on the untranscribed strand, defective translesion synthesis, and impaired repair of endogenous oxidative DNA damage. These factors contribute to the elevated mutation burden and distinct mutational landscapes observed in both skin and internal tumors of XP patients.

Investigating the carcinogenic and epigenetic modulating effects of per- and poly-fluoroalkyl substances (PFAS) on breast cancer development

L. Bilton¹, J. Greenman¹, J. Rotchell², M. Wade¹

¹University of Hull, Centre for Biomedicine, Kingston Upon Hull, United Kingdom

²University of Lincoln, College of Health and Science, Lincoln, United Kingdom

Introduction

In the UK, there are 56,000 new cases of breast cancer annually. Genetics and lifestyle choices contribute to BC risk, however, there is a concern surrounding environmental toxins, particularly microplastics and per- and poly-fluoroalkyl substances (PFASs), known as “forever chemicals”. Microplastics and PFASs are heavily used in industrial practices and consumer products and are ubiquitous in the environment. PFASs have been detected in human blood and breast milk, while microplastics have been detected in lung and whole vein tissue, suggesting they may be able to cross the blood barrier into other tissues, such as the breast. Microplastics are known to adsorb and leach PFASs, thereby being a potential route of PFAS exposure in humans.

Material and method

Non-transformed breast epithelial cells (MCF-10A) were exposed to physiologically relevant and supra-physiological concentrations of perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) for both acute (48 hours) and long-term exposure (30 cell passages). Analysis included investigating changes in cell transformation phenotypes such as cell proliferation, mammosphere formation, colony formation and cellular

metabolism. Further analysis through RNA sequencing, histone modifications and chromatin accessibility will be undertaken to further understand the mechanistic consequences of PFAS exposure to breast cells and whether they can induce breast cell transformation.

Result and discussion

Short-term exposure to 1 μM–100 μM PFOA and 0.0001 μM–1 μM PFOS increased non-cancerous breast cell growth, with a potential dose-response relationship effect on cell proliferation. At lower concentrations (10 μM PFOA and 0.0001 μM PFOS) minimal effects on cell number were observed however, when combined, there was a noticeable increase in cell number. In contrast, higher concentrations (100 μM PFOA and 1 μM PFOS) showed the highest increase in cell number individually but also induced cell death when combined. Long-term exposure of physiologically relevant concentrations (10 nM PFOA, 20 nM PFOS and a combination of both) resulted in an increase in cell number, with the highest increase being observed in the combination condition. Short- and long-term exposure to PFAS altered cellular metabolism causing a reduction in oxygen consumption suggesting mitochondrial damage or stress. Long-term exposure disrupted mammosphere formation, further indicating potential transformation of breast epithelial cells.

Conclusion

The results have shown that short- and long-term exposure to PFAS has affected the growth and transformation of breast epithelial cells, with long-term exposure of physiologically relevant concentrations mirroring more realistic human exposure conditions. Further analysis of epigenetic changes will aim to identify mechanisms causing phenotypic changes and therefore, potentially, how PFAS exposure may contribute to breast cancer development.

Obesity-Derived Circulating Extracellular Vesicles Promote Tumor-Stimulatory Functions of Stromal Fibroblasts in Breast Cancer

P. Del Console¹, L. Gelsomino¹, B. Győrffy², F. Accattatis¹, E. Avolio³, D. Bonofiglio¹, S. Andò¹, C. Giordano¹, I. Barone¹, S. Catalano¹

¹*University of Calabria, Department of Pharmacy and Health and Nutritional Sciences, Rende, Italy*

²*Semmelweis University, Department of Bioinformatics, Budapest, Hungary*

³*University of Calabria, Department of Biology, Ecology and Earth Science, Rende, Italy*

Introduction

Obesity significantly impacts incidence, prognosis, and treatment response of breast cancer (BC). It induces systemic and local alterations that influence the tumor microenvironment, with a particular effect on stromal fibroblasts. This complex interaction involves adipokines, growth factors, and extracellular vesicles (EVs), which play a crucial role in cell-to-cell communication. Despite their emerging importance, the involvement of obesity-derived EVs in modulating the tumor-promoting properties of stromal fibroblasts remains unexplored.

Material and method

Circulating EVs were isolated from the serum of normal weight (NW) and overweight/obese (OW/Ob) healthy women and characterized in accordance to MISEV2023 guidelines. Immortalised human mammary control fibroblasts (CFs), their cancer-associated counterparts (exp-CAFs), and human CAFs, isolated from biopsies of primary BC, were used as experimental models for stromal fibroblasts. Human MCF-7 and T47D BC cells were employed as experimental BC models in co-culture experiments.

Result and discussion

Treatment with OW/Ob-EVs induced neoplastic traits of CFs in terms of cell motility, invasiveness, contractility along with an up-regulation of CAF-like markers compared to the NW-EV counterpart. Moreover, OW/Ob-EVs sustain the tumor-promoting functions of exp-CAFs and hCAFs. Co-culture assays revealed that conditioned medium (CM) from OW/Ob-EV-treated CFs, exp-CAFs or hCAFs enhanced anchorage-independent growth and migration of BC cells. Cytokine profiling indicated that OW/Ob-EV treatment triggered Fibroblast Growth Factor 19 (FGF19) secretion by CFs, a finding further validated by ELISA and qRT-PCR. Both pharmacological and genetic (lentiviral) inhibition of FGF19 signaling counteracted the pro-tumorigenic effects of OW/Ob-EVs on fibroblasts. We previously showed that serum-derived EVs exhibited BMI-dependent miRNA profiles, with let-7a being significantly downregulated in OW/Ob patients and inversely correlated with BMI. Notably, miRWalk analysis identified FGF19 as a let-7a target. A BMI-dependent decline in let-7a levels within EVs was also confirmed in our OW/Ob cohort. Treatment of CFs and hCAFs with OW/Ob-EVs led to a significant reduction in let-7a expression compared to NW-EVs, and functional assays confirmed the regulatory role of let-7a on FGF19 translation. Accordingly, let-7a inhibitor transfection – mimicking OW/Ob-EV cargo – enhanced FGF19 and CAF-like gene expression, as well as NF migration, contractility, and tumor/stroma crosstalk. Conversely, let-7a mimic transfection decreased FGF19 secretion, counteracting the aggressive phenotype of hCAFs.

Conclusion

Our findings offer new insights into the impact of obesity-derived EVs on tumor-stroma interactions and BC progression, emphasizing the let-7a/FGF19 axis as a promising therapeutic target for personalized treatment strategies.

Sex differences in selection of somatic mutations in normal human bladder

R. Blanco Martínez-Illescas¹, F. Calvet¹, F. Muñoz¹, M. Tretiakova², E. Latorre-Esteves², J. Fredrickson², M. Andrianova¹, A. Gonzalez-Perez¹, N. Lopez-Bigas¹, R. Risques²

¹*Institute for Research in Biomedicine (IRB Barcelona), Barcelona, Spain*

²*University of Washington, Department of Laboratory Medicine and Pathology, Seattle, United States*

Introduction

Bladder cancer has an unexplained three to four times higher incidence among males than females. Lawson et al. (Science, 2020) showed that, as in other normal tissues, the human bladder undergoes constant clonal evolution by the acquisition and selection of mutations. Although most clonal expansions do not result in cancer development, some of them constitute the first step towards malignant tumors. Factors known to increase the risk of bladder cancer, such as sex, could be playing a role shaping the clonal landscape of the normal bladder and promoting the evolution of protumorigenic clones. Nevertheless, it is not clear whether they also influence the clonal landscape of the normal urothelium. In this study, we characterize the clonal landscape of the normal urothelium of a group of individuals using ultradeep sequencing to unravel potential differences associated with sex and other bladder cancer risk factors.

Material and method

We obtained brushes of cells from ~2cm² of normal urothelium covering the upper part (dome) and lower part (trigone) of the bladder of 42 individuals at autopsy (73 samples in total). We performed bulk DNA error-correcting duplex-sequencing at a depth of ~7000X on a panel of 15 protein coding genes, known to be under positive selection in normal urothelium and/or relevant drivers of bladder cancer, and the TERT promoter. We used several complementary methods to detect signals of positive selection (e.g.: functional impact bias and dN/dS) in the identified mutations and conducted an association study to investigate the link between measures of clonal selection and common bladder cancer risk factors.

Result and discussion

We identified hundreds to thousands of mutations in each sample (~70000 mutations in total), many more than those identified in all sequenced bladder cancers in over a decade. We demonstrate that ultradeep sequencing of normal tissues provides a pathway for natural saturation mutagenesis in genes under positive selection. This allows the calculation of the magnitude and mode of selection at the gene level and at sub-genic structures, such as exons or domains. While the magnitude of positive selection in the urothelium at the dome and the trigone of the same individual is very similar, it is highly heterogeneous across individuals. We found that the magnitude of positive selection in the urothelium increases with age, and that there is significantly stronger positive selection of truncating mutations of RBM10, ARID1A, STAG2 and CDKN1A in males than in females.

Conclusion

The normal human bladder shows pervasive positive selection and differences in its clonal landscape between males and females, and with age. Ultradeep sequencing provides a path towards natural saturation mutagenesis.

Secretome profiling of TNBC cells under an inflammatory condition enhances tumorigenic properties in non-tumoral breast epithelial cells

L. Melguizo-Salom¹, J. Sastre-Serra^{1,2}, M. Torrens-Mas¹, M. Nadal-Serrano¹

¹*I. Grupo Multidisciplinar de Oncología Traslacional, Institut Universitari d'Investigació en Ciències de la Salut (IUNICS), Universitat de les Illes Balears, Institut d'Investigació Sanitària de les Illes Balears (IdISBa), Palma, Spain*

²*2. CIBER Fisiopatología Obesidad y Nutrición (CB06/03), Instituto de Salud Carlos III, Madrid, Spain*

Introduction

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer, characterized by poor prognosis and high recurrence rates. Inflammation is known to play a key role in tumorigenesis. Therefore, this study aimed to identify cytokines in the secretome of breast cancer cells exposed to an inflammatory environment and to evaluate their effects on the malignant transformation of non-tumoral breast epithelial cells.

Material and method

TNBC MDA-MB-231 cells were pretreated for 48 hours with an inflammatory cocktail (17 β -estradiol (10 nM), TNF α (10 ng/ml), and IL-6 (50 ng/ml), called ETI) and subsequently starved in media containing 0.5% FBS for additional 48 hours. Conditioned media (CM) were collected, and secreted proteins were precipitated by cold acetone. The analysis of secretome was performed by LC-MS/MS and validated using a Proteome Profiler Human Cytokine Array (R&D Systems). The effect of the CM on cell proliferation and mammosphere forming efficiency (MFE) of non-malignant MCF10A cells was evaluated. Additionally, the prognostic value of the identified cytokines in TNBC patients was assessed through in silico studies.

Result and discussion

Notably, exposure of MCF10A cells to CM of ETI-treated cells led to increased cell proliferation and enhanced MFE. Proteomic and cytokine array analyses revealed a significant upregulation of IL-6, ICAM1, and CXCL8 in the CM of ETI-exposed cells compared to CTRL CM. Overrepresentation analysis (ORA) indicated that the overexpressed proteins in ETI secretome were strongly associated with Signaling by interleukins and Extracellular matrix organization pathways. In silico analysis further demonstrated that TNBC patients with higher expression of the identified cytokine signature (IL-6, CXCL8, and ICAM1) had a worse prognosis in terms of relapse-free survival.

Conclusion

Our findings suggest that the secretome of TNBC cells under inflammatory conditions enhances tumorigenic properties and cell proliferation in non-tumoral cells. The identified cytokines may serve as key effector molecules in tumor progression, highlighting their potential as prognostic biomarkers and therapeutic targets in TNBC.

Drug Resistance

EACR25-0003

Acquired resistance mechanisms to KRAS G12C inhibitors in lung cancer

M. Cucurull Salamero¹, M. Saigi Morgui¹, E. Pros², P. Navajas-Chocarro², M. Domenech Viñolas¹,

A. Hernández¹, A. Notario¹, M. Sánchez-Céspedes²

¹*Institut Català d'Oncologia, B-ARGO, Medical Oncology, Badalona, Spain*

²*Josep Carreras Leukaemia Research Institute (IJC), Cancer Genetics Group, Badalona, Spain*

Introduction

Approximately 20% of patients with lung adenocarcinoma (LuAD) have mutations in KRAS. KRAS alternates from an inactive GDP-bound to active GTP-bound state, activating downstream signaling pathways. This alternation is regulated by guanine nucleotide exchange factors (GEF) as SOS1 and GTPase activating proteins. About 85% of mutations are found at codon 12, and most of them consist of a change from glycine to cysteine (G12C). The first effective covalent G12C inhibitors (i) sotorasib and adagrasib bound to mutant cysteine, trapping KRAS in its inactive GDP-bound state. Sotorasib and adagrasib trials showed promising response rates but short duration of response (11 and 8 months, respectively). In this work we intend to study the possible mechanisms of acquired resistance to these inhibitors and possible strategies to overcome this resistance.

Material and method

We generated sotorasib-resistant (sr) KRAS G12C-mutated lung cancer (LC) cell lines (CLs) from two different commercial CLs (H358 and H2030) and we characterized them, genetically and molecularly, by exome (WES) and RNA sequencing as well as analysis of signaling pathways and KRAS activation status by western-blot and RAS assay test. We tested new drug combinations to revert off-target resistant mechanisms with a SHP2 inhibitor (TNO155) and a MEK inhibitor (trametinib), with and without sotorasib, and analyzed the efficacy by cell viability and colony formation assays. We validated these findings in other commercial LCCLs (H23, SW1573) and in a patient-derived CL from our hospital.

Result and discussion

We found the H2030 CL to be partially intrinsic resistant to sotorasib. Among the H358sr clones we identified KRAS G12C amplification in three clones, a secondary G12V mutation in one clone and AKT activation in two clones, as possible resistance mechanisms to sotorasib. We found that TNO155 couldn't overcome resistance but trametinib did. We also found that some sr clones are addicted to sotorasib. TNO155 and sotorasib showed synergy in the H2030 CL and in the patient derived CL.

Conclusion

On target KRAS mutations as mutant allele amplification and secondary KRAS nonG12C mutations are the most prevalent acquired resistance mechanisms. Upstream and downstream inhibitors as SHP2i and MEKi could be synergic in combination with sotorasib in partially resistant CLs.

EACR25-0051

Novel Topoisomerase I (Topo1) inhibitors with a non-Camptothecin core scaffold to overcome resistance to current Topo1-targeted drugs and ADCs

X. Fu¹, Y. Li¹, Q. Wang¹, H. Liu¹, D. Hu¹, Q. Dang¹

¹*Genuine Biotech, Discovery, Shanghai, China*

Introduction

Camptothecin (CPT) derivatives as DNA topoisomerase I (TOPO-1) are widely used to treat various cancers. However, their clinical efficacy was significantly undermined by both inherent resistance and the rapid development of emerging resistance. Although resistance mechanisms are complicated, some key factors are identified such as TOPO-1 mutations and drug efflux. Unfortunately, all clinical stage CPT-derived TOPO-1 inhibitors shared the original CPT core structure, thus little chance to address resistance via structural diversity. In this study, we aimed to discover a novel class of non-CPT core TOPO-1 inhibitors that specifically address the key enzyme mutations thus overcoming resistance to current TOPO-1 drugs in the clinic.

Material and method

Using a Computer-Assisted Drug Design (CADD) approach, a non-CPT core scaffold was designed to specifically improve binding to the clinically relevant R364H mutant. Molecules from the novel scaffold performed very well in our computational model showing significantly improved hydrogen bonding and polar interactions with both wild type and R364H mutated TOPO-1.

Result and discussion

More importantly, compared to irinotecan these molecules demonstrated 50 to 1000-fold higher potency in patient-derived, irinotecan-resistant tumor organoid models, thus successfully addressed tumor resistance to current TOPO-1 inhibitors. In vivo antitumor activity was also validated in various PD animal models. A PCC molecule was identified and moved into IND-enabling development, which shows significant promise as next-generation therapies for cancers overcoming resistant to traditional TOPO-1 inhibitors. Recent breakthrough discoveries of ADCs attracted more attention to TOPO-1 inhibitors, however most if not all payloads targeting TOPO-1 still utilized the original CPT core (e.g. DXD, SN-38). Therefore, it is anticipated that ADC treatment will lead to new resistance, and our novel molecules with a non-CPT core could address future resistance via structure diversity.

Conclusion

A novel series of TOPO-1 inhibitors was discovered with non-CPT core that addresses two major resistance factors associated with current CPT-based therapies: impaired binding to TOPO-1 mutants and susceptibility to drug efflux. These compounds demonstrated potent *in vitro*, organoids and *in vivo* efficacy against various cancer models. A PCC molecule was identified and moved into IND-enabling development, which shows significant promise as next-generation therapies for cancers overcoming resistant to traditional TOPO-1 inhibitors.

EACR25-0163**Chemotherapeutic Response and Resistance in a 3D MDA-MB 231 Triple-Negative Breast Cancer Spheroid Model***B. Abrahams¹, C. Gouws², M. Sekhoacha³*¹*University of the Free State, Basic Medical Sciences, Bloemfontein, South Africa*²*North-West university, Centre of Excellence for Pharmaceutical Sciences, Potchefstroom, South Africa*³*University of the Free State, Pharmacology, Bloemfontein, South Africa***Introduction**

Triple Negative Breast Cancer (TNBC) is known as an aggressive and fatal subtype of breast cancer. Chemotherapy remains the only available systemic therapeutic treatment option. However, patients often develop resistance, creating a major obstacle for effective cancer therapy. 2D cell culture models are usually used for *in vitro* screening of novel compounds for potential anti-cancer effects; however, these models do not accurately represent the complexity of the tumor microenvironment. 3D models are more mimetic of *in vivo* physiological function and offers higher accuracy in predictive drug responses. Our study elucidates the development of a cisplatin-resistant TNBC 3D spheroid model to assess chemotherapeutic drug response.

Material and method

A single cell suspension of cisplatin-resistant MDA-MB 231 cells were used to construct 3D spheroids using the rotating clinostat-based CelVivo, ClinoStar® bioreactor system. A density of 8x10⁴ cells were seeded in reactors and sorted after 6-days of spheroid induction. Cisplatin-resistant 3D MDA-MB 231 spheroids were characterized over 28 days using the following viability parameters: planimetry, soluble protein content, intracellular adenosine triphosphate (ATP), extracellular adenylate kinase (AK) and glucose uptake. The metabolically stable experimental window of the spheroids was determined, followed by cisplatin and doxorubicin clinical dose treatment over 96-hours, to validate the spheroid model. Cisplatin and doxorubicin doses were calculated using the biomass of the spheroids in each bioreactor daily and the dose adjusted for treatment. Viability and growth were assessed daily over the 96h and compared to untreated spheroids.

Result and discussion

Characterization of the spheroids showed a viable model for 28 days. The metabolically stable period of the spheroids was determined between days 12-22, which indicated the optimal experimental window for the model. The spheroid model demonstrated variable responses to cisplatin and doxorubicin treatment. A clinical dose of cisplatin (4,435 x 10-6 µg/µg protein) had no significant effect on planimetry. However, an increase ($p < 0.05$) in protein (1.81 µg) at 48 h versus 0.39 µg at 24 h was noted. ATP and glucose levels increased between 72-96h indicating metabolic activity. Doxorubicin (1.064 x 10-5 µg/µg protein) however, elicited profound reduction in spheroid viability, marked by decreased planimetry relative to control ($p < 0.0001$). AK levels increased ($p < 0.05$) over the duration of treatment period (24-96 h). This coincided with a

decrease in ATP 24-48 h ($p < 0.05$) and glucose uptake by spheroids, relative to control.

Conclusion

The spheroid model maintained its induced cisplatin resistant phenotype against cisplatin with no significant effect on the viability of the model; however, it was sensitive to a doxorubicin clinical dose. Our model may provide potential benefit as a screening tool for novel drug therapeutics.

EACR25-0208**Three-dimensional (3D) Cancer****Microenvironment that Confers****Chemoresistance to DNA Damaging Drug***L. Zhang¹, C. Du¹, J. Shi¹*¹*Hong Kong Baptist University, Center for Quantitative Systems Biology and Department of Physics, Kowloon, Hong Kong, China***Introduction**

Cancer cell behaviors in tissues/organs critically depend on the three-dimensional (3D) architectures and micro-environments, and cannot be recapitulated by traditional 2D cell lines. The development of 3D cancer spheroid and tumor organoid models have enabled the study of 3D-specific cancer mechanisms using human-derived cells. One important research area where cancer cell behaviors differ significantly in 3D vs. 2D is anti-cancer drug response of solid tumors. Extensive effort has been made using 3D culture tumor models to unravel 3D-specific drug resistance mechanisms that can be targeted to reverse chemoresistance. However, our knowledge of 3D chemoresistance mechanism is still limited.

Material and method

Here we employed 3D cancer spheroid models to investigate 3D-specific mechanisms that underlie chemoresistance to etoposide, a commonly used DNA-damaging chemotherapeutic. By comparing the cellular responses of p53 wild-type human cancer cell lines grown in 2D monolayer versus 3D spheroids following etoposide treatment, we identified a new mechanism of 3D-specific chemoresistance to etoposide that is associated with a global change in kinase signalling, which possibly arises from the significantly higher cell-cell contact and membrane interaction in 3D.

Result and discussion

Specifically, by western blot, flow cytometry and single cell imaging analysis, we found the 3D drug resistance that we observed is unrelated to reduced drug intake by the 3D cancer spheroid cells. Instead, it is attributed to attenuated etoposide-induced p53 signaling in 3D.

Through ensemble kinase profiling of the 3D spheroid models, our data suggest that the spheroid cells exhibited altered activities of signalling kinases compared to 2D cells that led to reduced p53 upregulation. And inhibition of the activity of a number of signalling kinases by gene knockdown or small-molecule inhibitor can effectively enhance 3D cancer spheroid response to etoposide and reverse chemoresistance.

Conclusion

Our study not only provided novel insights into 3D-specific chemoresistance but also revealed new combinatorial targets that could be exploited to enhance

resistant solid tumor response to DNA damaging chemotherapeutic.

EACR25-0209

Overcoming Gemcitabine Resistance in MDA-MB-231 Cells: A Synergistic Approach Using ABT-737 and NVP-BEZ235 Dual Inhibition of PI3K/mTOR

G. Selimoglu¹, S. Ayvaz¹, Z. Bolat¹

¹University of Health Sciences, Molecular Biology and Genetics Department, Istanbul, Turkey

Introduction

Triple-negative breast cancer (TNBC) is an aggressive subtype that lacks progesterone (PR), estrogen (ER) and human epidermal growth factor receptor 2 (HER2). Gemcitabine (GEM) is a drug commonly used for chemotherapy, but GEM resistance often develops, leading to more severe outcomes and relapse. This highlights the need for new targeted therapies, especially in GEM-resistant TNBC cases. The PI3K/AKT/mTOR pathway and anti-apoptotic Bcl-2 family proteins play crucial roles in cancer cell survival. Targeting both pathways might be an effective therapeutic approach. In this study, we explored the combination of NVP-BEZ235, a dual PI3K/mTOR inhibitor, with ABT-737, a BH3-mimetic Bcl-2 inhibitor, as a strategy to sensitize triple-negative breast cancer (TNBC) cells to gemcitabine (GEM) and overcome resistance.

Material and method

MDA-MB-231 cells were treated with increasing doses of GEM for over 8 months to generate GEM-resistant cells MDA-MB-231GEMR. The resistance factor was calculated, and qPCR assessed the expression of resistant related gene. Parental MDA-MB-231 and MDA-MB-231GEMR cell lines were used to find the cytotoxicity and the IC₅₀ values by Resazurin assay. Cell migration and growth ability were analyzed with Scratch and Colony Formation Assays, respectively. Cell cycle analysis was conducted by flow cytometry, and gene expression of mTOR pathway and apoptotic related genes were analyzed by qPCR.

Result and discussion
