Five human TC cell lines were used: TPC-1, BCPAP, 8505C, KAT18 and HTCC3. TIS was induced using the CDK4/6 inhibitor Palbociclib and ionizing radiation. Secretion of neurotrophic factors and axon-guidance molecules was assessed in conditioned media using ELISA and western blot analysis, while Trks receptor expression and Sortilin were examined by western blot and immunofluorescence assays.

Result and discussion

Release of neurotrophins and GDNF was observed in all tested TC cell lines, along with the release of axon-guidance molecule Ephrin-B1. Moreover, TC cells activate TrkB, which, along with its ligand BDNF, establishes a tumor-promoting autocrine loop that may further contribute to tumor innervation. In TIS-TC cells the secretion of neurotrophic factors and TrkB expression increases compared to untreated cells. Overall, both TC and TIS-TC cells release factors promoting innervation, with senescent cells potentially playing a greater role in this process.

Conclusion

These results show that TIS-TC cells may enhance processes of innervation in TC, further contributing to cancer progression and aggressiveness. Understanding the mechanisms underlying this interaction could reveal novel therapeutic targets for TC.

Introduction

Squamous cell carcinomas (SCC) originate from epithelial tissues in various organs across the body and are associated with exposure to environmental carcinogens such as tobacco, alcohol or ultraviolet radiation. Despite the overlapping histopathological features and driver mutations, SCCs from different anatomic sites have different prognoses. Oral and lung SCC are highly invasive and metastatic, whereas cutaneous SCC (cSCC) are seldom fatal and have a metastasis rate of approximately 2%. As fibroblast are key cells in the microenvironment and are critical for epithelial cell development and differentiation, we examined how fibroblasts from different tissues contribute to differences in SCC outcomes.

Material and method

Utilising normal human fibroblast and SCC cell lines from the skin, lung, and head and neck we modelled with in vitro organotypic models how fibroblasts and SCCs interact in a tissue specific manner to drive invasion and proliferation. Mechanisms were explored with lipidomics, RNA sequencing and validated in vivo. We validated our data in patient samples using spatial transcriptomics of clinical samples and analysis of public clinical cohorts.

Result and discussion

We discovered that fibroblasts contribute to SCC aggressiveness in a tissue-specific manner by modulating SCC proliferation and invasion. Oral and lung fibroblasts enhance SCC invasion by inducing epithelial-to-mesenchymal transition, whereas dermal fibroblasts lack this effect, aligning with the low metastatic potential of cSCC. Lipidomic profiling revealed distinct metabolic interactions between fibroblasts and SCCs. Oral fibroblasts transfer sphingomyelins, activating the ceramide/S1P/STAT3 pathway to drive oral SCC invasion, while lung fibroblasts supply triglycerides, fuelling cholesterol synthesis and promoting aggressive lung SCC behaviour. In contrast, dermal fibroblasts exhibit low lipid content, corresponding to the reduced invasiveness of cSCC. Blocking fibroblast lipid metabolism, SCC lipid uptake, or lipid processing suppressed oral and lung SCC invasion, highlighting potential therapeutic targets. Spatial transcriptomics and patient cohort analysis confirmed the presence of these fibroblast-epithelial lipid interactions in clinical samples and their correlation with SCC outcomes. Notably, these

interactions were evident in early-stage lesions, suggesting a role in SCC initiation and progression.

Conclusion

Our study establishes fibroblasts as key regulators of SCC progression through tissue-specific lipid metabolism. By shaping the tumour microenvironment, fibroblasts drive SCC aggressiveness in an anatomic site-dependent manner. These findings open avenues for targeting fibroblast-derived lipid pathways to prevent or mitigate SCC progression, with potential implications for early intervention and precision therapies.

Introduction

Patients with non-small cell lung cancer (NSCLC) often present with radiographic findings suggestive of two or more anatomically distinct synchronous lesions. The development of multiple primary tumors in smokers with lung cancer could be attributed to carcinogen-induced field cancerization, while the occurrence of multiple independent early-stage tumors in individuals with EGFR-mutant lung cancer who lack known environmental exposures remains unexplained.

Material and method

We identified ten patients with early stage, resectable, non-small cell lung cancer who presented with multiple, anatomically distinct, EGFR-mutant tumors. We reconstructed the phylogenetic relationships among multiple tumors from each patient using whole-exome sequencing (WES). To quantify the divergence between tumors, we generated poly(G) fingerprints, which measure insertions/deletions (indels) in hypermutable guanine mononucleotide repeats. These mutations occur at high rates during DNA replication as a consequence of polymerase slippage. Therefore, the divergence between the poly(G) genotypes of two somatic cell populations is a reflection of the number of cell divisions that separate them.

Result and discussion

In several patients, developmental mosaicism, assessed by WES and poly(G) lineage tracing, indicates a common non-germline cell of origin. Anatomically distinct primaries contain a number of shared somatic mutations comprising only a small fraction of the total exonic mutational burden and are inconsistent with both unrelated somatic origin nor intrapulmonary metastasis. Our analysis of poly(G) repeats in such tumors suggests that EGFR mutations may occur before cells have undergone half of the divisions on their way to tumor initiation. In two other patients, we identified germline EGFR variants, which confer moderately enhanced signaling when modeled in vitro. Our study suggests that a canonical and fully activating EGFR mutation may arise early during lung development, creating a mosaic of lung epithelial cells harboring this mutation and distributed across the adult organ. The high prevalence of normal lung specimens with rare detectable EGFR-mutant alleles as a result of field cancerization does not explain the occurrence of the multiple EGFR-mutant primary tumors described in the present study, because they would be genetically independent, lacking the multiple shared mutations that define the developmental, mosaically derived primaries.

Conclusion

In summary, patients presenting with multiple EGFR-mutant primary tumors, are likely to harbor either a germline EGFR variant or developmental mosaicism in the lung. These individuals are at risk of developing additional tumors during their lifetime, suggesting the importance of ongoing surveillance and raising consideration of new prophylaxis strategies.

Breast Cancer Cell-Adipose Tissue Interaction is Regulated by RET/PDGF-B Axis to Commit Immature Adipocytes in Favor of Tumor Growth

S. Vallone¹, A. Lara¹, I. Ruiz-Garrido², M. Palavecino¹, A. Arcones², M. García Solá¹, D. Flaks³, G. Acosta Haab³, G. Sabio², A. Gattelli¹

¹Institute for Physiology, Molecular Biology and Neurosciences (IFIBYNE), Laboratory of Therapeutic targets & Microenvironment in breast cancer, Buenos Aires, Argentina

²Spanish National Cancer Research Centre (CNIO), Laboratory of Interaction between Organs in Metabolic Diseases, Madrid, Spain

³Marie Curie Oncology Hospital, Breast Pathology, Buenos Aires, Argentina

Introduction

The breast tumor-adjacent adipose tissue harbors modified adipocytes that resemble their precursors, pre-adipocytes (PAs), and exhibit a pro-tumoral function. However, the molecular mechanisms governing the crosstalk between tumor cells and adipose tissue remain largely unknown. In this study, we identify RET, a receptor tyrosine kinase overexpressed in 50% of breast tumors, as a critical mediator of this interaction.

Material and method

To investigate the role of RET in tumor-adipose tissue crosstalk, we employed both in vitro and in vivo approaches. Breast cancer cells either expressing RET (RET-WT) or with RET knockout (RET-KO) were used in co-culture systems with adipocytes and in orthotopic allograft mouse models. Gene expression profiles were analyzed via RNA sequencing, and molecular changes in adipose tissue were assessed through RT-qPCR, Western blot, and histological staining. Additionally, we examined a novel cohort of breast cancer patients, evaluating RET and PDGF-B expression in tumor-adjacent adipose tissue and correlating these findings with clinicopathological features and adipocyte phenotype.

Result and discussion

In the RET⁺ tumor microenvironment, adipocytes exhibit a more immature phenotype, a finding supported by our in vitro results showing that RET-expressing breast cancer cells impair adipocyte differentiation. RNA-sequencing analysis in mouse transgenic RET-expressing glands revealed upregulation of genes involved in maintaining a PA phenotype, including PDGF ligands. In agreement, RET expression positively correlates with PDGF-B levels in human breast cancer biopsies. Functionally, PAs enhance tumor cell proliferation, and in vivo co-injection assays demonstrated that their protumoral effect is specifically dependent on RET expression in cancer cells.

Conclusion

Our findings indicate that the RET/PDGF-B axis mediates tumor-adipose tissue communication, driving a PA-like phenotype that fosters breast cancer progression. The validation of these results in a new patient cohort highlights the potential of targeting this interaction as a novel therapeutic strategy against breast tumors.

MCL-1 as a molecular switch between myofibroblastic and pro-angiogenic features of breast cancer-associated fibroblasts

C. Lefebvre¹, T. Bonneaud¹, P. Giowachini¹, J. Derrien¹, A. Basseville², L. Thirouard¹, I. Corre¹, M. Campone³, P. Juin¹, F. Souazé¹

¹Nantes Université, CRCINA, Nantes, France

²Université d'Angers, Institut de Cancérologie de l'Ouest, Angers, France

³Institut de Cancérologie de l'Ouest, Nantes, France

Introduction

Breast cancer-associated fibroblasts (bCAFs) comprise two pro-tumor populations: inflammatory CAFs (iCAF) producing pro-inflammatory cytokines and myofibroblastic CAFs (myCAF) characterized by their highly contractile and invasive phenotype. We have previously shown that bCAFs promote therapy resistance by overexpressing the anti-apoptotic protein MCL-1 and inducing its expression in luminal breast cancer cells by paracrine effects. This defines MCL-1 as a target in stroma-influenced breast cancers, and advocates for a comprehensive investigation of the effects of its targeting in distinct cellular components, such as myofibroblastic CAFs, of these tumor ecosystems.

Material and method

In this study, we explored the role of MCL-1 in the primary culture of CAFs obtained from treatment-naïve patients with invasive carcinoma after surgical resection by inhibiting MCL-1 pharmacologically with S63845, a BH3 mimetic developed to specifically antagonize its anti-apoptotic function or genetically by silencing MCL-1 gene expression using Crispr-Cas9.

Result and discussion

Single-cell RNA sequencing analysis of bCAFs reveals that MCL-1 knock down induces a phenotypic shift from wound-myCAF to IL-iCAF. Notably, MCL-1 depletion in bCAFs leads to a reduction in the expression of key myofibroblast activation markers, including α -SMA and Myosin IIb, accompanied by a significant loss of contractile, migratory, and pro-invasive properties in a 3D co-culture model with luminal breast cancer cells. Mechanistically, pharmacological inhibition of MCL-1, which stabilizes the protein, enhances its interaction with DRP1, triggering mitochondrial network fragmentation and cytoplasmic retention of the transcription factor YAP1. Concurrently, MCL-1 targeting in bCAFs stimulates VEGFA secretion, which in turn enhances endothelial cell tubulogenesis and drives extensive tumor vascularization in the chicken chorioallantoic membrane (CAM) model. Mechanistically, we identified NF- κ B activation as responsible for the overexpression of VEGF-A and the cytokines/chemokines CXCL1, CXCL8 and IL-1 β leading to the acquisition of an inflammatory phenotype by bCAFs in response to MCL-1 targeting. Importantly, we established that chemotherapeutic treatment promotes inflammatory and pro-angiogenic phenotype of bCAFs too.

Conclusion

These findings highlight a novel role for MCL-1 in regulating the phenotypic plasticity of bCAFs, and provide new insights into the characterization of distinct bCAF subpopulations, particularly post-chemotherapy.

EACR25-0458

Reprogramming of cancer-associated fibroblasts during the stepwise progression of colorectal cancer

E. Viitala¹, M. Sevigny¹, S. Ollila¹

¹University of Helsinki, Faculty of Biological and Environmental Sciences, Helsinki, Finland

Introduction

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths globally. It evolves a complex tumor microenvironment (TME), where cancer-associated fibroblasts (CAF) stand as the most abundant cell type with major impact on therapeutic responses. High CAF abundance is associated with aggressive cancer type and poor survival, highlighting the need to detailed understanding. Recent advances in single-cell RNA sequencing (scRNA-seq) have revolutionized the research of fibroblasts, leading to the identification of transcriptomic and functional distinctions among subsets. Yet, the exploration of CAFs in the context of CRC remains limited, complicating therapeutic targeting. About 80% of CRCs acquire early mutations in APC gene, followed by sequential accumulation of mutations in KRAS, TP53, and TGFBR2 genes or pathways,

eventually leading to metastasis. Despite extensive research on driver mutations, the impact of accumulating mutations on CAF reprogramming remains unclear. The aim of this study is to characterize how driver mutations activate CAF subsets during CRC tumorigenesis to enable the design of CAF-targeting therapies.

Material and method

We analyzed scRNA-seq and spatial transcriptomic data from human normal and CRC colon to define CRC CAF subtypes, assess their prognostic value and map their distribution. Additionally, we performed 3D mouse primary co-cultures with cancerous organoids modeling CRC progression, and analyzed available organoid-fibroblast co-cultures scRNA-seq data to assess how cancer-inducing mutations in intestinal organoids affect fibroblast activation.

Result and discussion

We identified four CAF subtypes (preCAF1, preCAF2, matrix(m)CAF and inflammatory (i)CAF), and found that they originate from different anatomical sites. Interestingly, the mCAF signature correlated with reduced survival and was significantly enriched in patients with CMS4 tumors and with KRAS mutations, suggesting that KRAS-driven tumor cells creates a TME favouring matrix-producing differentiation of adjacent fibroblasts, leading to more aggressive disease. To explore fibroblasts behavior during the stepwise CRC progression, we analyze data from fibroblasts co-cultured with CRC-modeling organoids and confirmed that epithelial cells induce early CAF expression.

Additionally, fibroblasts influenced the growth of Apc-mutant spheroids, supporting a bidirectional tumor-stroma cross-talk during early CRC steps.

Conclusion

Here, we correlate CRC CAF subtypes with CRC patients survival and clinical features, and investigate how driver mutations in the CRC epithelium reprogram fibroblasts in an ex vivo setting. Identifying specific CAFs signatures correlating with poorer prognostic will contribute to a better knowledge on CAF reprogramming and heterogeneity, which will pave the way to design CAF-targeting therapies.

EACR25-0486

Elucidating the molecular mechanisms involved in pancreatic cancer and liver microenvironment crosstalk facilitating liver metastasis

Y. Roth¹, K. Solomon¹, R. Kleiner¹, D. Vaskovich-Koubi¹, R. Satchi-Fainaro¹

¹Tel Aviv University, Physiology & Pharmacology, Tel Aviv, Israel

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers, ranking third in cancer-related mortality despite being only the eighth most common cancer. Its poor prognosis is due to late detection, therapy resistance, “cold” and fibrotic microenvironment, and frequent liver metastases, which significantly worsen outcomes compared to extrahepatic metastases. While the liver microenvironment plays a critical role in metastasis,

the molecular mechanisms underpinning these interactions remain unclear. This study aims to uncover the molecular and cellular interactions between PDAC cells and the liver microenvironment, with the goal of identifying therapeutic targets to prevent or slow the progression of liver metastases.

Material and method

We developed in vitro, and ex vivo models to study PDAC-liver TME interactions, including co-culture systems, conditioned media assays, and 3D spheroid invasion models. Cutting-edge techniques such as cytokine arrays, mass spectrometry, multiplex flow cytometry and immunohistochemistry are being used to identify molecules involved in PDAC-liver crosstalk. Promising targets and biological pathways are being analyzed in murine models of spontaneous PDAC liver metastases and validated on human clinical samples. Functional studies will evaluate the effects of target inhibition using antibodies, small molecules, and CRISPR-mediated gene editing.

Result and discussion

Preliminary results demonstrate that hepatocytes enhance PDAC cell proliferation, migration, and invasion through both direct contact and secreted factors. Proteomic analysis revealed candidate biological pathways and several potential key targets mediating these effects. The functional roles of the most promising candidates are being tested in preclinical models.

Conclusion

This study highlights the role of the liver microenvironment in driving PDAC metastasis. Targeting the molecular pathways involved may offer new therapeutic approaches to prevent liver metastases and improve survival outcomes for PDAC patients.

⁷Oslo University hospital, Department of Oncology, Oslo, Norway

⁸University of Oslo, Institute for Clinical Medicine, Oslo, Norway

Introduction

The tumor microenvironment plays a critical role in cancer prognosis and treatment response through complex interactions between cancer cells and their surrounding cells. Spatial analysis methods enable the study of these interactions but often result in highly complex datasets. Several factors may influence how cancer cells are affected by neighboring cells, including the number of cells within signaling distance, their proximity to the cancer cell, and their specific cell type. To address the challenge of analyzing these interactions, we developed a novel approach to characterize and cluster cellular neighborhoods based on the local distribution of neighboring cells. Our goal was to identify neighborhood types associated with treatment response.

Material and method

We profiled breast tumor samples from 13 patients enrolled in the neoadjuvant NeoAva clinical trial (NCT00773695) using cyclic immunofluorescence (cycIF) proteomics of whole tissue biopsies. Analysis was done on the Galaxy platform with manual gating used to classify cell types in pre-treatment samples from patients receiving bevacizumab. The range for each cancer cell neighborhood was chosen to be 200 µm, and any cancer cells too close to sample borders excluded to avoid edge effects. For each neighborhood, radial distribution functions were calculated for each cell type. The bins of the radial distributions are not independent and form a high-dimensional space, thus a downsampling step was required to enable clustering and dimensionality reduction. We performed downsampling using a variational autoencoder and principal component analysis, followed by clustering to identify distinct neighborhood types.

Result and discussion

Following exclusion of cancer cells close to sample boundaries, approximately 2*105 cellular neighborhoods remained for training, testing and validation. Using the autoencoder for downsampling enabled the identification of similar neighborhood types across patient samples. Notably, we found that specific neighborhood types are correlated with treatment response to bevacizumab, suggesting that the spatial organization of the tumor microenvironment influences therapeutic outcomes. Current work is exploring improvements in the down-sampling process with improved autoencoder architectures and tensor decomposition.

Conclusion

Spatial analysis reveals important insights into cancer biology by identifying and quantifying distinct cell interactions. To investigate the added spatial dimension, however, novel methods are required. We believe that the presented approach shows promise for the generalized investigation of cellular interactions in the micro-environment surrounding the tumor cells.

⁴*Sapienza University of Rome, Department of Surgery, Rome, Italy*

⁵*Clinica S. Rita, Department of Colorectal Surgery, Vercelli, Italy*

⁶*University of Turin, Department of Clinical and Biological Sciences, Turin, Italy*

Introduction

Colorectal cancer (CRC), the third most common cancer and the second leading cause of cancer-related deaths globally, presents clinical unmet needs and its molecular complexity remains a key challenge. Advancements in transcriptome analyses have enhanced the understanding of CRC heterogeneity. However, alterations involved in precancerous lesion (adenoma) formation and progression to CRC are unexplored. RNA-binding proteins (RBPs) play a crucial role in post-transcriptional regulation, impacting several processes such as alternative splicing (AS) and polyadenylation (APA). This study systematically explored alterations in RBP expression, AS, and APA patterns in CRC and adenoma patients' matched lesion/adjacent tissue whole transcriptome data.

Material and method

We analyzed total RNA-seq data generated from tissue pairs samples of CRC ($n = 90$) and adenomas patients ($n = 24$, both non-advanced (nAA) and advanced (AA)). We analyzed differential gene expression to evaluate RBP dysregulation from adenomas to advanced CRC. Using STRING, we constructed an RBP protein-protein interaction network to visualize altered RBP functional clusters. Relative isoform expression changes, AS, and APA events were assessed in our data and the RBP depletion experiment collection of the ENCODE Consortium. CLIP data from POSTAR3 and ENCODE were integrated to identify events directly regulated by the altered RBPs. Finally, RNA-seq data from TCGA were analyzed to validate recurrent AS and APA events.

Result and discussion

RBPs exhibited widespread and progressive dysregulation from adenomas to higher tumor stages. In particular, among 1,937 RBPs identified, 668 were consistently upregulated and 107 downregulated across AA and CRC stages. Ten RBPs showed consistently increased (AGO2, BOP1, CCT6A, DDX21, KPNA2, NME1, PCSK9, PUS7, RNASEH2A, WDR43) or decreased (PPARGC1B) expression levels from nAA to CRC stage IV. Functional RBP clusters were significantly affected, including the spliceosome, ribosomal proteins, and initiation factors. Alternative transcriptome analysis identified 624 ASE and 137 isoform switches in CRC and AA. Functional enrichment analysis highlighted alterations in pathways involved in the epithelial-to-mesenchymal transition, cytoskeletal organization, and adherence junctions. APA and splicing/APA/isoform event-RBP pairs are under further investigation using ENCODE and TCGA data.

Conclusion

Our data support cancer-related RBP dysregulation as an early molecular event of carcinogenesis occurring in adenomas, alongside specific isoform expression, AS, and APA events related to dysregulated RBPs. The integration and validation of single RBP perturbation and

CLIP data with those from our cohort offer a comprehensive approach to understand transcriptomic alterations linked to RBPs. Our findings may help to unravel the molecular complexity behind precancerous lesions and CRC progression.

⁴Henry Ford Health System, Henry Ford Health, Detroit, United States

⁵University of Alabama, Internal Medicine, Birmingham, United States

⁶Wayne State University Karmanos Cancer Institute, Oncology, Detroit, United States

Introduction

By 2030, pancreatic ductal adenocarcinoma (PDAC) is projected to become the second leading cause of cancer-related deaths worldwide. Its high mortality is driven by late diagnosis and ineffective treatments, underscoring the urgent need for the identification of novel targeted therapies. Circular RNAs (circRNAs) are a sub-group of ncRNAs that form a covalently closed continuous circular loop. CircRNAs play a significant role in regulating the transcription of oncogenes and tumor suppressor genes through miRNA sponging and RNA binding protein (RBP) interactions. Studies have shown that circRNA expression patterns can serve as prognostic markers for PDAC. However, whether these circRNAs can be targeted using less toxic treatment strategies, such as natural product derivatives, has not been explored. Here, we evaluated the impact of thymo-quinone (TQ), a derivative of Nigella sativa (black seed), on PDAC-associated circRNAs.

Material and method

We performed circRNA-seq profiling on MiaPaCa-2 and Panc-1 PDAC cell lines treated with TQ. The expression of the top prioritized differentially expressed circRNAs was verified by qRT-PCR using divergent primers. The biological relevance of the selected circRNAs modified by TQ was assessed using the publicly available PDAC circRNA microarray dataset (GSE79634), and pathway analysis was employed to evaluate their biological targets.

Result and discussion

TQ treatment resulted in the downregulation of PDAC gene set enrichment analysis (GSEA) identified oncogenic circRNAs, including hsa_circ_0000567, hsa_circ_0008344, hsa_circ_0058453, hsa_circ_0004405, hsa_circ_0012152, hsa_circ_0008193, hsa_circ_0001900, hsa_circ_0001495, hsa_circ_0006877, hsa_circ_0007643, hsa_circ_0002402, hsa_circ_0000707, and

hsa_circ_0001558. GSEA revealed that the TQ-altered circRNAs were associated with the Wnt and Hedgehog signaling pathways. RT-PCR demonstrated that the identified circRNAs were elevated in PDAC cell lines compared to normal HPNE cells, and their expression was significantly reduced following TQ treatment ($p < 0.05$). Furthermore, circR-0058453 was found to bind to specific miRNAs, miR-1248 and miR-1287, which have been reported to function as tumor suppressors. These findings suggest that circR-0058453 may act as an oncogenic circRNA by sponging tumor-suppressive miRNAs, thereby promoting PDAC growth – a process that can be reversed by TQ. Notably, circR-0058453 contains 22 binding sites for AGO2, and RNA immuno-precipitation assays confirmed that its binding to AGO2 was downregulated by TQ. These results suggest that TQ exerts its inhibitory effects on cell signaling through the regulation of circRNA and RBP interactions.

Conclusion

Conclusions: This study is the first to demonstrate that PDAC associated circRNAs can be targeted by the non-toxic natural product thymoquinone that warrants further clinical investigation.

Characterization of colon cancer metastases ecosystem by single nuclei RNA sequencing identifies a fibroblast subset as a biomarker for early relapse and as a potential therapeutic target

M. Picard¹, A. Guille¹, E. Denicolai¹, P. Finetti¹, F. Bertucci², D. Birnbaum³, E. Mamessier¹

¹Cancer Research Center of Marseille (CRCM), Translational research and innovative therapies, Marseille, France

²Paoli-Calmettes Institute, Departments of Pathology/Medical Oncology, Marseille, France

³North's Hospital, General and Visceral Surgery Department, Marseille, France

Introduction

The era of single-cell analysis has demonstrated the importance of accurate characterization of all organ-specific cell subtypes. In the context of malignancies, this has greatly improved our understanding of cell interactions and mutual influence. However, metastatic tissues are often forgotten, although they are the real cause of cancer-related mortality, especially in colorectal cancer (CRC), whose prognosis is directly linked to the presence of liver metastases (lm). One reason for this is the inherent difficulties in analyzing lm-CRC tissue at single-cell resolution: first, the liver is composed of cells that are extremely fragile and hardly recoverable after enzymatic digestion; second, most surgical specimens are from patients who have received chemotherapy and are therefore highly necrotic, fibrotic, and fragile. Due to these limitations, most studies have focused on characterizing the immune system, ignoring the role of other components of a rich and complex ecosystem.

Material and method

To address this gap, we characterized the ecosystem of pretreated lm-CRC using single-nuclei RNA sequencing.

The global landscape, subpopulation composition, cell-cell interactions, and tumor cell inference were analyzed across populations and with respect to disease relapse.

Result and discussion

We obtained 31,524 high-quality cells from 9 patients for a total of 30 clusters, including malignant epithelial cells of CRC, immune cells, fibroblasts, and normal liver cells, which together form one of the first comprehensive atlases of lm-CRC. Among all cells, we found a subset of cancer-associated fibroblasts (CAF) that was enriched in patients whose disease has progressed within less than one year (hereafter referred to as “early relapse”). We investigated the specificities of this CAF subset and deciphered its interaction with the microenvironment: it exhibits a myofibroblastic CAF profile and interacts strongly with myeloid immunosuppressive cells and cells in endo-mesenchymal transition. This was also confirmed at the protein level by multiplex imaging and spatial transcriptomic data of lm-CRC. To investigate the function of this subset in early relapse, we examined the secreted factors and inferred their effects on endothelial cells (increased permeability) and epithelial tumor cells (enhanced growth, resistance to chemotherapy and migratory capacity). We are now investigating the enrichment of this CAF subset in lm CRC annotated with clinical data to test their predictive value for early relapse. In parallel, we have identified drugs targeting them by analyzing their gene expression signature.

Conclusion

We have identified a subset of CAFs that can serve as a potential biomarker for early relapse and as a potential target in the context of personalized medicine for metastatic colorectal cancer.

Exploring glioblastoma and natural killer cell interactions in a fluidic microphysiological system

P. Žižek¹, T. Kolenc Milavec^{1,2}, A. Habic^{1,2}, Š. Kladnik¹, M. Novak¹, B. Breznički¹

¹*National Institute of Biology, Department of Genetic Toxicology and Cancer Biology, Ljubljana, Slovenia*

²*Jožef Stefan Institute, Jožef Stefan Postgraduate School, Ljubljana, Slovenia*

Introduction

Glioblastoma (GBM), a highly aggressive grade IV glioma, is the most common primary tumor of the central nervous system in adults. Despite aggressive conventional treatments, GBM remains incurable.

Efficient treatment is mostly prevented by heterogeneity and therapeutic resistance, latter driven by the complex and dynamic tumor microenvironment (TME). There is a lack of molecular understanding of GBM therapeutic resistance in the context of immune TME and of representative tumor models that mimic GBM-immune cell interactions in humans, especially the dynamic component of immune cell system. The aim of our study was to set up immune-competent glioblastoma ex vivo model to study immune cell tumor infiltration and to explore GBM-immune cell interactions after they enter the TME.

Material and method

To understand the role of GBM-immune cell interactions, we set up microfluidic platform (MIVO® platform, React4life), mimicking the influx of immune cells into the tumors. Tumor cell spheroids, established from patient-derived GBM cells and GBM stem cells, were embedded in Matrigel® and cultured in the tumor chamber above a microcirculation of natural killer (NK) cells for 24h at different effector:target cell ratios. Spheroids from patient-derived GBM cells were established using bioreactors (Clinostar® 2, CelVivo). Fluorescence microscopy, immunofluorescence and flow cytometry were used to determine the infiltration of labelled NK cells into the spheroids and the viability of GBM and NK cells.

Result and discussion

When NK-92 cells were placed in circulation, their infiltration within the GBM spheroids and their viability were investigated. Firstly, flow rate was optimized to ensure NK cell viability and circulation. NK cells interacted with GBM cells since we observed the infiltration of the NK cells into the tumor chamber into the tumor cell spheroids after 24h. Increased effector: target cell ratio did not increase the infiltration of NK cells into the tumor chamber. However, the infiltration of NK cells was increased by serum in the tumor chamber, acting as chemoattractant. We also confirmed that Matrigel is easily removed by washing with cold PBS and that flow-cytometry using non-fixed live cells is a feasible read-out after spheroid dissociation. GBM and NK cells from tumor chamber and circulation remained viable during experiments.

Conclusion

As immunotherapy is a promising approach and its success depends on the immune cells’ interaction with cancer cells, we have established a microfluidic platform that mimics tumor-immune cell interactions in human patients. Several conditions will be optimized such as the use of patient-derived immune cells and organoids and extended times of incubation. With such ex vivo brain tumor models we can explore GBM biology and test combinational anti-cancer approaches, including targeted therapy and immunotherapy.

RECQL4 Modulates MHC Class II Expression and Drives an Immune-Evasive Phenotype Associated with Resistance to Immune Checkpoint Therapy in Malignant Melanoma

S. Egea-Rodríguez¹, R. Váraljai², T. Nordmann³, R. Lubis⁴, A. Paschen², B. Klebl⁴, I. Hickson⁵, D. Schadendorf², M. Mann³, I. Helfrich¹

⁵University of Copenhagen, Center for Chromosome Stability, Copenhagen, Denmark

Introduction

Immune checkpoint inhibitors (ICIs) have revolutionized metastatic melanoma treatment, yet therapeutic resistance remains a major challenge. RECQL4, a RecQ-like helicase involved in DNA replication and repair through the DNA damage response (DDR), has been implicated in modulating immune signaling pathways. However, its impact on ICI therapy response and tumor immune evasion remains poorly understood.

Material and method

We performed an integrated analysis of whole exome and bulk RNA sequencing data from a pan-cancer cohort ($n = 25,775$) and cutaneous melanoma cohorts (untreated: $n = 471$, anti-PD-1 treated: $n=212$). We examined RECQL4 copy number variations and expression levels in relation to patient outcomes and conducted Gene Set Enrichment Analysis (GSEA) to uncover RECQL4-associated immune pathways. To assess the link between RECQL4 and therapy resistance, we analyzed melanoma cohorts of 95 responders and 85 non-responders before and after ICI therapy. Finally, we used genetically engineered RECQL4 variants and multi-omic profiling – including liquid chromatography coupled with tandem mass spectrometry – to elucidate mechanistic insights.

Result and discussion

Our findings identify RECQL4 as a key driver of poor prognosis and ICI resistance in melanoma. High RECQL4 expression correlates with elevated tumor purity, reduced Tumor Immunogenicity Associated with Response to Anti-PD1 (TIARA-PD1) signatures, and suppression of immune-related pathways.

Mechanistically, RECQL4 downregulates MHC class II expression, limiting antigen presentation and fostering immune evasion. We further identified CIITA as a key mediator of this regulation, linking RECQL4 activity to impaired anti-tumor immune responses.

Conclusion

This study highlights RECQL4 as a critical modulator of tumor immunogenicity and immune escape, demonstrating its potential as both a predictive biomarker and a therapeutic target for overcoming ICI resistance in melanoma and across various cancer entities.

Introduction

Gastric cancer (GC) is the fifth most common malignant tumor and the fourth leading cause of cancer related deaths worldwide. Due to missing early clinical symptoms, a high number of patients have an incurable cancer at time of initial diagnosis. Based on found mutations GC was classified into four molecular subtypes. Alterations in the EGFR, WNT, TGFβ, NOTCH and NFκB signaling pathways were identified as the main drivers of cancer progression. In addition, the Hippo signaling pathway has been pointed out as an important pathway as it is mutated in about 40 % of all GC patients. However, its role in GC has not yet been adequately investigated and the functional impact of the mutations is unclear. We therefore wanted to figure out the role of the Hippo signaling pathway in GC initiation and progression.

Material and method

To study the role of the Hippo signaling pathway in GC we used our in house generated stomach-specific, inducible Anxa10-CreERT2 mouse line. Since mutations in the Hippo signaling pathway are often associated with alterations in the WNT or EGFR pathway, we mutated the Hippo pathway and one of the above-mentioned signaling pathways in our mouse line. Observed primary tumors and metastases were histologically characterized. A murine tumor organoid biobank of primary tumor tissue was generated and organoids analyzed for their morphology, proliferation and therapy response. RNA sequencing was used to unravel potential altered signaling pathways in tumor organoids.

Result and discussion

The different mouse models allowed the investigation of the gastric epithelium over the time with respect to induced malignant changes. Interestingly, the model combining Hippo+EGFR mutations led to late stage cancer formation with liver and lung metastases while the model with the WNT mutation showed only early stage cancer. Interestingly, the generated tumor organoids of the Hippo+EGFR model showed a resistance to classical chemotherapeutics and small molecules in a medium-scale drug screen. Transcriptome analyses of these organoids revealed alterations in lipid metabolism and interleukin signaling as well as the reorganization of tight junctions.

Conclusion

The combination of a Hippo pathway alteration with other driver mutations led to different tumor stages, morphologies and metastatic pattern. The generated tumor organoids of the different tumor models revealed a divergent therapy response with the Hippo+EGFR model being the most resistant. Changes in lipid metabolism as well as interleukin signaling pathway could be responsible for the observed resistance. All in all, Hippo signaling pathway plays an important role in GC tumorigenesis and the generated tumor organoids can be further used as an excellent laboratory tool to test new therapeutic options with the overall aim to improve the treatment options for GC patients.

Introduction

High-grade serous ovarian cancer (HGSOC) remains the most common and lethal subtype among epithelial ovarian tumors. Despite being considered potentially immune-reactive, immunotherapy has yet to demonstrate a significant benefit in HGSOC and chemotherapy stays as the first line standard of care. When administered before surgery, neoadjuvant chemotherapy (NACT) induces a favorable response in most ovarian cancer patients, irrespective of their homologous recombination (HR) status. However, the distinct impact of NACT on the immune response in HR-deficient (HRD) and HR-proficient (HRP) patients remains uncertain. Our study seeks to elucidate the immune response dynamics following NACT in both groups with the goal of identifying novel biomarkers for personalized immunotherapy in HGSOC.

Material and method

Tumor samples were prospectively collected from newly diagnosed advanced HGSOC patients, either at baseline or after 3-4 cycles of NACT. The composition and spatial organization of the tumor immune microenvironment (TIME) were evaluated using flow cytometry (FC), multiplex immunofluorescence (mIF) tissue imaging and coupled single cell RNA sequencing (scRNA-seq) analysis. Dynamics of immune cell proportions, their co-regulation and cellular interactions were comparatively analyzed between HRD and HRP subgroups, both before and post-NACT. ID8p53-/- and ID8p53-/-brca1-/- tumor-bearing mice were respectively used as HRP and HRD NACT models.

Result and discussion

Our longitudinal data show that following NACT, HRD tumors exhibit a significant increase in B cells, cytotoxic T cells (CD8+) and dendritic cells (CD11c+), whereas HRP tumors have no major changes in all immune subpopulations, including macrophages (CD68+). Further spatial mIF tissue imaging revealed that, upon NACT, HRD tumors had prominent immune infiltration (CD11c+ and CD8+) and enhanced mutual cell interactions (CD19+:CD8+ and CD11c+:CD8+) within the stroma, while CD8+:CD68+ were increased within the tumor islets. Importantly, we found that tertiary lymphoid structures (TLS) significantly increased in HRD tumors upon NACT. Consistent with the previous findings, our

HRD model exhibited increased T cell infiltration and TLS-like lymphoid aggregates compared to the HRP model.

Conclusion

NACT differentially reshapes the TIME in HGSOC patients depending on HR status. The distinct immune response dynamics observed between HRD and HRP tumors provide new insights that could inform novel biomarker-driven immunotherapy strategies. Ongoing scRNA-seq analysis and in vivo experiments aim to further characterize the tumor-intrinsic and TIME-dependent mechanisms underlying these differences.

²Università Della Svizzera Italiana, Institute of Oncology Research (IOR), Bellinzona, Switzerland

³The Institute of Cancer Research, Data Science Team, London, United Kingdom

Introduction

Cancer dormancy poses a significant challenge in oncology, as dormant cells can reactivate years later, resulting in disease recurrence. Our research has shown that adaptation to endocrine therapy in ERα+ breast cancer (BC) involves non-genetic transitions between cell states, contributing to stochastic "awakening" and resistance (D. Rosano et al., 2024). While multi-omics approaches have revealed crucial aspects of dormant cells, these conventional end-point studies fail to capture their dynamic progression. To address this gap, we used longitudinal time-lapse imaging to track single-cell lineages, providing a detailed view of survival mechanisms during therapy. We discovered that the initial cell cycle status of the mother cell influences the fate of its lineage following treatment, suggesting that synchronizing cells could improve their susceptibility to therapy.

Material and method

We engineered MCF7 BC cells with a novel cell cycle reporter (p21-GFP and Geminin-mCherry) and a H2B nuclear marker. The p21-GFP reporter identifies G0/G1 arrest, while Geminin-mCherry labels cycling cells in SG2M. Using the Opera Phenix Plus microscope, we performed 48-hour time-lapse imaging to track cell lineages and survival dynamics. Automated lineage tracing and cell cycle analysis were done using Imaris software. Cells were classified based on their initial cell cycle stage at treatment initiation. For a broader comprehension of persister dynamics and long-term effect of therapy we performed an additional 12-day timelapse experiment.

Result and discussion

Our goal was to trace back to the cell of origin where a transient phenotype arose and inherited across a lineage, unveiling new survival mechanisms. We observed that dormancy led to an increased G0/G1 population, likely linked to prolonged cell cycle durations. Notably, G0/G1 cells at treatment initiation had a higher likelihood of

survival post-treatment compared to SG2M cells. Those results were confirmed by cell synchronization experiments with palbociclib. We conducted a second experiment over a 12-day treatment period to thoroughly disclose persistence dynamics. The volume of data collected necessitated a fully automated approach to evaluate a significantly higher number of single lineages. We developed novel segmentation and tracking algorithms to link nuclei across adjacent frames, thereby connecting mother cells to their daughter cells. This fully automated pipeline greatly improved lineage tracking across multiple fields of view, enhancing the reliability of our findings.

Conclusion

Our study highlights the importance of the initial cell cycle stage in determining cancer cell fate during dormancy and therapy, with implications for synchronizing treatment strategies. This automated pipeline offers a powerful tool for high-throughput screening and could enable further studies on persister cells and therapy resistance.

Dysadherin-mediated CA9 expression shapes an acidic tumor microenvironment to accelerate colorectal cancer aggression

J. Nam¹, C. Lee¹, H. Yun¹

¹Gwangju Institute of Science and Technology, Department of Life Sciences, Gwangju, Korea (Republic of)

Introduction

The tumor microenvironment (TME) plays a pivotal role in colorectal cancer (CRC) progression by fostering tumor survival and aggressive behavior. A key contributor to this process is the glycoprotein dysadherin, which is highly expressed in aggressive CRC cells and facilitates their adaptation to the TME.

Material and method

In this study, we performed a comprehensive bio-informatics analysis of clinical CRC genomic data, combined with functional studies using dysadherin-knockout CRC cells, patient tissue samples, and a xenograft mouse model.

Result and discussion

Our analysis revealed that increased tumor acidity is a hallmark of CRC progression and correlates positively with dysadherin expression. Functional studies further demonstrated that dysadherin enhances malignant traits, particularly in an acidic TME. Mechanistically, dysadherin activates the integrin/FAK/STAT3 signaling pathway, leading to the upregulation of carbonic anhydrase 9 (CA9). CA9 helps cancer cells thrive in an acidic TME by maintaining intracellular pH homeostasis, thereby promoting adaptability and resilience. Notably, dysadherin deletion in xenograft models reduced tumor growth, while CA9 reintroduction restored malignancy, underscoring the critical role of the dysadherin/CA9 axis.

Conclusion

Overall, these findings establish dysadherin and CA9 as key drivers of CRC adaptation to an acidic TME and

highlight their potential as therapeutic targets for disrupting tumor progression. This study provides new insights into how tumors exploit acidosis to enhance malignancy, offering avenues for novel therapeutic interventions.

⁵Max Planck Institute for the Science of Light & Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

Introduction

Although metastasis plays a significant role in the majority of deaths related to colon cancer (CC), its molecular mechanisms have not yet been fully deciphered. Cancer cell mechanobiology has greatly expanded our knowledge on cancer progression by linking the cells' mechanical properties to their metastatic potential. As the cancer driver and cell surface glycoprotein TROP2, known to advance invasion and metastasis, has found its way to the clinics as a novel target for antibody-drug-conjugates, we aimed to evaluate its function on cell mechanical properties in CC.

Material and method

Real-time deformability cytometry (RT-DC) and atomic force microscopy (AFM) were used to determine cell stiffness in CC cell lines and patient-derived organoids, chicken chorioallantoic membrane xenografts and human tumors. We modulated TROP2 expression by over-expression and knockout (KO) experiments via CRISPR/Cas9. A combined TROP2 immunoprecipitation (IP)/mass spectrometry approach and proteomics analysis were performed to assess new TROP2 interaction partners. In silico results were validated by Co-IP and proximity ligation assays (PLA). The intracellular localization of TROP2, its binding partners, YAP/TAZ as well as the cytoskeleton architecture were assessed by confocal and super-resolution microscopy. Gene expression of YAP/TAZ target genes upon RNAi approaches and modifications of the cytoskeleton was assessed by RT-qPCR.

Result and discussion

Results and Discussion High levels of TROP2 in colon cancer cell and organoids lines were associated with an increased cell stiffness, while decreasing TROP2 expression resulted in more compliant cells. By TROP2-IP followed by LC/MS based proteomics, ITGB5 and DIAPH1 were identified as novel interaction partners that were further validated by Co-IP and PLA. The triple

complex TROP2-ITGB5-DIAPH1 was only formed in stiff cells and was enriched at the perinuclear region. TROP2 binding to the cytoskeleton regulator DIAPH1 blocked DIAPH1 function followed by F-actin depolymerization and perinuclear microtubule condensation. The perinuclear localization of both the triple complex and condensed microtubules affected nuclear mechanics and YAP/TAZ gene expression. Thus, stiff cells upregulated YAP/TAZ target genes in 2D and 3D models which could be reversed when perturbing cytoskeleton or protein complex dynamics.

Conclusion

Our mechanistic study identified TROP2 as an essential mediator for cell stiffness in CC. We discovered a novel link between TROP2, ITGB5 and DIAPH1 that affects both the cytoskeleton architecture and gene expression. We suggest that stiffness is linked to an enhanced tumor aggressiveness and higher metastatic potential in CC.

Understanding the genetic heterogeneity within clonal spheroids and its interaction with the tumor microenvironment

A. Yadav¹, R. Chaturvedi¹, R. Singh²

¹Jawaharlal Nehru university, School of biotechnology, New Delhi, India

²Jawaharlal nehru university, School of life science, New Delhi, India

Introduction

Head and neck squamous cell carcinomas (HNSCC) exhibit significant inter- and intra-tumor heterogeneity, complicating diagnosis and treatment. Our previous work demonstrated that spheroids developed from patient-derived cells and HNSCC cell lines display distinct proliferative and migratory behaviors. We classified them as hyperproliferative and hypoproliferative spheroids. To uncover the molecular basis of this functional heterogeneity, we utilized single-cell RNA sequencing (scRNA-seq) and advanced computational tools like CellChat. Our analysis revealed key signaling pathways, cellular interactions, and surface markers defining spheroid phenotypes, offering insights into their genetic and functional diversity.

Material and method

scRNA-seq was performed on hyperproliferative and hypoproliferative spheroids derived from the UMSSC-22B cell line. Spheroids were cultured, dissociated into single cells, and subjected to high-throughput scRNA-seq. Bioinformatic analyses identified differentially expressed genes, signaling pathways, and cellular states. CellChat was employed to analyze intercellular communication networks within spheroids. Ligand-receptor interactions were modelled to identify pathways mediating cross-talk between distinct cell clusters.

Result and discussion

scRNA-seq revealed distinct transcriptional profiles between the two spheroids. Hyperproliferative spheroids expressed genes related to cell division and growth, while hypoproliferative spheroids expressed genes linked to migration and invasion. Pathway analysis identified differences in angiogenesis, metastasis, and tumor

microenvironment interactions. Midkine signalling (MDK-SDC) through basal cells was found to be the principal contributor to the proliferative advantage in hyperproliferative spheroids, supporting their role in tumor expansion and progression. While, Desmosomal signaling (DSC2-DSG2) through keratinocytes and fibroblasts was found to play a critical role in maintaining cellular adhesion and promoting migratory capacity in hypoproliferative spheroids. TCGA data linked MDK to advanced tumor stages, poor survival, and therapy resistance, while DSG2 and DSC2 were overexpressed in metastatic tumors. These findings highlight the distinct functional states of spheroids contributing to tumor heterogeneity.

Conclusion

The balance between proliferation and migration in spheroids reflects tumor heterogeneity's dual role in cancer progression. Midkine-driven hyperproliferative spheroids anchor tumor growth, while desmosome-mediated hypoproliferative spheroids drive metastasis. Targeting Midkine or modulating desmosomal remodeling could inhibit growth and prevent dissemination, enabling patient-specific therapies.

EACR25-0635

Insights into tumor-host interactions in high-grade serous ovarian cancer using a 3D model of the tumor ecosystem

M. Hincapié-Otero¹, A. Elomaa¹, J. Jukonen¹, T. Salo², A. Virtanen¹, U. Haltia¹, A. Färkkilä¹

¹University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland

²University of Helsinki, Department of Oral and Maxillofacial Diseases, Helsinki, Finland

Introduction

Drug resistance in high-grade serous ovarian cancer (HGSC) is strongly influenced by the tumor microenvironment (TME). However, conventional 2D models used for drug testing typically include only one or two cell types and lack the three-dimensional architecture needed to capture essential tumor-stroma and extracellular matrix (ECM) interactions, limiting their predictive value. Patient-derived 3D cultures provide a more physiologically relevant platform to study drug responses and identify predictive biomarkers. Here, we present a novel 3D HGSC model incorporating patient-derived cancer cells, tumor-resident immune cells, and cancer-associated fibroblasts (CAFs), embedded in a human omentum-derived ECM, to better recapitulate tumor complexity and improve drug testing approaches.

Material and method

Tissue samples were obtained from patients enrolled in the ONCOSYS-OVA clinical trial (NCT06117384). To optimize the isolation of cancer, immune, and non-immune stromal cells, we tested three enzymatic dissociation methods: (i) dispase, (ii) a collagenase-hyaluronidase (CH) cocktail, and (iii) sequential dispase treatment followed by the cocktail on the remaining tissue. The optimal method, selected based on cell recovery and viability, yielded two fractions: one enriched in cancer and immune cells, and another containing also non-immune stromal cells. The latter was further purified using magnetic-activated cell sorting.

The purified stromal cells were recombined with the cancer and immune cell fraction in a 1:1 ratio, embedded in an omentum-derived ECM, and cultured under serum-free conditions for up to nine days. Model characterization included flow cytometry for phenotyping and functional assessment, and immunofluorescence to evaluate cellular composition and viability. Further cell-type identification and transcriptional profiles will be assessed by scRNA-seq.

Result and discussion

Optimization of the tissue dissociation allowed efficient recovery of key cellular components. The sequential method effectively separated distinct cell populations into two fractions. Dispase treatment improved the recovery of cancer cells while also yielding immune cells with lower stress-response gene expression compared to those isolated with CH alone. Subsequent CH treatment significantly enhanced the recovery of CAFs. After culturing the cells in the 3D model, flow cytometry confirmed that the cellular composition remained stable over time and retained functional characteristics. Immunofluorescence stainings also demonstrated the persistence of key cell populations within the cultures, supporting the model's structural and phenotypic integrity.

Conclusion

We developed a novel 3D model of HGSC that successfully incorporates key components of the HGSC TME, providing a promising platform to study cell-cell interactions and patient-specific drug responses.

EACR25-0650

MLK4 role in the cross-talk between triple-negative breast cancer cells and tumour-associated macrophages

A. Mazan-Bury¹, D. Mehlich¹, K. Karpińska¹, M. Łażiewski², V. Truong¹, P. Jańczak¹, A. Marusiak¹

¹*IMol Polish Academy of Sciences, Laboratory of Molecular OncoSignalling, Warsaw, Poland*

²*National Institute of Public Health NIH - National Research Institute, Department of Bacteriology and Biocontamination Control, Warsaw, Poland*

Introduction

Triple-negative breast cancer (TNBC) accounts for about 10–15% of all breast cancers (BC) and have poor outcomes, where limited therapies have been proposed so far. Previously, our group reported that MLK4 kinase is highly upregulated in the samples of TNBC patients and is correlated with significantly shorter overall survival. Additionally, we showed that MLK4 can activate the NF-κB signalling, promotes mesenchymal phenotype of TNBC cells and regulates DNA damage response. Cancer progression is driven not only by cancer cells but also by tumour microenvironment (TME) cells. The largest group of immune cells in the TME are tumour-associated macrophages (TAMs), reaching up to 50% of a solid tumour mass. For this moment, there are still no studies investigating the role of MLK4 signalling in TNBC-TAMs communication.

Material and method

In this project, we examined the human monocytic cells (THP1) derived M2 macrophages, human monocyte-

derived macrophages (hMDMs) and two TNBC cell lines (SUM149, HCC1806) with inducible MLK4 knock-down. We performed a set of experiments involving the co-culture, colony-formation, migration and invasion assays, RNA sequencing and cytokine array.

Result and discussion

Our results showed that the co-culture of TNBC cells with TAMs-like M2 macrophages increased the proliferation, migration and invasion of TNBC cells. Importantly, the knock-down of MLK4 in TNBC cells significantly reduces these effects. Furthermore, we explored the MLK4-dependent changes in gene expression of TNBC cells stimulated or not by co-culture with M2 macrophages. Gene set enrichment analysis confirmed that genes elevated by MLK4 kinase and TAMs-like M2 macrophages (e.g., WISP1, ADAM12 and MMP28) are fueling epithelial to mesenchymal transition. Moreover, we marked out CXCL1 chemokine as one of the most significantly elevated factors in the medium from co-culture, high-MLK4 environment compared to the monoculture. Next, we performed the phenotypic assays using CXCL1 chemokine to mimic co-culture conditions. Our data showed that CXCL1 did not increase proliferation but significantly fueled the migration of TNBC cells in MLK4-related manner.

Conclusion

Taken together, TAMs-like M2 macrophages promote the proliferation, invasiveness and migratory potential of TNBC cells, and the knock-down of MLK4 in TNBC cells significantly reduces this effect. Importantly, we found genes potentially involved in these processes. We found that the medium from co-culture experiment is enriched with CXCL1 chemokine. Our phenotypic results showed that CXCL1 enhanced the migration of TNBC cells in an MLK4-dependent manner but was not the factor responsible for the increase in the proliferation rate of TNBC in the co-culture. In the near future, we will precisely describe the cross-talk between TNBC and TAMs, regulated by MLK4.

EACR25-0658

Secretomes of IFN-γ-Activated Colon Endothelial Cells Suppress Colorectal Cancer: Molecular Insights and Cell-Biological Effects

Y. Lyu¹, Q. Fang¹, J. Huang¹, M. Mohamed Abdou¹, K. Petter¹, E. Naschberger¹, M. Stürzl¹

¹*Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Division of Molecular and Experimental Surgery, Department of Surgery, Erlangen, Germany*

Introduction

Colorectal cancer (CRC) remains a leading cause of cancer-related deaths worldwide. Its progression is heavily influenced by the tumor microenvironment (TME). While angiogenesis is often associated with tumor growth and metastasis, tumor-associated blood vessels can also exert anti-tumor effects by secreting proteins, such as thrombospondin and SPARCL1, which inhibit tumor progression independently of blood flow. A Th1-dominated, IFN-γ-rich TME correlates with

improved patient prognosis in CRC. Here, we explore the molecular composition and functional impact of secretomes derived from IFN- γ -stimulated human intestinal endothelial cells (HIEC) on CRC cells.

Material and method

HIEC isolated from healthy colon tissues and dermal microvascular endothelial cells (MVEC) were treated with IFN- γ (10 U/mL) for 48 hours. Conditioned media (CM) were collected and analyzed using comparative hyper reaction monitoring mass spectrometry (HRM™ MS). The biological effects of these secretomes on CRC cell migration and proliferation were assessed using IFN- γ -resistant CRC cell lines (DLD-1, SW480) to exclude direct IFN- γ effects. Protein secretion profiles were validated via Western blot, while endothelial expression in CRC tissues was examined through immunohistochemical double staining (CD31/candidate proteins).

Result and discussion

Secretomes from IFN- γ -treated endothelial cells significantly reduced CRC cell proliferation and migration compared to untreated controls. Mass spectrometry analysis identified 1,084 proteins in the HIEC-CM, with 43 proteins showing significantly altered concentrations upon IFN- γ stimulation. Western blot confirmed the presence of the eight major differentially expressed proteins, while immunohistochemistry reconfirmed their endothelial expression in CRC tissues. These findings suggest that IFN- γ -activated endothelial cells secrete factors that may suppress tumor progression.

Conclusion

Endothelial secretomes play a pivotal role in shaping the TME, with IFN- γ -induced factors demonstrating potential anti-tumorigenic properties in CRC. Our study identifies novel angiocrine candidates with potential therapeutic implications, warranting further investigation into their functional roles in CRC suppression.

EACR25-0663

In vitro models to mimic tumor endothelial cell-mediated immune cell reprogramming in lung adenocarcinoma

E. Navarro¹, M. Krejbich¹, J. Fresquet¹, C. Chatelain¹, M. Cotinat¹, N. Boisgerault¹, I. Corre¹, C. Blanquart¹, L. Treps¹

¹CRCI2NA, Nantes Université, Nantes, France

Introduction

Responsible for an estimated 1.8 million deaths per year, lung cancer is one of the leading causes of cancer incidence and mortality worldwide, with non-small-cell lung cancers (NSCLC) accounting for 80-85% of cases. Over the past decade, immunotherapies have revolutionized patient outcome but still 60% of the patients remain in therapeutic failure. The tumor micro-environment (TME) is an important parameter mediating such resistance. Particularly, within the TME normal endothelial cells (NECs) are educated into tumor endothelial cells (TECs) and display deregulated immunoregulatory features with therapeutic relevance. However, the precise immuno-regulatory functions of NECs/TECs remain largely unknown and warrant further investigation.

Material and method

In this study we established various in vitro coculture models to unravel how tumor cells could remodel NECs into TECs, and how their remodeling impacts the immune system. As such, we combined multi-omics approaches including single-cell RNA sequencing (scRNA-seq), meta-analysis and various functional assays to dissect the immunoregulatory functions of NECs/TECs.

Result and discussion

We showed that coculturing ECs with various NSCLC cell lines induced profound alterations at the transcriptomic, proteomic and kinomic levels with the induction of pro-inflammatory pathways that reflect their activation state. Despite a limited impact of NSCLC-TECs on CD8 T lymphocytes proliferation and activation, we showed that CD4 T cells differentiate into various immunosuppressive subsets (Treg, Th22, and Th2) when cocultured with NSCLC-TECs. We also discovered that ECs could enhance the expression of M2-like markers on cocultured macrophages. For the first time, we brought to light that OX40L could play a role in the immunoregulatory function of TECs, where it appears downregulated as compared to NECs. In the seek to improve our 2D coculture system, we scrutinized at the single cell resolution, 3D multicellular tumor spheroids (MCTS) encompassing tumor cells, ECs, fibroblasts and monocyte-derived macrophages. We showed that cell heterogeneity was much more complex than 2D cultures, with several cell states identified. Particularly, 3 sub-clusters of MCTS-ECs were distinguished, among which the inflammatory subcluster that was absent from standard 2D culture but present in freshly-isolated ECs from NSCLC biopsies. Finally, MCTS presented various macrophage and fibroblast states that have particular therapeutic importance with regard to their interactions with the vascular compartment.

Conclusion

We established various 2D/3D culture models that allow to better delineate the precise function of TECs within the TME, and how they could modulate tumor immunity.

Introduction

The field of cancer neuroscience has recently highlighted the complex dialogues between cancer and nervous system components, emphasizing the pivotal roles of the nervous system in tumor initiation, growth, and invasion. Specifically, brain tumors have been shown to integrate into bona fide neuron-to-cancer synaptic networks while

also capturing neural activity-dependent factors that shape their tumor properties. This has opened up new therapeutic opportunities, particularly in the pediatric population, where nervous system tumors are among the most frequent. However, knowledge of neuro-cancer crosstalk in the peripheral nervous system (PNS) remains fragmented, especially in malignancies arising within peripheral nervous tissues. Neuroblastoma (NB) is a hallmark and deadly pediatric cancer of the PNS, with primary tumors arising in sympathetic ganglia or the adrenal gland. Despite its anatomical localization and its neural crest origin, it remains completely unknown whether neural activity impacts NB tumor characteristics and metastatic progression.

Material and method

To assess the crosstalk between the developing PNS and NB, we develop innovative methodologies that associate neuroscience paradigms and *in vivo* models of NB within its embryonic environment. We conduct electrophysiology experiments combined with optogenetic and chemogenetic approaches to assess the functionality of the identified interactions and integrate them with omics methodologies at single-cell and spatial scales.

Result and discussion

We have documented the presence of neuro-NB synaptic contacts both in patient biopsies and in our *in vivo* models, along with a reorganization of the innervation pattern in the presence of NB tumors. We have shown that a subset of NB cells in primary tumors depolarize in response to electrical stimulation of tumor-invading nerve fibers, and characterize the pharmacology of this neurotransmission. We investigate the impact of nervous activity on the composition of the tumor microenvironment and its subsequent effects on NB tumor and metastatic properties. Both direct (synaptic) and indirect (paracrine) neural activity-dependent effects on NB are being explored. Together, our data from patient samples and functional experiments suggest that NB tumor and metastatic properties are actively shaped by, and evolve in parallel with, the developing peripheral nervous system, further supporting the idea of specific neural vulnerabilities in early childhood tumors.

Conclusion

Ultimately, our goal is to identify a neuro-responsive class of NB tumors that may benefit from novel therapeutic strategies targeting the neuro-cancer axis.

³*University of Toronto, Department of Chemical Engineering and Applied Chemistry, Toronto, Canada*

⁴*University of Toronto, Institute of Biomedical Engineering, Toronto, Canada*

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive type of pancreatic cancer characterized by a dense stromal compartment and abundant presence of fibroblasts and macrophages. Preclinical studies have shown that these stromal cells play a critical role in tumour progression, including mediating paracrine chemoprotective effects on gemcitabine treatment. Recent clinical data suggest that the spatial arrangement of these stromal cells within the tumour microenvironment impacts their phenotypes, functions, and tumour behaviour, influencing patient outcomes. However, studying the mechanistic contribution of these spatial phenotypes to chemoresistance remains challenging due to a lack of suitable models. To address this, we have developed fully human 3D tumour niches that replicate stromal spatial heterogeneity, enabling the study of paracrine effects on gemcitabine response in PDAC.

Material and method

We utilize pancreatic stellate cells (PSCs) and peripheral blood monocyte-derived macrophages as stromal components. These cells are co-cultured with whole PDAC patient-derived organoids (PDOs) to model direct interactions with cancer cells. Paracrine interactions are modelled by culturing PSC and macrophage monocultures or co-cultures in a PDO-conditioned medium. All cells are embedded in a collagen-based matrix and seeded as microgels in our GLAnCE (Gels for Live Analysis of Compartmentalized Environments) platform. The platform supports imaging assays and single-cell extraction for downstream analysis, enabling cell phenotypic characterization within established niches. We apply the niches for medium conditioning and then screen secreted factors in the presence of gemcitabine to assess the niche impact on PDO viability.

Result and discussion

The established niches reflect key characteristics of PDAC tumours. PDOs show varying growth and epithelial marker expression levels depending on the presence of PSCs and macrophages. Macrophage presence and direct or indirect contact with organoids influence PSC proliferation and activation. Macrophage phenotypes range from inflammatory (CD86+ CD206-) to immunoregulatory (CD206+ CD163+), shaped by their interactions with organoids and fibroblasts, respectively. Screening viability data show that niche-conditioned media protect PDOs from gemcitabine toxicity to varying extents, with the most substantial chemoprotective effects observed for niches maintained in PDO-conditioned medium.

Conclusion

Our novel 3D tumour niches capture spatial stromal-cancer cell interactions and more clinically relevant stromal phenotypes. We anticipate that screening niche-conditioned media with gemcitabine, followed by omic profiling and hit validation, will elucidate how distinct fibroblast and macrophage populations mediate gemcitabine resistance, offering new opportunities for stromal-targeted therapies to overcome chemoresistance in PDAC treatment.

Introduction

In lung cancer, Spread Through Air Spaces (STAS) corresponds to the presence of cancer cells, either isolated or in small clusters, within the lung airways beyond the boundaries of the tumor. In human lung adenocarcinoma (LUAD), the detection of STAS is associated with local recurrence, poor prognosis and architecture patterns. However, the mechanisms underlying this dissemination remain unknown and controversial. Since STAS may represent a mode of tumor growth and contribute to the formation of secondary tumors, understanding its biology is crucial. We hypothesize that STAS results from an alteration in cellular interactions and signaling within the tumor microenvironment (TME). Our objective is to identify tumor microenvironmental and transcriptomic features associated with STAS.

Material and method

A cohort comprising 246 STAS-negative (STAS(-)) and 152 STAS-positive (STAS(+)) tumors was analyzed. Tissue microarrays were constructed and the TME was characterized using a 35-antibody panel including immune, stromal, and tumor markers, on the Hyperion mass cytometry imaging platform (Fluidigm). Following cell type identification, cellular interaction parameters (cellular neighborhoods (CNs)) were evaluated. We then used regression analysis to compare the frequencies of each cell type, CN, and interaction probabilities between the two groups. In parallel, tumor mRNA from 487 patients (including 261 STAS(-) and 226 STAS(+)) was sequenced. Gene set enrichment analyses (GSEA) were conducted to compare the expression of canonical signaling pathways between the groups.

Result and discussion

We observed an increased frequency of tumor cells in STAS(+) tumors. The CN analysis indicated a higher occurrence of cell clusters involving tumor cells, endothelial cells, and fibroblasts and a decreased frequency of clusters of neutrophils. GSEA indicates alterations in specific signaling pathways suggesting potential extracellular matrix alterations. These results highlight a distinct TME and cellular signaling profile in STAS(+) LUAD, offering new insights into the role of the TME in the biology and clinical progression of this cancer.

Conclusion

Since STAS represents a form of tumor dissemination, identifying the cellular and molecular characteristics

associated with STAS will enhance our understanding of the biological mechanisms underlying tumor spread in LUAD.

Introduction

Tumor cells are in constant dynamic communication with each other and with their microenvironment. We have previously shown that tumor cells dying during therapy can secrete various spliceosome proteins into the extracellular space, which can be taken up by recipient tumor cells and, thereby, promote their survival, increasing their resistance to subsequent treatment. However, the specific molecular mechanisms of this type of intercellular communication remain unclear. By virtue of their nature, many spliceosome proteins are able to bind to different classes of proteins and nucleic acids. A growing body of evidence suggests that spliceosome proteins can influence a variety of cellular processes in a splicing-independent manner, for example, by binding to chromatin in promoter regions, controlling mRNA export from the nucleus, maintaining genome stability, and participating in DNA repair. A striking example of such multitasking is the SYNCRIPI protein, which in addition to its function in pre-mRNA splicing, is involved in almost all aspects of mRNA metabolism, plays a key role in the biogenesis of RNA-containing extracellular vesicles, and, according to our proteomic data, is an important component of secretomes from dying cancer cells.

Material and method

We conducted a comprehensive analysis of the responses of SKOV3 ovarian adenocarcinoma cells with SYNCRIPI knockdown or overexpression when exposed to cisplatin, which included proteomic and transcriptomic analyses supplemented by investigations of changes in protein-protein (IP-MS) and RNA-protein interactomes (CLIP-seq, poly(A)-tail-seq) of SYNCRIPI under the same experimental conditions.

Result and discussion

Our findings revealed that SYNCRIPI knockdown leads to significant alterations in the polyadenylation pattern of mRNA molecules in SKOV3 cells. Specifically, we observed a shortening of the poly(A) tails of mRNAs associated with DNA repair (PRIMPOL, POLL, PARP3) and an elongation of the poly(A) tails of transcripts that

negatively regulate cell cycle progression (CDK11A, CDKN1A, CDK19). Furthermore, for several SYNCRIP target mRNAs, we demonstrated that their binding to SYNCRIP correlated with an increase in the abundance of the corresponding proteins (e.g., FANCI). We hypothesize that this association may enhance the mRNA stability or efficiency of mRNA translation. Intriguingly, in response to cisplatin, we found an increase in the binding of SYNCRIP to proteins such as RFC5, TRIM25, and USP10 which facilitate translesion DNA synthesis and cell division, as well as MRPL39 involved in mitochondrial translation; and TOP3B, TDRD3 (components of stress granules).

Conclusion

These mechanisms may play a crucial role in enabling tumor cell survival in the presence of chemotherapeutic agents, particularly for cells that receive extracellular vesicles containing the SYNCRIP protein.

BRCA1 mutations in high-grade serous ovarian cancer affect stromal phenotypes in the tumor microenvironment

H. Lavon¹, Y. Stein¹, R. Scherz-Shouval¹

¹Weizmann Institute of Science, Biomolecular sciences, Rehovot, Israel

Introduction

Tumors are complex ecosystems where cancer cells depend on the recruitment and reprogramming of normal cells to support their survival and progression. Cancer-associated fibroblasts (CAFs) are key players in this process, creating a supportive microenvironment for cancer cells. Recent advances in Single-cell RNA sequencing (scRNAseq) have revealed that CAFs are heterogeneous, arising from multiple mesenchymal origins and exhibiting diverse phenotypes, which could be broadly divided to subsets of myofibroblastic CAFs (myCAF), immune-regulatory CAFs (iCAF), and antigen-presenting CAFs (apCAF). High-grade serous ovarian cancer (HGSOC) is the most lethal gynecological malignancy, with a 5-year survival rate of less than 30% for patients diagnosed at stages III-IV. BRCA1/2 germline mutations increase the risk of ovarian cancer, and over 40% of HGSOC tumors show BRCA1/2 suppression. Studies from our lab and others suggest that BRCA1/2 mutations in pancreatic and breast cancers can alter the tumor microenvironment (TME) by increasing the proportion of iCAF at the expense of myCAF. However, the mechanisms underlying these changes in the TME remain unclear.

Material and method

In this study, we aimed to characterize the TME of BRCA1/2 wild-type (WT) and mutant HGSOC and to explore the mechanisms by which BRCA1/2 mutations induce phenotypic alterations in the TME. To achieve this, we analyzed published scRNAseq data as well as performed multiplex immunofluorescence (MxIF) and histochemical staining on a cohort of HGSOC patient samples. Furthermore, to investigate the mechanisms

underlying these stromal changes, we examined HGSOC BRCA1 mutant and WT cell lines metabolic signaling.

Result and discussion

Analysis of pentachrome and MxIF staining showed that BRCA1/2 WT tumors were enriched in fibrillar extracellular matrix components compared to BRCA1/2 mutant tumors. Furthermore, BRCA1 mutant tumors had higher levels of iCAF and mesothelial cells compared to BRCA1 WT tumors. Similarly, analysis of published scRNAseq data revealed increased levels of mesothelial and steady-state fibroblasts in BRCA1 mutant tumors compared to BRCA1/2 WT. Testing metabolic activity of BRCA1 WT and mutant HGSOC cancer cell lines in-vitro showed higher levels of glycolysis and increased lactate secretion in BRCA1 mutant cells compared to BRCA1 WT cells. scRNAseq data analysis of the non-immune TME of HGSOC showed that mesothelial cells and steady-state fibroblasts – the stromal subpopulations enriched in BRCA1 mutant tumors – upregulated MCT1, a lactate influx transporter, at higher levels than other stromal subpopulations.

Conclusion

Taken together, these findings suggest a possible cross-talk between BRCA1 mutant cancer cells and specific subpopulations of the non-immune TME, leading to distinct TME compositions driven by altered glucose metabolism in BRCA1 mutant cancer cells in HGSOC.

²Agora Cancer Research Center, Lausanne, Switzerland

³Swiss Institute of Bioinformatics (SIB), Lausanne, Switzerland

⁴Lund University Cancer Centre, Lund, Sweden

⁵Ludwig Institute for Cancer Research, Lausanne Branch, Lausanne, Switzerland

Introduction

Fragile X mental retardation protein (FMRP) has been extensively studied in neuronal development, but its role in cancer biology remains underexplored. Our recent findings (Zeng et al., 2022) demonstrated that elevated FMRP levels in cancer cells promote immune evasion in murine and human tumors. We further investigated whether FMRP plays a role in the stromal compartment. Single-cell RNA sequencing analysis of pancreatic ductal adenocarcinoma (PDAC) tumors identified cancer-associated fibroblasts (CAF) as the primary stromal cell subtype expressing FMRP. Since CAFs are pivotal in tumor progression and therapeutic resistance, we examined whether FMRP expression contributes to CAF-driven immunosuppression in PDAC and breast tumors.

Material and method

To assess FMRP-expressing CAFs, we performed scRNA-seq on murine PDAC tumors and validated

findings in breast tumors. FMRP knockdown and overexpression experiments were conducted in CAFs and naïve fibroblasts to determine phenotypic and functional changes. The impact of FMRP on CAF-mediated immunosuppression was assessed using immune profiling assays and gene expression analyses, focusing on inflammatory CAF (iCAF) and myofibroblastic CAF (myCAF) signatures. To evaluate *in vivo* relevance, we used an orthotopic tumor model in *Fmr1* full-body knockout (KO) mice. Additionally, bulk RNA sequencing was performed to derive an FMRP-associated CAF gene signature, which was applied to human PDAC and breast cancer datasets.

Result and discussion

Our analyses revealed elevated FMRP expression in CAFs from PDAC and breast tumors, whereas it was absent in naïve fibroblasts from healthy tissues. FMRP knockdown in CAFs diminished their immuno-suppressive properties, whereas FMRP overexpression in naïve fibroblasts was sufficient to induce a CAF-like phenotype. Mechanistically, FMRP overexpression led to increased iCAF and myCAF signatures, suggesting its role as a pan-CAF regulator influencing extracellular matrix (ECM) remodeling and the secretory phenotype. *In vivo*, tumors orthotopically implanted in *Fmr1*-KO mice exhibited significantly reduced growth, underscoring the role of FMRP-expressing CAFs in tumor progression. Furthermore, loss of stromal FMRP conferred a substantial survival benefit. Analysis of human datasets revealed that the FMRP-CAF signature was enriched in CAFs from PDAC and breast cancer patients and negatively correlated with immune cell infiltration. Notably, a high FMRP-CAF signature strongly predicted poorer overall prognosis in breast cancer patients, reinforcing its clinical significance.

Conclusion

Our findings establish FMRP as a key regulator of CAF function, linking its expression to tumor progression and immune evasion. Identifying FMRP as a pan-CAF regulator highlights its potential as a novel therapeutic target in cancer treatment. Targeting FMRP in CAFs may enhance immune infiltration and improve patient outcomes in PDAC and breast cancer.

EACR25-0769

Analysis of cellular plasticity of DTPs induced by chemotherapy in triple negative breast cancer

A. Horochowska¹, F. Woesteland¹, E. Fontaine¹, X. Le Bourhis¹, F. Anquez², C. Lagadec¹

¹UMR9020 – UMR1277 – Canther – Cancer Heterogeneity, Plasticity and Resistance to Therapies, LILLE, France

²UMR 8523 - PhLAM - Physique des Lasers Atomes et Molécules, Villeneuve-D'Ascq, France

Introduction

Recent studies have revealed the existence of “Drug Tolerant Persisters” (DTP), cancer cells capable of surviving chemotherapies and reconstituting a sensitive tumor after a period of tumor dormancy. Although initial descriptions of DTP have already been made, the processes of transition into and out of this phenotype are poorly understood. The aims of this study are to elucidate

the transcriptional mechanisms associated with these transitions, identify potential markers and exploitable vulnerabilities, and thus improve the prognosis and therapeutic strategies of patients with triple-negative breast cancer (TNBC).

Material and method

We establish two models of DTP from two TNBC cell lines (MDA-MB-231 and SUM159PT) treated with a high-dose chemotherapy (gemcitabine). To characterize the heterogeneity of the temporalities of interest (entry, maintenance, and exit of the DTP phenotype), we monitor the proliferation, dormancy, and death state of cells from the start of treatment until their return to a control phenotype (20 days), using an ultra-wide field imaging system allowing high throughput at the single-cell scale. In parallel, using scRNA-seq, we analyze the evolution of the transcriptomic profiles over time. We combine the identification of the dynamics of the clusters of interest with timelapse imaging analyses to reveal the transcriptional changes that initiate the conversion of cells to DTP, maintain this phenotype, as well as those that promote the exit of the DTP phenotype with the resumption of growth.

Result and discussion

With our models, while 7.5% of cells survive after one week of treatment, only 0.3% of cells can resume growth and generate colonies. Moreover, if we challenge the cells a 2nd time after one month of drug holiday, the cells are still sensitive to the chemotherapy. Through the scRNA-seq, data are being analyzed to identify specific markers. On the one hand, we observed radical changes in the transcriptomic profiles of the DTP population, and on the other, we observed that the proliferating DTP-derived population at day 20 had transcriptomic profiles similar to those of the untreated population, as predicted by the DTP model. Also, cells under the 1st and 2nd rounds of chemotherapy have the same transcriptomic profiles. Furthermore, in correlation with the literature, we observed that in response to the chemotherapy, the cells express transiently a higher diapause and stem cell phenotype signature, which might be involved in the entry in the DTP phenotype.

Conclusion

These mechanisms will be validated by imaging with expression reporters, complemented by pharmaceutical targeting. This project will characterize the transcriptional mechanisms underlying the phenotypic switches associated with phenotype entry and exit to identify vulnerabilities.

Mimicking liver inflammation to identify essential genes in hepatocellular carcinoma: Towards a CRISPR screen based on IL-6/STAT3 signaling

A. Krumme¹, T. Huth¹, E. Eiteneuer¹, A. Inal¹, M. Kaulich², S. Roessler¹

¹Heidelberg University Hospital, Institute of Pathology, Heidelberg, Germany

²Goethe University Frankfurt, Institute of Biochemistry II, Medical Faculty, Frankfurt, Germany

Introduction

Hepatocellular carcinoma (HCC), the predominant form of liver cancer, is a leading cause of cancer-related mortality worldwide. Inflammation plays a critical role in HCC progression, with the interleukin-6 (IL-6)/STAT3 signaling pathway being hyperactivated in HCC. Loss of heterozygosity (LoH) of the short arm of chromosome 8 (chr8p), is a crucial factor in HCC pathogenesis and chr8p loss correlates with increased mortality in patients possibly due to altered IL-6 signaling. CRISPR screens involving inflammation are just starting to emerge. Here, we aim to establish a screen delineating essential genes in regards to IL-6 in liver cancer.

Material and method

This study performed a genome-wide CRISPR/Cas9 knockout (KO) screen to identify genes that are essential in HCC under inflammatory conditions uncovering vulnerabilities for possible treatment. HCC cell lines were analyzed for their IL-6 responsiveness and STAT3 phosphorylation by Western blot and analysis of target gene expression by qRT-PCR. Cells were infected with the genome-wide Alexandria sgRNA CRISPR library and treated with IL-6 to activate IL-6/STAT3 signaling, mimicking liver inflammation.

Result and discussion

The HCC cell line HuH7 was selected due to its responsiveness to IL-6 and efficient activation of STAT3 by phosphorylation. HuH7 cells which have chr8p LoH were successfully infected with a Cas9-blast vector for stable Cas9 integration. Additionally, an IL-6 over-expressing cell line was established to secrete the cytokine into the medium, which was then used to activate the IL-6/STAT3 pathway in HuH7-Cas9 cells. Furthermore, the CRISPR/Cas9 screen will be performed in isogenic HCC cells with chr8p wildtype or loss of heterozygosity (LoH) of chr8p to dissect potential differences in HCC subgroups with or without chr8p deletion.

Conclusion

This research has the potential to identify clinical markers and drug targets for diagnosing and treating HCC patients, particularly those with inflammation-driven tumors with chr8p LoH. By elucidating gene essentialities in the context of IL-6 signaling, this study may contribute to the development of targeted therapies for HCC.

EACR25-0783

The role of prematurely drug-induced senescent peritoneal cell exosomes in the awakening and progression of dormant ovarian cancer cells

S. Rutecki¹, A. Leśniewska-Bocianowska¹, A. Krawiec¹, J. Matuszewska¹, J. Mikula-Pietrasik¹, K. Książek¹

¹*Poznań University of Medical Sciences, Department of Pathophysiology of Ageing and Civilization Diseases, Poznań, Poland*

Introduction

The mechanisms behind the relapse of epithelial ovarian cancer (EOC) remain unclear. In this project, we aim to investigate the hypothesis that EOC relapse may be induced by the presence of peritoneal mesothelial cells

(PMCs) and fibroblasts (PFBs) which entered senescence due to exposure to carboplatin and paclitaxel.

Specifically, we propose that the relapse of EOC is driven by exosomes secreted by senescent PMCs and/or PFBs, which have the ability to activate dormant EOC.

Material and method

Experiments were conducted using PMCs and PFBs isolated from the omentum of non-oncologic patients. The study also utilized EOC cells, including primary high-grade serous EOC and three commercial cell lines: A2780, OVCAR-3, and SKOV-3. To induce senescence, PMCs were exposed to 50 μM carboplatin and 25 nM paclitaxel, while PFBs were treated with 25 μM carboplatin and 10 nM paclitaxel. Exosomes were isolated from the conditioned medium through precipitation and quantified by flow cytometry, based on the expression of specific markers: CD9, CD63, and CD81. The size and morphology of the exosomes were assessed using SEM. The induction and termination of EOC cell dormancy were achieved through sequential serum withdrawal and reintroduction. Additionally, the expression of exosomal microRNA was quantified using qPCR, while the concentration of exosomal proteins was measured with a Human custom array.

Result and discussion

PMCs and PFBs that experienced senescence triggered by the combination of carboplatin and paclitaxel generate considerably more exosomes than untreated cells. Notably, the exosomes released by senescent cells have a greater capacity to activate dormant cancer cells. This activation is evidenced by an increased expression of the proliferation marker Ki67 and a higher proportion of cells entering the S phase of the cell cycle. The ability of exosomes to awaken dormant cancer cells surpasses the effects of soluble proteins secreted to the environment. Analysis of the exosomal cargo, which mediates their biological effects, revealed that exosomes from senescent cells exhibit down-regulation of certain microRNAs: miR-210-3p, miR-409-3p, and miR-421. Additionally, proteomic analysis showed that exosomes derived from senescent PMCs are enriched in proteins such as bFGF, HGF, MMP-1, MMP-3, TIMP-1, and VEGF. In contrast, exosomes from senescent PFBs contain higher levels of amphiregulin, eotaxin-1, MCP-1, CXCL5, SDF-1α, IL-6R, osteopontin, and TGF-β1. Ongoing research aims to further investigate the progression of these awakened cells in both 2D and 3D culture models, along with their molecular and genetic characteristics.

Conclusion

Exosomes produced by drug-inducible senescent normal peritoneal cells may drive the awakening of dormant cancer cells, potentially contributing to cancer relapse.

The study was supported by a grant from the National Science Centre, Poland (2020/37/B/NZ5/00100).

³University of Eastern Finland, School of Medicine, Institute of Clinical Medicine, Oncology, and Cancer Center of Eastern Finland, Kuopio, Finland

⁴Kuopio University Hospital, Cancer Center, Kuopio, Finland

⁵Kuopio University Hospital, Biobank of Eastern Finland, Kuopio, Finland

⁶University of Eastern Finland, Genome Center of Eastern Finland, Institute of Clinical Medicine, School of Medicine, Kuopio, Finland

Introduction

The discovery of novel biomarkers for earlier diagnosis and better therapy response remains a major focus in cancer research. Small non-coding RNAs such as small nucleolar RNAs (snoRNAs) have recently emerged as promising biomarkers and potential therapeutic targets for various cancer types including breast cancer.

However, additional research with larger sample sizes and high-throughput methods is essential to fully establish their possible role in breast tumorigenesis.

Material and method

We have performed small RNA sequencing in 195 fresh-frozen tumor samples from patients with invasive BC from the Eastern Finnish Kuopio Breast Cancer Project to evaluate the predictive potential of snoRNAs in invasive local breast cancer. Total RNA was extracted from fresh-frozen tissues using the Ambion mirVana miRNA Isolation Kit, followed by processing with the Illumina TruSeq Library Prep Kit and sequencing. The bio-informatic analysis involved assessing read quality, trimming adapters, removing reads aligning to e.g. rRNAs, and aligning the data to the human reference sncRNA transcriptome. The univariate and multivariable survival analyses were conducted using the Cox's proportional hazards model in R. The multivariable analyses calculated hazard ratios and confidence intervals for death (either breast cancer-specific or overall survival) or recurrence. Adjuvant chemotherapy (yes/no), adjuvant endocrine therapy (yes/no), and clinical data were included in the analyses as covariates.

Result and discussion

In invasive local breast cancer cases who underwent radiotherapy, significant associations between 15 snoRNAs and patient outcome were identified, indicating that these snoRNAs may serve as predictors of radiotherapy response. Poorer outcome was observed with the radiotherapy-treated cases with higher expression of eight snoRNAs, whereas the increased expression of seven snoRNAs associated with better outcome. For example, increased SNORD60 expression associated with poorer overall survival and increased SNORD67 level with better breast cancer-specific survival in radiotherapy-treated cases. The identified candidate snoRNAs could help elucidate the mechanisms underlying resistance to RT, and the following further validation of their biological importance may lead to the discovery of novel therapeutic targets.

Conclusion

Our findings suggest that snoRNAs may serve as potential predictive biomarkers for radiotherapy response in invasive local breast cancer, and further validation of these candidates could pave the way for novel therapeutic targets in precision medicine.

EACR25-0813

Identifying transcript variants associated with colon cancer: a comparative analysis of 3D spheroid cultures and patient-derived tissues

J. Despotović¹, T. Babić¹, B. Banović Deri¹, J. Karanović¹, S. Dragičević¹, D. Pavlović¹, A. Nikolić¹

¹Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia

Introduction

Colon cancer remains one of the leading causes of cancer-related deaths worldwide, necessitating a deeper understanding of the molecular factors contributing to its development. By exploring the transcriptomic landscape of colon cancer cell lines and patient-derived tissues, this study aspires to uncover novel biomarkers and potential therapeutic targets for improving colon cancer diagnosis and treatment.

Material and method

The SW620, HCT116 and DLD-1 colon cancer cell lines and immortalized cells derived from healthy gut mucosa HCEC-1CT were cultivated in 3D as spheroids and analyzed by RNA sequencing using Illumina's NovaSeq 6000 platform. Our transcriptomic data were compared with the results of previously published comprehensive transcriptomic study based on 473 patient-derived tumor and 417 non-tumor tissues.

Result and discussion

Comparison of the transcriptomic results obtained for cell lines grown as spheroids with the results of the RNA sequencing data for patient-derived tissues was conducted for 375 transcripts identified by the previously published study as significantly differentially expressed in colon cancer (39 overexpressed and 336 under-expressed). Among these, 32 transcripts were identified with expression patterns in colon cell lines corresponding to the expression patterns observed in patient-derived tissues (4 overexpressed and 28 under expressed). Most prominently deregulated transcripts among those with corresponding deregulated expression patterns in colon cell lines and patient-derived tumors were NTMT1-204 (overexpressed in cancer) and DCTN1-205 (under-expressed in cancer). For other 343 transcripts, matching deregulation pattern observed in patient-derived tissues was not confirmed in colon cell lines and their expression patterns in stromal cell types should be further investigated.

Conclusion

Overall, comparison of RNA sequencing data between colon cell lines grown as spheroids and patient-derived tissues revealed a set of 32 transcripts that may be relevant for colon carcinogenesis and their role in gut epithelial cells should be further explored. Additionally, NTMT1-204 transcript could potentially be used as diagnostic marker for colon cancer, and DCTN1-205 as a potential therapeutical agent.

EACR25-0824**The impact of CFTR impairment on endothelial cell and its role during tumor progression**M. Cotinat¹, M. Le Claire¹, I. Corre¹, L. Trep¹¹CRCI2NA, Nantes, France**Introduction**

Affecting more than 100,000 people worldwide, cystic fibrosis (CF) is caused by pathogenic variants of the CFTR gene. This debilitating disease affects a broad spectrum of organs but thanks to latest therapeutic advances with CFTR modulators, patient life expectancy now exceeds 40 years, hence transforming CF into a chronic disease of adulthood. Unfortunately, while ageing, patients with CF develop comorbidities including cardiovascular diseases, diabetes and cancer. The increased risk of developing cancer is likely multifactorial but could relate to the persistent pro-inflammatory state seen in patients with CF. Indeed, it is estimated that 25% of cancers worldwide are associated with infection and chronic inflammation. And chronic endothelial inflammation is implicated in pathologies leading to the development of cancer (e.g. obesity, diabetes, chronic inflammation of the intestine). However, the precise mechanism linking CFTR defect, the vascular compartment, and cancer onset is not fully understood.

Material and method

In this study we combined in vitro, in vivo and scRNA-seq approaches to study the endothelium features after CFTR impairment. Particularly, we treated a normal model of endothelial cells (ECs) with a specific CFTR inhibitor to unravel, how CFTR loss impacts cancer cell invasion and immune cell trafficking. The effect of CFTR inhibition was also assessed in ovo using the chorioallantoic membrane (CAM) assay in chicken eggs combined with in situ imaging. Moreover, we investigated the vascular compartment of CF lung explant at the single cell level to have a glimpse into disease progression. Finally, we developed and characterize a unique mouse model of conditional and restricted CFTR invalidation in the vascular compartment (CFTR EC KO).

Result and discussion

We showed that CFTR impairment directly dampen ECs and lung cancer cell migration. Interestingly, we present that CFTR-deficiency altered the endothelial barrier property, thereby increasing cancer cell migration and invasion and thus contributes to tumor progression. We have evidence that the endothelial-to-mesenchymal transition (EndMT) could be involved in this phenomenon. Moreover, our scRNA-seq data from CF lung explant revealed an endothelial state characterized by an exacerbated pro-inflammatory phenotype, which was absent in normal lung tissues. Hence, mirroring our recent data obtained in liver explants from CF patients. Finally, our first results in CFTR EC KO mouse model indicate vascular defects compared to control animals, which could have relevance for tumor onset.

Conclusion

The link between CFTR and cancer risk is clear, but the roles of CFTR during tumorigenesis and the involvement

of ECs in this phenomenon are not yet well defined. In this study we have started to explore the mechanism by which endothelial CFTR-impairment could contribute to tumor progression via various mechanisms linked to endothelial plasticity and inflammation.

EACR25-0837**The CMS4 marker HTR2B serotonin receptor is critical in colorectal cancer cell invasion**I. Carmi¹, A. Orosz¹, S. Hajdó¹, A. Zeöld¹, T. Tölgyes², Z. Wiener¹¹Semmelweis University, Genetics, Cell- and Immunobiology, Budapest, Hungary²Uzsoki Teaching Hospital, Oncosurgery, Budapest, Hungary**Introduction**

Colorectal cancer (CRC) is one of the most frequent cancer types. Patient-derived organoids (PDO) maintain the intratumoral heterogeneity, representing a modern tool to study human cancers. The gene expression-based CRC classification identified a cluster of patients (CMS4) with epithelial-mesenchymal transition (EMT), the accumulation of fibroblasts, and a dismal prognosis. Of note, NOTCH3 activation drives cancer progression in a model of mesenchymal CRC. For CRC, the accumulation of collagen-I in the extracellular matrix (ECM) correlates with an adverse prognosis. Although the serotonin receptor HTR2B is one of the epithelial markers of this CMS4 subgroup, its precise role in CRC tumorigenesis is not yet well known.

Material and method

PDOs were isolated from CRC patients, and they were cultured with or without fibroblasts under different conditions. For specific experiments, cells were sorted into high and low-expressing populations for HTR2B and NOTCH3. Cell viability was determined with a luminescence assay, while survival and proliferative potential were determined with flow cytometry (FC). Confocal and light microscopic image analysis were used to quantify changes in invasive potential and EMT. CMS4 and EMT marker expression were additionally quantified using RT-qPCR and FC.

Result and discussion

HTR2B, under the control of the mTOR pathway, is expressed heterogeneously intra- and inter-tumorally. Unfavorable conditions, co-culturing with fibroblasts, and collagen-I accumulation in the ECM increased the number of HTR2B-positive tumor cells. Interestingly, whereas serotonin or an HTR2B agonist did not affect PDOs under normal conditions, they reduced cellular survival when carbohydrates were absent from the medium. In contrast, collagen-I represented a permissive ECM for serotonin-induced invasion, but only in organoids derived from HTR2B+ tumor cells. CRC cells positive for this molecule also expressed NOTCH3 and NOTCH target genes. Similar to HTR2B+ organoids, NOTCH3+ cells had increased levels of EMT markers, and a higher invasion potential in collagen compared to NOTCH3 negative cells. Hence, similar to HTR2B stimulation, inhibition of Notch activity changed EMT marker levels and PDO invasion.

Conclusion

Collectively, we show that the serotonin receptor HTR2B+ marks a CRC cell population with increased proliferative and invasive potential, and serotonin has a dual role under unfavorable conditions and in ECM enriched for collagen. Furthermore, the cell population with active NOTCH signaling overlaps with HTR2B+ cells, and similarly promotes aggressive tumoral behavior.

Human immune cell composition of TME depends on tumor cell line-derived xenograft subtype and tumor burden in genO-BRGSF-HIS mice

F. Creusat¹, S. Hedir¹, A. Gonon¹, A. Marguier¹, Y. Cherif¹, F. Sónego¹, G. Martin¹, K. Thiam¹

¹genOway, Lyon, France

Introduction

Emergence of immunotherapies for treating cancer has been an important step towards a more efficient, selective and safe approach for patients. However, only a fraction of patients can respond to treatments currently available, requiring the identification of additional therapeutic targets. The relevance of preclinical models in the identification of new therapeutic targets and assessment of immunotherapies has vastly improved with mice bearing a human immune system. genO-BRGSF (Balb/C Rag2^{-/-}, IL2Rγ^{-/-}, SIRPaNOD and Flt3^{-/-}) is a highly immunodeficient mouse featuring reduced murine myeloid cells. genO-BRGSF mice reconstituted with human cord blood CD34+ cells (genO-BRGSF-HIS) develop functional lymphoid and myeloid compartments. This engraftment is stable for over a year (Labarthe et al., 2019) and mice do not develop GvHD. Human myeloid compartment can be transiently boosted with exogenous human Flt3L injections. In contrast to other models, which overexpress human cytokines to develop human myeloid cells, Flt3L-treated genO-BRGSF-HIS mice do not show side effects. genO-BRGSF-HIS mice are permissive to mouse and human cancer cell lines engraftment and represent a valuable preclinical model to study cancer development and evaluate novel therapeutics. Here, we show that composition of tumor microenvironment (TME) is tumor burden-dependent.

Material and method

For that, genO-BRGSF-HIS mice were inoculated with different tumor types and TME analyses were performed at different timepoints.

Result and discussion

genO-BRGSF-HIS mice grafted with triple negative cancer cell line MDA-MB-231 have a diverse TME, enriched in myeloid cells. The major cell type present in tumors of approximately 200mm³ is CD206+/CD163+ M2-like macrophages, which express high levels of PD-L1 and other immunomodulatory proteins. At this tumor volume, TME is also composed of a small fraction of T cells. However, the frequency of conventional CD4+T cells increase from <5% to 15% of human infiltrate when

tumors reach approximately 500 mm³. Interestingly, NK cells are detected at very low levels in tumors of 200 mm³, but increase to 10% in the TME of tumors of 500 mm³. The infiltration of human immune cells in the TME is also tumor type dependent. Indeed, NK cells are the main cell type present in the TME of A549, an adenocarcinomic human alveolar basal epithelial tumor type, while conventional CD4+ T cells are the major cell type present in the TME (40%) of tumors of 200 mm³, in a colon-derived adenocarcinoma SW480 tumor model. Interestingly, SW480 tumors show an infiltrate of γδ T cells as well, ranging from 6% to 8% of human immune cells in tumors of 200 mm³ and 800 mm³, respectively.

Conclusion

genO-BRGSF-HIS mice hence represent a valuable tool to investigate immune cell infiltration in the TME, enabling a translatable assessment of mechanism of action of immunotherapies.

Emerging Subtypes in Ovarian High Grade Serous Carcinoma: Decoding Genomic and Functional Landscapes

G. Micoli¹, K. Lavikka¹, Y. Li¹, A. Pirttikoski¹, W. Senkowski², A. Vähärautio¹, K. Wennerberg², J. Hynninen³, J. Oikkonen¹, S. Hautaniemi¹

¹University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland

²University of Copenhagen, Biotech Research & Innovation Centre (BRIC), Copenhagen, Denmark

³Turku University Hospital, Department of Obstetrics and Gynecology, Turku, Finland

Introduction

Ovarian high-grade serous carcinoma (HGSC) is marked by extensive chromosomal instability (CIN) and heterogeneity. Homologous recombination proficient (HRP) tumors, defined by the absence of homologous recombination deficiency (HRD), are associated with poor prognosis, lack established biomarkers, and have limited treatment options, underscoring the need for improved molecular classification. Our study addresses the heterogeneity driven by CIN and provides a biologically and clinically meaningful stratification of HGSC.

Material and method

We derived CIN signatures from 640 whole-genome sequencing (WGS) HGSC tumors in the DECIDER clinical trial exploiting structural variation and copy number features. Signature activities were used to cluster samples, and the resulting subtypes were further characterized using bulk and single-cell RNA sequencing. Patient-derived organoids were then employed to explore potential targeted treatment options.

Result and discussion

Using CIN signatures from patient WGS data, we identified five distinct HGSC subtypes, each characterized by unique structural variation patterns and biological phenotypes. Notably, three subtypes provided further stratification within the heterogeneous HRP patient group, while the remaining two differentiated BRCA1-like from BRCA2-like HRD tumors. The most prevalent HRP subtype, termed core HRP, was marked by moderate genomic instability, immune evasion in

primary tumors, and high hypoxia in metastatic sites. In contrast, the EMT HRP subtype, which exhibited the lowest genomic instability, was driven by epithelial-to-mesenchymal transition (EMT) phenotype. Lastly, the proliferative HRP had the highest levels of genomic instability and presented high proliferation activity. Furthermore, organoid experiments suggested that CHK1 inhibition may be ineffective for EMT HRP tumors, whereas patients with core and proliferative HRP subtypes could benefit from this treatment. Our data enabled separation of patients with dysfunctional BRCA1 and BRCA2 genes, revealing subtypes with aligned genomic features. BRCA2-like patients showed better demonstrated improved overall survival despite comparable initial treatment responses, implying lower resistance to second-line therapies. Additionally, this approach refined HRD classification by identifying potential HRP patients with poor responses among those classified as HRD based on genomic scars, as well as likely HRD patients with favorable outcomes among scar-defined HRP cases, thereby improving clinical stratification.

Conclusion

In summary, we analyzed the genomic landscape of HGSC in a real-world patient cohort and uncovered clinically and biologically significant subtypes using CIN signature clustering. These findings provide a foundation for developing new therapeutic strategies for patients facing limited treatment options.

Genetic Ancestry Influence on the Tumor Microenvironment of Colombian Patients with Triple-Negative Breast Cancer

Y. Zambrano Ordóñez¹, J. Ramírez Mejía¹, A. Mejía-García², P. Morales³, L. López-Kleine⁴, P. López-Correa³, J. Rodríguez³, J. Riaño³, S. Serrano³, C. Orozco³

¹National Cancer Institute (Colombia), Bogota, Bogota, Colombia

²McGill University, Canada, Canada

³National Cancer Institute (Colombia), Bogota, Colombia

⁴National University of Colombia, Bogota, Colombia

Introduction

Triple-negative breast cancer (TNBC) is a highly heterogeneous disease, with a tumor microenvironment shaped by genetic and immune factors. In Latin American populations, genetic ancestry may influence immune infiltration and cytokine activity, potentially impacting tumor progression and response to immunotherapy. Understanding these interactions is crucial for improving personalized treatment strategies. AIM: To evaluate the relationship between genetic ancestry and immune infiltration in Colombian TNBC patients, distinguishing between sporadic and hereditary cases.

Material and method

We analyzed 42 TNBC patients treated at the National Cancer Institute between 2018 and 2023. Genetic ancestry and germline mutations were inferred from NGS data using the TruSight Oncology panel. Immune infiltration was characterized using RNA-Seq data. XCell

was employed to estimate the immune cell composition, while CytoSig was used to assess cytokine and growth factors activity. Statistical analyses were performed in RStudio.

Result and discussion

Heredity TNBC patients exhibited a more active immune response compared to the sporadic group.

- Ancestry and immune cell composition: In the overall cohort, higher European ancestry (EUR) was associated with a lower proportion of naïve CD8+ T cells ($p = 0.048$). In sporadic TNBC, CD8+ ($p = 0.005$), CD4+ ($p = 0.015$), and NK cells ($p = 0.019$) positively correlated with EUR, whereas in hereditary TNBC, naïve CD8+ T cells showed a negative correlation with EUR ($p = 0.021$).

- Ancestry and cytokine activity: Increased African (AFR) and Native American (NAM) ancestry correlated with elevated cytokine activity, including IFNG ($p = 0.003$), IL3 ($p = 0.019$), IFNL ($p = 0.041$), and IL18 ($p = 0.045$). In hereditary TNBC, FGF2 ($p = 0.004$) and IFNG ($p = 0.010$) were negatively associated with EUR and positively with NAM ($p = 0.016$).

Conclusion

Our findings suggest that genetic ancestry influences the tumor immune microenvironment in TNBC, with hereditary cases displaying a more inflammatory profile. These results highlight the importance of integrating ancestry into immuno-oncology research, as it may contribute to immune response heterogeneity and affect treatment outcomes. Understanding these ancestry-driven immune variations could improve precision medicine approaches for TNBC patients.

²Taipei, Taiwan

³Department of Dentistry, College of Dentistry, National Yang Ming Chiao Tung University, Taipei, Taiwan

⁴Cancer and Immunology Research Center, National Yang Ming Chiao Tung University, Taipei, Taiwan

Introduction

Cancer cachexia (CC), progressed with numerous chronic and end-stage diseases including carcinogenesis, sequentially, with involuntary weight loss via skeletal muscle, fat mass reduction, and imbalance in metabolic regulation, is a multifactorial syndrome and cannot be reversed by nutritional support. CC develops as a secondary disease in 80% of cancer patients and becomes the main cause of death in 22–30% of cancer patients. Approximately, 50–70% of Head and neck squamous cell carcinoma (HNSCC) patients are diagnosed with malnutrition of varying severity, with progressive weight loss causing cachexia. It has also been reported that advanced tumors stage prone to developing CC due to chemotherapy resistance.

Material and method

We established a highly malignant HNSCC cell line, VO4, by sequential rounds of syngeneic transplantation; then a cisplatin-resistant VO4 cell line (VO4cisPtR) was established by stepwise treatment with increased concentrations of cisplatin. The VO4 and VO4cisPtR cells were inoculated subcutaneously into the C57BL/6 mice to observe the progression of cachexia *in vivo*, respectively. Then, the gastrocnemius muscle and adipose tissues were collected and examined for abnormality by immunoblot assays. As *in vitro* progressive cachectic models, the VO4 and VO4cisPtR adipogenic conditioned medium, which collected after cultivation of cancer cells and 3T3-L1 preadipocytes, afterward, treated in C2C12 myoblasts to analyze lipid metabolism and muscle atrophy by immunoblot assays. Further, a compound X was used to assess its anti-cachexia therapeutic regimen both *in vivo* and *in vitro* cachexia models.

Result and discussion

We observed VO4cisPtR tumor-bearing mice showed significant loss of body weight, epididymal white adipose tissue (eWAT), inguinal white adipose tissue (iWAT), and brown adipose tissue (BAT) compared to that of the VO4 tumor-bearing mice. The immunoblot results revealed the expression of the lipolysis marker, ATGL, and beta-oxidation marker, CPT1A, were up-regulated in eWAT; meanwhile, the expression of muscle atrophy marker, artogin-1, was up-regulated in gastrocnemius muscle of the VO4CisPtR-tumor bearing mice. We observed that the differentiation ability of C2C12 was inhibit, and the expression of MyoD and MyHC were significantly downregulated after the treatment with VO4 and VO4cisPtR adipogenic conditioned medium, respectively. Lastly, the compound X treatment ameliorated the loss of body weight, adipose tissues and muscle tissues both *in vivo* and *in vitro*. Further, the molecular mechanisms mediating the above findings are under elucidation.

Conclusion

Overall, we generated a novel syngeneic HNSCCcisPtR cachexia model and characterized the progression and pathophysiology of cancer cachexia. Additionally, compound X would be a potential therapeutic drug for anti-cachexia.

Establishing the Immune-Profile of Cholangiocarcinoma and the Utility of Human Precision-Cut Tumour Slices (hPCTS) as a Platform to Assess Immunotherapy Response

O. McGreevy¹, M. Jessel¹, T. Gilbert¹, R. Jenkins², L. Dalah¹, L. O'Leary¹, S. Fenwick³, H. Malik³, C. Goldring¹, L. Randle¹

¹*University of Liverpool, Department of Pharmacology and Therapeutics, Liverpool, United Kingdom*

²*University of Liverpool, CDSS Bioanalytical Facility, Liverpool, United Kingdom*

³*Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom*

Introduction

Cholangiocarcinoma (CCA) is a rare but aggressive malignancy of the biliary tract, encompassing intra-hepatic (iCCA), perihilar (pCCA), and distal subtypes. Late-stage detection, limited treatment options, and frequent chemoresistance contribute to poor outcomes. Although recent phase III trials (TOPAZ-1, KEYNOTE-966) have investigated immunotherapy-based regimens, many patients derive minimal benefit, highlighting the need for improved insight into the tumour micro-environment (TME). This study combines human precision-cut tumour slices (hPCTS) and mass time-of-flight cytometry (CyTOF) to develop a physiologically relevant *ex vivo* model for exploring CCA biology and refining immunotherapeutic strategies.

Material and method

Patient consented [1] fresh iCCA and pCCA tumour specimens were surgically resected and cut into 250 µm slices (5 mm diameter) using a Krumdieck MD6000 Tissue Microtome. Slices were cultured for up to 15 days. MTS assays assessed metabolic viability, while haematoxylin and eosin staining evaluated tissue architecture. Immunohisto-chemistry (IHC) stained for immune cell subsets, tumour, and apoptosis markers over time (Days 0, 3, 7, 11, 15). SWATH-based proteomic profiling assessed slice proteome stability from day 0 to 15 in culture. A 35-marker CyTOF panel, allowed the identification of major and sub-immune populations and their activation status from single-cell suspensions of resected tumours. CyTOF analyses of day 7 hPCTS was used to determine whether immune phenotypes and activation states are sustained *ex vivo*. Proof-of-concept studies with chemotherapeutic and immunomodulatory agents tested the feasibility of hPCTS for evaluating dose-dependent responses.

Result and discussion

Following an initial dip, the hPCTS proteome was stable from day 3 onwards. There was no significant change in viability over the 15 days in culture. Histological evaluations showed intact tissue architecture, and IHC confirmed the persistence of immune cells. This indicate that hPCTS preserve key TME features over prolonged *ex vivo* culture, including immune components. Preliminary drug treatments revealed dose-dependent responses, suggesting that CCA hPCTS can be used for pharmacological studies. Ongoing CyTOF analysis will characterise immune subsets and activation markers in both primary tumour tissues and hPCTS, providing insight into the functional status of immune populations and informing immunotherapeutic targeting.

Conclusion

Our data establish hPCTS as a robust *ex vivo* model for CCA, retaining architecture, viability, and immune cells for at least 15 days. When integrated with comprehensive CyTOF-based immune profiling, this platform can delineate TME interactions and guide the development of more precise immunotherapeutic interventions.

Ultimately, leveraging hPCTS for mechanistic and drug-response studies may improve clinical outcomes for patients with CCA.

²Institute for Lung Health (ILH), Justus-Liebig University Gießen, Gießen, Germany

³Genomics Core Facility, Philipps University Marburg, Marburg, Germany

⁴Department of Cardiac Development and Remodeling, Member of the German Center for Lung Research (DZL), Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany

⁵Max-Planck Institute for Heart and Lung Research, Member of the German Center for Lung Research (DZL), Member of the Cardio-Pulmonary Institute (CPI), Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany

Introduction

Preclinical mouse models are indispensable for studying tumor biology and evaluating therapeutic strategies. Especially autochthonous tumor models, developed through somatic gene editing, closely mirror natural disease progression as in patients. However, monitoring tumor growth within internal organs relies on sophisticated imaging techniques that require anesthesia, are time-consuming, and demand substantial resources. To address these challenges, we have established a blood-based monitoring approach for tumor burden using secreted luciferases, offering a minimally invasive, accessible, scalable, and cost-effective alternative to imaging.

Material and method

To enable longitudinal monitoring of autochthonous tumor models, we engineered a Cre-inducible reporter mouse that conditionally expresses the secreted luciferase from *Gaussia princeps* (GLuc). Additionally, we designed a flexible adenoviral (AV) toolkit for delivering Cre recombinase alongside CRISPR nucleases targeting essential tumor suppressor genes.

Result and discussion

Intratracheal infection of GLuc reporter mice with CRISPR-AVs successfully induced GLuc-expressing lung tumors with defined genetic profiles. The secreted GLuc, released by proliferating tumor cells, entered the blood stream, and its circulating levels strongly correlated with viable tumor burden. This allowed for the detection of tumor growth months before animals reached endpoint criteria. Unlike imaging techniques that require specialized equipment and trained personnel, GLuc levels can be rapidly and inexpensively measured from small blood samples without the need for anesthesia, substrates, or contrast agents. This minimally invasive approach minimizes animal distress and permits

frequent, real-time monitoring of tumor dynamics with high temporal resolution in both genetically engineered and transplantable tumor models. While blood GLuc levels integrate signals from the entire body, including small or diffuse metastases, they lack spatial resolution. However, this limitation can be overcome by combining GLuc with classical luciferases, such as Firefly luciferase, enabling simultaneous quantification of tumor burden and spatial tracking of tumor growth, thereby integrating the benefits of blood-based assays and imaging.

Conclusion

Implementing blood-based longitudinal monitoring of tumor burden with secreted luciferases offers a 3R-compliant, sensitive, cost-effective, and scalable strategy to increase the accessibility of autochthonous mouse tumor models for preclinical research and drug development.

Understanding the Role of Leukemia Inhibitory Factor (LIF) in the Bone Metastatic Microenvironment

C. Galera-Martínez¹, I. Cuartas¹, L. Carrillo-Bosch¹, L. Cuesta-Casanovas¹, R. Iurlaro¹, C. Duran-Castells¹, A. Neva-Alejo¹, M. López-Vázquez¹, S. Espinosa-Gil¹, J. Seoane^{1,2}

¹Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

²Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain

Introduction

Bone metastasis is predominant in certain cancer types, particularly those originating from the prostate (85%). While Leukemia Inhibitory Factor (LIF) plays a key role in bone remodelling, its involvement in bone metastasis remains insufficiently explored. Data from Stand Up To Cancer (2019) highlight a significant disparity in survival outcomes among prostate cancer patients with bone metastasis based on LIF expression. Patients in the highest quartile of LIF expression exhibit more than a 50% reduction in median overall survival compared to those in the lowest quartile ($p < 0.05$; $n = 12$), alongside an increased expression of osteoclast-related genes, as determined through an unbiased approach ($\log_2\text{-ratio} > 1$). We hypothesise that LIF secreted by tumour cells may induce aberrant bone remodelling, leading to the release of growth factors stored in the bone, thereby facilitating tumour growth.

Material and method

In this study, we investigated the role of LIF within the bone metastatic niche using in vitro, ex vivo, and in vivo methodologies. Also, we compared its effects with those of Receptor Activator of Nuclear Factor Kappa-B Ligand (RANKL), the main target of currently approved therapies. For in vitro, bone marrow cells obtained from the long bones of C57BL/6j mice were treated with recombinant mouse LIF or RANKL (20 ng/mL) for one week. In ex vivo, coculture of RM1 prostate cancer cells with 2 mm calvaria discs from C57BL/6j mice following LIF treatment (20 ng/mL) for 4 weeks was performed. For in vivo, RM1 cells were inoculated into 7-week-old

C57BL/6j male mice and treated over 12 days with anti-LIF (15 mg/kg) or anti-RANKL (10 mg/kg).

Result and discussion

In vitro, both cytokines upregulated the expression of osteoclast-related genes by qPCR. However, the RANKL:OPG mRNA ratio only increased upon treatment with LIF. Flow cytometry analysis revealed a comparable increase in the CD68+CD265+CD11BLow population following both treatments. TRAP staining was consistent with these findings. Moreover, ex vivo co-culture of RM1 prostate cancer cells with 2 mm calvaria discs from C57BL/6j mice revealed a more than two-fold increase in tumour growth following LIF treatment after 4 weeks ($p < 0.05$). These results led us to perform a pilot syngeneic in vivo experiment where RM1 cells were inoculated into 7-week-old C57BL/6j male mice (H&E for tumour area). Upon two doses of treatment with anti-LIF (15 mg/kg) over 12 days, the RANKL:OPG mRNA decreased to less than half ($p < 0.05$). In the same setting, treatment with anti-RANKL (10 mg/kg) decreased mRNA expression of MMP9 ($p = 0.05$), CTSK and ACP5 ($p < 0.001$ both), but increased RANKL:OPG ($p < 0.01$).

Conclusion

In conclusion, these findings unveil the role of LIF in regulating RANKL:OPG dynamics within the bone metastatic niche, offering promising prospects for therapeutically targeting LIF.

EACR25-0911

Proteomic Landscapes of Ewing Sarcoma Unravel Immune Regulation of Tumor Progression and Ferroptosis Inhibition Driving Chemotherapy Resistance

S. Gordon¹, R. Shukrun², V. Mohan¹, S. Metzger¹, O. Golani³, R. Oren⁴, L. Fellus-Alyagor⁴, R. Elhasid², T. Geiger¹

³Weizmann institute of science, Life Sciences Core Facilities, Rehovot, Israel

⁴Weizmann institute of science, Veterinary Resources, Rehovot, Israel

Introduction

Ewing sarcoma (EWS), a rare pediatric bone tumor defined by EWSR1-ETS fusions, poses unique therapeutic challenges due to its distinct microenvironment and limited molecular understanding. Despite being the sole genetic driver, the oncogenic mechanisms of the fusion protein and its therapeutic potential remain elusive. Genomic and transcriptomic analyses have yet to improve patients' outcomes, prompting the need for a proteomic approach. Our study aims to reveal molecular pathways associated with treatment resistance and the immune landscape related to tumor aggressiveness.

Material and method

We took a cutting-edge mass spectrometry-based proteomic approach to obtain a comprehensive picture of EWS clinical samples. We combined it with multiplexed

imaging to associate the proteomics data with the cancer immune profiles. We assembled the largest cohort of EWS tumors, including primary, treatment-naïve tumors, post-treatment samples, relapsed tumors, and metastases from bones and lungs. We analyzed 170 tumor samples from 74 patients and investigated their association with clinical parameters, including survival, chemotherapy response, and metastatic state.

Result and discussion

We analyzed EWS proteomes at different tumor stages, identifying upregulated ferroptosis inhibitors in post-NACT samples, suggesting a mechanism by which EWS cells evade chemotherapy-induced cell death. Functional assays revealed that chemotherapy-resistant EWS cells exhibit reduced sensitivity to doxorubicin but show enhanced susceptibility to ferroptosis induction via GPX4 inhibition. Treatment with the GPX4 inhibitor RSL3 restored sensitivity to chemotherapy in resistant cells, highlighting ferroptosis as a potential therapeutic vulnerability to overcome drug resistance in EWS. Unsupervised clustering of primary tumors revealed three distinct prognostic groups. Examination of the significantly changing proteins between clusters showed that the good prognosis cluster expresses high antigen presentation proteins and 20S proteasome levels. In contrast, the poor prognosis cluster presented a network of neutrophil proteins, supporting a tumor-promoting role of neutrophils in EWS. Multiplexed immunofluorescence imaging validated the association between poor patient prognosis and tumor neutrophils and the association of macrophages and T-cells with a favorable prognosis. These results suggest that immuno-oncological treatments might be efficacious for a subset of patients.

Conclusion

Our work presents the first EWS clinical proteomics dataset, with a proteome coverage of over 10,000 proteins in 170 samples. Our analysis identified potential combination therapies to enhance chemotherapy responses and immune-related features that could guide better immunotherapeutic approaches. Our database can serve as a resource for the broad cancer biology and EWS communities.

EACR25-0912

Monocyte/macrophage crosstalk with colorectal cancer in co-cultures - in vitro studies

P. Pieniądz-Feculak^{1,2}, M. Pięt¹, A. Pawłowska-Łachut², D. Suszczyk², W. Skiba², K. Włodarczyk-Ciekańska², I. Wertel², R. Paduch^{1,3}

¹Maria Curie-Skłodowska University, Department of Virology and Immunology, Lublin, Poland

²Medical University of Lublin, Independent Laboratory of Cancer Diagnostics and Immunology, Lublin, Poland

³Medical University of Lublin, Department of General and Paediatric Ophthalmology, Lublin, Poland

Introduction

The tumor microenvironment (TME) critically influences colorectal cancer (CRC) progression, either inhibiting or promoting malignancy. Tumor-associated macrophages (TAMs), comprising up to 50% of the tumor mass, exhibit phenotypic plasticity, shifting between pro-inflammatory (M1) and immunosuppressive (M2) states.

While M1 macrophages possess tumoricidal properties, M2-polarized TAMs support tumor growth, angiogenesis, and immune evasion. This study investigated interactions between CRC cells and monocytes/macrophages to better understand their role in modulating the TME.

Material and method

This study examined an *in vitro* co-culture model of human monocytes (THP-1) and stage I colorectal cancer cells (HT-29) to assess the impact of tumor-derived soluble factors. Inserts with 0.4 µm pores allowed the exchange of factors while maintaining physical separation. Models with monocytes/macrophages infiltration at 50% and 20% relative to the cancer cell density were analyzed. Flow cytometry was used to evaluate apoptosis, necrosis, and CD68 expression, a marker of macrophage differentiation.

Result and discussion

The study demonstrated that after 24 hours of incubation with CRC cells, the viability of monocytes/macrophages did not show statistically significant changes. The proportion of live cells, as well as those undergoing different stages of apoptosis and necrosis, remained comparable in co-cultures with 20% and 50% infiltration compared to their respective controls. However, after 48 hours, a significant ($p < 0.01$) reduction in immune cell viability was observed, particularly in the 20% co-culture, suggesting that at lower cell densities, macrophages are more susceptible to tumor-derived soluble factors. Analysis of CD68 expression revealed a slight increase (<1%) in the 20% co-culture compared to the control at both 24 and 48 hours. The small magnitude of this change indicates only a weak differentiation of monocytes into macrophages under the influence of tumor-derived factors. This may be attributed to the activation of monocytes/macrophages under conditions of increased environmental stress and limited direct cell-cell communication. In the 50% co-culture, CD68 expression remained unchanged, suggesting that at higher macrophage densities, exposure to tumor-derived factors does not induce a distinct activation response.

Conclusion

This study demonstrates that prolonged exposure to tumor-derived factors in an *in vitro* model of stage I CRC reduces the viability of monocytes/macrophages, particularly at lower infiltration densities, which suggests increased sensitivity to the tumor microenvironment. The slight increase in CD68 expression in the co-cultures suggests that stage I CRC cells have limited potential to induce macrophage differentiation.

Differential Scanning Fluorimetry and compound screening enabled the identification of novel series of microRNA-21 targeting compounds

C. Hanack¹, L. Iuzzolino¹, V. Wanke¹, S. Bradberry², D. Caretoni³

¹Axxam SpA, Biochemistry, Bresso (Milano), Italy

²Axxam SpA, Data Sciences, Bresso (Milano), Italy

³Axxam SpA, Biological Sciences, Bresso (Milano), Italy

Introduction

Aberrant expression of microRNA-21 (miR-21) is recognized as a key determinant in cancer progression through dysregulated post-translational control of several tumor suppressor genes. Hence, identification of compounds directed against miR-21 is representing an emerging opportunity for the development of candidate drugs with innovative modalities, such as riboabs or interferents with pre-miR-21 maturation. Here, we report the identification of compounds targeting pre-miR-21 through screening of small-molecule collections and using differential scanning fluorimetry (DSF) as biophysical binding assay.

Material and method

DSF monitors the ability of small molecules to engage RNA through increased thermal stability. The assay was developed using a hairpin-structured pre-miR-21 and a fluorogenic RNA-binding dye. Compound-induced thermal shift of pre-miR-21 was detected by QuantStudio® RT-qPCR system in 384 well plate format. Reference compounds, as well as single-point pre-miR-21 mutant and equivalent DNA sequences were assessed to validate the assay selectivity. Screening was performed on an unbiased collection of 1300 biologically active compounds and on a focused library of 2200 compounds enriched for RNA binding moieties.

Result and discussion

The DSF assay was optimized to achieve a screening-suited performance while enhancing its sensitivity towards putative RNA-binding molecules. Selectivity was proven by using as positive control dovitinib, a pre-miR-21 binding molecule that inhibits miR-21 biogenesis. The assay displayed very high robustness, with RZ' of 0.83 and CV% of 0.7. Combined screening of unbiased and focused libraries of 3500 compounds in total identified 10 primary hits (0.3% hit rate) triggering a significant Tm shift for pre-miR-21. Primary hits were triaged at increasing concentration, with 8 compounds confirmed to display dose-dependent saturation curves with aKD values in the 1-/2-digit micromolar range. Some chemical scaffolds of confirmed hits displayed similarity with biologically active compounds known to target nucleic acids, while others appeared to be new structures. A subset showed selective binding to pre-miR-21 over other ribonucleotides. In all cases, confirmed hits are novel in the pre-miR-21 binding mechanism, and follow-up studies are currently ongoing with orthogonal biophysical assays, as well as on cancer cell systems to confirm their ability to interfere with pre-miR-21 processing.

Conclusion

The combination of DSF and screening has identified novel series of pharmacophores acting as pre-miR-21 binders, with the potential to serve as building blocks for the development of lead compounds offering an unconventional modality to target cancer progression.

EACR25-0924

Cellular enlargement causes mitotic errors and aneuploidy in cells that evade senescence following chemotherapy

A. Pareri¹, L. Petty¹, A. Saurin¹

¹University of Dundee, School of Medicine, Dundee, United Kingdom

Introduction

CDK4/6 inhibitors (CDK4/6i) arrest cells in G1 to cause cellular overgrowth and p53-dependent senescence. CDK4/6i are licenced to treat metastatic HR+/HER2+ breast cancer where they have dramatically improved patient outcomes. Sadly, resistance is still common, and this has recently been associated with TP53-loss and senescence evasion. This study examines the fate of enlarged CDK4/6i-treated cells that evade senescence following CDK4/6i-treatment, demonstrating that these enlarged cells are primed to experience mitotic errors and become genetically unstable.

Material and method

Live and fixed single cell analysis is used to examine the fate of cells that escape senescence following CDK4/6i-treatment. A range of mitotic assays are used to characterise key processes that control chromosome segregation and single cell DNA sequencing is used to characterise copy number changes and aneuploidy.

Result and discussion

We show here that enlarged CDK4/6i-treated cells that evade senescence experience chromosome mis-segregations due to defective chromosomal alignment and a weakened mitotic checkpoint. This leads to aneuploidy, as assessed by single cell DNA sequencing, and DNA damage. The chromosome segregation defects are associated with impaired Sgo1 localisation to centromeres and defective sister chromatid cohesion during mitosis. Importantly, all these defects can be rescued by constraining cell size during the CDK4/6i-treatment, and specifically restoring cohesion rescues the chromosome segregation errors. Together, this demonstrates mechanistically how cell enlargement drives genetic and karyotypic changes in cells that re-enter the cell cycle following CDK4/6 inhibition. Similar results are observed with other chemotherapeutics that induce a DNA-damage checkpoint arrest in G1, implying that cell overgrowth could widely contribute to chromosomal instability following chemotherapy. This could help fuel the emergence of chemotherapy-resistant clones, especially in TP53-null cells that evade senescence, perhaps explaining why TP53-loss drives drug-resistance in CDK4/6i-treated breast cancer patients.

Conclusion

In summary, these findings explain how anti-cancer drugs that arrest cells in G1 can have unanticipated consequences later in mitosis. Our data explains how CDK4/6i cause irreversible cell cycle exit, and how they can produce the type of chromosomal aberrations that drive rapid tumour evolution and drug resistance in cells that continue to proliferate, such as those lacking p53.

EACR25-0926

Characterization of hPBMC-ASID and hPBMC-ASID β 2m $^{−/−}$ models for Immune-Oncology Studies

H. Hsu¹, S. Fang¹, C. Chang¹, L. Huang¹, C. Chang¹, Y. Lin¹

¹NLAC, Taipei, Taiwan

Introduction

The humanized immune system (HIS) mouse models are the preferred *in vivo* preclinical platforms to evaluate novel immune-oncology (IO) therapeutic candidates.

Among these HIS mice models, human peripheral blood mononuclear cells (hPBMC)-HIS mouse model is one of the most commonly used HIS mouse models due to its rapid engraftment. However, the limitation of hPBMC-HIS model is that mice may suffer from xenogeneic graft-versus-host disease (GvHD), where the human immune cells could attack and damage mouse tissues, leading to the death of mice and a very limited experimental window. Thus, the aim of this study is to identify an optimized protocol for hPBMC-HIS mouse model by using immunodeficient mice developed by NLAC.

Material and method

First, we transplanted 2×10^6 or 5×10^5 hPBMC cells into ASID (NOD.Cg-PrkdcscidIl2rgtm1Wjl/YckNarl) mice pretreated with total body irradiation (TBI), or 1×10^7 or 5×10^6 hPBMC cells into ASID mice without irradiation treatment. Furthermore, it has been reported that β 2m $^{−/−}$ mice can reduce the severity of GvHD due to the lack of MHC class I molecule expression. Thus, we also transplanted 1×10^7 hPBMC cells into ASID β 2m $^{−/−}$ (NOD.Cg-PrkdcscidIl2rgtm1WjlB2M $^{−/−}$ /YckNarl) mice (\varnothing) without irradiation treatment and 2×10^6 hPBMC cells into ASID β 2m $^{−/−}$ mice (\varnothing) with irradiation.

Result and discussion

The higher engraftment rate (>25% hCD45) was found in the following groups: 2×10^6 w/ irradiation (\varnothing), 1×10^7 w/o irradiation (\varnothing) and 5×10^6 (δ) w/o irradiation. However, compared with the lower engraftment groups, mice in these groups showed weight loss, scaly skin, and shorter survival time, implying the occurrence of GvHD. Moreover, compared with ASID mice, the variation of survival periods in ASID β 2m $^{−/−}$ mice was smaller than that of ASID mice, and GvHD score was lower in earlier experimental period, although the engraftment rate of ASID β 2m $^{−/−}$ mice was lower than that of ASID mice.

Conclusion

Thus, using different conditions, both ASID and ASID β 2m $^{−/−}$ mice could serve as the suitable models for hPBMC immune system reconstitution.

Introduction

Survival in recurrent/metastatic head and neck mucosal squamous cell carcinoma (HNmSCC) remains poor. Anti-programmed death (PD)-1 therapies have demonstrated improved survival with lower toxicity when compared to standard chemotherapy. However, response to anti-PD-1 therapy remains modest, at 13–17%. Understanding the immunological basis for response to such treatments at mucosal surfaces is critical for improving outcomes.

Material and method

We evaluated the tumour microenvironment (TME) using Imaging Mass Cytometry (IMC) on 27 tumour specimens from 24 advanced HNmSCC patients prior to receiving anti-PD-1 based treatment.

Result and discussion

We provide the first detailed sub-cellular, high-dimensional, *in situ* tissue map of the TME in advanced HNmSCC and identify hallmarks of patients most likely to benefit from anti-PD-1 therapy. Our results showed that the immune landscape largely remained similar irrespective of HNmSCC subsite or p16 status. Quantification of cell densities showed significantly increased central memory T cells and B cells in responders ($n=8$) when compared to non-responders ($n=16$). Spatial mapping identified unique interactions between phenotypically distinct malignant squamous cells, T cells and endothelial cells in responders, and avoidance of these cells in non-responders. Importantly, regional analysis shows responders have more lymphoid aggregates akin to early tertiary lymphoid structures (TLS), with their presence in high proportion (>20%) also associated with longer progression free survival.

Conclusion

Anti-PD-1 therapy response in HNmSCC is associated with specific interactions within the TME and the presence of TLS. This study identifies mechanisms of anti-PD-1 therapy response and resistance in HNmSCC patients, providing a unique opportunity to guide immunotherapy strategies and improve outcomes.

EACR25-0932

Cholesterol Transfer from PI-Activated TREM2+ Macrophages to Tregs Drives Lymph Node Immunosuppressive Pre-Metastatic Niche

C. Huang¹, X. Guan²

¹LKS Faculty of Medicine, The University of Hong Kong, Department of Clinical Oncology, Hong Kong, China

²LKS Faculty of Medicine, The University of Hong Kong, Department of Clinical Oncology, Hong Kong, Hong Kong, China

Introduction

The formation of an immunosuppressive pre-metastatic niche in lymph nodes (LNs) is critical for cancer metastasis, yet how tumor-secreted factors reprogram myeloid cells to drive immune evasion remains poorly understood. Here, we investigate the role of lipid metabolic crosstalk between tumor-primed macrophages and regulatory T cells (Tregs) in establishing a metastasis-permissive LN microenvironment.

Material and method

We integrated scRNA-seq from our lab and GEO datasets to map metastasis-associated immune landscapes. Lymph node metastasis was dynamically monitored via immunofluorescence and IVIS bioluminescence. The phosphatidylinositol (PI)-TREM2 axis was mechanistically dissected using promoter-luciferase assays. *In vitro* and *in vivo* functions of Trem2 were evaluated using Trem2 knockout mice, CRISPR-edited cell lines (Raw264.7), and bone marrow-derived macrophages (BMDM) from mouse models. Metastatic lymph node lipid profile and spatial metabolism were used to verify the metabolic crosstalk.

Result and discussion

Tumor-derived IL8 mobilized monocytes to draining LNs prior to metastasis. These monocytes differentiated into TREM2+ macrophages upon sensing high level of PI in lymph node. TREM2 activation triggered the whole cholesterol metabolism in macrophages, leading to cholesterol efflux via extracellular vesicles (EVs). Recipient Tregs exhibited enhanced suppressive function via cholesterol-dependent activation of liver X receptor (LXR) signaling. Genetic ablation of Trem2 and Trem2 antibody suppressed LN metastasis *in vivo*.

Conclusion

Our findings unveil a lipid-centric mechanism by which PI-activated TREM2+ macrophages license metastasis through cholesterol transfer to Tregs. Targeting this macrophage-Treg metabolic axis may reverse immunosuppression in pre-metastatic LNs, offering a therapeutic strategy to impede early metastatic spread.

EACR25-0940

Translational Value of Hepatic Dnaja3-deficient Mice in Preclinical Testing of Novel HCC Therapeutics

W. Teo¹, J. Lo¹

¹Institute of Oral Biology, Taipei, Taiwan

Introduction

Globally, hepatocellular carcinoma (HCC) is the dominant type of liver cancer and accounting for 75% of the total. Nowadays, there are lacking off therapies to cure or reverse the HCC. Therefore; an effective pre-clinical model recapitulate human HCC is crucial to validate and respond to current disease. Dnaja3, a tumor suppressor and mitochondrial co-chaperone protein, is responsible for maintaining mitochondrial polarization and integrity of mitochondrial DNA. Recently, we have demonstrated that hepatic Dnaja3-deficient mice spontaneously developing HCC along with significant mitochondrial dysfunction, sequentially, accompanied by excessive lipid accumulation and inflammatory responses. Hereto, in this study, the hepatic Dnaja3-deficient mice were used as HCC preclinical model to assess the anti-cancerous effect of Sorafenib, a first-line therapy for advanced HCC, and of a promisingly screened compound X.

Material and method

We investigated the in vivo anti-tumor activity of sorafenib on Diethylnitrosamine (DEN)-induced Alb-Dnaja3f/f, and of compound X on spontaneous Alb-Dnaja3f/f mice, respectively. The Alb-Dnaja3f/f mice were randomly divided into two groups: Placebo and Experimental (Sorafenib or compound X). The Placebo group was orally gavage with saline, while the Experimental group was orally administered with 30 mg/kg Sorafenib or 8 mg/kg compound X once a day for 2 weeks, respectively. After the mice were sacrificed, the blood and tissue samples were harvested for biochemical, pathohistological and functional analyses.

Result and discussion

First, the overall median survival of the sorafenib group was significantly longer than that of the Placebo group, however, the sorafenib treatment did not effectively inhibit the tumor growth. Meanwhile, we discovered compound X markedly prevented and suppressed tumor progression. In fact, the biochemistry analyses including AST, ALT, T-CHO and TG levels were ameliorated. We also observed the downregulation of Acc2 protein (an enzyme for converting acetyl-CoA to malonyl-CoA for biosynthesis of fatty acids) in liver tissues of treatment group. Together, these results revealed that the lipogenesis was attenuated. Subsequently, the excessive accumulation of white adipose tissue was suppressed. Strikingly, compound X treatment reversed the remodeling of extracellular matrix.

Conclusion

Overall, we designed a preclinical trial using compound X and to prevent and suppress the tumor progression in hepatic Dnaja3-deficient mice. Apparently, we demonstrated that compound X altering the lipid metabolism homeostasis in liver.

EACR25-0948

Autophagy activation in response to cigarette smoke: Exploring the disparity in laryngeal cancer incidence and outcomes between sexes in South Korea

A. Jung¹, M. Kwon²

¹Nowon Eulji Medical Center, Otolaryngology, Seoul, Korea (Republic of)

²Asan Medical Center, Otolaryngology, Seoul, Korea (Republic of)

Introduction

Laryngeal cancer (LC) presents a significant health challenge globally, with smoking being a major risk factor. Interestingly, LC incidence in females is significantly lower than in males; however, female smokers are more likely to develop Reinke edema (RE) than LC. This study sought to investigate whether autophagy, a major mechanism for RE development, acts as a defense mechanism in laryngeal tissue against cigarette exposure and suppresses LC development in females who smoke.

Material and method

This study analyzed the National Health Insurance Service (NHIS) data of South Korea to explore sex differences in LC incidence and clinical outcomes. Protein expression was compared between tissues from LC and RE patients. The changes in autophagy-related markers were analyzed after exposure to human vocal fold fibroblast (hVFF) and cigarette smoke extract (CSE). In addition, to explore the relationship between the level of autophagy-related gene expression and clinical features, female LC patients were compared with male patients through an analysis of data from The Cancer Genome Atlas (TCGA).

Result and discussion

In the NHIS data analyses, male LC patients had an 11 times higher incidence than female patients, even after adjusting for smoking and age. Additionally, female LC patients had significantly better survival rates. RE tissues exhibited increased autophagy-related protein expression compared with LC tissues. hVFFs after CSE exposure demonstrated elevated autophagy markers along with protein expression similar to RE tissue, suggesting autophagy's role in RE development over LC. The TCGA data analysis did not find a significant difference in autophagy-related gene expression, which would explain the favorable female clinical outcomes, between male and female LC patients.

Conclusion

This study implies autophagy activation by cigarette smoke is a crucial mechanism for lower LC incidence and better outcomes in females, highlighting the potential for autophagy-targeted LC prevention and treatment strategies.

Investigate the Anticancer Immunomodulation Mechanism of Fluoxetine Treatment in Oral Squamous Cell Carcinoma

P. Wang¹, P. Yueh², I. Chiang³, P. Chang¹, F. Hsu⁴

¹China Medical University, Department of Biological Science and Technology, Taichung, Taiwan

²National Yang Ming Chiao Tung University, Institute of Traditional Medicine, Taipei, Taiwan

³Show Chwan Memorial Hospital, Department of Radiation Oncology, Changhua, Taiwan

⁴National Central University, Department of Life Sciences, Taoyuan, Taiwan

Introduction

Oral squamous cell carcinoma (OSCC) is one of the most common types of oral cancer. It has been reported that OSCC could achieve metastasis and proliferation by overexpressing galectin-1 (gal-1), even inducing resistance to immune checkpoint inhibitors (ICIs). Meanwhile, due to the dense structure in OSCC, the activation of hypoxia-inducible factor-1 alpha (HIF-1 α) is still the challenge for cancer treatment, and the tumor microenvironment (TME) will transform into an unfavorable situation for immunotherapy. Hypoxia is a common phenomenon in malignant tumors, caused by the fast proliferation of tumor cells and unusual angiogenesis, which can promote tumor growth. When tumor tissues exposure to hypoxic condition, HIF-1 α may reduce or inactivate cytotoxic lymphocytes, including NK cells and CD8+ T cells, leads to the reduction of their anti-tumor efficacy. Fluoxetine is one of the commercially available antidepressants, it has been demonstrated to have the ability to suppress cancer cell growth and increase the sensitivity to antineoplastic agents. However, whether fluoxetine could rescue ICIs' curative effect and mechanism on OSCC is still unclear. Therefore, we aim to the potential pathway of fluoxetine treatment that could regulate the TME of OSCC.

Material and method

CCK-8 assay was used to validate cytotoxicity of fluoxetine. RNA-seq analysis revealed pathways that related to following fluoxetine treatment, and protein levels were showed by western blot. Additionally, transwell migration clarified how fluoxetine change the TME in OSCC. Orthotopic model was established to confirm the therapeutic effect of OSCC *in vivo*, populations of immune cells were analyzed by flow cytometry.

Result and discussion

According to our data, fluoxetine exerted cytotoxic effects on MOC1 cells and reduced the surface expression of programmed cell death 1 ligand 1 (PD-L1). INF- γ pathway was upregulated by fluoxetine treatment, while protein level of HIF-1 α was decreased despite unchanged mRNA expression. Additionally, fluoxetine enhanced the migration capacity of BMDCs in the presence of MOC1 cells. Furthermore, combining fluoxetine with immunotherapy significantly improved therapeutic outcomes and suppressed tumor growth. Cytotoxic lymphocytes were markedly upregulated, whereas immunosuppressive cells such as M2 macrophages, myeloid-derived suppressor cells (MDSCs), and Tregs were downregulated, suggesting that fluoxetine effectively modulates the TME and holds promise as a novel strategy for OSCC treatment.

Conclusion

In summary, our study demonstrates the anticancer effects of fluoxetine in OSCC by alleviating hypoxia through the promotion of HIF-1 α ubiquitination, inhibiting PD-L1 expression, and recruiting cytotoxic lymphocytes while suppressing immunosuppressive cells. These effects, validated in an orthotopic OSCC model and enhanced by combination with immunotherapy, offer a promising new approach for OSCC treatment.

EACR25-0954

Reprogrammed fibroblasts promote melanoma progression and immune evasion in the lymph node niche

M. Chapeau¹, C. Rovera², C. Tavernier¹, L. Delhayé¹, D. Graça¹, F. Larbret¹, M. Irondelle¹, M. Deckert¹, S. Tartare-Deckert¹, V. Prod'homme¹

¹*Université Côte d'Azur, INSERM U1065, C3M, Nice, France*

²*Université Côte d'Azur, INSERM U1065, C3M, Marseille, France*

Introduction

Melanoma is an aggressive skin cancer arising from the malignant transformation of melanocytes, the cells responsible for skin pigmentation. When localized in the skin, melanoma is treatable by surgical resection; however, if it is not detected early, it will invariably metastasize, starting by invading the lymph nodes. This lymphatic invasion is a critical step in melanoma progression, as it allows cancer cells to enter the bloodstream and spread to other organs such as the liver, bones, lungs, and brain. Understanding the mechanisms underlying lymph node invasion could lead to earlier and more effective interventions. During the pre-metastatic phase, lymph nodes are reprogrammed by factors secreted by melanoma cells in the skin, creating a niche favorable to tumor invasion and proliferation. During this phase, lymph node fibroblasts, known as Fibroblastic Reticular Cells (FRCs), are reprogrammed. In healthy lymph nodes, FRCs play a key role in organizing the structure of lymph nodes and in regulating T cell recruitment, survival, and activation. In many tissues, fibroblasts in the tumor microenvironment, also known as cancer-associated fibroblasts, are known to promote cancer progression, but little is known about the role of FRCs in the lymph node.

Material and method

To mimic the pre-metastatic reprogramming in the lymph node, healthy human FRCs are incubated with factors secreted by melanoma cells. Reprogrammed FRCs are then cocultured with T cells or tumor cells to understand the dysregulation of their interactions using flow cytometry and real-time microscopy approaches.

Result and discussion

We identified by RNAseq analysis that FRCs are transcriptionally reprogrammed by factors secreted by melanoma cells. Indeed, our previous work demonstrated that IL-1 secreted by dedifferentiated melanoma cells inhibit the contractility of reprogrammed FRCs, thereby facilitating melanoma cell invasion. My research also reveals that reprogrammed FRCs enhance the proliferation of tumor cells, their motility and their resistance to targeted therapies used in the clinic. Additionally, these reprogrammed FRCs disrupt the anti-tumor immune response by altering T cell motility and upregulating immune checkpoint molecules (PD1, LAG3, and CTLA4) on T cells. Future studies will focus on deciphering the precise molecular mechanisms by which FRCs acquire their tumor-promoting phenotype and identifying potential targets for intervention.

Conclusion

These findings highlight the critical role of FRCs in creating a tumor-permissive microenvironment in early melanoma progression, and suggest new therapeutic approaches based on targeting the interactions between reprogrammed FRCs, tumor cells, and immune cells.

EACR25-0966

The NRG1/ERBB axis as a potential target to prevent targeted cancer therapy resistance

S. Peltola^{1,2}, K. Kurppa^{1,2}, K. Elenius^{1,2}

¹University of Turku, MediCity Research Laboratories and Institute of Biomedicine, Turku, Finland

²University of Turku and Åbo Akademi University, Turku Bioscience Centre, Turku, Finland

Introduction

Although targeted cancer therapies are widely used in the clinic, their long-term efficacy is compromised by the emergence of acquired drug resistance. One well-documented mechanism contributing to resistance across various oncogene-addicted cancer models is autocrine or paracrine neuregulin 1 (NRG1). NRG1 serves as a ligand for receptor tyrosine kinases ERBB3 and ERBB4, while ERBB2 also participates as a coreceptor in NRG-mediated signaling. The aim of the project is to determine the functional relevance of the NRG1/ERBB signaling axis in the response to targeted therapies and to develop strategies to target this pathway to prevent or delay the onset of drug resistance.

Material and method

Using a panel of oncogene-addicted cancer cell lines, the expression of molecular components of the NRG/ERBB axis was characterized upon long-term treatment with standard-of-care (SOC) targeted therapies. CRISPR-Cas9-mediated ERBB knockouts were used for assessing the functional relevance of the ERBB receptors for drug-tolerant cells. The effect of different therapeutic approaches for targeting the NRG1/ERBB axis, including pan-ERBB inhibitors and antibody-drug conjugates, will be studied *in vitro* using cell viability and apoptosis assays. Most promising drug combinations will be further evaluated in relevant mouse xenograft tumor models.

Result and discussion

Our findings demonstrate that the NRG/ERBB axis is upregulated at both at the transcriptional and protein levels following SOC targeted therapy treatment in a panel of five oncogene-addicted cancer cell lines. This upregulation occurs alongside increased activation of NRG receptors and enhanced downstream signaling. CRISPR-Cas9-mediated knockout of ERBB receptors suggested a dependency of drug-tolerant BRAF-mutant colorectal cancer cells on ERBB2 and ALK-positive non-small cell lung cancer cells on EGFR, ERBB2 and ERBB3. Based on these findings we hypothesize that the drug-tolerant cells upregulate the NRG1/ERBB axis to overcome sensitivity to targeted therapies. Currently we are investigating whether targeting ERBB receptors in combination with the SOC targeted therapy could prevent the emergence of resistance to SOC.

Conclusion

The NRG1/ERBB signaling axis is upregulated upon long-term targeted therapy treatment in multiple oncogene-addicted cancer cell lines. Targeting this axis

in combination to the current SOC targeted therapies could lead to improved treatment efficacy.

EACR25-0969

Tissue-Resident Resting Fibroblasts Function as Tumor Suppressors in the Tumor Microenvironment

D. Lee¹

¹Ajou University School of Medicine, Pathology, Suwon, Korea (Republic of)

Introduction

Our previous research identified the presence of tissue-resident resting fibroblasts (tr-RFs) within the tumor microenvironment (TME). In contrast to tr-RFs, conventional cancer-associated fibroblasts (CAFs) exhibit hallmark characteristics of mesenchymal stem cells (MSCs). However, the biological role of tr-RFs in the TME remains largely unexplored.

Material and method

To elucidate the functional significance of tr-RFs, we conducted single-cell RNA sequencing (scRNA-seq) analyses of gastric cancer tissues and normal gastric mucosa, identifying distinct CAF subsets. Gene ontology (GO) and gene set enrichment analysis (GSEA) were performed to characterize their molecular signatures. The phenotypic plasticity of tr-RFs and MSCs was assessed via co-culture with gastric cancer cells (NUGC4) using qRT-PCR. Additionally, the impact of tr-RFs and MSCs on tumor progression was evaluated using a mouse xenograft model.

Result and discussion

scRNA-seq analyses delineated seven distinct CAF clusters. Uniform Manifold Approximation and Projection (UMAP) revealed that three of these clusters exhibited phenotypic overlap with normal stomach-resident fibroblasts. Among them, one specific cluster was devoid of mesenchymal stem cell markers (ITGB1, THY1, ENG) and active CAF markers (PRRX1, TNC), thereby identifying this population as tr-RFs. GO analysis of this subset demonstrated significant enrichment in pathways associated with the negative regulation of cellular proliferation, humoral immune activation, and complement system engagement, indicative of a potential immune-mediated tumor-suppressive function. *In vitro*, MSCs co-cultured with NUGC4 exhibited significant upregulation of CAF-associated genes (FAP, TNC, COL1A2, IL1A, IL6, LIF, CXCL12), whereas tr-RFs co-cultured with NUGC4 did not induce such transcriptional changes; instead, select CAF-related genes were downregulated. *In vivo*, MSCs markedly accelerated tumor growth in a nude mouse xenograft model, whereas tr-RFs profoundly suppressed tumor progression. Histological and immunohistochemical analyses further revealed that tumors with tr-RFs displayed significantly reduced MIB-1 labeling indices, and in some cases, elicited a robust immune response, corroborating our scRNA-seq findings.

Conclusion

Our study demonstrates that tr-RFs consist of a subset of CAFs, which remain transcriptionally stable in the presence of cancer cells and function as tumor suppressors, likely by inducing an immune response within the TME. Further mechanistic investigations are

warranted to elucidate the underlying pathways of this tumor-suppressive effect.

EACR25-1003

Impact of L-serine on the pro-carcinogenic effects of colibactin-producing *Escherichia coli* and the microbial community in APCmin/+ mice

A. Devaux¹, G. Roche¹, M. Rodrigues¹, C. Juban¹,

N. Barnich¹, D. Boucher¹, R. Villéger¹, M. Bonnet²

¹*M2iSH - UMR1071 Inserm / UCA / USC INRAE 1382, Clermont-Ferrand, France*

²*M2iSH - UMR1071 Inserm / UCA / USC INRAE 1382, France*

Introduction

Colonic tissues in colorectal cancer (CRC) patients are colonized by colibactin-producing *Escherichia coli* (CoPEC). Colibactin is a genotoxin synthesized by the pks genomic island. Metabolomic studies have revealed that CoPEC infection leads to a reprogramming of intestinal epithelial cell metabolism, resulting in a decrease in L-serine. This study aims to investigate whether L-serine contributes to CoPEC persistence in the gastrointestinal tract and enhances its pro-carcinogenic functions.

Material and method

The serine utilization on adhesion, survival and persistence of CoPEC was assessed using a CoPEC strain unable to metabolize L-serine (11G5-ΔtdcA) in human colorectal carcinoma T84 cells. Additionally, the impact of an L-serine-depleted (SD) diet on CoPEC persistence, genotoxic effects (γ H2Ax immunolabeling) and pro-carcinogenic properties was evaluated in a model predisposed to intestinal adenoma formation (APCmin/+ mice). The composition of the fecal microbial community following the SD diet was studied using 16S DNA gene sequencing at an early stage of cancer development.

Result and discussion

In vitro, exposure to CoPEC in T84 cells led to a decrease in both intracellular and extracellular L-serine levels. Consequently, infection with the 11G5-ΔtdcA strain resulted in reduced adhesion, survival and persistence, underscoring the essential role of L-serine utilization. Furthermore, this amino acid conferred a competitive advantage to CoPEC. To highlight the role of L-serine, APCmin/+ mice were fed an SD diet. This diet induced an early and transient decrease in CoPEC colonization, which was associated with a decrease in DNA damage. The pro-carcinogenic potential of CoPEC was significantly lower in APCmin/+ mice on the SD diet compared to those on the control (S) diet. Concerning the fecal microbial community, the SD diet led to a reduction in microbial richness and a decrease in diversity, specifically in mice that were infected. Additionally, the SD diet increased the abundance of the phylum *Bacillota* while decreasing the abundance of the phylum *Bacteroidota*, a shift associated with reduced carcinogenesis. Consistent with bacterial colonization patterns, the abundance of *E. coli*, belonging to the *Pseudomonadota* phylum, was significantly lower in the feces of mice fed the SD diet compared to those on the S diet.

Conclusion

These findings suggest that L-serine modulates the gut microbiota composition in APCmin/+ mice, promoting the expansion of CoPEC. In addition, this study supports the hypothesis that CoPEC exploit host-derived L-serine to persist in the gut and exert its genotoxic and pro-carcinogenic effects. This work may help identify potential therapeutic targets.

Introduction

Prostate cancer (PCa) is the most common visceral neoplasm and the third leading cause of cancer-related death in men worldwide. With the decline in prostate-specific antigen (PSA) testing – a widely used biomarker for PCa screening – the incidence of advanced cases, including metastatic disease at diagnosis, is rising. Understanding the mechanisms driving PCa progression is therefore of utmost importance for identifying candidate biomarkers and therapeutic targets to limit disease spread.

Material and method

Circulating biomarkers were analysed on 77 patients with newly diagnosed PCa from the HormOS cohort (Paris University Hospitals). Further investigations were conducted with a preclinical mouse model of PCa in which the tumor suppressor gene PTEN is selectively inactivated in prostatic epithelial cells (PECs) at adulthood (Pten(i)pe-/ mice).

Result and discussion

PSA levels and polynuclear neutrophil counts were both negatively associated with circulating vitamin D levels in treatment-naïve PCa patients. To investigate the role of vitamin D signaling in PCa progression, we compared prostatic tumorigenesis in Pten(i)pe-/ and Pten/Vdr(i)pe-/ mice, where PECs are deficient in VDR and/or PTEN. Our results demonstrate that enhanced oxidative stress and increased proliferation during prostatic intraepithelial neoplasia formation in PTEN and VDR-deficient PECs are prevented by treatment with the antioxidant N-acetyl cysteine. Moreover, a combination of single-cell RNA

sequencing and immunophenotyping revealed that the recruitment of tumor-infiltrating immunosuppressive neutrophils is higher in Pten/Vdr(i)pe^{-/-} than in Pten(i)pe^{-/-} mice. Further investigation of prostate tumorigenesis in Pten/Vdr(i)pe^{-/-} mice uncovered the presence of pan-cytokeratin-positive (PanCK+) micro-metastases in the liver, a marker of poor prognosis in patients. These infiltrates contained immune and endothelial cells, and positively correlated with the circulating neutrophil frequency. Moreover, treatment with a CXCR1/CXCR2 inhibitor reduced neutrophil recruitment and decreased the prevalence of micro-metastases in Pten/Vdr(i)pe^{-/-} mice.

Conclusion

Taken together, our findings demonstrate that VDR signaling plays a protective role in PTEN-deficient PECs by limiting oxidative stress, proliferation, and neutrophil recruitment. Furthermore, we provide evidence that reducing neutrophil chemotaxis represents a promising therapeutic target to prevent metastatic spreads in treatment-naïve PCa.

EACR25-1024 Characterizing Neuron-Neuroblastoma circuit development and its role in tumor progression

B. Braz¹, C. Roussel¹, O. Otero Laudouar¹, B. Fricaud¹, M. Pratviel¹, Q. Fort¹, B. Dumont², F. Reynaud¹, O. Pascual³, C. Delloye-Bourgeois¹

¹Cancer Research Center of Lyon, Lyon, France

²Centre Léon Bérard, Institut d'Hématologie et d'Oncologie Pédiatrique, Lyon, France

³Institut NeuroMyoGène, MeLis, Lyon, France

Introduction

The influence of the nervous system on cancer progression has been increasingly recognized, yet remains enigmatic in many aspects, especially for cancers like Neuroblastoma (NB), a devastating childhood cancer arising in the developing peripheral nervous system (PNS). NB originates from neural crest cells with primary tumors emerging throughout the sympathetic paravertebral chain and the adrenal medulla. While significant progress has been made in aggressive brain gliomas, where synapses between neurons and tumor cells drive disease progression, it remains unknown whether similar synaptic contacts exist in peripheral nervous tumors such as NB. Our general aims are to determine whether NB cells receive synaptic contacts, to assess their ability to respond and propagate electrical signals, and to evaluate the impact of such dialogs on disease progression.

Material and method

We performed a multidisciplinary approach combining electrophysiology, high resolution imaging and scRNA-Seq analysis. We examined patient samples to study synaptic structures and used a NB-grafted avian embryo model, which recapitulates key aspects of NB pathology, for a comprehensive investigation of synaptic structures and functions.

Result and discussion

In a series of patient biopsies, we could detect synaptic contacts involving NB cells by electronic microscopy. scRNA-Seq in the NB avian embryo model revealed that

NB cells progressively acquire neuronal features during tumorigenesis and dissemination, including the expression of synaptic proteins, neurotransmitter receptors, and ionic channels. In this model, immunohistochemical analyses also evidenced the presence of synaptic structures in NB tumors. These synaptic structures increased in size during embryonic development. To assess synaptic function, we setup and implemented ex vivo whole-cell patch clamp recordings in NB cells. We observed that a fraction of cells exhibited synaptic excitatory currents in response to electric stimulation. We are currently working to identify the involved neurotransmitters using specific blockers. Furthermore, a high fraction of recorded NB cells showed voltage-dependent sodium currents, and this fraction increased during development. Impressively, NB cells were capable of firing action potentials with current injection.

Conclusion

NB cells in primary tumors progressively acquire neuronal features, including the formation of synaptic structures and the ability to respond and propagate electrical stimuli through action potential generation. We propose that these neural characteristics may enhance their capacity for growth and dissemination. Understanding these neuro-cancer mechanisms could uncover critical targets for future drug development, paving the way for innovative treatments.

EACR25-1034 Comprehensive screening of A-to-I editing in colorectal cancer: implications for tumour progression and therapeutic targeting

M. Niemira¹, K. Chwialkowska², G. Sokolowska¹, A. Ostrowska¹, A. Zeller¹, W. Turska³, A. Michalska-Falkowska⁴, J. Reszec-Gielazyn⁵, M. Moniuszko⁶, A. Kretowski¹

⁵Medical University of Bialystok, Department of Medical Pathology, Bialystok, Poland

⁶Medical University of Bialystok, Centre of Regenerative Medicine, Bialystok, Poland

Introduction

Adenosine-to-inosine (A-to-I) RNA editing is a post-transcriptional modification that has been shown to influence gene expression, RNA stability, and protein function. In colorectal cancer (CRC), A-to-I editing may contribute to tumor progression by modulating key cellular pathways involved in proliferation, apoptosis, and metastasis. Despite its potential importance, a comprehensive investigation into the role of A-to-I editing in CRC has not yet been fully explored. This study aims to characterise A-to-I RNA editing patterns in CRC and explore its implications for tumor progression.

Material and method

To identify A-to-I editing events, we performed high-throughput small RNA-sequencing on 116 CRC tissue samples and matched 119 normal colorectal tissues. The mapped output file was subjected to identifying reads containing A-to-G changes representing A-to-I editing in mature miRNA using the miRge 3.0 package. The A-to-I editing level was defined as the ratio of the mapped reads with changed nucleotides relative to the total mapped reads for each miRNA. A-to-I editing events were further analysed based on the respective percentage and expression level at the RPM scale. To reveal the biological function of the edited miRNAs, we identified putative target genes using Ingenuity Pathway Analysis (IPA), mirDB and TargetScanHuman 8.0 and performed WikiPathways analysis to investigate cancer-related pathways.

Result and discussion

We identified four unique A-to-I miRNA editing hotspots. Among them, miR-200b-3p ($\log_{2}FC = 1.17$; FDR-adjusted p-value = 1.91×10^{-15}) was overedited, but miR-411-5p ($\log_{2}FC = -1.18$; FDR-adjusted p-value = 1.71×10^{-31}), miR-497-5p ($\log_{2}FC = -1.06$; FDR-adjusted p-value = 6.66×10^{-18}) and miR-99a-5p ($\log_{2}FC = -0.48$; FDR-adjusted p-value = 1.68×10^{-06}) were underedited in tumors relative to normal tissues. All editing events were located in the seed region at the position 1-8 mature miRNAs. The functional analysis of edited miRNA target genes revealed that dysregulated pathways were mainly associated with EMT (Epithelial-Mesenchymal Transition) (FDR-adjusted p-value = 3.44×10^{-10}), PI3K/AKT pathway (FDR-adjusted p-value = 2.48×10^{-11}), mTOR pathway ((FDR-adjusted p-value = 8.50×10^{-09}), and cell cycle control (FDR-adjusted p-value = 4.21×10^{-10}). By ranking the PPI network nodes using the cytoHubba plugin of Cytoscape software, we found that CCND1, IGF1R, AKT1, PTEN, CDK6, CDK4, CDKN2A, SNAI1, GRB2, PRAS40 scores ranked in the top 10 hub genes.

Conclusion

The findings highlight the potentially crucial role of A-to-I editing in the pathogenesis of CRC. Dysregulated A-to-I editing of identified miRNAs could contribute to tumorigenic processes, including metastasis, by altering key regulatory pathways involved in cancer progression.

EACR25-1036

The Role of Hypoxia-Inducible Factor-1 α in shaping Cancer-Associated Fibroblast phenotypes in colorectal cancer

M. Gabola¹, D. Cheung², E. Koncina², E. Letellier²

¹*University of Luxembourg, Department of Life Sciences and Medicine, Belvaux, Luxembourg*

²*University of Luxembourg, Department of Life Sciences and Medicine, Belvaux, Luxembourg*

Introduction

Colorectal cancer (CRC) is a leading cause of cancer-related mortality worldwide. Despite significant advancements in understanding CRC pathogenesis, patient prognosis remains poor due to metastatic dissemination. A key factor in cancer progression is the presence of cancer-associated fibroblasts (CAFs) in the

tumor microenvironment, which regulate processes such as extracellular matrix (ECM) deposition and immune suppression. Additionally, hypoxia and its central regulator, hypoxia-inducible factor-1 α (HIF-1 α), are hallmark features of advanced cancers. HIF-1 α is a transcription factor responsible for adaptive responses to low-oxygen environments, promoting tumor cell survival and resistance to therapy. However, the role of HIF-1 α in CAFs within CRC remains largely unexplored.

Material and method

To unravel the effects of hypoxia on CAF biology, we generated a hypoxia-specific gene signature from patient-derived CAFs exposed to hypoxic conditions. Gene set enrichment analysis (GSEA) was conducted to determine the enrichment of pathways associated with hypoxia in CAFs. Additionally, we employed in vitro functional assays to assess changes in CAF contractility and matrix remodeling capabilities under hypoxic conditions. Furthermore, we will use in vitro co-culture systems using patient-derived CAFs and matched tumor organoids to investigate their reciprocal interactions under hypoxic conditions. A colitis-associated carcinogenesis model in mice with fibroblast-specific deletion of hif-1 α , will allow us to study its role in tumor initiation and progression.

Result and discussion

GSEA revealed that the hypoxic signature in CAFs is enriched in pathways related to epithelial-to-mesenchymal transition (EMT), inflammatory responses, and mTORC signaling, suggesting that hypoxia promotes a tumor-supportive CAF phenotype. Functional assays demonstrated that hypoxic CAFs displayed increased contractility and enhanced matrix remodeling capabilities, highlighting their active role in shaping the tumor microenvironment. Mining in-house scRNAseq data with the hypoxia-associated gene sets will allow us to identify hypoxia-responsive CAF subsets across different stages of CRC progression and metastasis. The in vivo mouse model will further elucidate the role of hif-1 α in CAFs during tumorigenesis.

Conclusion

This project aims to uncover the underappreciated contribution of HIF-1 α in shaping CAF phenotypes during CRC progression. By integrating in vitro and in vivo approaches, we will provide new insights into how hypoxia influences CAF function and identify potential therapeutic targets for disrupting tumor-supportive CAF activity in CRC.

³Genomics Core Facility, Philipps-University Marburg, Marburg, Germany

Introduction

CRISPR-based mouse models play a crucial role in lung cancer research, enabling the *in vivo* generation and analysis of cancer mutations. Adenoviral delivery of single guide RNAs (sgRNAs) allows the flexible targeting of various cancer genes and has been previously used to generate an autochthonous model for small cell lung cancer (SCLC). Unfortunately, not all relevant cancer mutations can be investigated, since the canonical CRISPR system predominantly produces knockouts via insertions or deletions, limiting its ability to introduce single-nucleotide substitutions. These mutations, which include nonsense and missense variants, are the most prevalent in cancer patients and frequently affect critical tumor suppressor genes such as TP53.

Material and method

We adopted a novel approach utilizing cytosine base editing (CBE), a CRISPR-based genome editing tool facilitating the conversion of a cytosine to a thymine, enabling the precise induction of point mutations in DNA. Our optimised CBE consists of a human deaminase with increased editing efficiency and a near-PAMless Cas9, allowing for greater flexibility in the choice of the sgRNA and consequently the target mutation. In our SCLC model, adenoviral delivery of the optimised CBE system induces point mutations in the tumor suppressor genes Trp53, Rb1 and Rbl2, resulting in the autochthonous development of lung tumours. Over the course of the experiment, tumour development can be monitored using small blood samples, as specific reporter mice are used in which cancer cells secrete luciferase into the bloodstream.

Result and discussion

For all target mutations, sgRNAs were first validated *in vitro* and then used to generate recombinant adeno-viruses. The first mice developed lung tumours autochthonously 8–9 months after adenoviral delivery of the CBE system, which correlated with an increase in luciferase levels in the blood. The resulting tumours were confirmed to be SCLC by immunohistochemistry as they expressed typical neuroendocrine markers. Moreover, the tumours harbour the specific target mutations – tumours with a Trp53 knockout via a nonsense mutation, as well as the hyperstabilized Trp53-R270C missense variant, were generated and can now be used for further analysis into the role of mutant p53 in SCLC. A major advantage of our CBE-based model is the ability to induce defined nonsense and missense mutations in any gene of interest with great flexibility, allowing for the comparison of various different mutant variants within a defined genetic setting.

Conclusion

This novel CBE-based autochthonous SCLC model successfully generates tumours harbouring either a Trp53 nonsense or the R270C missense mutation, providing a valuable platform for investigating the functional impact of p53 mutations in lung cancer. This approach enhances our ability to study specific cancer-associated mutations, advancing precision cancer research.

EACR25-1062

Large-scale integrative analysis of fecal samples sequencing data from healthy and CRC patients supports novel miRNA-mediated host-microbiota interactions

A. Camandona¹, G. Ferrero¹, S. Tarallo², B. Genta², V. Vymetalkova³, B. Zwinsová⁴, N. Segata⁵, G. Piccinno⁵, B. Pardini², A. Naccarati²

⁴Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic

⁵University of Trento, Department CIBIO, Trento, Italy

Introduction

Dysregulated microRNA (miRNA) profiles were repeatedly reported in studies on Colorectal Cancer (CRC) tissues. More recently, analyses of stool from CRC patients have clearly shown that altered miRNA levels reflect the presence of neoplastic lesions. Moreover, studies in model organisms reported that miRNAs released into the gut lumen, and detectable in stool, can modulate microbial gene expression. However, a comprehensive investigation of miRNA-microbiota interactions in humans is still lacking. Combined profiling of fecal miRNAs and microbial species in a large population of CRC patients and healthy individuals could provide novel insights into host-microbiota interactions dysregulated in this tumor.

Material and method

An integrative analysis of fecal shotgun metagenomic sequencing and small RNA-Seq (sRNA-Seq) data of 1,052 subjects from eight European cohorts was performed. The study included 332 CRC patients, 87 subjects with precancerous lesions, 165 with non-tumoral gastrointestinal diseases, and 468 healthy controls. Microbial profiling was performed using MetaPhlAn 4.1 while a Docker4Seq pipeline was applied for fecal miRNA quantification. Diversity analysis of miRNA and microbial profiles (by Richness, Shannon, Inverse Simpson, Evenness indices) across study groups was performed with an investigation of significant and consistent miRNA-microbial associations across cohorts.

Result and discussion

From the fecal miRNome/microbiome characterization, a significant decrease ($p < 0.05$) of miRNA heterogeneity was observed from healthy to CRC, while the microbial diversity increased in CRC was driven by the oral-to-gut introgression of oral species. 216 detectable miRNAs across cohorts were confirmed to be transcriptionally active in the intestinal tissue and some of them were dysregulated in CRC tissue, as also reported in public datasets. Analysing miRNA levels with respect to abundances of 461 commonly detected microbial species, 2,223 significant and coherent miRNA-microbial associations across cohorts were identified. Despite the observed associations were predominantly positive and detected in CRC ($n = 916$, 47%), 780 associations (35%)

were uniquely detected in controls while only 53 (3%) showed opposite direction among controls and CRC. The associations involved oral species including the previously reported miR-1246 and *Fusobacterium nucleatum* association. The associations changed from healthy to late-stage CRC, with only 3% of them shared among main disease categories.

Conclusion

Our findings indicate that gut microbial composition is associated with fecal miRNA profiles. Most of the associations are specific to CRC and may reflect alterations in both the fecal miRNome and microbiome. To conclude, these data support the role of miRNAs as potential mediators of host-gut microbiota interactions.

EACR25-1063

Reconstructing spatiotemporal dynamics of the tumor and micro-environment in a triple-negative breast cancer murine model

K. Lisek¹, I. Theurillat¹, T. Pentimalli¹, S. Beier¹, A. Boltengagen¹, M. Müller², D. Leon-Perinan¹, S. Raimundo³, W. Birchmeier², N. Rajewsky¹

¹MDC-BIMSB, Systems Biology of Gene Regulatory Elements, Berlin, Germany

²MDC, Signal Transduction in Development and Cancer, Berlin, Germany

³MDC, Advanced Microscopy Unit, Berlin, Germany

Introduction

Triple-negative breast cancer (TNBC) is a highly aggressive malignancy with a strong metastatic potential and limited therapeutic options. While tumor-intrinsic factors contribute to disease progression, the tumor microenvironment (TME) undergoes dynamic remodeling, influencing tumor evolution through mechanisms that remain to be fully elucidated. Cellular interactions within the TME promote immune evasion and therapeutic resistance, further driving malignancy. To investigate these processes, we developed a murine TNBC model carrying patient-relevant mutations that spontaneously generate tumors, closely recapitulating human TNBC progression. By applying single-nucleus and high-resolution spatial transcriptomics, we generated a spatiotemporal atlas of TME remodeling, uncovering sequential cellular transitions that shape tumor progression.

Material and method

Four time points – healthy, early, intermediate, and late tumors – with three biological replicates per stage were analyzed. snRNA-seq was performed on all samples, capturing 59,000 cells. OpenST spatial transcriptomics, recently developed by our group (Schott et al., 2024, Cell), was applied to the same timepoints, covering 770,000 7 µm pseudocells. Over 200 mammary ducts were isolated for pseudotemporal alignment. DestVI mapped snRNA-seq clusters onto spatial data, while CellChat inferred cell-cell communication.

Result and discussion

In this project, we developed a TNBC mouse model carrying p53, PIK3CA, and β-Catenin mutations, which spontaneously formed multifocal tumors. Tumor

progression was marked by a progressive trans-differentiation of epithelial cells from a luminal to a basal-like phenotype, giving rise to distinct micro-environmental niches. By calculating pseudotime, we aligned ducts according to tumor advancement, revealing an ordered remodeling process that linked epithelial transitions to stromal reorganization. This transformation of the TME occurred through orchestrated, sequential events driven by TGF-β signaling activation, leading to the emergence of cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs). Syngeneic transplants in immunocompetent mice demonstrated that a specific myCAF subpopulation strongly enhances tumor growth, establishing its role as a key regulator of TNBC progression.

Conclusion

Our study reveals that TNBC progression is driven by a stepwise remodeling of the TME, where tumor cell transitions are tightly linked to orchestrated stromal reprogramming. We identify myCAFs as key drivers of an aggressive tumor niche, promoting malignancy through extracellular matrix remodeling and TGF-β signaling. These findings provide a framework for targeting early tumor-stroma interactions as a therapeutic strategy in TNBC.

EACR25-1068

Identifying Metastatic Drivers and Biomarkers in Colorectal Cancer – the zAvatar model as a surrogate for patient metastatic potential

B. Costa¹, A. Gomes², C. Oliveira³, R. Fior¹

¹Champalimaud Foundation, Cancer Development and Innate Immune Evasion Lab, Lisbon, Portugal

²Hospital Prof. Dr Fernando da Fonseca, Surgery Department, Amadora, Portugal

³i3S – Instituto de Investigação e Inovação em Saúde, Expression Regulation in Cancer Lab, Porto, Portugal

Introduction

Metastasis remains the biggest challenge in cancer treatment, accounting for ~90% of cancer-related deaths. Colorectal cancer (CRC) is no exception, with distant metastasis predominantly affecting the liver and lungs. Despite significant advances, the molecular mechanisms driving CRC metastasis remain controversial, and reliable biomarkers for identifying patients at risk of metastatic disease are still lacking in the clinical practice. Our recent work established the zebrafish xenograft model (zAvatar) as a fast predictive platform for personalized treatment in CRC, forecasting patient progression with 91% accuracy.

Material and method

We observed that zAvatars derived from CRC patients with disease progression exhibited a significantly higher incidence of micrometastases compared to those without progression. Among locoregional tumors, the absence of metastases was sufficient to classify patients as non-progressive, whereas if the zAvatar presented micrometastases, then patient outcome would depend on the efficacy of adjuvant chemotherapy (Costa et al, Nat Commun 2024). This suggests that the model reveals the

inherent biological ability that tumor cells may have or not to metastasize, providing a unique opportunity for patient stratification. To further explore this, we analyzed transcriptional differences between stage III CRC tumors that developed micrometastases in zAvatars those that did not.

Result and discussion

Preliminary RNA sequencing of stage III CRC patients identified a clear metastatic gene signature, consisting of five overexpressed genes associated with micro-metastases in the zAvatars, suggesting their potential role as metastasis drivers. To validate and map these genes within the tumor microenvironment, we will apply spatial transcriptomics to the same tumor samples. The final goal is to perform a functional validation on target genes, by overexpressing them in CRC cells or in the zebrafish host, and assess their role in metastatic progression.

Conclusion

The zAvatar model provides a powerful tool to identify tumors with metastatic potential. With this project we aim to improve patient stratification and expand our understanding of the molecular mechanisms underlying CRC metastasis.

EACR25-1090

miR-27a Targets the Circadian clock circuitry to Drive Lung Adenocarcinoma Progression

E. Murgo¹, M. Bellet², G. Marasco³, V. Manuti³, A. Saponaro³, M. Ciarnelli⁴, G. Maxxoccoli³, T. Colangelo³

¹*Fondazione IRCCS Casa Sollievo della Sofferenza, Manfredonia, Italy*

²*Università degli Studi di Perugia, Perugia, Italy*

³*Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy*

⁴*Università degli Studi di Foggia, Foggia, Italy*

Introduction

Circadian rhythms regulate essential cellular processes, including metabolism, proliferation, and DNA damage response, through transcriptional-translational feedback loops (TTFLs). Core circadian genes, such as ARNTL (Bmal1) and CLOCK, orchestrate these oscillations, maintaining cellular homeostasis. Dysregulation of the circadian machinery has been implicated in tumorigenesis, enhancing cancer aggressiveness and therapy resistance. MicroRNAs (miRNAs) are key post-transcriptional regulators, with miR-27a-3p identified as a modulator of circadian genes. This study investigates the role of miR-27a-3p in lung adenocarcinoma by evaluating its impact on ARNTL and CLOCK expression and associated tumorigenic properties.

Material and method

Lung adenocarcinoma cell lines were genetically modified to overexpress or inhibit miR-27a-3p. The effects on ARNTL and CLOCK expression were assessed at mRNA and protein levels via qPCR and immunoblotting. Functional assays – including proliferation, migration, invasion, and metabolic profiling – were performed to evaluate tumor behavior. Target Site Blockers (TSBs) were used to selectively disrupt miR-27a-3p binding to ARNTL and CLOCK, followed by additional functional assays. To assess in vivo effects,

modified cells were transplanted into immunocompromised mice, and tumor growth was monitored. RNA sequencing (RNA-seq) was conducted to identify downstream pathways regulated by miR-27a-3p.

Result and discussion

miR-27a-3p negatively regulates ARNTL and CLOCK, promoting a more aggressive and invasive phenotype in lung adenocarcinoma cells. Functional assays revealed that miR-27a-3p overexpression enhances migration, metabolic reprogramming, and tumor progression. RNA-seq analysis identified IL-8 as a downstream effector of the miR-27a-3p/ARNTL-CLOCK axis, where its suppression further increased tumor cell invasiveness while reducing proliferative capacity. The in vivo model confirmed that miR-27a-3p promotes an invasive phenotype, reinforcing the role of circadian gene dysregulation in lung cancer progression.

Conclusion

This study demonstrates that miR-27a-3p drives lung adenocarcinoma progression by targeting ARNTL and CLOCK, influencing tumor metabolism, invasion, and proliferation. The identification of IL-8 as a downstream effector highlights a potential link between circadian disruption and oncogenic signaling. Targeting the miR-27a-3p/ARNTL-CLOCK axis may represent a novel therapeutic approach to mitigate lung adenocarcinoma aggressiveness and improve treatment outcomes.

EACR25-1094

Developing Comprehensive In Vitro and In Vivo Models: Patient-Derived Organoids (PDOs) and Xenografts (PDXs) for Morphological and Functional Analysis and Drug Screening in Head and Neck Squamous Cell

A. Francia¹, C. Girone¹, D. Filippini¹, G. Querzoli¹, M. Fermi¹, C. Miroglio¹, E. Montacci¹, A. Ardizzone¹, M. Lauriola¹, D. Romaniello¹

¹*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy*

Introduction

About 90% of head and neck cancers originate from the mucosal epithelial cells of the oral cavity, pharynx and larynx referred as HNSCCs. The FDA has approved the use of the anti-epidermal growth factor receptor (EGFR) monoclonal antibody cetuximab (CTX) as a radiosensitizer for recurrent or metastatic HNSCCs. However, despite most of HNSCC exhibit EGFR overexpression, response rate remains limited and nowadays CTX has been replaced by new recently approved immune checkpoint inhibitors, which also show low efficacy. Thus, it is crucial to investigate compensatory mechanisms and new molecular targets that improve CTX sensitivity, identifying subgroups that may benefit the most.

Material and method

Considering the diversity of HNSCCs and lack of representative models, we created a small set of characterized patient-derived xenografts (PDXs), using fresh samples collected during patients' surgery. PDX models were obtained by implanting tumor fragments into the flanks of immunocompromised mice. Palpable

tumors were partially harvested for HNSCC-PDX biobank creation, partially expanded for drug testing and ex vivo analysis, and partially digested in single cells suspension and enclosed into a 3D matrix for patient-derived organoids (PDOs) generation (namely tumoroids). Ex vivo analysis through Immunohistochemistry, RT-qPCR and Western Blot was performed for PDX characterization.

Result and discussion

To date, we have successfully developed three stable HNSCC PDX models achieving a 30% success rate. Through immunohistochemical staining, we demonstrated that PDX samples recapitulate the morphological and functional traits of the patients' tumors. Additionally, HPV genotyping and E6 viral oncogene transcript analysis showed that one out of three samples was HPV-positive while EGFR protein expression varied across PDX samples thus suggesting a differential response to anti-EGFR blockade.

Conclusion

In conclusion, studying molecular mechanisms using well-characterized PDX and PDO models would have a significant impact on therapeutic advances, especially for HNSCCs, where there is an urgent need to identify new potential biomarkers for earlier diagnosis and develop tailored and more personalized treatments to improve survival.

EACR25-1103

Development of a Tumor-On-Chip Model to Predict Drug Response in Breast Cancer

Z. Gunyuz¹, M. Guzelgulgen², D. Pesen Okvur¹, E. Ozcivici², G. Mese¹, M. Gursoy³, O. Yalcin Ozuyosal¹

¹Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey

²Izmir Institute of Technology, Department of Bioengineering, Izmir, Turkey

³Izmir Katip Celebi University, Department of Radiology, Izmir, Turkey

Introduction

Based on its highly heterogeneous neoplasm with distinct subtypes, breast cancer necessitates innovative strategies for personalized treatment. Here, we present a novel on-chip approach to evaluate the drug response of human breast tumor samples. Previously, we employed this platform with breast cancer cell lines, demonstrating its ability to assess drug response and invasion towards different homing cells. In this study, we extend this platform's versatility by utilizing core needle biopsy samples to gain deeper understanding of drug response and invasion capacity for primary breast tissues.

Material and method

We obtained biopsy samples from breast tumors categorized as BI-RADS 5 during radiological assessment. We used a custom-made slicer to section the tissue into discs of ~400 um. To assess initial viability of the samples for potential exclusion, we used PrestoBlue viability assay and analysed the mean grey value of fluorescence signal detected at 560/590 nm (excitation/emission). Three tissue slices per trial were incubated at 65 °C for one hour to serve as a negative control

representing dead tissue. To mitigate inherent viability variations arising from biopsy sampling, we established a viability index to ensure consistent results across different patient tissues. This index was calculated as the ratio of the mean grey value of the sample to the mean grey value of the negative controls. Samples falling below a predefined threshold were excluded from subsequent drug response experiments.

Result and discussion

To optimize tissue viability, we evaluated various culture media such as DMEM-F12 supplemented with EGF, hydrocortisone, cholera toxin, ITS (Insulin, transferrin, selenium), 3,3',5 Triiodothyronine and adenine. The optimal media was determined as DMEM-F12 supplemented with EGF, hydrocortisone, cholera toxin, and insulin. Subsequently, we assessed the viability of primary breast tissues in the presence and absence of paclitaxel, at a concentration range of (1.6 uM-14 uM), commonly used in clinical settings. Our results showed a significant decrease in tissue viability after 24h of paclitaxel exposure, while control samples were viable for up to 14 days. To investigate invasion capability, tissues were stained with a cell tracker and then embedded in Matrigel on a tumor-on-chip platform consisting of three channels connected to each other. Few cells were migrated towards the channel containing the chemoattractant (20% FBS).

Conclusion

In conclusion, our study demonstrated the applicability of a less-labour-intensive and cost-effective approach without the need for advanced equipment that can be applied for the advancement of precision oncology for breast cancer patients. Additionally, our model allows real-time monitoring of cellular dynamics such as drug responses, providing valuable insights into tumor behavior and potential therapeutic strategies.

EACR25-1106

Peritoneum specific fibroblasts that can arise in response to various local disorders promote colorectal cancer peritoneal metastasis

²University of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy

³Amsterdam UMC and University of Amsterdam, Cancer Center Amsterdam, Amsterdam, Netherlands

⁴Oxford University Hospitals, Department of Colorectal Surgery, Oxford, United Kingdom

Introduction

Peritoneal membrane injury induces the activation of local fibroblasts and tissue remodelling, which ultimately can progress to fibrosis. Metastasis of colorectal cancer (CRC) to the abdominal cavity results in such peritoneal damage. Patients with colorectal cancer peritoneal metastasis (CPM) have a particularly poor prognosis, and CPM tumours are characterised by a high infiltration of

fibroblasts. Here, we characterised the molecular and functional features of these fibroblasts, and investigated their interaction with other cells in the peritoneal microenvironment.

Material and method

Primary fibroblasts were isolated from 89 patients with different malignant and benign disorders of the peritoneum. We performed comprehensive analyses of single cell and transcriptome profiling, secretome characterization, and functional enzymatic activity.

Result and discussion

We were able to identify a peritoneum specific fibroblast population that increases in response to different types of damage inducing peritoneal pathologies, including metastasis. These fibroblasts are characterised by the IGFBP2 dependent expression of CD38, which mediates extracellular non canonical adenosinergic activity and contributes to the suppression of macrophages and T cells. Importantly, peritoneal fibroblasts promoted the growth and invasiveness of tumour cells in a xenograft mouse model of peritoneal metastasis, highlighting their pro tumorigenic role. Their specific gene signature was associated with poor prognosis in a dataset of 51 patients suffering from colorectal peritoneal metastasis. This study revealed that the CPM is infiltrated by a peritoneal fibroblast subtype, which is absent in healthy tissue, but also observed in benign peritoneal diseases.

Conclusion

Given the limited therapeutic options for these patients, these pro tumorigenic peritoneal fibroblasts could represent an attractive target for inhibiting the peritoneal spread of tumour cells.

EACR25-1134

N106S mutation in eIF6 may prevent tumour onset caused by mRNA translation defects in Shwachman-Diamond Syndrome

G. D'Andrea^{1,2}, I. Ferrari^{1,2}, S. Biffo^{1,2}

¹*INGM, Milano, Italy*

²*Università degli Studi di Milano, Milano, Italy*

Introduction

mRNA translation defects are at the basis of many cancer types. In particular in Shwachman-Diamond Syndrome (SDS) hematopoietic stem cells frequently inactivate p53 to overcome ribosomal stress. Mutations in the SBDS gene are identified in most patients with SDS. The SBDS protein is involved in ribosome biogenesis, and its deficiency leads to impaired ribosomal function that is thought to contribute to bone marrow failure and the predisposition to hematologic malignancies observed in SDS patients. eIF6 is a ribosome anti-association factor that prevents premature joining of the 40S and 60S ribosomal subunits. Overexpression of eIF6 has been linked to increased aggressiveness in certain cancers. However, in the context of SDS, somatic mutations in eIF6, particularly the N106S mutation, have been observed associated with a protective effect against leukemogenesis in SDS patients.

Material and method

HEK293T has been used to install the N106S mutation in eIF6 gene by means of Prime Editing. Cell growth has

been evaluated by metabolism assays and toxicity has been measured by MTT. At molecular level, specific gene patterns have been investigated using both bulk RNAseq and RiboSeq to have a comprehensive view of gene expression

Result and discussion

HEK293T cells were successfully edited to carry the N106S eIF6 mutation in heterozygosis, mirroring the condition observed in SDS patients. The homozygous mutation is not viable, indicating a loss of function that negatively regulates the cell cycle. When SBDS is depleted, wild-type cells – which do not undergo transformation – experience a 20% reduction in protein expression. In contrast, eIF6-mutated cells can tolerate up to an 80% reduction in SBDS levels without undergoing malignant transformation. Puromycin incorporation was used as a proxy for protein synthesis rate. eIF6-mutated cells exhibited a dramatic and significant impairment in protein synthesis. Polysome profiling revealed an accumulation of the 80S ribosomal subunit in eIF6-mutated cells, suggesting a perturbation in mRNA translation that becomes more pronounced when SBDS is reduced.

Conclusion

While SBDS mutations are strongly linked to leukemia risk, somatic mutations in eIF6, such as N106S, may serve as a protective adaptation by restoring translational balance. Understanding this interplay could provide insights into the molecular mechanisms of leukemogenesis in SDS. To further explore the role of eIF6 N106S in SDS and its potential impact on tumor biology, RNA-seq and Ribo-seq data are being analyzed to identify translational programs affected by SBDS loss and determine whether the eIF6 mutation modulates ribosome function to counteract vulnerabilities relevant to malignancy. Targeting eIF6 modulation could represent a potential therapeutic strategy.

EACR25-1139

Chromosomal instability as a driver of cGAS-STING dysfunction

A. Hall¹, M. Khan¹, M. Guscott¹, M. Lockley¹, S. Martin², S. McClelland¹

¹*Barts Cancer Institute, London, United Kingdom*

²*The Francis Crick Institute, London, United Kingdom*

Introduction

Chromosomal instability (CIN) is defined as the continual gain or loss of chromosome fragments or whole chromosomes and is a feature of high grade serous ovarian cancer (HGSOC). CIN is associated with various aspects of tumour biology, but its the impact of CIN on the tumour immune microenvironment (TME) is less well-defined. One consequence of ongoing CIN is the accumulation of cytoplasmic self-DNA which promotes the activation of innate DNA sensing pathways such as cGAS-STING. Acute cGAS-STING activation is reported to promote CD8+ T cell recruitment and synergize with immunotherapy. Yet, the consequences of chronic cGAS-STING activation, such as in CIN-high tumors, remain undefined. Therefore, we aim to explore the differences in cGAS-STING signaling in CIN-low and CIN-high models, and the implications of such on the wider TME using murine models of HGSOC.

Material and method

Molecular biology techniques including microscopy, RT-qPCR, western blotting, and flow cytometry were utilized to evaluate CIN, and cGAS-STING functionality in human and murine HGSOC-representative cell lines. Bulk RNA sequencing will be used to evaluate differences in response to STING agonists in CIN-low and CIN-high cell lines, and to determine differences in the immune microenvironment of tumors with varying CIN rates.

Result and discussion

CIN-high HSGOC-representative murine cells demonstrated reduced basal STING expression in comparison to matched CIN-low cells. As a consequence, CIN-high cells fail to induce PD-L1 and key cytokines that promote T cell activation and recruitment in response to STING agonism. We mimicked these changes to cGAS-STING signaling in the CIN-low cell line models through repetitive STING agonism using cGAMP. Our current work aims to determine if the changes to cGAS-STING signaling in CIN-high models are reversible. Preliminary data suggests that STING downregulation is maintained when the pressure of CIN is removed, and cells remain unresponsive to STING agonism with regard to PD-L1 and cytokine induction. We are currently investigating if differential responses to STING agonism occur in CIN-low and CIN-high settings using bulk RNA sequencing, with a particular focus on if a differential cytokine profile occurs in CIN-high cells upon STING agonism. In addition, we are evaluating the immune microenvironment in CIN-low vs. CIN-high tumor models both pre- and post-chemotherapy.

Conclusion

cGAS-STING dysfunction is apparent in CIN-high mouse and human cell line models of HGSOC. This may be an irreversible phenotype and can be mimicked by repetitive STING agonism. Current work aims to determine if cGAS-STING downregulation in a CIN-high context results in differential cytokine release upon STING agonism, and how the TME differs in CIN-low and CIN-high *in vivo* models. This work begins to provide insight into how CIN impacts immune-related pathways and may impact the wider TME.

³*Yarmouk University, Department of Pharmaceutics and Pharmaceutical Technology, Irbid, Jordan*

⁴*Institute of Pharmacy, Department of Medicinal Chemistry, Halle, Germany*

⁵*University Hospital, Department of Gynecology, Halle, Germany*

Introduction

High-grade serous ovarian cancer (HGSC) accounts for the majority (>70%) of ovarian cancer-associated deaths, with only minor therapeutic advancements achieved in recent years. Among the four proposed molecular subtypes of HGSC, the C5 subtype is characterized by high proliferative potential and pronounced immune evasion. However, the molecular drivers underlying the C5 subtype remain unclear.

Material and method

Using single-cell and bulk RNA sequencing, we identified RNA-binding proteins (RBPs) as crucial players of the immune desert phenotype in C5-HGSC tumors. Their role in modulating the immune response was evaluated through an siRNA screen in C5-like cell lines. The molecular mechanisms by which the top candidate RBP, IGF2BP1, governs immune evasion were investigated through RNA sequencing, binding and turnover assays, co-culture experiments, and syngeneic mouse models. Spatial biology by multi-spectral imaging was employed to validate regulatory networks in human HGSC tissue. The small molecule inhibitor BTYNB, alone or in combination with PD-1-targeting antibodies, was assessed *in vitro* and *in vivo* to explore its therapeutic potential.

Result and discussion

We identified eight oncofetal RBPs as molecular drivers of C5-HGSC tumors, contributing to the immune desert phenotype and facilitating immune evasion.

Mechanistically, the lead candidate RBP, IGF2BP1, represses intra-tumoral interferon-gamma signaling by promoting IRF1 protein degradation to diminish MHC-I presentation. Concomitantly, IGF2BP1 uncouples PD-L1 synthesis from IRF1-dependent transcription. This reshapes the intra-tumoral immune receptor landscape to limit immune cell infiltration and activation, while promoting the escape for T cell mediated tumor cell killing. BTYNB-mediated inhibition of IGF2BP1 synergized with immune checkpoint inhibition (ICI) by Nivolumab to counteract IGF2BP1-driven immune evasion.

Conclusion

The inhibition of oncofetal RBPs represents a novel therapeutic strategy to enhance the efficacy of established ICI therapies in the treatment of immunologically cold ovarian tumors.

EACR25-1177

Extracellular Vesicle Subtypes in Mediating Ovarian Cancer Metastasis

J. Liu¹, A. Wong¹

¹*The University of Hong Kong, School of Biological Sciences, Hong Kong, China*

Introduction

Ovarian cancer is the most lethal gynecological cancer due to their extensive peritoneal metastasis and ascites formation. Extracellular vesicles (EVs), a class of nanoparticles released by cells to facilitate communication over short and long distances, plays a significant role in promoting metastasis. Tumor-derived EVs, particularly exosomes (50–190 nm) and exomeres (<50 nm) exhibit distinct cargo profiles compared to those released by normal cells. Little is known about exomeres, aside from

different cargo profiles, they are also smaller and possess different structural properties compared with exosomes. Tumor-derived exosomes have demonstrated to promote metastasis and chemoresistance, while the role of tumor-derived exosomes in promoting metastasis remains unclear. The objective was thus to determine the effect of tumor-derived exosomes in metastasis compared with tumor-derived exosomes as well as to identify potential new candidates and targets in ovarian cancer metastasis.

Material and method

Using sequential differential ultracentrifugation and a three-prong approach validation, the exosomes and exosomes were isolated from metastatic ovarian cancer cell lines. Nude mice were implanted with non-metastatic tumors then treated with metastatic tumor-derived exosomes or exosomes to mimic endogenous EV release in patients.

Result and discussion

Mice bearing non-metastatic tumors treated with tumor-derived exosomes showed increased peritoneal metastasis and mesenteric tumors compared to those treated with tumor-derived exosomes. Treatment of tumor-derived exosomes also increased ascites formation compared to treatments of exosomes.

Conclusion

These findings suggest that tumor-derived exosomes are more potent in promoting pro-metastatic effects than tumor-derived exosomes. Further research on tumor-derived exosomes could lead to the identification of novel targets involved in the peritoneal metastasis of ovarian cancers and ascites formation.

This work is supported by RGC GRF17103523

Identify the efficacy and mechanism of engineering UMSC/miR-145-5p-TRAIL and its derived exosome on hepatocellular carcinoma

P. Chang¹, P. Wang¹, F. Hsu², I. Chiang³

¹*China Medical University, Biological Science and Technology, Taichung, Taiwan*

²*National Central University, Life Science, Taoyuan, Taiwan*

³*Show Chwan Memorial Hospital, Radiation Oncology, Changhua, Taiwan*

Introduction

Hepatocellular carcinoma (HCC) is a highly lethal liver cancer with one of the highest mortality rates worldwide. Standard treatments often lead to low survival rates and severe side effects, underscoring the urgent need for innovative therapies and advanced drug delivery systems. This brings us to exosomes, key mediators of cell communication that have recently emerged as promising carriers for cancer therapy due to their stability, low toxicity, and targeted drug delivery capabilities. Building on this concept, we selected miR-145-5p, a tumor suppressor that is downregulated in HCC and plays a crucial role in regulating oncogenic pathways. Restoring miR-145-5p expression has been shown to inhibit tumor progression. Similarly, TRAIL selectively induces apoptosis in tumor cells but faces clinical challenges, including a short half-life and resistance. Encapsulating TRAIL in exosomes enhances its stability and therapeutic

efficacy. This study aims to utilize exosomes derived from engineered UMSCs as a delivery system for HCC-targeted therapeutics.

Material and method

To evaluate therapeutic efficacy of exosomes, we conducted *in vitro* experiments. Colony formation assay was performed to assess HCC cell proliferation, while a Transwell assay was used to analyze migration and invasion capabilities. Additionally, flow cytometry was conducted to examine cell cycle arrest.

Result and discussion

Our initial findings indicate that the model was successfully constructed. Exosomes loaded with miR-145-5p and TRAIL effectively inhibited cell proliferation, as demonstrated by the colony formation assay. Additionally, they induced cell cycle arrest at the G1 phase. Sphere formation was significantly reduced in the exosome-treated group, accompanied by a marked suppression of HCC migration and invasion.

Conclusion

By leveraging the homing properties of UMSCs and their exosomes, we have achieved precise and targeted delivery of miR-145-5p and TRAIL to HCC tumors. Exosomes secreted by engineered UMSCs effectively regulate tumor migration and invasion, reduce cancer stemness, and induce cell cycle arrest at the G1 phase, ultimately inhibiting tumor growth. Thus, combining miR-145-5p and TRAIL-loaded exosomes represents a promising strategy for improving HCC treatment outcomes. We hope that the findings of this study will pave the way for novel therapeutic approaches for HCC patients, offering them renewed hope.

EACR25-1188

The DNA repair factor NEIL-like DNA glycosylase 3 activates tumor-associated macrophage polarization through regulating genomic stability in HCC

W. Huang¹, J. Chang¹, Y. Lee¹

¹*National Cheng Kung University, Medical Laboratory Science and Biotechnology, Tainan, Taiwan*

Introduction

The DNA damage response and repair in tumor cells are closely linked with immune responses in the tumor microenvironment (TME). DNA damage stress triggers generation of the damage-associated molecular patterns (DAMPs), which stimulate specific pattern recognition receptor (PRR) complexes, leading to immune cell activation and infiltration. The DAMP signaling pathway has been proposed as a promising target for anti-tumor immunotherapies. We recently found that the DNA repair factor NEIL3 enhances epithelial-mesenchymal transition (EMT) and worse prognosis in HCC.

Material and method

We aim to characterize the role of NEIL3 in HCC TME and to develop novel DNA damage stress-related TME markers that can serve as biomarkers for the HCC immunotherapy responses.

Result and discussion

We found that NEIL3 blocks DNA damage stress-induced DAMPs activation and the associated tumor-associated macrophages (TAMs) phagocytotic activities.

Furthermore, the NEIL3 glycosylase activity was shown to be required for TAMs phagocytic activities, suggesting a direct functional linkage between tumor DNA repair and macrophage activation in TME.

Conclusion

In conclusion, the DNA repair factor NEIL3 in the HCC affects TAMs and to develop potential novel immunotherapy biomarkers in HCC.

Dysregulated m5C RNA Methylation of HDGF Promotes Colorectal Cancer

Growth via De Novo Lipogenesis

G. Kim^{1,2}, E. Hwangbo¹, K. Hur^{1,2}

¹School of Medicine, Kyungpook National University, Department of Biochemistry and Cell Biology, Daegu, Korea (Republic of)

²School of Medicine, Kyungpook National University, Cell and Matrix Research Institute (CMRI), Daegu, Korea (Republic of)

Introduction

Colorectal cancer (CRC) is a leading cause of cancer-related mortality worldwide, driven by genetic and epigenetic alterations. Among epigenetic modifications, 5-methylcytosine (m5C) RNA methylation plays a crucial role in RNA stability and gene expression. Hepatoma-derived growth factor (HDGF) has been implicated in cancer progression, yet its RNA methylation status and functional significance in CRC remain unclear. This study investigated the role of m5C methylation change on 3' UTR of HDGF mRNA in CRC development.

Material and method

Human colorectal cancer tissues and matched adjacent normal colonic tissues ($n = 7$ pairs) were obtained from Kyungpook National University Chilgok Hospital. CRC cell lines were cultured under varying fetal bovine serum (FBS) and glucose-insulin conditions to assess the impact of metabolic changes on HDGF m5C RNA methylation and expression. Cells were treated with 5-aza-2'-deoxycytidine (decitabine) to inhibit m5C methylation. Total RNA was extracted and subjected to quantitative bisulfite pyrosequencing to measure HDGF mRNA methylation levels. Gene expression analysis was performed using qRT-PCR, and protein levels were assessed by Western blotting. Statistical significance was determined using Student's t-test.

Result and discussion

HDGF m5C methylation and expression levels were significantly upregulated in CRC tissues compared to adjacent normal colonic tissues. In CRC cell lines, high FBS and glucose-insulin conditions increased HDGF m5C methylation, HDGF protein expression, and cell proliferation, while serum starvation decreased these effects. Notably, insulin-glucose treatment upregulated DNL-related genes (ACACA, ACLY, FASN), alongside increased HDGF m5C methylation. Conversely, Decitabine treatment suppressed HDGF m5C methylation and downregulated DNL-related gene expression. These findings indicate that HDGF m5C methylation supports CRC growth by promoting de novo lipogenesis,

suggesting RNA methylation as a potential therapeutic target.

Conclusion

Our study identifies HDGF m5C RNA methylation as a key regulator of CRC progression via metabolic reprogramming. Targeting RNA methylation may provide novel therapeutic strategies for CRC.

EACR25-1197

ADAM10 promotes pancreatic cancer progression and modulates the immune microenvironment

S. Arora¹, M. Vail¹, A. Scott², P. Janes¹

¹Olivia-Newton John Cancer Research Institute, Receptor Biology Lab, Melbourne, Australia

²Olivia-Newton John Cancer Research Institute, Tumour Targeting Laboratory, Melbourne, Australia

Introduction

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest cancers, with a five-year survival rate below 10%. New treatment options are urgently needed to improve patient outcomes. ADAM10, a membrane-bound metalloprotease, is overexpressed in pancreatic tumour cells and contributes to stromal fibrosis, promoting cancer cell invasiveness and metastasis. It reportedly cleaves a range of substrates involved in tumour progression, including notch, growth factor ligands/receptors, adhesion molecules and immune cell regulators (MICA, PD-L1), highlighting its potential as a therapeutic target. We set out to further investigate the role of ADAM10 in pancreatic cancer with the view to developing novel antibody-drug conjugate (ADC)-based treatments targeting ADAM10.

Material and method

We generated ADAM10 knockout (KO) KPC cell lines using CRISPR-Cas9. KPC ADAM10 KO and control cells were analysed in vitro and as subcutaneous tumours in immunocompetent C57BL/6 mice to evaluate tumour growth kinetics. Quantitative mass spectrometry was used to identify differentially shed proteins in conditioned media (the secretome) from WT and KO KPC cells and differentially expressed proteins in tumour samples. Tumour tissues were also analysed by western blot and immunohistochemistry (IHC) to assess expression of key markers.

Result and discussion

ADAM10 KO in KPC cells showed reduced proliferation and impaired wound healing capacity in vitro, and analysis of the secretome identified changes in proteins involved in adhesion, ECM organisation, notch and other transmembrane receptor signalling. ADAM10 KO tumour growth was significantly slower in vivo, and western blot analysis confirmed reduced expression of ADAM10 and notch in KO tumours. Proteomic analysis of tumours also showed changes in ECM organisation and immune related pathways, including upregulation of the Granzymes (cytotoxic T cell proteases), and Fas, a key regulator of apoptosis and downregulation of EPDR1, which is linked to increased PD-L1 expression and tumour immune evasion. Notably, ADAM10 KO tumours showed increased CD8+ T cell infiltration, and

greater response to the immune-checkpoint inhibitor anti-PD1, suggesting enhanced anti-tumour immunity.

Conclusion

Loss of ADAM10 decreases tumour growth and appears to enhance anti-tumour immunity by modulating diverse pathways, including regulating ECM and immune cell activation within the pancreatic cancer micro-environment. These findings highlight ADAM10 as a promising therapeutic target, with potential to improve immunotherapy responses in PDAC. Disclosures PWJ and AMS are inventors on a patent regarding anti-ADAM10 antibody 8c7.

A Novel Exosome Inhibitor Limits Tumor Growth in Mice with Melanoma (B16F10) Allograft

Z. Li¹, H. Guan¹, Y. Chen¹, X. Wen¹, N. Li¹, K. Deng¹, C. Zhong¹, J. Lu², A. Lyu¹, J. Liu¹

¹Hong Kong Baptist University, Hong Kong, Hong Kong, China

²Chengdu University of Traditional Chinese Medicine, Chengdu, China

Introduction

The incidence of melanoma continues to escalate, while the overall therapeutic efficacy of current anti-melanoma strategies remain unsatisfactory. Emerging evidence has implicated exosomes in tumor progression and tumoral immune tolerance. Notably, the melanoma-derived exosomes have been found to contribute to immunosuppression and was associated with anti-PD-1 response. Therefore, it is highly desirable to develop druggable exosome inhibitors for melanoma treatment.

Material and method

The cytotoxicity and exosome inhibitory activity of C1 were tested in murine B16F10 melanoma cells in vitro by MTT assay and a commercialized exosome quantification kit, respectively. The anti-tumor effect of C1 was evaluated in a B16F10 melanoma-bearing mouse model in vivo. The tumor-immune phenotypes were verified by flow cytometry. The classic exosome inhibitor GW4869 was employed as a positive control.

Result and discussion

C1 markedly restricted the exosome secretion in B16F10 melanoma cells in vitro which exhibited no cytotoxicity. In mice with melanoma (B16F10) allograft, C1 could significantly restrict tumor growth. Moreover, C1 increased the proportion of tumor-killing immune cells as determined by flow cytometry, aligning with the effects of the exosome biosynthesis inhibitor GW4869. Future studies will concentrate on the key steps of restricted exosome secretion and the specific target of C1. The prospective utilization of C1 will also be investigated in additional cancer types characterized by poor response to existing therapies attributable to exosome-mediated processes.

Conclusion

C1 effectively limits melanoma growth in vivo, which is probably associated with the inhibition of melanoma exosome release and the restoration of anti-tumor immunity.

EACR25-1213

Small nucleolar RNA host gene 10 promotes pancreatic ductal adenocarcinoma via regulating EGFR/AKT/ERK1/2/mTOR cascade

G. Pandya¹, P. Garg¹

¹Amity University, AIMMSCR, NOIDA, India

Introduction

Pancreatic ductal adenocarcinoma (PDAC) the most lethal cancer due to its late diagnosis, high rate of metastasis and drug resistance. Therefore, the discovery of novel molecular targets is an urgent need. The aim of this study is to delineate the potential of SNHG10 in PDAC.

Material and method

Bioinformatic and qRT-PCR analysis was used to determine the expression of SNHG10. Antisense oligonucleotide and siRNA mediated approach were utilized to unravel SNHG10 role using MTT, clonogenic assay, boyden chamber assay, cell cycle and apoptosis assay. Mechanism of SNHG10 was discovered through western blot analysis. NOD-SCID mice model of PDAC validated the in vitro analysis. Immunohistochemical analysis was used to analyze the altered expression of key oncogenic protein. Furthermore, SNHG10 involvement in gemcitabine resistance was evaluated by developing gemcitabine resistance PDAC cell lines.

Result and discussion

Our analysis displayed a significant upregulation of SNHG10 transcript in 179 PDAC cases and in a panel of PDAC cell lines. Upregulation of SNHG10 showed correlation with clinical stages of PDAC. Depletion of SNHG10 transcript level displayed significant reduction in cell proliferation, clonogenic ability, cell migration, EMT while inducing cell cycle arrest and cell death of PDAC cells. Mechanistically, the depletion of SNHG10 inhibited protein expression of cyclinB1, CDK4, cyclin D1, CDK6, N-cadherin, vimentin, survivin, aurora Kinase A & B. The depletion of SNHG10 led to enhanced expression of p21 and E-cadherin in PDAC cells. Moreover, depletion of SNHG10 significantly suppressed the tumor growth in PDAC xenograft model. Silencing of SNHG10 increased the expression of miR-532-3p and miR-150-5p leading to inhibition of EGFR/AKT/ERK/mTOR/MET signaling in both in vitro and xenograft PDAC mouse model. Noticeably, silencing of SNHG10 transcript increases the gemcitabine sensitivity of PDAC cells resistant to gemcitabine.

Conclusion

Our data indicated the oncogenic role of SNHG10 in PDAC through the EGFR/AKT/ERK1/2/mTOR axis as well as involved in gemcitabine resistance.

Development of relevant mouse models for the R&D of therapeutics for Pancreatic Ductal AdenoCarcinoma

M. Xiao¹, M. Lecomte¹, S. Creusot¹, C. Ragonnet¹, C. Magliocco¹, P. Berson¹, F. Marquet¹, C. Gallou¹, M. Gilles¹

¹Servier R&D Paris-Saclay Institute, In vivo Pharmacology, Gif sur Yvette, France

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers worldwide with a 5-year overall survival of 10-13%. It is defined by a dense fibrotic barrier and an immunosuppressive network, both contributing to therapeutic resistance. Identifying relevant PDAC animal models is critical for R&D given the urgent need to develop PDAC therapeutics to improve patients' quality of life. This project aims to characterize and classify PDAC tumor microenvironment (TME) in current available syngeneic PDAC mouse models including subcutaneous and pancreas tail injections. Second, based on these comparative studies, we have proposed and developed innovative PDAC mouse models mirroring the human TME. In the context of our R&D strategy, this project focuses on two main applications: (i) Early-stage project: Subcutaneous model with rapid tumor growth and easy monitoring (ii) Advanced project: Orthotopic model (head versus tail) with a more robust TME

Material and method

Starting from the transgenic KPC gold standard, the above cited models will be grafted with either cell line or tumor fragment. Cartography of the TME in every model will be evaluated over time and in response to several standard of care. This characterization workflow includes flow cytometry for immune-phenotyping, immunohistochemistry to define TME fibrosis, gene expression associated to PDAC subtyping and disease related monitoring i.e metastasis.

Result and discussion

Based on collagen-I and a-SMA expressions along with fibrosis scoring we observed similar levels of fibrosis between the subcutaneous and orthotopic tail models. However, the orthotopic tail model appears to exhibit a more relevant PDAC-mimicking immune infiltration. Indeed, we observed a majority of M2 macrophage and MDSC infiltrated cells in the orthotopic tail model, representative of human PDAC immune infiltration. Moreover, compared to xenografted subcutaneous models, the orthotopic tail model showed a lower expression of CK19+ cells. To further improve PDAC mouse models, we have developed an orthotopic pancreas head injection. As 80% of PDAC patients developed cancer in the head of the pancreas, developing such model represent a true technical challenge but may constitute a real benefit for drug testing in PDAC therapeutics.

Conclusion

Altogether this project will help to build a full mapping of PDAC TME including immunophenotyping, spatial localization, transcriptomic and response to standard of care. In the effort of upgrading current available models, robust PDAC immunocompetent mouse models are key for PDAC therapeutics drug testing. Therefore, reinforcing Servier's ambition to improve survival rate for these patients.

Disruption of the Pentraxin 3/CD44 Interaction can be an Efficient Strategy for Malignant Cancer Therapy

J. Wang¹, Y. Hsiao², J. Chi², H. Liang¹, F. Chen³

¹National Cheng Kung University, Tainan, Taiwan

²Leadgene Biomedical, Inc., Tainan, Taiwan

³National Health Research Institutes, Tainan, Taiwan

Introduction

The tumor microenvironment (TME) is characterized by persistent low-grade inflammation, resembling a chronic inflammatory state. Within this environment, tumor-associated stromal cells facilitate tumor cell migration, invasion, stemness, drug resistance, and immune evasion by suppressing antitumor immunity and enhancing immunosuppression. Pentraxin 3 (PTX3), a secretory factor induced by pro-inflammatory cytokines and various stressors, is primarily expressed by fibroblasts and monocytes/macrophages and has been observed to be upregulated in the TME.

Material and method

Loss-of-function assays, including knockdown, genetic knockout, and inhibitor-based approaches, were utilized to investigate PTX3's role in the inflammation-like TME and its association with tumorigenesis. In vitro and in vivo experiments involving conditioned medium and co-injection models were conducted to assess PTX3's protumour functions. Protein-protein interaction assays were performed to elucidate the PTX3/CD44 interaction.

Result and discussion

Our findings indicate that PTX3 not only promotes cancer cell migration, invasion, stemness, and drug resistance but also contributes to immunosuppression by activating M2 macrophages and inactivating cytotoxic CD8+ T cells. WHC-001, a PTX3-specific neutralizing antibody, binds to PTX3 and prevents its interaction with CD44. WHC-001 demonstrated a suppressive effect on colon and triple-negative breast cancer (TNBC) tumor progression by reducing tumor-infiltrating M2 macrophages and increasing cytotoxic CD8+ T cell infiltration.

Conclusion

Our results suggest that the PTX3/CD44 interaction promotes tumor malignancy, and WHC-001 represents a potential therapeutic agent for cancer treatment.

EACR25-1226

Characterization of cysteine peptidase interplay between different cell populations in tumour microenvironment

M. Lipužić¹, J. Kos¹, A. Mitrović¹

¹Jožef Stefan Institute and University of Ljubljana, Faculty of Pharmacy, Department of Biotechnology, Ljubljana, Slovenia

Introduction

In cancer many cell types interact with each other in the tumour microenvironment (TME). Among other enzymes cysteine peptidases are known to play a role in the development and spread of tumours. The dynamic and reciprocal connection between different cell populations, especially cancer cells and cancer-associated fibroblasts (CAFs), within the TME has a major impact on tumour

growth, metastasis and resistance to therapy. The aim of our study was to find whether co-cultivation of tumour cells and CAFs affects the expression and activity of cysteine peptidases, in particular cathepsins B, X, V and L.

Material and method

First, to evaluate if secreted cysteine peptidases from one cell population can affect the expression in another cell population breast cancer cell lines were cultured for 3 days, then the cell medium was added to cancer-associated fibroblasts (CAFs) and vice versa. Cell lysates were prepared at different time points, namely after 0, 24 and 72 hours. The protein levels and activity of the observed cathepsins were assessed by western blot and enzyme activity assay. Additionally, indirect and direct co-cultures to evaluate crosstalk between cells that are not in direct contact using transwell inserts were prepared and evaluated for cathepsin expression and activity.

Result and discussion

Our results show that in co-cultures and when the one cell population is supplied with medium from another cell population cathepsin protein levels and activity change. Thus, we demonstrate that cysteine cathepsins are involved in communication between cells in the TME.

Conclusion

In conclusion results of this study show that crosstalk between cell populations does affect expression of peptidases in different cell populations in TME and should be investigated and considered in antitumour therapy.

EACR25-1249

The local microenvironment suppresses the synergy between irradiation and anti-PD1 therapy in breast-to-brain metastasis

V. Wischnewski¹, P. Guerrero Aruffo², M. Massara¹, R. Mass¹, K. Soukup¹, J. Joyce²

¹*UNIL, Lausanne, Switzerland*

²*UNIL, DOF, Lausanne, Switzerland*

Introduction

Metastatic dissemination to the brain occurs in approximately one-third of patients with breast cancer (BC) and can lead to life-threatening neurological damage. Stereotactic radiosurgery (SRS), a standard-of-care treatment for brain metastasis (BrM), controls over 80% of targeted lesions. However, the emergence of new BrM lesions outside the irradiation field and the progression of extracranial disease limit median overall survival to just over one year. Therefore, there is an urgent need to develop more efficient therapies. To achieve this, it is crucial to understand how the local tumor microenvironment (TME) responds to treatment.

Material and method

To study the changes in the BC-BrM TME, we used various *in vivo* studies, transcriptional analyses, and functional assays to directly compare orthotopic BC tumors with their BC-BrM counterparts.

Result and discussion

Here, we show that while CD8+ T cells can infiltrate breast cancer-brain metastases, their anti-tumor cytotoxicity is locally suppressed in the brain. Conversely, CD8+ T cells exhibited tumoricidal activity

in extracranial mammary lesions originating from the same cancer cells. Consequently, combined high-dose irradiation and anti-PD1 therapy was effective only in extracranial tumors, but not intracranial lesions.

Transcriptional analyses and functional studies identified neutrophils and Trem2-expressing macrophages as key sources for local T cell suppression within the brain, providing rational targets for future therapeutic strategies.

Conclusion

In this study, we show that while CD8+ T cells infiltrate BC-BrM, they lack anti-tumor cytotoxicity even under T cell-stimulating conditions. Single-cell profiling and ex-vivo functional assays identified BrM-infiltrating neutrophils and Trem2+ monocyte-derived macrophages and microglia (collectively termed tumor-associated macrophages, TAMs) as key sources of local T cell suppression.

EACR25-1258

The effects of selected piRNAs on ovarian cancer stem-like cells through piRNA mimic transfection

E. Gumusoglu-Acar¹, S. Ozdemir¹, T. Gunel¹

¹*Istanbul University, Department of Molecular Biology and Genetics, Istanbul, Turkey*

Introduction

Ovarian cancer (OC) is the most common cancer among women and has the highest mortality rate among gynecological cancers. Cancer stem cells (CSCs), a subpopulation within the tumor mass, play a critical role in metastasis, chemotherapy resistance, and disease recurrence. CSCs possess tumor-initiating potential and multipotent differentiation ability. Piwi-interacting RNAs (piRNAs), a class of non-coding RNAs involved in epigenetic regulation, have been implicated in CSC maintenance and tumor progression. In this study, we investigated the effects of piR-823, piR-36712, and piR-020326 on ovarian CSCs, employing mimic approaches to assess their regulatory roles.

Material and method

To investigate the effects of piR-823, piR-36712, and piR-020326 on CSC characteristics, the OVSAHO cell line was used. The expression levels of these piRNAs, previously identified as upregulated in ovarian CSCs, were modulated through siRNA mimic transfection. The impact on CSC properties was evaluated by comparing gene expression profiles of key stem cell markers, including ALDH1A1, ALDH1A2, ALDH1A3, SOX2, CD133, and NANOG in between 2D adherent and 3D spheroid cultures using qRT-PCR. The expression differences of piRNAs and CSC-specific genes mRNAs compared to control genes were calculated using the $2^{-\Delta\Delta Ct}$ method based on GraphPad Prism Version 9.2.0 (283).

Result and discussion

In the comparison of gene expression levels in 3D and 2D cell culture groups, significant changes were observed following piRNA mimic transfection. Specifically, piRNA-823 mimic transfection led to a significant reduction in the expression of stem cell markers such as ALDH1A3, ALDH1A1, NANOG, and CD133 in the 3D groups ($p < 0.05$), suggesting a suppressive role of piRNA-823 in cancer stem cell gene expression. In the

case of piRNA-36712, a significant increase in CD133 expression was detected in the 3D group, while ALDH1A1 expression showed a notable reduction, with no significant changes in NANOG, ALDH1A2, or ALDH1A3 expression levels. Similarly, piRNA-20326 overexpression in the 3D group resulted in a decrease in ALDH1A1 and ALDH1A3 expression, whereas ALDH1A2 expression significantly increased. These findings highlight the differential regulatory effects of piRNAs on cancer stem cell-associated gene expression in 3D spheroid cultures.

Conclusion

This study demonstrates that piR-823, piR-36712, and piR-20326 regulate ovarian cancer stem cells (CSCs). piR-36712 supports CSC maintenance, while piR-823 influences pluripotency genes and may have an anti-cancer regulatory effect on CSCs. piR-20326 negatively regulates stem cell markers in adherent cultures but has no significant impact in spheroids. These findings suggest that piRNAs play crucial roles in CSC regulation and may serve as potential therapeutic targets in ovarian cancer.

The level of genomic instability in progression of malignant brain cancer

N. Ademović¹, T. Tomic², B. Murganić², N. Tanić², M. Milić³, N. Tanić¹

¹*Institute for Biological Research "Siniša Stanković", University of Belgrade, Belgrade, Serbia, Department of Neurobiology, Belgrade, Serbia*

²*Institute of Nuclear Science "Vinča", University of Belgrade, Belgrade, Serbia, Department of Radiobiology and Molecular Genetics, Belgrade, Serbia*

³*Clinic for Neurosurgery, Clinical Center of Serbia, Belgrade, Serbia, Belgrade, Serbia*

Introduction

Astrocytoma and glioblastoma are diffuse malignant brain cancers, characterized as the most aggressive and fast-growing types of brain tumors. Glioblastoma IDH wild-type is a primary tumor that develops de novo, while a secondary type is Astrocytoma IDH mutant which progresses from lower grades of brain tumors. Genomic instability is a hallmark of cancer characterized by an increased rate of mutations and chromosomal alterations and plays a critical role in cancer initiation and progression.

Material and method

We analyzed genomic instability in 78 patients with malignant brain cancer, using AP-PCR (arbitrarily primed PCR) a DNA profiling method. Comparing DNA profiles between tumor tissue and normal tissue (blood) of the same patient, we detected qualitative and quantitative differences. Quantitative differences are detected as changes in the intensity of bands and represent chromosomal instability (CIN), while qualitative changes are detected as the presence and absence of bands and are the manifestation of microsatellite instability (MIN). Associations between genomic instability, represented as the frequency of DNA alterations, type and grade of brain cancer were

performed using one-way analysis of variance (ANOVA) and Fisher's exact test.

Result and discussion

The overall mean values of the frequency of DNA changes for MIN, CIN and total genomic instability are 0.175, 0.170 and 0.344, respectively. Based on the frequency distribution of DNA changes we determined the threshold value for each type of instability based on which the samples were divided into two groups, with high and low frequency of DNA changes. The percentage of high total genomic instability, high MIN and high CIN is 53%, 47%, 41%, respectively. The contribution of qualitative and quantitative changes to the level of genomic instability was almost equal. A statistically significant correlation was found between the level of genomic instability and the types of brain cancer ($p = 0.017$). Low genomic instability is characteristic of Glioblastoma IDH wild-type found in 61% of patients, while high genomic instability is characteristic of Astrocytoma IDH mutant grades 4, 3 and 2, found in 81%, 72% and 60% of patients, respectively. There is also a statistically significant difference in the level of high genomic instability between Astrocytoma IDH mutant grades ($p = 0.028$). Astrocytoma IDH mutant grade 2 is characterized by a higher level of high genomic instability (0.58), then grade 3 (0.44) and then grade 4 (0.34).

Conclusion

Our results suggest that MIN and CIN contribute equally to total genomic instability. During the progression of Astrocytoma IDH mutant genomic instability decreases, while low genomic instability is characteristic of Glioblastoma IDH wild-type. This all makes genomic instability a good progressive malignant marker.

EACR25-1272

A single-cell atlas of the clear-cell renal cell carcinoma (ccRCC) tumor microenvironment (TME) identifies an interferon-responsive malignant cell subpopulation associated with lymphocyte-enriched TME

S. García-Esteve^{1,2,3}, C. Rubio-Pérez¹, I. Cobo-Diego⁴, N. Jiménez^{1,2}, L. Fernández-Mañas¹, M. García de Herreros¹, L. Ferrer-Mileo¹, A. Prat¹, B. Mellado¹, Ò. Reig¹

³*Universitat de Barcelona, Departament de Medicina, Barcelona, Spain*

⁴*Institut de Recerca Biomèdica Barcelona (IRB), Bioinformatics/Biostatistics core unit, Barcelona, Spain*

Introduction

Intratumoral heterogeneity in ccRCC has been widely observed (Turajlic et al., 2018), but its ultimate implications for disease evolution and treatment outcome remain poorly understood. Here, we aimed to explore intratumoral heterogeneity at the single-cell level and

sought to identify potential ways by which this heterogeneity can shape the TME.

Material and method

We retrieved nine publicly available ccRCC single-cell RNA sequencing (scRNA-seq) datasets, adding up to 68 treatment-naïve patients across all stages and grades. Standard scRNA-seq analysis with Seurat and integration with Harmony in R were applied. TME clustering was based on cell-type proportional data, and compositional data was analyzed with sccomp. Characterization of clusters was analyzed with Gene Set Enrichment Analysis (GSEA), and cell-to-cell communication was assessed using LIANA in combination with tensor-c2c.

Result and discussion

Clustering of cell-type proportions revealed four major TME configurations across samples: Lymphoid-, Immune-, Endothelial-, and Malignant-enriched. Tumor-infiltrating lymphocytes within Lymphoid- and Immune-enriched TMEs also exhibited distinct states: the former had more effector/proliferating T-cells, reduced exhaustion, and increased neoantigen-reactive TCRs, while the latter was enriched in regulatory/memory T-cells and had increased exhaustion. Malignant cell reanalysis identified 15 transcriptionally distinct subpopulations. GSEA revealed that subcluster (Sc.) 3 – RBP4 was enriched in interferon- γ response, MHC-II antigen presentation, and protein quality control processes (proteasome, unfolded protein response, and protein maturation). This subpopulation was highly represented in the Lymphoid-enriched TME. Pathway and transcription factor inference showed high involvement of the TNF- α and JAK-STAT signaling pathways, alongside high expression of RFX5 and CIITA, key MHC-II transcription regulators. Cell-to-cell communication pattern analysis revealed factors linked to hypoxia, TGF- β , TNF- α , and JAK-STAT pathways, the former two positively and the latter negatively associated with Lymphoid- and Immune-enriched TMEs.

Significant ligand-receptor interactions included the chemokines CXCL9/10/11, all three overexpressed in Sc. 3 – RBP4, interacting with CXCR3.

Conclusion

Our analysis reveals that the interferon-responsive malignant cell subpopulation Sc. 3 – RBP4 is highly enriched in lymphocyte-infiltrated TME configurations and represents a putative key player in antigen presentation and MHC-II processing pathways. These findings provide insights into malignant-immune interactions, highlighting potential targets for improving immunotherapy response in ccRCC.

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a lethal malignancy with a 5-year survival rate of 12%. Its resistance to immune modulatory treatments stems from an immunosuppressive tumor microenvironment (TME) and a low mutational burden. Rab27a, a key regulator of exosomes secretion, has been implicated in disease progression and therapy resistance. Targeting Rab27a offers a potential strategy to remodel the TME, enhance immunotherapy efficacy, and improve patient outcomes.

Material and method

Pancreatic ductal adenocarcinoma (PDAC) is a lethal malignancy with a 5-year survival rate of 12%. Its resistance to immune modulatory treatments stems from an immunosuppressive tumor microenvironment (TME) and a low mutational burden. Rab27a, a key regulator of exosomes secretion, has been implicated in disease progression and therapy resistance. Targeting Rab27a offers a potential strategy to remodel the TME, enhance immunotherapy efficacy, and improve patient outcomes.

Result and discussion

Rab27a deficiency impairs exosomes-mediated signaling, leading to earlier tumor onset and reduced survival. Loss of TSP1, which is carried in cancer-derived exosomes, triggered recruitment of CD31+ endothelial cells and MRP8+ pro-inflammatory macrophages, which activated cancer-associated fibroblasts (CAFs). CAFs, in turn, released pro-inflammatory cytokines (i.e. IL-6), driving CD4+ T cell polarization toward a Th17 phenotype, which promoted tumor growth. Targeting this inflammatory axis with dexamethasone or depletion of CD4+ T cells or inhibiting IL-17 significantly impaired tumor growth and improved survival.

Conclusion

Rab27a plays a crucial role in PDAC by shaping the TME and modulating immune and inflammatory responses. This subset of PDAC tumors may be particularly responsive to immunomodulatory and anti-inflammatory therapies targeting the Th17-driven protumorigenic axis, offering a promising avenue for improving patient prognosis.

⁴University of Applied Sciences Merseburg, Germany, Leipzig, Germany

Introduction

Prostaglandin E2 (PGE2), a main mediator of inflammation, is a product of cyclooxygenase-2 (COX-2) activation, whose expression is increased in human colorectal cancer. In addition to its role in inflammation, PGE2 also acts as a mitogenic signaling molecule released by dying tumor cells and is thus involved in the repopulation of tumors. To improve the effect of chemotherapy by elimination of the mitogenic signal mediated by PGE2, a drug with cisplatin core – platinum(IV) complex was synthesized bearing the anti-inflammatory drug flurbiprofen. Additionally, the conjugate was immobilized into mesoporous silica nanostructural material SBA-15 in order to enable improved delivery of the drug into tumor tissue. The cytotoxicity was assessed in 2D and 3D culture system, as well in vivo using a syngeneic mouse model of colon cancer.

Material and method

The potential cytotoxicity of free and immobilized platinum(IV)-flurbiprofen conjugate was determined in murine cell lines 4T1, B16, CT26, and MC38 using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide and crystal violet as viability assays. Organoids were established from MC38-induced tumors in C57BL/6 mice which were then isolated, digested and further propagated. A CellTiter-Glo™ luminescent cell viability assay was employed to evaluate the antitumor effect of the drugs on organoids. The in vivo efficacy of the drugs was investigated in tumor-bearing C57BL/6 mice.

Result and discussion

All tumor cell lines showed a dose-dependent decrease in viability after treatment with the drug conjugate and the corresponding SBA-15 formulation. MC38 cells were selected for further studies as they proved to be very sensitive to the applied treatments. Colon cancer organoids, which better simulate the architecture of tumor tissue than 2D cultures, showed a remarkable decrease in viability after 6 days of treatment with both drug formulations, while IC50 values were approximately several times higher than those obtained in 2D cultures. Finally, administration of both the drug conjugate and the corresponding nanostructured material to tumor-bearing C57BL/6 mice in a therapeutic regimen resulted in a statistically significant reduction in tumor volume compared to the control group.

Conclusion

The strong antitumor potential of the platinum(IV)-flurbiprofen conjugate free and immobilized into SBA-15 in a model of mice colon cancer opens up many opportunities for further research.

Introduction

Recent data suggest a paradoxical link between the dying cells in tumor tissue and accelerated tumor growth. Dying tumor cells trigger a "regeneration" process through a signaling pathway known as "Phoenix rising". To delineate the process of therapy-induced repopulation in advanced colorectal cancer, we developed a mouse model that mimics communication between dying and live cells in a tumor microenvironment (TME). Following the 3R principle in animal experiments, we established mouse-derived organoids from these tumors and used transcriptional analysis to confirm whether this complex 3D model could mirror TME and be used in comprehensive drug screening in the future.

Material and method

The appropriate mouse model representing apoptosis-induced compensatory proliferation was developed by subcutaneous inoculation of the mixture of live and dead MC38 cells into C57BL/6 mice. The dead cells were collected after in vitro treatment with 5-fluorouracil. During the optimization, the number of live cells and the ratio between live and dead cells in the mixture were varied and finally determined. Additional groups representing controls received the same number of only live or only dead MC38 cells. Also, the group receiving the optimal number of MC38 cells to form tumors in the classic animal model was used for comparison. After tumor isolation, one part of each tumor was frozen, and the other part was digested and used to establish mouse-derived organoids. Both tumors and organoids derived from the compensatory proliferation model and classic model were further analysed by RNA sequencing.

Result and discussion

The group that received only live MC38 cells had a low incidence rate and slow tumor growth rate. However, when the same number of live cells is injected with dead cells in a 1:50 ratio, the tumors' earlier onset, fast growth, and 100% incidence rate revealed that this type of inoculation dramatically enhanced tumor aggressiveness. The transcriptional analysis of isolated tumors and their matching organoids from two different models of disease showed 80% of gene expression homology, indicating that organoids represent a valid model system for drug screening.

Conclusion

The suitable mouse model reflecting compensatory proliferation in colorectal cancer was established and compared to the typical form of the disease, showing important features that can be used as targets to prevent tumor repopulation and thus amplify the effect of chemotherapy.

EACR25-1295**Targeting ROCK Pathway in Diffuse Midline Glioma: Implications for Cell Motility and Invasion**

G. Pericoli¹, S. Pires Celeiro^{1,2,3}, M. Pellegrino⁴, E. de Billy⁴, G. Zanni⁵, M. Vinci⁴

⁴Bambino Gesù Children's Hospital - IRCCS, Department of Onco-hematology and Pharmaceutical Factory, Rome, Italy

⁵Bambino Gesù Children's Hospital - IRCCS, Unit of Neuromuscular and Neurodegenerative Disease, Rome, Italy

Introduction

Diffuse Midline Glioma H3K27-altered (DMG) is an aggressive Central Nervous System (CNS) tumor affecting children and adolescents, with no cure and a median survival of 9–12 months. DMG typically arises in the midline regions of the brain such as the pons and thalamus, where pontine lesions are inoperable. A key factor contributing to DMG's dismal prognosis is its highly infiltrative nature that leads to tumor cell spreading in the CNS although the mechanisms associated with this disseminative growth remain not yet well understood. Rho-associated protein kinase (ROCK) is involved in various cellular functions, including cell migration and invasion. While the modulation of ROCK activity has been studied in other tumor types, its role in DMG remains underexplored. Given ROCK's pivotal role in regulating cell motility, targeting this pathway may provide a potential therapeutic option for limiting DMG cells spreading. Our study aims to investigate the role of ROCK in DMG cell motility and explore the implication of targeting this signaling pathway.

Material and method

Three primary patient-derived DMG cell lines (QCTB-R059, OPBG-DIPG002 and HSJD-DIPG007) were used. Cells were cultured as neurospheres and the basal expression levels of Rho, Rac and ROCK were analyzed by Western blot. Immunofluorescence was performed to assess the levels of ROCK substrate MYPT1 and its phosphorylated form (P-MYPT1) in 3D migration and invasion assays. ROCK activator, lysophosphatidic acid (LPA), and three inhibitors (HA1077, Y27632, GSK429286) were used to modulate ROCK activity and their effects on cell viability, migration, invasion and MYPT1 expression and phosphorylation were analyzed.

Result and discussion

Variable basal expression levels of Rho, Rac and ROCK were observed among the three DMG cell lines. QCTB-R059 cells exhibited the lowest levels of P-MYPT1 and the highest levels of MYPT1 in 3D invasion, whereas HSJD-DIPG007 cells showed the highest levels of both forms in 3D migration. Treatment with ROCK inhibitors did not affect cell viability but reduced P-MYPT1 levels, although the effect on P-MYPT1 differed between 3D

migration and invasion in the three DMG cell lines.

While a significant increase in cell invasion was observed for QCTB-R059 and HSJD-DIPG007, an increase in cell migration was observed only for OPBG-DIPG002. However, activating ROCK with LPA, induced an increase in P-MYPT1 levels and decreased cell motility for all the cell lines.

Conclusion

This study provides evidence for a role of ROCK in regulating DMG cell motility. Interestingly, our data suggest that activating ROCK pathway is a potential therapeutic approach to limit DMG cell dissemination, with differences based on the cell motility phenotype.

EACR25-1296**Prognostic and Molecular Features Associated with Tumour Border****Properties in Colorectal Cancer**

A. Kehusmaa¹, J. Härkönen², P. Sirniö¹, V. Äijälä¹, H. Karjalainen¹, M. Kastinen¹, V. Tapiainen¹, M. Mäkinen¹, A. Tuomisto¹, J. Väyrynen¹

¹University of Oulu, Oulu University Hospital, Translational Medicine Research Unit, Medical Research Center Oulu, Oulu, Finland

²Hospital Nova of Central Finland, Well Being Services County of Central Finland (1), University of Eastern Finland (2), Department of Pathology (1), Faculty of Health Sciences, A.I. Virtanen Institute for Molecular Sciences (2), Jyväskylä (1), Kuopio (2), Finland

Introduction

Tumour border configuration, characterized by either expansile or infiltrative growth, has been found to be an important prognostic feature in colorectal cancer (CRC), but it has not been widely adopted to current clinical guidelines due to the challenges in reproducibility. Here, we introduce a reproducible, quantitative method for evaluating tumour border configuration based on characteristics of the deepest invasion and assess its value in determining patient survival and association with molecular characteristic of CRC.

Material and method

We developed Tumour Invasive Border Index (TIBI), a novel approach for assessing tumour border configuration, using two CRC cohorts ($N = 1011$ and $N = 776$ patients). TIBI was assessed from HE-stained slides within representative circular regions of 12.6 mm^2 at the deepest area of invasion, where amounts of tumour epithelium and stromal constituents were recorded. Associations between TIBI and clinicopathological features, immune cell infiltration, prognosis, and inter-rater agreement were examined. Additionally, molecular features (mutations, gene expression patterns) associated with tumour border configuration were analysed in a 3rd cohort of 630 CRC cases from The Cancer Genome Atlas (TCGA).

Result and discussion

TIBI proved to be a reproducible method with an inter-rater agreement comparable to or higher than that of tumour budding and Jass classification (mean kappa 0.69). High TIBI, indicative of an infiltrative growth pattern, was associated with advanced stage, lympho-vascular invasion, mismatch repair proficiency, and wild-type BRAF (all $p < 0.001$, except for BRAF in cohort 2

$p=0.007$). High TIBI was also linked to TP53 and KRAS mutations, expression of EMT-associated genes such as L1CAM, and downregulation of MYC signalling.

Additionally, high TIBI was associated with tumour immune cell composition, including lower densities of M1-like macrophages and CD66⁺ granulocytes, but higher densities of mast cells (all $p<0.001$), suggesting that myeloid cells may influence tumour growth pattern. High TIBI was independently associated with higher CRC-specific mortality when adjusted to disease stage, MMR status, lymphovascular invasion, tumor budding, and other conventional prognostic features, with multi-variable hazard ratios of 1.54 (95% CI 1.07–2.21) in cohort 1 and 2.10 (95% CI 1.17–3.75) in cohort 2.

Conclusion

TIBI proved reproducible method for assessing tumour border configuration and demonstrated its independent prognostic value in CRC. Our findings support its clinical integration as a prognostic marker. By analysing two large cohorts and the TCGA cohort, our study also provides deeper insights into the molecular mechanisms underlying infiltrative growth pattern in CRC.

²National Cancer Institute, Department of Pathological Anatomy, Bratislava, Slovakia

³Slovak Medical University in Bratislava and National Cancer Institute, Department of Surgical Oncology, Bratislava, Slovakia

⁴Medical University Innsbruck, Molecular Oncology Research and Diagnostic Laboratory, Department of Otorhinolaryngology, Innsbruck, Austria

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with a five-year survival rate of only 3% in advanced-stage patients. Its dense tumour microenvironment (TME), composed of stromal and immune cells, contributes to therapeutic resistance. Existing preclinical models, including 2D cultures, organoids, and patient-derived xenografts (PDX), fail to fully recapitulate the native TME. Organotypic slice cultures (OTSCs) preserve tissue architecture and cellular heterogeneity, making them a promising model for precision therapy testing. Here, we established OTSCs from KPC cell line-derived tumour xenografts and patient-derived tumours to assess viability, optimise culture conditions, and evaluate their suitability for therapeutic screening.

Material and method

OTSCs were generated from KPC cell line-derived tumour xenografts, five CryoStor-preserved patient tumour samples, and one freshly resected patient tumour. C57BL/6 mice were orthotopically implanted with 100,000 KPC cells into the pancreas to establish a tumour

model that mimics the pancreatic TME, including stromal components and immune cell infiltration, characteristic of human PDAC. Tumour specimens were excised and embedded in 8% agarose. Sectioning was performed using a Compressionsome® VF-510-0Z. OTSCs were cultured in RPMI 1640 medium supplemented with 10% FBS, 8 ng/mL EGF, 4 µg/mL insulin, 0.3 µg/mL hydrocortisone, and 1% penicillin/streptomycin. Cultures were incubated at 37°C for 3, 5, or 6 days. After cultivation, OTSCs were fixed in formalin and processed for histological and immunohistochemical (IHC) analyses. Hematoxylin and eosin (H&E) staining was performed to assess tissue integrity, and IHC was conducted using antibodies against cleaved-caspase-3 (CC3), Ki-67, granzyme B, CD4, and CD8 to evaluate apoptosis, proliferation, and immune cell infiltration.

Result and discussion

All OTSCs remained viable and structurally intact throughout cultivation. H&E staining confirmed tissue integrity, and CC3 staining determined minimal apoptosis. Ki-67 staining indicated active proliferation, while immune markers revealed immune cell presence within the slices. CryoStor-preserved OTSCs were successfully maintained for up to six days, supporting their feasibility for extended cultures.

Conclusion

OTSCs provide a robust ex vivo model that preserves tumour cytoarchitecture, cellular viability, and immune interactions. Their potential for studying PDAC biology and testing precision therapies makes them a valuable tool in preclinical research. Further studies should explore their use in therapeutic screening and mechanistic investigations of tumour-stroma interactions. Alveolar macrophages control fibroblast into CAF fate in Non-Small Cell Lung Cancer (NSCLC)

E. Gavín-Jiménez¹, D. Cáceres¹, A. Mantrana¹, M. Gómez¹, E. Zarzuela², M. Isasa², F. Calvo³, M. Casanova-Acebes¹

¹Centro Nacional de Investigaciones Oncológicas, CNIO., Molecular Oncology Program, Madrid, Spain

²Centro Nacional de Investigaciones Oncológicas, CNIO., Proteomics Unit, Madrid, Spain

³Instituto de Biomedicina y Biotecnología de Cantabria, IBBTEC., Tumor Microenvironment Laboratory., Santander, Spain

Introduction

Cancer-associated fibroblasts (CAF) phenotype is associated with poor prognosis in the vast majority of solid tumors, as they contribute to hallmarks of cancer progression, such as inflammation, metastasis, angiogenesis, and critically, immune evasion. Yet, the fundamental cues that control fibroblast into CAF malignant state remain unclear. In the lab, we showed that macrophages from embryonic origin (Alveolar Macrophages or AMs) closely interact with fibroblasts

present in the tissue before the onset of cancer. Interestingly, longitudinal confocal imaging, flow cytometry of lung tumor stroma and macrophage-depleted models, established that AMs play an important role in the malignant conversion from naive fibroblast into CAF in NSCLC.

Material and method

Single-cell RNA sequencing (scRNA-seq) was performed on both CD45+ and CD45- compartments of lung tissue to investigate stromal populations targeted by AMs. A new mouse model, Dpt-CreERT2-LSL-TdTOMO crossed with CD169DTR/+ mouse (AMs-depleted upon Diphtheria toxin administration), was generated to track universal fibroblast to CAF conversion in tumors with/without AMs (CD169+). Flow cytometry and confocal imaging were used to analyze this conversion. CellChat Ligand-receptor analysis was conducted to identify potential AM-secreted factors regulating CAF fate.

Result and discussion

We found that AM-depleted lungs showed an expansion of universal fibroblasts (Pdgfra+Pdpn+Dpt+) but completely lacked CAF-activated phenotypes. Importantly, AM-depleted tumors confirmed significant downregulation of canonical CAF activation genes, as Acta2, Tgfb1, or Fn1 compared with AM-sufficient tumors. Noteworthy, CAF activation profile remained unchanged in mice missing Monocyte-derived macrophages Mo-Macs (CCR2KO/KO), suggesting AM-specificity in the universal to CAF fate conversion. Using flow cytometry and confocal imaging on the fibroblasts tracking model Dpt-CreERT2-LSL-TdTOMO crossed with CD169DTR/+ mouse, we showed that universal fibroblast contributes to CAFs and more importantly, that universal fibroblasts into-CAF conversion is unequivocally controlled by AMs. CellChat Ligand-receptor analysis based on our scRNA-seq dataset identified AM-derived fibronectin (Fn1) and efferocytic Pros1 as macrophage factors interacting with CD44, integrins and AXL in fibroblasts. Finally, as AM-depleted tumors are significantly infiltrated with CD4 and CD8 T cells resulting in a longer survival, we plan to interrogate the impact of early AXL inhibition (Bemcentinib) in KP-tumors to boost T cell surveillance in otherwise T cell desert tumors.

Conclusion

Altogether, our work highlights a novel regulatory axis between AM and CAF that can be therapeutically exploited to promote immune T cell surveillance in NSCLC. We identified AMs as drivers of pathological responses in CAFs via AXL activation.

EACR25-1370

The role of periostin in the adhesion of pancreatic cancer cells

C. Alder¹, C. Barra Domingos¹, E. Knight¹, O. Hale¹, L. Marriott¹, M. Jones¹, P. Laurance-Young¹, A. Cameron², N. Hill¹

¹University of Plymouth, Plymouth, United Kingdom

²Queen Mary University of London, London, United Kingdom

Introduction:

Pancreatic tumours have a prominent stroma that can

promote tumour progression through various mechanisms including modulating cell adhesion. In addition to anchoring cells to the environment and mediating migration, adhesion facilitates ECM-cell signalling through activation of adhesion molecules such as integrins. Periostin is a matricellular protein over-expressed in the stroma of 90% of pancreatic tumours and high expression correlates with poor patient survival. While periostin is often described as an adhesion molecule, evidence supporting its role in modifying cell adhesion is limited and the role of periostin in pancreatic cancer cell adhesion has yet to be elucidated. This study aims to clarify the role of periostin in pancreatic cancer cell adhesion.

Material and method

Pancreatic cell lines were adhered to a collagen I-coated plate with periostin added either to the coating or in solution during recovery from trypsin. Crystal violet staining was used to quantify cell adhesion after 60 minutes and staining with anti-vinculin and phalloidin was used to image focal adhesions at 24 hours.

Result and discussion

The adhesion of AsPC-1 cell to collagen was increased by exposure to periostin. Although further study is needed, this could suggest that periostin has a role in adhesion receptor trafficking in AsPC-1 cells. However, adhesion of MiaPacA and PANC-1 cells was not affected by the presence of periostin during trypsin recovery. Instead, these cell lines responded to the presence of periostin in the matrix coating, with periostin-coating increasing the adhesion of MiaPacA cells and decreasing the adhesion of PANC1 cells. AsPC-1 cell adhesion was unaffected by the presence of periostin in the matrix coating. Together, this suggests that different pancreatic cancer cell lines have varying capacities to respond to periostin in specific contexts. Interestingly, the adhesion of Capan-1 cells, which are relatively well differentiated, as well as the adhesion of normal pancreatic epithelial Hpde6C7 and PS-1 stromal cells, was unaffected by periostin. Responsiveness to periostin may therefore be associated with an aggressive cancer phenotype. Low numbers of focal adhesions were observed in pancreatic cancer cells and neither focal adhesion number nor area correlated with changes in cell adhesion. This discordance may indicate that alternative types of adhesion such as hemidesmosomes are important for pancreatic cancer cell adhesion.

Conclusion

Overall, this study shows that the role of periostin in pancreatic cancer cell adhesion is context-dependent and varies between cells. Further investigation of the mechanisms by which periostin affects adhesion may reveal novel targets for the therapeutic modulation of adhesion and ECM-cell signalling in pancreatic cancer.

EACR25-1372

Perilipin 2 in Adipocytes of Omental Tumor Microenvironment Promotes Ovarian Cancer Cell Survival and Metastasis Through CXCL12/CXCR4 Axis

M. Xu¹, X. Wang¹

¹The First Affiliated Hospital, Zhejiang University School

of Medicine, Department of Obstetrics and Gynecology, Hangzhou, China

Introduction

High-grade serous ovarian cancer (HGSOC) is the most aggressive subtype of ovarian cancer and exhibits a strong tendency for omental metastasis. Upon interacting with ovarian cancer cells, adipocytes undergo phenotypic changes, acquiring invasive and pro-metastatic characteristics. This highlights the crucial role of adipocytes in driving ovarian cancer metastasis. In this study, we aim to elucidate the crosstalk between ovarian cancer cells and adipocytes within the omental tumor micro-environment and explore an adipocyte-targeted therapeutic strategy.

Material and method

Metastatic lesions were collected from HGSOC patients, followed by paraffin embedding and laser capture microdissection to separate adjacent adipocytes (cancer-associated adipocytes, CAAs) and distant adipocytes (at least 2 mm away from cancer cells and fibrosis areas). Spatial proteomic sequencing was performed to analyze adipocytes protein profiles. For adipocyte differentiation, fully grown 3T3/L1 pre-adipocytes were treated with a differentiation cocktail for six days. Stable Plin2 knockdown (KD) and overexpression (OE) cell lines were generated by infecting 3T3-L1 with lentivirus carrying mouse Plin2 shRNA or Plin2 cDNA, followed by puromycin selection for one week.

Result and discussion

Spatial proteomic profiling revealed a higher perilipin 2 (PLIN2) expression in adjacent adipocytes than distant adipocytes. In co-culture model, Plin2-OE or KD adipocytes could enhance or repress ovarian cancer cells migration and invasion, respectively, compared to controls. Similarly, in chemoinvasion assay, Plin2-OE adipocytes displayed increased chemotactic activity toward ovarian cancer cells, while Plin2-KD adipocytes exhibited reduced chemotaxis. Conditioned media from Plin2-OE adipocytes increased proliferation of ovarian cancer cells, while Plin2-KD attenuated these effects. Mechanistically, Plin2-KD adipocytes exhibited reduced CXCL12 protein secretion in conditioned media, leading to decreased CXCR4 activation in co-cultured ovarian cancer cells. Transcriptomic analysis revealed enhanced oxidative phosphorylation activity in Plin2-deficient adipocytes, suggesting potential metabolic reprogramming.

Conclusion

Our findings indicate that elevated PLIN2 levels in adipocytes promote ovarian cancer cell proliferation, migration, and invasion, highlighting the suppression of PLIN2 in adipocytes as a promising therapeutic target for HGSOC omental metastasis.

⁴Innovative Biotechnology In Therapy- Renato Dulbecco (BIT-RD), Roma, Italy

⁵University of Rome, Department of Clinical Sciences, Roma, Italy

Introduction

Malignant Melanoma (MM), an aggressive form of skin cancer, is highly curable in its early stages but still carries a poor prognosis once metastasis occurs. A deeper understanding of the molecular drivers of melanocyte transformation is essential for identifying novel therapeutic targets and predictive biomarkers.

MicroRNAs play a crucial role in tumor progression. Specifically, miR-221 promotes cell proliferation and inhibits apoptosis, and is therefore a compelling target in cancer. Notably, the clinical translation of LNA-i-miR-221, the first microRNA inhibitor to enter a first-in-human study in solid cancer patients, has paved the way for exploring its therapeutic potential in MM.

Material and method

miR-221 expression was quantified via qRT-PCR in a panel of primary and metastatic MM cells, with stromal cells serving as controls. MM cell lines were transfected with 100 nM of the LNA-i-miR-221 or a scrambled control for 72 hours. Cell proliferation was evaluated using the CellTiter-Glo assay, while cytotoxicity was determined by flow cytometry using 7-Amino-Actinomycin D staining. Protein levels of miR-221 canonical targets were assessed by Western blot, and transcriptomic changes were analyzed through microarray profiling.

Result and discussion

MM cells exhibited significantly elevated levels of miR-221 compared to stromal cells. Treatment with LNA-i-miR-221 resulted in a pronounced reduction of cell proliferation and a concomitant increase of cytotoxicity across all cell lines. These effects correlated with a marked decrease in miR-221 expression and restoration of key regulatory miR-221 targeted proteins involved in cell cycle control and apoptosis. Comprehensive gene expression and microRNA profiling further revealed that miR-221 inhibition down-regulated multiple oncogenic pathways associated with MM progression.

Conclusion

Our preclinical findings demonstrate that targeting miR-221 with LNA-i-miR-221 significantly impairs MM cell growth and viability by modulating critical molecular pathways. These promising results underscore the potential of miR-221 inhibition as a transformative miRNA-based therapeutic strategy for MM, further bolstered by its successful translation into a first-in-human study.

Analysis of immunoglobulin producing tumour cells in colorectal cancer utilising

highplex immunohistochemistry techniques

C. Enright¹, A. Hennessy¹, É. Fennell², O. Mahon¹, P. Murray³, K. McGourty¹

¹*University of Limerick, Limerick, Ireland*

²*University of Zurich, Zurich, Switzerland*

³*Royal College of Surgeons Ireland, Busaiteen, Bahrain*

Introduction

Although an integral part of our immune system, in many epithelial cancers an increase in immunoglobulins is linked to worse prognosis. Recent work has shown that in a variety of epithelial cancers tumour cells can produce immunoglobulin G, termed cancer-derived immunoglobulin (cIgG). cIgG's possess a unique sialylation, detected by the RP215 antibody, which allow cIgG to be distinguished from healthy immunoglobulins. RP215 has never been investigated through multiplex immunohistochemistry, which prompted us to develop a highplex panel to analyse RP215+ cells and their environment.

Material and method

Utilising the PhenoCycler-Fusion system, a tissue microarray featuring 43 malignant and 37 healthy cores was stained with 52 oligonucleotide-conjugated antibodies. This panel was designed to identify the lineage, behaviour and structural context of cells.

Following antibody incubation, complementary oligonucleotide-reporters were cyclically added, imaged and removed. Image preprocessing was performed using a custom pipeline and the resulting data analysed through a purpose-built package developed in-house.

Result and discussion

RP215+ cells often formed small epithelial clusters at the invasive front and were more likely to exhibit tumour budding (≤ 4 epithelial cells per bud) than RP215- cells (6.8 vs 3.2%). They showed lower proliferation (12 vs 25.4% Ki67+) but were also less likely to be dormant (2.1 vs 9.4% p27+), suggesting that while most cells are not proliferating, they are still active. This aligns with previous work showing that migratory tumour buds have a lower proliferative index. Significant changes were observed in the immune milieu of RP215+ cells.

Examining the 50 nearest immune cells, the abundance of regulatory T cells rose from 9.5 to 23.7% around RP215+ cells. In contrast, CD8+ T cells decreased from 31.9 to 11.8%. Notably, PD1 expression was higher in CD8+ T cells near RP215+ cells (48.2 vs 23.1%), indicating a more exhausted state and that PD1 inhibitors may be of benefit in these patients. 36.3% of the immune cells surrounding RP215+ cells were macrophages which often express immunoinhibitory SIGLEC receptors that are capable of binding cIgG, fostering a tolerogenic environment. RP215+ cells were often embedded in dense networks of collagen I, collagen VI and fibronectin. Similarly, the number of fibroblasts and myofibroblasts around these cells increased (1 to 5.2% and 1.2 to 9.6% respectively).

Conclusion

Our findings show that RP215+ cells frequently exist as small clusters and tumour buds within an immunosuppressive niche, enriched with regulatory T cells and depleted of functional cytotoxic T cells. Their association with matrix proteins and fibroblast populations suggest a fibrotic environment. We believe that treatments

targeting the sialic-acid-SIGLEC axis in combination with immune checkpoint inhibitors could potentially be a viable treatment option for patients who express RP215 positivity.

Translational 3D human cell models to decipher invasion and immunosuppression in the high-grade glioma tumor microenvironment

*I. de Sá¹, G. Domenici^{*1}, C. Gomes¹, J. Escandell², Y. Kim³, C. Brito¹*

¹*iBET & ITQB-NOVA, Oeiras, Portugal*

²*iBET, Oeiras, Portugal*

³*Department of Chemical and Biological Engineering, The University of Alabama, Tuscaloosa, USA*

Introduction

High-grade gliomas (HGGs) are central nervous system (CNS) tumors characterized by an immunosuppressive tumor microenvironment (TME) that drives invasion and therapy resistance. Crosstalk between CNS-resident cells (e.g., astrocytes, microglia) and HGG cells fosters extracellular matrix (ECM) remodeling and tumor progression. Understanding HGG immunosuppression and invasion mechanisms is critical for improving therapeutic strategies. However, interpatient heterogeneity in invasion and immune modulation remains poorly captured by existing models. This work aims to develop a human cell model that recapitulates key cellular and molecular interactions within HGG TMEs.

Material and method

We employed a CNS-HGG 3D co-culture approach using stirred-tank culture systems. As the CNS component, we resourced to neurospheres (iNSoids) derived from human induced pluripotent stem cells, composed of functional neurons, astrocytes, and oligodendrocytes within their native ECM. As HGG component, we employed enhanced green fluorescent protein (eGFP)-expressing adult and pediatric HGG cell lines (A172, JX6, SF7761).

Result and discussion

Co-cultured CNS and HGG cells remained viable and retained their identity at the phenotypic and gene expression levels. Confocal microscopy imaging revealed that eGFP+ HGG cells infiltrated iNSoids with distinct, cell line-dependent invasion dynamics. Invasion depths exceeded 30 μm , with HGG cells exhibiting diverse morphological adaptations, ranging from rounded amoeboid-like migration to elongated mesenchymal-like processes. Gene expression analysis indicated that each cell line differentially regulated ECM remodeling, with upregulation of matrix metalloproteinases (e.g., MMP2, MMP14) and hyaluronan-associated genes (e.g., HYAL2, HAS2), suggesting distinct invasion mechanisms.

Beyond invasion, HGG cells also influenced the surrounding immune microenvironment. Upregulation of key immunosuppression-associated genes (e.g., TGFB1, CSF-1) suggests the establishment of an anti-inflammatory TME.

Conclusion

Ongoing work is focused on the incorporation of microglia and patient-derived primary HGG cells to

dissect onco-neuroimmune interactions at the single-cell level, increase the clinical translatability of the model, and depict HGG patient cell response to invasion and immunosuppression modulators. Ultimately, our model will provide a platform for preclinical testing that captures the heterogeneity of HGG behavior and better predicts individualized clinical response.

³*Swiss Institute of Bioinformatics (SIB), Switzerland*

Introduction

Prostate cancer (PCa) is the leading cause of cancer-related mortality among men, largely due to acquired resistance to standard therapies. Comprehensive transcriptional analyses across thousands of PCa specimens revealed a marked upregulation of critical DNA methylation regulators, including DNA methyltransferases and demethylases, particularly during progression to androgen independence. Importantly, these enzymes were identified as direct targets of miR-29a/b/c-3p, whose expression is notably suppressed during PCa progression. We hypothesized that restoring miR-29 expression could reverse aberrant epigenetic regulation, potentially reactivating epigenetically-silenced tumor-suppressive pathways.

Material and method

To test this hypothesis, androgen-independent prostate cancer cell lines (PC3, DU145, LNCaP-abl, 22Rv1) were treated with miR-29 mimics for isoforms a, b, and c. Cells were collected at multiple time points (48–192 hours), followed by transcriptomic analyses, real-time PCR, Annexin V-PI apoptosis and migration assays to evaluate gene expression changes and functional outcomes.

Result and discussion

Transcriptomic analysis following miR-29 mimic in PC3 cells revealed substantial gene expression changes, notably increased pro-apoptotic mediators and decreased expression of genes involved in cell invasion and extracellular matrix remodeling. Functional assays confirmed significant miR-29-induced apoptosis and inhibition of migration capacities. Furthermore, a single miR-29 mimic treatment induced sustained cell-cycle arrest in PC3 cells for up to 10 days. Our expanded analyses demonstrated that miR-29 mimic treatment preferentially induced significant growth inhibition in TP53-deficient prostate cancer cell lines (PC3, DU145), whereas TP53

wild-type cells (LNCaP-abl, 22Rv1) remained largely unaffected. This selective sensitivity highlights a novel context-dependent mechanism, whereby miR-29 restoration compensates for TP53 loss by directly reactivating downstream p53-related apoptotic pathways. Notably, miR-29 itself is a TP53-induced transcript, suggesting that its reactivation may bypass the loss of functional TP53.

Conclusion

Collectively, these findings position miR-29 reactivation as a potential therapeutic strategy to reverse epigenetic dysregulation and overcome treatment resistance in advanced prostate cancer.

Introduction

Lung cancer represents one of the most diagnosed and lethal tumours worldwide, with non-small-cell lung cancer (NSCLC) subtypes accounting for the majority of diagnosed cases. NSCLC management is complicated by frequent relapses and the development of resistance to treatment protocols. Over the past few years, a growing body of literature is highlighting how the tumour microenvironment (TME) can influence different mechanisms involved in cancer establishment and evolution, such as proliferation, metastasis formation and therapy resistance acquisition. Cancer-associated fibroblasts (CAFs) represent the most prominent cell population within the TME, being involved in key mechanisms, sustaining the pro-inflammatory milieu. Thus, developing novel compounds targeting NSCLC-CAFs could impair their activity, representing a viable strategy to overcome the current NSCLC-management limitations. Nucleic acid aptamers could represent effective tools for a precision medicine approach. The plasticity of their selection procedure allows for the identification of aptamers which can recognize and bind with high stability a complexity of different targets.

Material and method

In order to identify a novel RNA aptamer able to recognize NSCLC-CAFs phenotype, we performed an internalizing cell-Systematic Evolution of Ligands by EXponential enrichment (SELEX) procedure on functionally characterized NSCLC patient-derived CAFs.

Result and discussion

We identified different sequences which can effectively distinguish CAFs from normal fibroblasts. The most potential aptamer (Apt1) has undergone length optimization and deeper characterization to assess its binding and functional activities *in vitro*.

Conclusion

Our results suggest that Apt1 could represent a potential novel strategy for the therapeutic targeting of CAFs in NSCLC, with the possibility to hinder the CAFs-tumour cells cross-talk, thus hampering cancer progression.

²CNR, IBBC, Naples, Italy

³CNR, IBB, Naples, Italy

Introduction

Triple-negative breast cancer (TNBC), accounting for ~15–20% of all breast cancer (BC) diagnoses worldwide, has the poorest prognosis, due to its great heterogeneity and limited treatment options, with a death rate in the metastatic setting disproportionately higher than any other BC subtypes. Analysis of the tumor microenvironment (TME) in TNBC have revealed a marked infiltration of tumor associated macrophages (TAMs), a heterogeneous population with high plasticity. TAMs include both M1 (anti-tumor) and M2 (pro-tumor) phenotypes, with the latter predominating in TNBC. The M2-like TAMs contribute to the establishment of an immunosuppressive milieu, promoting tumor growth, metastasis, and resistance to therapy. During tumorigenesis, there is a complex and dynamic interplay between cancer cells and TAMs. Here, we aim to explore the crosstalk between chemoresistant cancer cells and TAMs within the TNBC microenvironment.

Material and method

Cisplatin-resistant (Cis-Pt-R) and doxorubicin-resistant (Dox-R) cell lines were generated by chronic exposure of TNBC MDA-MB-231 cells to the chemotherapeutics. Human THP-1 monocytes were differentiated into M0 macrophages by incubation with PMA. Once adherent, cells were maintained in PMA-free medium to obtain resting macrophages. Conversely, murine RAW264.7 cells were directly used as M0 macrophages. For polarization experiments, human and murine M0 macrophages were treated with LPS and IFN-γ to induce the M1 phenotype, or IL-4/IL-10 to induce the M2 phenotype. To mimic the TNBC microenvironment in vitro, M0 macrophages were exposed to conditioned medium (CM) from TNBC 4T1 (murine setting) or Cis-Pt-R and Dox-R cells (human setting). In addition, to further investigate tumor-M2 like TAMs crosstalk within the TME, chemoresistant TNBC cells were co-cultured with TAMs. Macrophage phenotype and M1/M2 marker expression were validated by immunoblotting and confocal microscopy. Functional characterization was performed using ELISA assays.

Result and discussion

TAMs generated using CM from chemoresistant TNBC cells showed a significant increase in the expression of M2-like TAMs (e.g. CD206, CD44) while M1-like

TAMs marker levels (e.g. CD86) remained substantially unchanged. Quantification of inflammatory and anti-inflammatory cytokine production revealed M2 polarization. Furthermore, co-culture experiments confirmed that cultured with TAMs, chemoresistant TNBC cells promote the M2-polarization in TAMs. Studies are ongoing to assess the effects of polarized M2 macrophages in increasing EMT, stemness, and chemo-resistance of TNBC cells.

Conclusion

Our findings show that chemoresistant TNBC cells actively modulate the TME by skewing macrophage differentiation toward the M2 phenotype, thus providing an opportune system to investigate therapeutic approaches targeting the crosstalk between tumor cells and TAMs.

³Cancer Research UK Scotland Institute, Glasgow, United Kingdom

⁴Leiden University Medical Center, Medical Oncology, Leiden, Netherlands

Introduction

Colorectal cancer (CRC) frequently metastasizes to the liver, which is the leading cause of CRC-related deaths. The Consensus Molecular Subtypes (CMS) classification suggests a link between transforming growth factor (TGF)-β signaling, cancer-associated fibroblasts (CAFs), and the risk of liver metastasis. However, the key downstream effectors of TGFβ signaling in CAFs and their role in hepatic metastases remain poorly understood.

Material and method

This study investigates whether and how TGFβ signaling in CAFs leads to the formation of a hepatic pre-metastatic niche for CRC metastasis. Primary and liver metastasis-derived CRC CAFs were stimulated with TGFβ1, followed by qPCR arrays and ELISA to identify differentially expressed genes. Results were cross-referenced with RNA sequencing data from CMS-classified CRC samples and fresh patient specimens. Next, hepatocytes were exposed to TGFβ primed CAF-derived cytokines, and their effect on pro-inflammatory gene expression and neutrophil migration was assessed. To determine the underlying molecular mechanism, chemical inhibition and genetic ablation were performed to block specific pathways. Lastly, an orthotopic murine model of CMS4 CRC was used to evaluate these findings *in vivo*.

Result and discussion

TGFβ signaling in primary CRC-derived CAFs increased the expression of different members of IL-6 family of

cytokines, which in turn upregulated Serum Amyloid A1 (SAA1), a key neutrophil chemoattractant, in hepatocytes. This led to increased neutrophil-to-hepatocyte migration in vitro. Chemical inhibition and genetic ablation experiments revealed that gp130, the IL-6 family cytokine co-receptor, plays a critical role in JAK/STAT-mediated induction of neutrophil chemoattractants in hepatocytes, ultimately driving pro-metastatic neutrophil migration to the liver. Furthermore, *in vivo* experiments showed increased neutrophil migration to the liver before overt hepatic metastasis, alongside increased IL-6 family of cytokine-dependent stromal signaling.

Conclusion

TGF β signaling in CAFs promotes a neutrophil-dependent pre-metastatic hepatic niche, potentially driving liver metastasis in CMS4 CRC.

⁴University Hospital Schleswig-Holstein, Department of Surgery, Section for Translational Surgical Oncology and Biobanking, Lübeck, Germany

⁵<https://www.outlive-crc.uni-luebeck.de/projekte>, Lübeck, Germany

Introduction

The rising incidence of early-onset colorectal cancer (eoCRC) may be a consequence of accelerated colonic biological aging driven by diet-related chronic inflammation. We aimed to study consumption of an optimized plant-based diet (PbD) on the development of eoCRC in adolescent mice.

Material and method

Multi-omics analyses (RNA sequencing, mass-spectrometry based proteomics, NMR metabolomics), immunohistochemistry and *ex vivo* colonic 3D organoid cultures were performed using 6-week-old male and female C57BL/6JRj mice, corresponding to a human age of 12 years. Acute colitis was induced in 16-week-old, corresponding to a human age of 23 years, male and female C57BL/6JRj mice by application of dextran sodium sulphate (DSS) via the drinking water for 7 days. Finally, 6-week-old male or female C57BL/6JRj mice were fed a control or an isocaloric PbD (sucrose-free, high content of fiber and w-3 fatty acids) for 20 weeks. At week 10, colitis-driven CRC was initiated by two cycles of azoxymethane (AOM) i.p. injection followed by DSS treatment. Mice were sacrificed at the end of week 20, corresponding to a human age of 29 years, for further analysis.

Result and discussion

RNA-seq and proteomic analyses of colonic tissue revealed sex-specific clusters. In young male mice, markers for glycolysis and mitochondrial oxidative phosphorylation as well as pro-inflammatory markers such as caspase-1 and NLRP6 were upregulated compared to young female mice. In contrast, adaptive immune marker levels such as IGG2B, IGHM or IGHG were higher in young female mice. Metabolic phenotyping unraveled low serum levels of the poly-unsaturated w-6 fatty acid arachidonic acid (AA) in young male mice compared to young female mice. Furthermore, colonic levels of the lipoxygenase ALOX15 were significantly reduced in young male mice. Multi-omics data were validated in colonic 3D-organoid cultures from analyzed mice, demonstrating significantly increased growth rates of young male mice derived organoids under AA stimulation, pointing to stronger adaptation of intestinal stem cells to AA stimulation in young female mice. Higher energy level and increased basal inflammation in young male mice was reflected by low survival rates during acute DSS-induced colitis experiments. Unexpectedly, PbD consumption for 20 weeks resulted in a significantly higher tumor load compared to control diet in young AOM/DSS treated male mice, with a lower effect in young AOM/DSS treated female mice.

Conclusion

Our findings suggest a higher glucose-driven mitochondrial activity together with low w-6 fatty acid serum level in young male mice compared to young female mice that resulted in exacerbated colitis-driven CRC under plant-based diet.

⁴University of Parma, Dipartimento di Medicina e Chirurgia, Parma, Italy

⁵University of Turin, Department of Molecular Biotechnology and Healthy Sciences, Torino, Italy

⁶University of Turin, Molecular Biotechnology Center, Torino, Italy

Introduction

Homeostatic Iron regulator (HFE) is the main altered gene in the Hereditary Hemochromatosis (HH) disease. Of the two main HFE polymorphisms, H63D rarely causes overt HH symptoms, but has been described as a risk factor for the development of cancer. Little is known about H63D impact on Pancreatic Ductal Adeno-carcinoma (PDAC), a devastating disease that still represents an unmet medical need. The few curing progresses achieved through the years compared to other types of cancer still underline the necessity of finding

strategies to better stratify and manage PDAC patients. PDAC patients bearing HFE polymorphisms displayed smaller tumors which were surgically resected in a higher percentage of them compared to HFE wild-type patients. Unfortunately, H63D-mutant patients also displayed a lower overall survival. In the attempt to understand better the tumor progression in these patients, we have generated a spontaneous mouse model of PDAC bearing the Hfe orthologue mutation, namely H67D.

Material and method

KC and KPC mice were crossed with HfeH67D/H67D mutant mice (KCHfeH67D/H67D and KPC/HfeH67D/H67D) and pancreas and organs were collected to histological analyze tumor progression and spreading and characterize the immune infiltrate by immunohistochemistry or flow cytometry. HfeH67D/H67D mutant mice were also immunized with non-proliferating OVA-overexpressing PDAC cells and 3 weeks later with live OVA-PDAC cells to investigate the antigen specific immune response. Antibody and cellular responses were analyzed by ELISA and ELISpot with sera and splenocytes collected two weeks after the challenge with live OVA-PDAC cells.

Result and discussion

Histological analyses of tumors arose in KC/HfeH67D/H67D and KPC/HfeH67D/H67D mice evidenced an increased tumor aggressiveness, with a higher propensity to metastasize and invade neurons into the pancreas. Additionally, H67D-mutant tumors were highly infiltrated by suppressive cells. Functionally, H67D-bearing mice were able to mount an antigen-specific immune response, but in vitro experiments evidenced a tendency towards a suppressive type-II response with a massive production of antibodies, which, however, seem to play a role in the attempt to contrast the tumor growth. Comparable lesion extensions highlighted strong differences in infiltrating immune cells in tumors arose in KC mice bearing or not Hfe mutation.

Conclusion

Overall, the H67D polymorphism seems to worsen PDAC progression and strongly affects immune cell activation, representing a promising prognostic biomarker that deserves further investigations to find better way to manage and treat these patients.

EACR25-1492

Molecular characterization of long non-coding RNA MINCR isoforms and their impact on prostate cancer progression

I. Cassotti¹, S. Gasti¹, A. Restellini¹, G. Pagani¹,

C. Pandini¹, P. Gandellini¹

¹*University of Milan, Department of Biosciences, Milan, Italy*

Introduction

The gene encoding for MINCR (MYC induced long non-coding RNA) is located on chromosome 8, 15 Mb telomeric to MYC. While the two genes are often coamplified, we identified a substantial proportion of patients with advanced prostate cancer where MINCR is amplified independently of MYC, implying a distinct oncogenic potential for MINCR. While MINCR has emerged as a significant player in many cancers, no efforts have been made to elucidate its impact on prostate

cancer progression and the specific role of MINCR isoforms remains unexplored.

Material and method

MINCR transcript characterization was performed through in silico analyses using publicly available cancer datasets and annotation databases. MINCR silencing was obtained using either blocking or degrading antisense oligonucleotides. For overexpression, isoform-specific sequences were cloned in plasmids. RNA sequencing followed by gene set enrichment analysis (GSEA) was used to provide mechanistic hints on how MINCR impacts prostate cancer tumorigenesis. Quantitative PCR analysis and in vitro cellular assays were performed to validate GSEA results.

Result and discussion

We found that MINCR expression levels positively correlate with tumor grade and negatively with disease-free survival, highlighting that MINCR is highly expressed in more aggressive and advanced cases of prostate cancer. The analysis of PolyA site database, FANTOM CAGE data, and long-read sequencing data revealed the existence of two main isoforms, that we named short and long, localizing in the cytoplasm and in the nucleus, respectively. Modulation of MINCR short in prostate cancer cells resulted in more profound changes in gene expression, as compared to MINCR long.

Overall, silencing of both isoforms impacted on cell growth, with cell cycle related genes (specifically M phase) being downregulated. MINCR involvement in cell proliferation was further confirmed in vitro; indeed, knocked-down DU145 and PC3 prostate cancer cells both showed decreased proliferation, whereas stably overexpressing clones displayed variably increased growth. Moreover, manipulation of both isoforms induced alterations of genes involved in androgen response, immunogenicity and NOTCH-pathway, features typically observed in neuroendocrine, aggressive prostate cancers. On the other hand, metabolism-related pathways, like glycolysis, resulted altered only when the short isoform was overexpressed, while genes involved in cell migration, cytoskeleton and extracellular matrix appeared selectively governed by MINCR long.

Conclusion

Our study reveals that MINCR isoforms exhibit distinct behaviors, yet both play crucial roles in driving prostate cancer progression and enhancing its aggressiveness. Investigating how MINCR influences cancer hallmarks and resistance to treatment could pave the way for novel targeted RNA-based therapeutic strategies.

Introduction

Recent *in vitro* 3D models have shown that dormant state of disseminated cancer cells can be induced by physical confinement of the extracellular matrix (ECM), either by its high density and/or low adhesion. In this work, we aim to understand ECM-mediated dormant state of cancer cells by comparing mechanically tuneable stiffness-matched semi-synthetic matrices.

Material and method

MDA-MB-231 cell line as a model for triple-negative breast cancer and MCF7 for the luminal subtype were used. Genetically modified with the FUCCI2 cell cycle reporter, with mCherry as G0/G1 phase indicator and mVenus as S/G2/M phase marker, both cell lines were encapsulated in stiffness-matched hydrogels. Norbornene-modified inert alginate gels were used to mimic dormancy-inducing microenvironments, while adhesive and degradable gelatin methacryloyl (GelMA) gels were chosen as proliferation-permissive microenvironments. Stiffness and swelling values of hydrogels were evaluated by rheology. 3D confocal images of single cells and clusters formed over time were stained with F-actin and segmented using Deep Learning algorithms in ORS Dragonfly. Then, cell morphological features such as volume changes and sphericity were quantified. To determine the role of the matrices in dormancy induction, the cell cycle state and the cyclin-dependent kinase (CDK) inhibitor p27/Kip1 were analysed with FUCCI2 and immunofluorescence, respectively. Currently, further analyses are ongoing connecting dormancy and mechanotransduction.

Result and discussion

We obtained stiffness values of 1 and 10 kPa for soft and stiff matrices, respectively, both for alginate and GelMA gels. First, we observed a higher number of single cells in alginate gels compared to a greater number of clusters in GelMA. Limiting the analysis to single cells, the number of cells in S/G2/M phase decreased while those in G0/G1 increased in all groups, especially in MCF7 cells. Furthermore, cells in G0/G1 phase showed a significantly lower cell volume compared to cells in S/G2/M phase in all groups, regardless of matrix stiffness. Comparing both cell lines, MCF7 cells showed higher volume in both single cells and clusters compared to MDA-MB-231 cells. In terms of sphericity, only MDA-MB-231 cells in soft GelMA gels showed significant morphological elongations, indicative of proliferative behaviour, while MCF7 cells remained rounded. Finally, we validated a dormant phenotype of MCF7 cells by a nuclear translocation of p27/Kip1, which was enhanced in soft matrices.

Conclusion

Inert alginate models restrict breast cancer cluster formation, limiting cell volume increase in growth-arrested cells for both triple-negative and luminal models and independent of matrix stiffness. Interestingly, MCF7 cells express an enhanced dormant phenotype in soft microenvironments.

⁵*University of Turku, Department of Life Technologies, Turku, Finland*

⁶*University of Turku, InFLAMES Research Flagship Center, Turku, Finland*

Introduction

Mucinous colorectal carcinoma (MUC CRC) dissemination into the tumor stroma and metastasis to multiple organs, including the peritoneum, is associated with poor prognosis. Disseminating MUC CRCs exhibit either a conventional ‘apical-in’ or an inverted ‘apical-out’ polarity phenotype that influence patient outcome. Identifying the mechanisms controlling MUC CRC polarity is critical to understand disease progression.

Material and method

Here, we analyze patient-derived MUC CRC xenografts, with apical-in or apical-out polarity, *ex vivo* or within collagen gels to mimic the peritumoral stroma. Single-cell analyses reveal $\alpha 2\beta 1$ -integrin as a key collagen-binding receptor in these models.

Result and discussion

Collagen- $\alpha 2\beta 1$ -integrin interaction activates Src and ERK/MAPK signaling and upregulates the expression of SorLA, an endosomal sorting receptor. SorLA supports apical-in polarity and carcinoma-stroma interactions by promoting integrin recycling to the plasma membrane and HER2/HER3 expression through a positive feedback mechanism. Accordingly, we observe positive correlation between HER2, HER3 and SorLA in patient samples with the highest HER2 expression in apical-in-presenting tissues. Treatment of tumor spheres with clinically relevant HER2/HER3-targeting antibodies reverts sphere polarity and impedes collagen remodeling and adhesion to mouse peritoneum

Conclusion

This SorLA-integrin-HER2/HER3 signaling axis may represent a basis for MUC CRC-patient stratification and shed light on other carcinomas with similar apical-out phenotypes.

EACR25-1498

The role of RNA Modifiers in Prostate Cancer Bone Metastasis: Insights from m6A RNA Methylation

K. Detkiewicz¹, S. Kalogera¹, M. Persson², M. Sjöström², Y. Ceder¹

¹Lund University, Department of Clinical Sciences, Lund, Sweden

²Lund University, Department of Laboratory Medicine, Lund, Sweden

Introduction

Prostate cancer (PCa) is one of the most common malignancies among men in industrialized countries and a leading cause of cancer-related mortality. While the five-year survival rate for localized early-stage PCa approaches almost 100%, it declines dramatically to 30–35% upon metastasis, with skeletal bone being the predominant metastatic site (observed in ~80% of cases) and no curative treatments currently available. The interplay between tumor cells and bone cells plays a pivotal role in the establishment and progression of bone metastases. Emerging evidence suggests that RNA-editing and modification processes enable cancer cells to adapt to new microenvironments, facilitating metastatic progression.

Material and method

In this study, we investigated the effects of the bone microenvironment on the expression of almost 100 different RNA-modifying enzymes in PCa cells and validated them in two distinct patient-derived PCa cohorts. Next, we continued with functional studies of the most significant RNA regulators.

Result and discussion

Our findings demonstrate that many RNA modifiers were deregulated in PCa cell lines in our in vitro model for the bone microenvironment compared to normal medium. In silico analyses of patient-derived PCa cohorts support these results, revealing significant upregulation of two key RNA modifiers, RBM15 and RBM15B, in bone metastases compared to primary tumors at both RNA and protein levels. These proteins are components of the m6A methyltransferase complex (MTC), which mediates N6-methyladenosine (m6A) RNA modifications – the most common RNA modification in all eukaryotes. Functional studies employing siRNA knockdown confirmed the essential role of the proteins in regulating m6A RNA methylation and significantly decreased cell growth of PCa cell lines.

Conclusion

In conclusion, these results identify m6A RNA methylation and its regulatory proteins; RBM15 and RBM15B as contributors to PCa progression. Furthermore, the in vitro screening results, as well as patient cohort analyses, suggest a role in bone metastasis and highlight their prognostic potential.

EACR25-1508

A Multiomics Imaging Approach to Characterize lncRNA-Protein Dynamics in Colorectal Cancer Progression

D. Azorin¹, L. Nechyporenko¹, P. Bordignon², X. Ficht¹, A. Moor¹

¹ETH Zurich, Department of Biosystems Science and Engineering, Basel, Switzerland

²Lunaphore Technologies, Tolochenaz, Switzerland

Introduction

Colorectal cancer (CRC) is one of the deadliest cancers worldwide. Increasing incidence and mortality rates highlight the need for a more in-depth understanding of

its underlying characteristics. Since tumor heterogeneity contributes to therapy resistance and disease progression, it is crucial to identify biomarkers at both the protein and RNA levels. Long non-coding RNAs (lncRNAs) are considered promising biomarkers in CRC, but despite their potential role in cancer prognosis and diagnosis, their spatial distribution is not well understood. We aim to address this knowledge gap by leveraging the COMET™ multiomics platform. Here, immunofluorescence (mIF) has been recently integrated with RNAscope™ (RNA fluorescence in situ hybridization, RNA-FISH) to enable multiplexed imaging of RNA and protein on the same slide. This approach will provide an unprecedented view of lncRNA-protein interactions in CRC.

Material and method

We will select formalin-fixed, paraffin-embedded (FFPE) healthy and CRC specimens covering stages I-IV to construct a tissue microarray (TMA). Using the COMET™ system combined with RNAscope™ technology, we aim to dissect the spatial distribution of selected lncRNAs (MALAT1, ANRIL, NEAT1, and TUG1), which have been shown to play a role in CRC progression. The multiplex immunofluorescence panel consists of EMT markers (E-cadherin, N-cadherin, Vimentin, Fibronectin, ZEB1, ZEB2), proliferation markers (Ki-67, PCNA), stromal markers (CD44, Plexin B2, α-SMA, Desmin, CD31, CD45), and CRC-specific markers (Pan-CK, CDX2, SATB2).

Result and discussion

We assume that multiplex imaging will reveal distinct lncRNA expression patterns across CRC stages. Patients with MALAT1+/ZEB1+/N-cadherin+ profiles have been shown to have poorer outcomes. Our hypothesis is that MALAT1 and NEAT1 may be significantly upregulated in advanced CRC (Stages III-IV) and could correlate with an EMT shift, quantified by high N-cadherin/ZEB1/ZEB2 and low E-cadherin expression. Similarly, ANRIL and TUG1, potentially localized predominantly in stromal regions, might increase in Stage II tumors, suggesting a role in microenvironment remodeling. We anticipate that ANRIL expression could correlate with stromal activation (α-SMA, Desmin, CD31), while high CD45 levels may inversely correlate with MALAT1 expression, potentially indicating immune evasion. Additionally, we hypothesize that the loss of CDX2 and SATB2 could be associated with EMT-driven dedifferentiation.

Conclusion

Acquiring spatial information on lncRNAs associated with poor tumor prognosis and proteins involved in EMT activation across different CRC stages will provide key insights into their interactions. This may help link these lncRNA-protein interactions to both tumor progression and the functional role of the lncRNAs.

EACR25-1526

Stromal-immune interactions shape the bone metastatic niche

M. Langer¹, L. Monteran¹, Y. Scharff¹, L. Fantini¹, N. Erez¹

¹Tel-Aviv University, Pathology, Tel-Aviv, Israel

Introduction

Mortality from breast and lung cancers is almost exclusively a result of tumor metastasis, and the most common site for metastatic spread from these cancers is the bone. Advanced metastatic disease is still incurable and therefore, a better understanding of the bone microenvironment as a central niche for breast and lung cancer metastasis is critical. We previously showed that stromal cells in multiple metastatic organs are key players in facilitating metastatic progression. However, the function of osteoblasts in creating a hospitable metastatic niche in the bones remains largely unknown. We hypothesize that the dynamic plasticity of osteoblasts in the bone metastatic niche is a driving force in enabling metastatic relapse by modulating the immune compartment in the bone microenvironment.

Material and method

We utilized a mouse model of spontaneous breast cancer metastasis to bone, following resection of the primary tumor, providing us with a clinically relevant platform to study the changes in the bone metastatic niche and the interactions between stromal and immune cells that facilitate bone metastasis. In addition, utilizing transgenic reporter mice (*Col1a-YFP*) to enable tracking and isolation of osteoblasts at distinct metastatic stages and from defined metastatic niches, we study the functional heterogeneity of osteoblasts during breast and non-small cell lung carcinoma (NSCLC) bone metastasis, at the single-cell level.

Result and discussion

We found that secreted factors from bone-metastasizing breast cancer cells reprogramed primary osteoblasts to an elongated spindle-shaped CAF-like immature phenotype. Cancer-secreted factors also induced upregulation of pro-inflammatory and bone turnover genes indicating increased osteolysis. Following activation, osteoblasts were capable of chemoattracting myeloid-derived suppressor cells and suppressing CD8 T-cell activity and proliferation. Interestingly, cancer-activated osteoblasts also produced less abundant and highly anisotropic cell-derived matrixes, suggesting that they contribute to bone matrix remodeling during the metastatic process.

Conclusion

In summary, a better understanding of the reciprocal interactions of osteoblasts and immune cells in the bone metastatic microenvironment will enable identification of therapeutic targets to treat bone metastasis.

EACR25-1531

Role of mammary adipose tissue-derived versican proteoglycan in breast cancer progression and aggressiveness

A. Parascandolo¹, V. D'Esposito², M. Di Tolla¹, F. D'Alterio^{1,2}, L. Zinna¹, S. Cabaro¹, G. Ferraro¹, P. Formisano¹

¹*University of Naples Federico II, Department of Translational Medicine, Naples, Italy*

²*National Council of Research (CNR), Institute of Endotypes in Oncology, Metabolism and Immunology "G. Salvatore" (IEOMI), Naples, Italy*

Introduction

In Breast cancer (BC) cell-cell interactions are a prominent mechanism for cancer progression. Mammary

adipose tissue (MAT) represents 90% of breast tissue where epithelial cells and adipose cells constantly interact. In BC, MAT and mesenchymal stem cells (MCSs) have a key role in sustaining tumor development, secreting signaling molecules and proteins. Among them, Extracellular matrix (ECM) proteins secreted by MAT have an essential role in cell-cell communication. Proteoglycans, components of ECM, are involved in the regulation of different pathological processes. Versican (Vcan) proteoglycan sustains cancer progression either by having an impact on the cancer cell or by influencing the tumor microenvironment. Since Vcan is highly expressed in adipose tissue, MAT derived-Vcan might act on BC epithelial cells and vice versa. Therefore, the aim of our work is to study the role of Vcan in BC-MAT bidirectional communication and its potential identification as a novel diagnostic biomarker of BC progression and aggressiveness in MAT.

Material and method

MAT biopsies have been obtained from healthy women (N=16) and from patients with BC (N=17). Total RNA and protein lysates have been collected and analyzed for Vcan expression by Real Time PCR and Western blot analysis respectively. MCSs have been isolated from MAT and co-cultured with MCF7 BC cells in transwell systems and in Ultra low Attachment 96well for spheroids formation. Vcan content was investigated by immunohistochemistry (IHC). Data were analyzed using GraphPad Prism 8.

Result and discussion

In BC-MAT Vcan was detected by IHC at higher extent in the proximity of the tumor, compared to more distant sites. Higher Vcan expression correlates with BC aggressiveness. Vcan expression positively correlates with patients glycemia and cholesterol in MCSs, suggesting that Vcan expression in MAT-MSCs was reminiscent of the physiological patients metabolic status. Moreover, in 2D-co-culture with MCF7 cells, MSC expressing high levels of VCAN (MSC-VCAN+) displayed increased levels of Vascular Endothelial Growth Factor (VEGF), Interleukin-6 (IL-6), Fibroblast Activation Protein (FAP) and ACTA2 genes, and induced Matrix Metalloprotease-9 (MMP-9) expression in MCF7 cells, compared with MSC expressing lower VCAN levels (MSC-VCAN-). These data suggest that MSC-VCAN+, in contact with BC cells, showed an up-regulation of pro angiogenic, inflammatory and fibrotic markers. Finally, spheroids composed of MCF7 cells and MSC-VCAN+ showed higher dimension and number compared to spheroids composed of MCF7 cells and MSC-VCAN-.

Conclusion

All together this evidence pointed out Vcan as a target molecule with a strategical role in the connection between BC and MAT. Characterization of Vcan in MAT surrounding BC may lead to identify a novel biomarker associated to BC progression and aggressiveness.

³Molecular Pathology of Sarcomas and Other Tumors, Institute of Biomedicine of Seville-Hospital Universitario de Sevilla, Coimbra, Portugal

⁴Univ Coimbra - University of Coimbra, CIBB, Faculty of Pharmacy, Coimbra, Portugal

Introduction

Desmoplastic Small Round Cell Tumor (DSRCT) is a rare, aggressive soft tissue sarcoma primarily affecting the peritoneal cavity of children and young adults. It is defined by a specific chromosomal translocation t(11;22) (p13;q12), that leads to the aberrant transcription factor EWSR::WT1, and a rich desmoplastic extracellular matrix (ECM) that supports tumor growth while hindering drug delivery and immune infiltration. Currently, there are no 3D DSRCT in vitro models, which are critical to evaluate treatment strategies. Moreover, it is crucial to identify potential therapeutic targets. Nucleolin (NCL), described by our group as a safe and specific therapeutic target when expressed on the cell surface [1] remains unexplored in DSRCT. Herein, we develop a novel organotypic DSRCT model that closely mimics the ECM-tumor dynamics to study tumor progression and NCL-targeted therapies.

Material and method

JN-DSRCT cells alone/and MRC5 fibroblasts were embedded in a matrix with different ratios of type I and III collagen, with/without fibronectin. Cell growth and spatial distribution within the matrix were analyzed by microscopy. ECM remodeling was assessed by exposure to different compounds: collagenase type I, losartan, a lysyl oxidase-like 2 (LOX2) inhibitor and a fibroblast activation protein (FAP) inhibitor. Cytotoxicity was evaluated using MTT at 72 h in 2D models, prior to 3D model generation. ECM permeability was analyzed via a transwell assay followed by absorbance studies, using calcein and 90 nm NCL-targeted liposomes to mimic therapeutic delivery. NCL expression in DSCRT was analyzed by flow cytometry (FACS) and western blot, compared to a panel of normal/tumoral cell lines.

Result and discussion

The organotypic model successfully mirrors the human DSRCT architecture. Specifically, collagen I concentrations up to 1 mg/ml supported DSCRT cell growth and distribution for at least 9 days. ECM remodeling was observed in response to treatment, leading to a reduced matrix stiffness, observed by microscopy. DSRCT were not affected by collagenase I up to 12U/ml in 2D. However, calcein penetration improved after treatment with collagenase. Furthermore, DSRCT cells expressed NCL on the cell surface highlighting NCL relevance as a potential therapeutic target. NCL modulation studies are currently ongoing.

Conclusion

Our findings suggest that DSRCT ECM can be effectively recapitulated in vitro using an organotypic model, providing a valuable platform for DSRCT research. This study highlights the potential of combining ECM modulation with NCL targeting in tumor cells as a novel therapeutic approach to treating DSRCT.

Clinical and molecular characterization of colorectal cancer: is the tumor micro-environment reflected on fecal miRNome and microbial profiles?

V. Alberini¹, A. Gagliardi², L. Franchitti², E. Berrino³, S. Tarallo³, B. Pardini², G. Ferrero¹, A. Naccarati²

¹University of Torino, Turin, Italy

²Italian Institute for Genomic Medicine, Turin, Italy

³Candiolo Cancer Institute, Turin, Italy

Introduction

Colorectal cancer (CRC) develops within a heterogeneous microenvironment in which immune and stromal cells interact with tumor cells, influencing disease progression. The balance between tumor-promoting and tumor-suppressing mechanisms within this ecosystem determines clinical outcomes. This study explores the relationship between tissue transcriptome data, including deconvolution of tumor microenvironment (TME) composition, and their reflections on fecal molecular markers (miRNA profiles and microbiome composition). The aim is to explore novel insights for an accurate characterization of non-invasive biomarkers for CRC diagnosis and monitoring.

Material and method

RNA-sequencing data from tumor and paired adjacent tissue of 93 CRC patients were analyzed using the MCP-Counter algorithm to estimate TME cell population scores. Clinical and molecular data, including tumor mucinous, immunoscore, microsatellite instability, and consensus molecular subtypes, were integrated to identify specific patterns with respect to the immune infiltrate. Gut microbiome composition obtained by shotgun sequencing and fecal miRNA profiles from small-RNA sequencing were investigated according to previously identified patterns by a multi-omics integration approach. Results were validated on an independent cohort of 159 CRC patients.

Result and discussion

Significant differences in immune cell infiltration were observed between tumor and adjacent tissues, with an increase of cancer associated fibroblasts (CAFs) in tumors and Natural Killer cells in adjacent tissues. Three distinct clusters of stromal and immune cell infiltrate were identified, highlighting reflections across histopathological, molecular and clinical features, also confirmed on the validation cohort. Tumor tissue miRNome profiles showed a pattern of dysregulation when compared with adjacent mucosa that reflected the TME populations. Despite an apparent similar trend of correlations between differentially expressed miRNA

levels and TME scores, either in tumor or adjacent mucosa stronger associations could be appreciated for specific populations such as CAFs and B cells. Putative stool miRNA levels associated with the tumor infiltrate included a positive correlation of macrophage score with miR-342-3p and miR-30a-3p observed also in tissues. Conversely, endothelial cells exhibited a positive correlation with miR-130a-3p tissue levels and a negative correlation with its levels in stool. Analysis of gut microbiome composition in relation to identified TME clusters is ongoing.

Conclusion

These preliminary results highlighted distinct TME patterns and their association with miRNA alterations, in both primary and surrogate tissues. Further analyses will focus on functionally characterizing the associations between TME clusters and fecal molecular signatures, aiming to refine their potential as non-invasive biomarkers for CRC.

EACR25-1576

The role of complement in pancreatic cancer: from complement activation and effector mechanism/s to combination with therapy

M. Dambra¹, G. Pezone¹, S. Carloni¹, E. Magrini¹, C. Garlanda^{1,2}

¹*IRCCS Humanitas Clinical and Research Center, Milan, Italy*

²*Humanitas University, Pieve Emanuele, Italy*

Introduction

The complement system has long been recognized for its role in cancer immunosurveillance, but more recently, it has also been identified as a system that promotes tumor development in several cancer types. Our laboratory previously demonstrated that lectin-dependent complement activation drives sarcoma progression via a C3a/C3aR-dependent mechanism. Although a potential pro-tumoral role of the complement system in pancreatic cancer has already been described, the underlying mechanisms and its potential as a therapeutic target have not yet been fully investigated. This study aimed at investigating the pathway/s involved in complement activation in pancreatic cancer, the potential triggers, and effector mechanisms, and also at evaluating the therapeutic potential of complement inhibition in combination with established treatments, such as radiotherapy (RT).

Material and method

Combining subcutaneous and orthotopic preclinical mouse models of pancreatic cancer (Panc02) with C3 deficiency, we investigated the impact of complement activation on tumor development. Additionally, we examined the role of C3 upstream (C4^{-/-}, MBL1/2^{-/-}, C1q^{-/-}, and fB^{-/-}) and downstream (C3aR^{-/-} and C5aR1^{-/-}) complement molecules. To explore potential trigger/s of complement activation, such as gut micro/mycobiose alterations and tumor cell glycosylation, we employed in vivo antibiotic/antifungal treatments and in vitro C3 deposition assay on tumor cells, upon treatment with glycosylation inhibitor/s. Finally, we assessed the

therapeutic potential of complement inhibition in combination with local RT in vivo.

Result and discussion

Our results in C3^{-/-} (both subcutaneous and orthotopic), C4^{-/-} and MBL1/2^{-/-} mice show reduced susceptibility to Panc02 tumor growth. The use of a specific N-glycosylation inhibitor (Tunicamycin) in vitro resulted in reduced C3 deposition on Panc02 cells, suggesting that alterations in cell membrane glycosylation weaken complement recognition. The downstream effector mechanisms of C3 activation appear to be independent from C3aR and C5aR expression in vivo. Furthermore, we explored the potential benefit of complement deficiency in combination with tumor RT. Notably, MBL deficiency combined with RT led to a more efficient control of tumor growth compared to either RT treatment or MBL1/2 deficiency alone, suggesting an additive effect.

Conclusion

Our work demonstrated that complement activation driven by the lectin pathway upon recognition of altered tumor cell glycocalyx, promotes Panc02 tumor growth. C3-downstream mechanisms need to be clarified. Results obtained with the combination of MBL-deficiency with RT indicate that targeting complement may lead to better response to classical therapies.

EACR25-1582

Exploring the Interactions within the Tumor Microenvironment of pancreatic neuroendocrine tumors (P-NETs)

A. Marangolo¹, P. Benedikt-Kühnast¹, H. Mohr², N. Pellegata¹

¹*Helmholtz Munich, Munich, Germany*

²*Helmholtz Institute, Munich, Germany*

Introduction

The tumor microenvironment (TME) plays a crucial role in the progression and clinical behaviour of various cancers. However, its significance in neuroendocrine tumors (NETs) remains largely unexplored. This study aims to elucidate the mechanisms governing the interaction between pancreatic NETs (P-NETs) and their microenvironment, with a focus on identifying factors that influence tumor growth, differentiation, and aggressiveness.

Material and method

Our experimental model is the NT-3 cell line derived from a human well-differentiated P-NET. NT-3 cells were injected into immunodeficient mice to generate xenografts. Subsequent tissue stainings were performed to observe growth patterns and phenotypic characteristics of the tumors. We will also assess the crosstalk between NT-3 cells and several human derived cancer associated fibroblasts (CAFs) as stromal component in co-culturing conditions. Our models were infected with the TurboID system to tag every protein secreted in cell culture media allowing the proteomics analysis of each cellular component in co-culturing conditions.

Result and discussion

Histological analysis of the xenografts revealed two distinct tissue phenotypes. Some tumorgrafts exhibited the conventional morphology of well-differentiated P-

NETs, while others displayed extensive stromal infiltration, deviating from the traditional growth pattern. The presence of these divergent histopathological phenotypes provides a unique experimental setting to study the complex interactions between tumor cells and the TME. We positively validated the stable expression of the TurboID biotin ligase and a good biotinylation efficiency in the infected models, overall confirming the setup of a functional system for the proteomics analyses of the co-cultures' secretome.

Conclusion

Our findings highlight the heterogeneity within the TME of NETs and underscore the importance of understanding these interactions. The distinct growth phenotypes observed in the NT-3 xenografts offer valuable insights into the factors driving tumor behavior and present opportunities for developing novel targeted therapeutic strategies and advance our knowledge of NET biology.

Oncofetal-chondroitin sulfate, key to tumor immune surveillance?

A. Martin Salazar¹, E. Vidal-Calvo¹, M. Nordmaj¹, S. Choudhary^{1,2}, J. Bisenberger¹, R. Dagit^{1,2}, M. Gögenur^{3,4}, I. Gögenur³, T. Gustavsson^{1,2}, A. Salanti^{1,2}

¹University of Copenhagen, Centre for translational Medicine and Parasitology, Copenhagen, Denmark

²VAR2 Pharmaceuticals, Copenhagen, Denmark

³Zealand University Hospital, Center for Surgical Science, Køge, Denmark

⁴Denmark

Introduction

Onco-fetal chondroitin sulfate (ofCS) glycosaminoglycan is a cancer-associated modification, initially described in placenta. While absent from healthy tissues, it is extensively expressed in tumors of different origins. We recently developed two antibodies binding with high affinity and specificity to ofCS enabling its depth characterization in cancer. The tumor agnostic expression of ofCS points to a crucial role in tumor development and progression, however the biological role of ofCS remains elusive.

Material and method

In this study we have generated CRISPR-Cas9 ofCS genetic knock-out (KO) cell lines from 4T1 murine breast and A375 human melanoma to study the biological roles of ofCS. The biological implication of the KO was assessed in vitro and in vivo. Differences in the immune cell infiltration were studied with immunofluorescence staining of tissues and flow cytometry analysis of single cell tumor suspensions.

Result and discussion

We observed increased tumor T-cell infiltration in immunocompetent 4T1 ofCS KO allograft compared to wild type (WT) tumors. In line with this, we observed increased immune cell infiltration in A375 tumors in a humanized murine model co-treated with human immune cells. We also observe an opposite spatial correlation between CD3+ cell location and ofCS staining in human colorectal patient biopsies.

Conclusion

Altogether, our studies indicate that ofCS may play a key role in tumor immuno-surveillance.

EACR25-1603

Study of master regulators involved in brain metastasis development in triple-negative breast cancer

F. Woesteland¹, N. Jouy², O. Molendi-Coste³, A. Horochowska¹, E. Fontaine¹, M. Tardivel⁴, T. Chassat⁵, X. Le Bourhis¹, C. Lagadec¹

¹CANTHER, Lille, France

²BICel - PLBS, Lille, France

³BICel - PLBS - Pasteur, Lille, France

⁴PLBS, Lille, France

⁵PLEHTA - Pasteur, Lille, France

Introduction

Although breast cancer survival rates have improved in recent years, 90% of its mortality is attributed to the development of metastases to vital organs. Among the various subtypes of breast cancer, triple-negative breast cancer (TNBC) is the most aggressive and has the highest metastatic potential. In fact, 50% of patients with TNBC will develop brain metastases, presenting a significant challenge to survival in these patients. Surgical excision is not always feasible, and the lack of specific targets distinguishing TNBC complicates therapeutic targeting, sometimes making it impossible. Consequently, when brain metastases occur, a patient's survival decreases to six months. In this context, it is essential to characterize cerebral metastatic dissemination by identifying cellular factors that may be responsible for subsequent relapses in patients.

Material and method

Therefore, we propose investigating the master regulators (transcription factors, or key regulators of gene) implicated in the early stages of brain metastatic dissemination. To achieve this, we developed an *in vivo* brain metastasis model using intracardiac injections in SCID mice. Next, we established a protocol for recovering tumor cells that have spread to the brain (brain DTCs) to conduct a single-cell omic analysis. Simultaneously, we track brain metastatic dissemination over time utilizing an *in toto* clarification and light-sheet 3D imaging.

Result and discussion

Monitoring cancer cells through bioluminescence after intracardiac injections in SCID mice enabled the establishment of the kinetics of brain metastatic development. A few hours post-injection, most cells are located in the brain. By day 5 after injection the number of disseminated cells decreases drastically, followed by slow growth until day 21, reaching maximum development on day 28. Consequently, brain DTCs were collected at four time-points (D5, D14, D21, and D28) for ongoing transcriptomic analyses following brain dissociation. Simultaneously, an examination of the localization of brain DTCs at the same intervals is conducted through *in toto* clarification of the organ. This highlights the relationship between tumor cells, blood vessels, and the brain microenvironment, including astrocytes, microglia, and neurons.

Conclusion

This project enhances our understanding of early cerebral metastatic dissemination in TNBC. First, we developed a model of brain metastases suitable for scRNA-Seq analysis. Using the results from this model and

leveraging the bioinformatics tool created by our team, we will generate networks of master regulators identified at each stage of early brain metastasis. Additionally, it provides a precise spatio-temporal mapping of the implantation of metastatic cells in the brain, while emphasizing their dynamic interactions with the brain microenvironment.

EACR25-1618

XPO6-Mediated Immune Evasion Limits TCR-T Efficacy in Nasopharyngeal Carcinoma

Z. Oi¹, L. Gong¹, J. Luo¹, Y. Yang¹, X. Guan¹

¹The University of Hong Kong, Department of Clinical Oncology, Hong Kong, Hong Kong, China

Introduction

Nasopharyngeal carcinoma (NPC) is an epithelial malignancy characterized by a complex immuno-suppressive tumor microenvironment (TME) with abundant infiltrating immune cells and cytokines. T cell receptor-engineered T cell (TCR-T) therapy, particularly targeting the NY-ESO-1 antigen, has emerged as a promising adoptive cell immunotherapy for NPC.

Through a genome-wide CRISPR screen, we identified exportin-6 (XPO6), a nuclear exporter, as a critical regulator of immune evasion in NPC cells, enabling resistance to TCR-T-mediated cytotoxicity.

Material and method

We established a genome-wide CRISPR knockout library in the NY-ESO-1-expressing C666-1 cell line and developed a co-culture system with NY-ESO-1-specific TCR-T cells to model tumor cell killing. Following TCR-T-mediated cytotoxicity, surviving tumor cells were collected for genomic DNA extraction and next-generation sequencing (NGS). Model-based Analysis of Genome-wide CRISPR/Cas9 Knockout (MAGECK) analysis identified XPO6 as a key factor regulating immune evasion in NPC, as evidenced by the down-regulated abundance of guide RNA sequences targeting XPO6. Functional validation was performed by knocking out XPO6 in additional NPC cell lines (HK1, NPC43) to assess its roles in tumor progression and immune resistance.

Result and discussion

XPO6 was identified as a potent anti-immune factor, promoting immune evasion by enabling NPC cells to resist TCR-T-mediated killing. Additionally, XPO6 exhibited oncogenic properties, driving tumor progression and enhancing immune tolerance in NPC. Knockout of XPO6 significantly sensitized NPC cells to TCR-T therapy and reduced tumor growth, highlighting its dual role as both an immune evasion regulator and an oncogene.

Conclusion

Our findings reveal that XPO6 plays a critical role in NPC immune evasion and tumor progression. Targeting XPO6 may represent a novel strategy to enhance the efficacy of TCR-T therapy and overcome immune resistance in NPC. These results provide new insights into the mechanisms of immune evasion in NPC and underscore the therapeutic potential of combining XPO6 inhibition with adoptive cell immunotherapy.

⁵National and Kapodistrian University of Athens, Medical School, Second Department of Neurosurgery, Athens, Greece

Introduction

Mechanical cues regulate key features of cancer cells. Polycystin-1 (PC1) and polycystin-2 (PC2) are critical proteins that mediate mechanotransduction in cells. The aim was to investigate the impact of PC1 and PC2 on solid tumors.

Material and method

The expression of polycystins was investigated immunohistochemically in archival material of human breast, glioma, and prostate tumors. Functional assays were performed on corresponding neoplastic cell lines. Xenografts of the respective human tumors were developed in immunosuppressed mice.

Result and discussion

There are significant positive correlations between PC1 and PC2 expression in all tumor types, between PC2 expression and glioma grade, PC1 and PD-L1 expression in lung cancer, PC1 with extraprostatic extension and stage in prostate cancer ($p < 0.05$). Functional assays on respective cancer cell lines showed that PC1 gene (PKD1) silencing or PC1 protein's functional inhibition with a specific antibody decreased the clonogenic and migration potential of cancer cells. The A-549 and PC3 cancer cell lines were used to perform xenografts for lung and prostate cancer, respectively, and then the NSG mice were split into control and treated groups with PC-1 inhibitor. After tumor extraction, a 28.09% reduction in volume was observed in treated lung xenografts and a 1.53-fold reduction in tumor weight ($p = 0.071$). Then, immunohistochemistry was performed for markers for epithelial to mesenchymal transition such as E-cadherin, cytokeratins and vimentin. E-cadherin and cytokeratins present increased expression while vimentin was decreased in treated mice ($p = 0.018$, $p = 0.004$ and $p = 0.011$ respectively). In treated xenografts of the prostate cancer there was a reduction in volume by 18.12% and a decrease in weight by 1.39 times ($p = 0.27$). An increase in E-cadherin and cytokeratins was found in treated mice ($p = 0.008$, $p = 0.005$ respectively)

Conclusion

In conclusion, our data suggest that polycystins are involved in the development of solid tumors and influence disease progression, potentially acting as oncogenes.

The research project was supported by the Hellenic Foundation for Research and Innovation (H.F.R.I.) under the "2nd Call for H.F.R.I. Research Projects to support Faculty Members & Researchers" (Project Number: 3226).

⁴INSERM ERL1321, Biotechnology and Cell Signaling UMR 7242, Strasbourg, France

Introduction

Colorectal cancer (CRC) is the third most common cancer, with tumor progression influenced by interactions between the tumor microenvironment and the extracellular matrix (ECM). Fibrillar collagen, the main ECM component, is more abundant in tumor tissues than in normal tissues and its remodeling plays a crucial role in CRC tumor progression. Cells interact with collagen through integrins and discoidin-domain receptors (DDR), particularly DDR1. A clinical study carried out by our research team on CRC patients revealed high DDR1 expression in tumors tissues, associated with shorter event free survival. As metastases occur in 40-60% of CRC cases, this study aims to investigate the role of DDR1 in metastatic progression.

Material and method

To investigate DDR1's role in CRC progression, HT-29 and HCT-116 colorectal cell lines were selected. DDR1 inhibition was achieved using the pharmacological tyrosine kinase inhibitors, DDR1-IN-1 and Nilotinib, while DDR1 knockdown was performed using shRNA targeting DDR1. Cell migration and invasion were assessed using wound healing assays, Boyden chamber assay and live-cell imaging. Invasion efficiency was analyzed in spheroid collagen type I invasion assay. DDR1 interaction with its new partner was performed using BRET saturation assays and proximity ligation assays (PLA).

Result and discussion

Our findings reveal that DDR1 overexpression in poorly invasive HT-29 cells enhances cell escape and spheroid growth. Conversely, DDR1 pharmacological inhibition by Nilotinib or DDR1-IN-1 and DDR1 downregulation by shRNA in HCT-116 cells significantly reduce migration (wound healing assay) and invasion (Boyden chamber assay). Time-lapse videomicroscopy study confirms that DDR1 inhibition significantly decreases migration in a 3D collagen matrix, while spheroid models

show a decrease in invasive capacity of colorectal cancer cell lines within a type I collagen rich matrix. As metalloproteinases (MMPs) play a key role in ECM degradation and tumor invasion, we demonstrate that DDR1 promotes matrix remodeling through MMP activation. Moreover, DDR1 can also form heterodimers with other receptors leading to cancer progression. Using a BRET saturation assay, we identified a novel DDR1 partner involved in CRC. This result was confirmed by PLA.

Conclusion

These findings highlight DDR1's key role in CRC cell migration and invasion through ECM remodeling. Furthermore, the discovery of a novel DDR1 partner offers promising insights into CRC molecular mechanisms and potential therapeutic strategies for colorectal cancer.

Deciphering lncRNA MTAAT-Mediated PD-L1 Regulation in T-cell Lymphoma: Implications for Immune Checkpoint Therapy

S. Mallia¹, G. Gambarelli¹, M. Zanelli¹, B. Donati¹,

F. Reggiani¹, S. Luminari¹, F. Merli¹, A. Neri¹,

A. Ciarrocchi¹, V. Fragliasso¹

¹AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

Introduction

Immune checkpoint blockade has revolutionized cancer treatment, demonstrating significant efficacy in both solid tumors and hematological malignancies. However, the PD-1/PD-L1 axis exhibits variable activity in T-cell lymphomas, with some subtypes responding favorably while others experiencing hyper-progression. While the role of long noncoding RNAs (lncRNAs) in these mechanisms is emerging, predictive biomarkers for response or hyper-progression remain elusive. This study investigates the functional relationship between ALK-anaplastic large cell lymphoma (ALCL)-associated lncRNA MTAAT and PD-L1.

Material and method

Formalin-fixed paraffin-embedded (FFPE) sections from retrospective cohorts of ALCL were analyzed using diagnostic/relapsed primary lymphoma biopsies, with diagnoses based on WHO classification. In vitro experiments integrated omics (RNA-seq) and functional approaches (CRISPR dCas9-KRAB interference system, immunofluorescences and flow cytometry).

Result and discussion

PD-L1 protein expression was evaluated by immunohistochemistry in 20 primary ALK-ALCL cases. PD-L1 positivity was observed in 60% of cases (12/20) with variable expression (25% of cases with >5% PD-L1+ lymphoma cells and 35% of cases with >20%). PD-L1 exhibited predominant membranous staining in 33% of cases (4/12) and combined membranous and para-nuclear/Golgi-like patterns in 66% of cases (8/12). PD-L1 localization, not overall positivity, correlated with lncRNA MTAAT expression. Low lncRNA MTAAT expression was associated with membrane localization of PD-L1 ($p < 0.05$). No other ALK-ALCL-associated lncRNAs ($n = 5$) showed a significant correlation with

PD-L1 localization, candidating MTAAT as a potential regulator of PD-L1 localization in ALK-ALCL. Given this correlation, we explored the lncRNA MTAAT-dependent PD-L1 regulation in ALK-ALCL cells. Depletion of lncRNA MTAAT using a CRISPR dCas9-KRAB interference system led to a time-dependent increase in surface PD-L1 expression in ALK-ALCL cells (10% at 48h and 20% at 72h in MAC2A cells). No changes in PD-L1 transcript level was observed suggesting an indirect regulatory mechanism. RNA-seq data analysis from lncRNA MTAAT knockdown ALK-ALCL cells identified 12 up-regulated pathways, including endocytosis, lysosome, and membrane trafficking. Among these, ADP-Ribosylation factor 6 (ARF6), a small GTPase involved in membrane protein recycling and PD-L1 regulation, was identified as a potential mediator. Immunofluorescence revealed intracellular co-localization of PD-L1 and ARF6 in ALK-ALCL cells with high lncRNA MTAAT expression, which was lost in cells expressing low levels of lncRNA MTAAT, highlighting ARF6 as a potential PD-L1 regulator.

Conclusion

These findings support a role for lncRNA MTAAT in PD-L1 regulation via ARF6 and suggest MTAAT as a predictive biomarker for response to PD-1/PD-L1 inhibitor therapy.

EACR25-1658

miR-30d inhibition activates the cGAS/STING/IFN-I pathway stimulating an innate immune response via LATS2/YAP axis in breast cancer

S. Chatterjee^{1,2}, S. Torrini³, F. Di Camillo¹, A. Rustighi^{1,3}, L. Triboli¹, V. Cancila⁴, C. Tripodo⁵, G. V. Beznoussenko⁵, F. Mantovani¹, G. Del Sal^{6,3}

⁶*University of Trieste, Trieste, Trieste, Italy*

Introduction

Lying at the heart of the tumor ecosystem, cancer cells actively shape a dynamic tissue microenvironment that impacts tumor growth, stromal invasion and metastatic evolution. In particular an immune-cold TME, lacking infiltration by antitumor immune populations, allows unrestrained tumor growth and limits the efficacy of both chemo- and immune-therapies. We have previously highlighted that stress- and mutant p53-induced over-expression of the onco-miRNA miR-30d in breast cancer (BC) cells promotes the release of a pro-malignant secretome, which reprograms the TME and enhances tumor progression (Capaci V et al. 2020 Nat Commun).

Material and method

To further explore the cellular pathways regulated by miR-30d in BC cells, we first performed a transcriptomic analysis and further validated the findings with different techniques like Real-time PCR (qPCR), Western blot analysis, ELISA, Immunofluorescence on 2D and 3D system both on cancer and normal cells. We further expanded our findings through in-vivo model and on BC patients' samples. All the statistical analysis was conducted using unpaired Student's t-test in GraphPad Prism software.

Result and discussion

Interestingly, transcriptomic analysis highlighted that miR-30d overexpression inhibits innate immune signaling by attenuating the cGAS/STING/IFN-I cascade. Notably, inhibition of miR-30d both triggered upstream induction of cGAS and enhanced STING/TBK/IFN-I downstream steps of the pathway in BC cells, while not in normal breast epithelial cells. Mechanistically, we found that miR-30d controls the expression of proteins that sustain nuclear envelope integrity via LATS2/YAP axis, thus preventing the release of cGAS-inducing cytosolic DNA in cancer cells. Inhibition of miR-30d led to activation of cGAS/STING/IFN-I response and of antitumor immune surveillance in BC preclinical models. Consistently, analysis of publicly available gene expression datasets revealed a significant inverse correlation between higher miR-30d activity and established gene expression signatures reflecting anti-tumor immunity in BC patients' samples, suggesting that elevated miR-30d activity in breast tumors is associated with an immune-cold, poorly infiltrated TME.

Conclusion

Altogether, our result identifies miR-30d as a key driver of immune evasion in BC and suggests that its inhibition may restore an antitumor immune microenvironment, thus contributing to ameliorate the effectiveness of immune therapies.

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is one of the

most lethal cancers, with a dismal 5-year overall survival of 13%. One of the major factors leading to this poor outlook is the presence of a highly fibrotic and immunosuppressive microenvironment, characterized by activation and expansion of fibroblasts and their extracellular matrix (ECM), and immunosuppressive immune cells, representing a challenge that often impedes the success of chemotherapies and immuno-therapies. During PDAC development, cancer-associated fibroblasts (CAFs) produce large amounts of ECM, growth factors, and immunosuppressive cytokines and chemokines, but despite their pivotal pro-tumor roles, the drivers of their activation and pro-tumor functions are still unknown. Paradoxically, elimination of CAFs and their ECM is unfavorable to patients, suggesting that modulation, rather than elimination, of pro-tumor CAFs, is an innovative and attractive approach in developing PDAC therapies. CAFs are highly secretory, which increases the load of misfolded proteins in their endoplasmic reticulum (ER). We postulate that PDAC CAFs are under ER stress, and that ER stress promotes and sustains their pro-tumor functions, catalyzing PDAC tumorigenesis.

Material and method

For *in vitro* functional assays, we used primary fibroblasts from healthy donor pancreata and PDAC tissue. Cells were cultured in a physiologically relevant, 3D culture system, composed by fibroblasts and their secreted ECM. Genes of interest were knocked down using the CRISPRi system. Cytokines were detected in the cell conditioned media by ELISA, and protein levels in cell lysates by western blotting. Naïve CD8 T cells were obtained from healthy donor and their proliferation assessed by flow cytometry. An *in vivo* pancreatic cancer model was developed orthotopically by injecting murine syngeneic pancreatic cancer cells, and treatments with IRE-1 RNase inhibitor were conducted intraperitoneally, five days/week.

Result and discussion

PDAC CAFs upregulated ER stress markers compared to normal fibroblasts, suggesting a role for ER stress in CAF functionality. This was confirmed in human PDAC tissue, using state of the art spatial transcriptomics and single cell RNA sequencing from over 150 PDAC patients. Modulating ER stress in CAFs decreased their secretion of immunosuppressive factors, which in turn allowed CD8+ T cells to proliferate more. Moreover, mice bearing pancreatic tumors treated with an IRE-1 RNase inhibitor (25 mg/kg) had smaller tumors and higher percentage of CD8+ T cells compared to control mice, supporting the notion that ER stress is an important pro-tumor mechanism in PDAC.

Conclusion

Our results suggest that upregulation of ER stress is one of the mechanisms involved in the regulation of tumor supportive functions of fibroblasts in pancreatic cancer, and an important immunosuppressive mechanism in pancreatic cancer.

Introduction

Oral squamous cell carcinoma (OSCC), the most common histological subtype of oral cancer, accounts for approximately 90% of cases and is a major public health concern, particularly in socioeconomically vulnerable regions. Current therapies often result in significant patient mutilation and are limited by high recurrence and metastasis rates, emphasizing the need for improved treatments and a deeper understanding of this disease. OSCC progression is not solely driven by tumor cells; it involves a complex tumor microenvironment where cancer-associated fibroblasts (CAFs) play a crucial role in promoting tumor growth, metastasis, and resistance to therapy. In this context, CAF-derived extracellular vesicles (EVs) are key mediators of tumor-stroma communication, transferring bioactive molecules that influence tumor behavior. This study aims to characterize EVs derived from CAFs in OSCC.

Material and method

Following cell starvation, the EVs were obtained from a CAF-conditioned medium and subjected to centrifugation and filtration to improve their recovery. Protein extraction was performed using the Total Exosome Isolation Kit (Invitrogen), and protein quantification was done using the QubitTM Protein Assay Kit (Thermo Scientific). Nanoparticle tracking analysis (NTA) was conducted to determine the size and concentration of the EVs using the NanoSight NS300 (Malvern Panalytical), and proteomic analysis was performed to determine the protein composition of the CAF-EVs.

Result and discussion

Preliminary results from NTA showed that the CAF-derived EVs had an average size of 92.9 nm, with a predominant size of 68.9 nm and a concentration of 2.83×10^{10} particles/ml. Protein quantification revealed a concentration of 277.5 µg/ml, suitable for further assays.

Proteomic analysis identified enrichment related to structural molecule activity, protein binding, and cell adhesion molecule binding, suggesting a role in remodeling the extracellular matrix and promoting tumor progression. Additionally, immune modulation pathways were observed, indicating a potential for CAF-EVs to suppress anti-tumor immunity.

Conclusion

These findings underscore the relevance of CAF-derived EVs in OSCC, highlighting their role in tumor progression and potential as therapeutic targets. By mediating tumor-stroma communication, CAF-EVs contribute to the complex biology of OSCC, which has implications for novel therapeutic strategies to improve patient outcomes. To further investigate the role of CAF-derived EVs in OSCC progression, our next steps will include the morphological assessment of EVs using transmission electron microscopy, surface marker labeling of EVs with Annexin-V-FITC (BD Biosciences), CD63-PE (Beckman Coulter), CD81-PE (Invitrogen) and CD90-APC (Invitrogen), and the characterization of EVs obtained from three-dimensional CAF spheroids.

EACR25-1717

CPAP promotes immunosuppression in the tumor microenvironment of Hepatocellular Carcinoma

C.-J. Cheng¹, L. Hung¹

¹National Cheng Kung University, Biotechnology and Bioindustry Sciences, Tainan, Taiwan

Introduction

Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related mortality globally, and the five-year survival rate is below 12% due to late-stage diagnosis and the immunosuppressive tumor immune microenvironment (TIME). Tumor-associated macrophages (TAMs), a predominant immune cell population in the TIME, play a vital role in immune suppression by inhibiting T cell-mediated antitumor responses and macrophage phagocytosis. Cancer cells evade TAM-mediated immune surveillance through "don't eat me" signals, notably involving CD47 and CD24, which bind to SIRP α and Siglec-10 on the cell surface of TAMs, suppress phagocytosis and promote immune evasion. Our previous research identified CPAP is overexpressed in HCC, enhanced tumor growth and liver inflammation. Notably, overexpression of CPAP in human HCC cell lines not only elevated CD24 levels but also impaired macrophage-mediated phagocytosis. Despite these findings, the specific role of CPAP within the TIME remains poorly understood.

Material and method

The mouse liver cancer cell Hep55.1c stably expressing mCherry or mCherry-CPAP were established. Liver orthotopic injection by C57BL/6 was performed to investigate the role of CPAP in HCC TIME in vivo. Immune cell populations were analyzed by flow cytometry and qPCR. Bone marrow-derived macrophages (BMDMs) and splenic T cells obtained from wild-type C57BL/6 mice were co-cultured with conditioned medium collected from mCherry-CPAP-overexpressing Hep55.1c cells to evaluate the effects of

tumor intrinsic CPAP on anti-tumor immunity by flow cytometry analysis, qPCR analysis, trans-well assay, phagocytosis assay, and CCK-8 assay.

Result and discussion

Overexpression of CPAP can increase PD-L1 expression in cancer cells. Tumor intrinsic CPAP stimulates macrophage infiltration, promotes M2 macrophage polarization, increases Siglec-10 expression, and inhibits macrophage phagocytosis and T-cell activation in the TIME. Our results found that CPAP-educated TAMs affect the migration and proliferation of cancer cells. These results suggest that CPAP overexpression contributes to immune suppression and tumor progression within the TIME. Additionally, CPAP may influence other immune cell populations within the TIME, further amplifying its immunosuppressive effects. However, the other roles of CPAP in immune modulation remain unclear.

Conclusion

Our findings indicate that CPAP can regulate the CD24-Siglec-10 axis within the TIME, promoting macrophage-mediated immunosuppression in HCC. This study supports the idea that CPAP may be a potential target for HCC therapy.

EACR25-1729

Unveiling the Influence of Tumor-Derived CCL20 on B Cell-Mediated Immune Responses in Nasopharyngeal Carcinoma

Q. Liu^{1,2}, Y. Yang^{1,3}, J. Luo^{1,2}, Z. Qi¹, L. Gong^{1,2}, X. Guan^{1,2}

¹The University of Hong Kong, Department of Clinical Oncology, Pok Fu Lam, Hong Kong, China

²Clinical Cancer Center, The University of Hong Kong-Shenzhen Hospital, Shenzhen, China

³The University of Hong Kong, Department of Clinical Oncology, Pok Fu Lam, China

Introduction

Nasopharyngeal carcinoma (NPC) is characterized by high B cell infiltration and a strong association with Epstein-Barr virus (EBV), which preferentially targets both B cells and epithelial cells. However, the impact of tumor-derived factors on B cell function remains unclear. This study investigates the role of tumor-secreted CCL20 in modulating B cell-mediated immunity and its implications for prognosis.

Material and method

We used multi-center single-cell RNA sequencing data from 12 NPC patients to analyze immune cell dynamics and tumor-immune interactions. Bulk RNA sequencing data from a public dataset ($n = 88$) and an in-house dataset ($n = 82$) were utilized for validation. In vitro experiments included co-cultures of B cells (primary B cells isolated from PBMCs and EBV-immortalized lymphoblastoid B cell lines) with NPC cell lines (C666 and NPC43). RNA sequencing was performed on co-cultured B cells to explore the underlying pathways. Clinical validation was conducted using multiplex immunohistochemistry (mIHC) and spatial transcriptomics on patient samples.

Result and discussion

Our analysis revealed that high infiltration of memory B cells correlated with favorable treatment outcomes, while tumor-derived CCL20 emerged as a prognostic marker for early relapse. We identified increased cell-cell interactions between tumor cells and B cells via the CCL20-CCR6 axis, suggesting a direct role of CCL20 in modulating B cell behavior. Memory B cell abundance was negatively associated with CCL20 expression. In vitro experiments demonstrated that CCL20 significantly reduced the proportion of memory B cells, as evidenced by the downregulation of CD27, a key memory B cell marker. Pathway analysis further revealed that CCL20 impaired B cell activation and BCR signaling, fostering an immune-evasive tumor microenvironment. Co-culture experiments showed that CCL20 suppressed early activation markers (e.g., CD80, MHC-II, CD95) and memory B cell markers (e.g., CD27), while impairing antigen presentation via reduced MHC-I/II expression, which directly impedes T cell activation. Importantly, these effects were reversible upon treatment with an anti-CCL20 neutralizing antibody, highlighting the potential therapeutic value of targeting this axis. Spatial transcriptomics confirmed negative associations between CCL20 expression and B cell markers (CD20, CD27). Multiplex IHC performed on patient samples validated that patients experiencing early relapse exhibited high CCL20 levels and low expression of CD27 and MHC-I on CD20+ B cells, reinforcing the clinical relevance of these findings.

Conclusion

Tumor-derived CCL20 undermines B cell function, promoting immune evasion and treatment failure in NPC. Targeting the CCL20-CCR6 axis may restore anti-tumor immunity, offering a novel therapeutic strategy. Our findings highlight CCL20 as a biomarker for risk stratification and a potential therapeutic target in NPC.

EACR25-1737

Patient-Derived Tumor Tissue Cultures (PDTTCs) to assess immunotherapy responses in Glioblastoma

L. Carrillo-Bosch¹, A. Neva-Alejo¹, M. López Vázquez¹, L. Cuesta-Casanovas¹, R. Iurlaro¹, I. Cuartas¹, J. Seoane¹

¹Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Introduction

Glioblastoma (GBM) is the most common and aggressive primary brain tumor. While immunotherapy has shown promise in treating various cancers, it has not significantly improved outcomes for GBM patients. The unique tumor microenvironment (TME) of GBM, coupled with the lack of models that fully recapitulate its complexities, has limited the development of effective immunotherapeutic strategies. For instance, GBM tumors present elevated levels of Leukemia Inhibitory Factor (LIF), a member of the IL-6 cytokine family, which has been shown to modulate tumor-associated macrophages (TAMs) toward an immunosuppressive phenotype.

Material and method

To address these challenges, we developed Patient-Derived Tumor Tissue Cultures (PDTTCs) as a model to evaluate immunotherapy responses in human GBM. PDTTCs consist of tumor tissue slices (350 µm) cultured

in a semi-wet system that allows for the introduction of treatments. Using this platform, we investigated the impact of anti-LIF therapy on the TAM population within GBM tumors.

Result and discussion

After confirming that PDTTCs preserve tumor architecture and TME composition, we utilized this system to analyze transcriptomic responses to immunotherapy. Single-cell RNA sequencing (scRNA-seq) was performed on nine GBM tumors exposed to anti-LIF therapy, with a focus on the myeloid population. This approach revealed target genes regulated by LIF in TAMs that may contribute to the failure of other immunotherapies. These targets were further validated in mouse models, both *in vitro* and *in vivo*.

Conclusion

PDTTCs offer a robust preclinical model that can be used to gain deeper insights into human tumor responses to immunotherapy. By maintaining the native tumor spatial architecture and preserving TME populations, PDTTCs provide a more accurate platform for studying the effectiveness of immunotherapies in GBM.

EACR25-1784

Repurposing Tricyclic Antidepressants for Glioblastoma Treatment

E. Lamprou¹, A. Chryplewicz¹, D. Hanahan¹

¹École Polytechnique Fédérale de Lausanne (EPFL), School of Life Sciences, Agora Translational Cancer Research Center, Lausanne, Switzerland

Introduction

Glioblastoma (GBM) remains a daunting challenge in oncology due to its resistance to existing standard-of-care therapies and inevitable progression to a lethal outcome. Our lab has previously proposed a successful novel combinatorial regimen, including the tricyclic antidepressant (TCA) imipramine, the vascular endothelial growth factor (VEGF) inhibitor bevacizumab, and the immune checkpoint inhibitor anti-PD-L1, which demonstrated significant therapeutic benefit in GBM mouse models (Chryplewicz et al.; *Cancer Cell*, 2022). This triple combination was effective by inducing immunostimulatory autophagy in cancer cells, reprogramming tumor-associated macrophages, and remodeling the tumor vasculature, all contributing to the recruitment and activation of T cells. These promising results have incentivized a proof-of-concept clinical trial, where GBM patients who fail the standard-of-care treatment will receive this triple combination as a second-line therapy. Motivated by these results and encouraged by the clinical support, we aim to further improve this therapeutic regimen by disrupting various capabilities of tumors required for their growth and therapeutic resistance.

Material and method

To optimize this regimen for clinical translation, we screened multiple TCAs - trimipramine, clomipramine, and amitriptyline - alongside imipramine in mouse and human GBM cell lines to evaluate their impact on cell viability. In parallel, we conducted *ex vivo* experiments using bone marrow-derived macrophages polarized toward an M2-like phenotype to assess the reprogramming potential of TCA treatment.

Result and discussion

Among the tested TCAs, trimipramine exhibited the strongest induction of GBM cell death across multiple viability assays. Additionally, all TCAs significantly downregulated M2-like macrophage markers, suggesting their potential to reverse the immunosuppressive tumor microenvironment. These initial findings indicate that TCAs possess anticancer and immunomodulatory properties, prompting further evaluation in preclinical models. Moreover, we are investigating mechanisms of adaptive resistance and relapse following the proposed triplet immunotherapy, with the goal of identifying pharmacological strategies to extend the survival benefit in GBM mouse models.

Conclusion

This study aims to delve deeper into TCA mechanisms of action, assess potential synergies with VEGF pathway inhibitors and immune checkpoint blockade, and ultimately provide critical insights to optimize the proposed triple combination regimen. By leveraging drug repurposing and simultaneously targeting multiple tumor hallmarks, this approach holds significant promise for improving GBM therapeutic outcomes.

EACR25-1787

CircFIRRE and circPROX1 are highly expressed in primary and metastatic colon cancer cells

T. Phanaksri¹, N. Plongthongkum², M. Kaewmanee¹, M. Paenthong¹, P. Tiraratchailert¹

¹*Thammasat University, Chulabhorn International College of Medicine, Pathum Thani, Thailand*

²*King Mongkut's University of Technology Thonburi, Biological Engineering Program, Faculty of Engineering, Bangkok, Thailand*

Introduction

Circular RNAs (circRNAs) are the class of noncoding RNA associated with physiological and pathological conditions. The circRNAs have been upregulated in diverse types of cancer that are involved in tumorigenesis, proliferation, invasion and metastasis. This study aimed to compare the expression of circRNAs between normal colon epithelial cells (CCD841 CoN), primary colon cancer cells (SW480), and metastatic malignant cells (SW620), while also validating the expression of selected circRNAs across these colon cancer cell lines.

Material and method

RNA sequencing was performed on normal colon epithelial cells (CCD841 CoN), and primary (SW480) and metastatic (SW620) colon cancer cell lines.

Differential expression, gene ontology (GO) and KEGG pathway enrichment analysis were conducted on the RNA-seq data. Selected upregulated circRNAs were also validated by RT-qPCR.

Result and discussion

Differentially expressed circRNA analysis identified 906 and 935 upregulated circRNAs in SW480 and SW620, respectively, compared to CCD 841 CoN. Additionally, 184 circRNAs were upregulated in SW620 compared to SW480 cells. KEGG pathway analysis of differentially expressed circRNA-associated genes between SW480, SW620, and CCD841 CoN highlighted pathways

involved in cancer development and progression. The analysis revealed significant enrichment in pathways related to cellular processes, human diseases, and genetic information processing, with distinct alterations observed in the metastatic SW620 and primary SW480 cells compared to normal colon epithelial cells (CCD841CoN). The circRNAs derived from FIRRE and PROX1 genes showed high-ranking expression in both SW480 and SW620 cell lines. The candidate circFIRRE (hsa_circ_0001944) was dramatically increased by 2789.55 ± 551.44 and 7593.61 ± 818.72 folds in SW480 and SW620, respectively, compared to the normal colon epithelial cells. Additionally, circPROX1 (hsa_circ_0111952) was also highly upregulated by 1810.88 ± 477.11 and 2851.46 ± 498.75 folds in SW480 and SW620, respectively.

Conclusion

This study identifies some predominant levels of circRNAs in primary and metastatic colon cancer cells. The finding reveals high expression of circFIRRE and circPROX1, with even greater levels in the metastatic cancer cell line. The overexpression characteristics of these circRNAs may serve as potential tumor biomarkers for diagnostic, prognostic, or therapeutic applications. However, additional studies are essential to enhance understanding of biological mechanisms and roles in colon cancer progression.

Metastatic peritoneal fibroblasts mobilize and respond to TGF- β 1 from the extracellular matrix of colorectal cancer

C. Ramos¹, E. D'Angelo², G. Spolverato², M. Agostini², R. Oehler¹

¹*Medical University of Vienna, Department of General Surgery, Vienna, Austria*

²*University of Padova, Department of Surgery, Oncology, and Gastroenterology, Padova, Italy*

Introduction

Colorectal cancer (CRC) peritoneal metastases (PM) are characterized by a high stromal infiltration and activation of the transforming growth factor-beta (TGF β). This multifunctional cytokine mediates crucial interactions between cancer cells, stromal cells and the extracellular matrix (ECM), driving tumour growth and metastatic dissemination. Fibroblasts play a pivotal role in ECM remodelling and promoting cancer cell invasion and metastasis, with TGF- β signalling being a key pathway. TGF- β is secreted by various cell types, including fibroblasts, and is stored in the ECM in an inactive latent form. Among others, proteases activity can release the active TGF- β , enabling downstream activation of the TGF- β receptors (TGFBRs). However, the interplay between patient-derived dECM and fibroblast remains under investigated due to the lack of accurate in vitro models. This study describes the ability of fibroblast from primary CRC (CAFs) and CRC peritoneal metastasis (MAFs) to mobilize TGF β from a patient-derived dECM and characterizes their molecular responses to TGF β .

Material and method

Decellularized CRC- and healthy colon derived ECM (CRC-dECM and HC-dECM) samples were prepared from human biopsies (detergent-enzymatic treatment). Cancer-associated fibroblasts were isolated from primary cancer and from peritoneal metastases, and cultured in the presence of dECM. Secreted proteins were analysed by mass spectrometry (MS) and with a direct antigen-labelling protein array. Gene expression was evaluated by RT-qPCR. The cellular distribution and abundance of TGF β and TIMP1 were investigated using single cell RNA sequencing (scRNA seq) and multiplex IHC in matched CRC and PM patients.

Result and discussion

Exposing peritoneal fibroblasts (MAFs) to CRC-dECM resulted in a substantial increase in free TGF β , growth factors, matrix metalloproteinases (MMPs) and its inhibitors (TIMPs). In vitro exposure of MAFs to exogenous TGF β increased the gene expression of TIMP1, SPARC and SERPINE1, in a dose-dependent manner, which was abolished by TGFBR-I/II blockage. TGFB1 silencing did not affect the CRC-dECM response, indicating TGF β mobilization rather than de novo synthesis and secretion by MAFs. Interestingly, CAFs showed no such activity. Furthermore, PM-dECM contained higher levels of trapped TGF β compared to both CRC- and HC-dECM. To validate our results, we combined scRNA seq and multiplex IHC analysis to demonstrate that MAFs were the stromal cells with increased TIMP1 expression, exhibiting a peritumoral localization in PM.

Conclusion

These results show that peritoneal fibroblasts can mobilize TGF β from the ECM which in turn induces the release of the known pro-tumorigenic modulators TIMP-1/SPARC. Therefore, metastatic-specific peritoneal fibroblasts might be a promising therapeutic target to inhibit this effect in patients with PM.

Bioengineering Unitary Lung Tumor-Stroma Organoids in a Biomimetic Human Extracellular Matrix

M. Pereira¹, B. Cardoso¹, L. Ferreira², M. Monteiro¹, J. Mano¹, V. Gaspar¹

¹*University of Aveiro, Department of Chemistry, CICECO, Aveiro, Portugal*

²*Cellularis Biomodels, Aveiro, Portugal*

Introduction

Lung cancer (LC) remains the leading cause of cancer-related deaths worldwide, highlighting the urgent need for novel therapeutic strategies. However, progress in drug development is hindered by the lack of in vitro models that accurately replicate the complexity of the tumor microenvironment. Three-dimensional patient-derived tumor organoids (3D-PDTOs) have emerged as promising tools due to their ability to mimic patient-specific tumor characteristics. Despite their advantages, conventional 3D-PDTOs often lack stromal components and rely on animal-derived hydrogels, which fail to replicate the biomechanical properties of the human tumor extracellular matrix (ECM). Moreover, conventional culture organoid models tend to generate multiple heterogeneous organoids, limiting

reproducibility and standardization for drug testing. We propose the bioengineering of unitary, stromal-enriched lung tumor organoids embedded in a mechanically tunable human collagen type I matrix. This physiomimetic platform aims to enhance biomimicry and improve preclinical assessment of anti-cancer nanomedicines.

Material and method

The HuLu051421 LC cell line was cultured in suspension to generate tumor organoids, which were subsequently processed to obtain unitary organoids with defined size. To enhance biomimicry, these organoids were co-cultured with stromal cells and embedded in a human collagen type I hydrogel with adjustable stiffness. The generated unitary tumor-stroma organoids were characterized using immunohistochemistry, gene expression profiling, and live-cell imaging to assess cellular composition, ECM deposition, and tumor architecture. To evaluate the model's suitability for drug screening, liposomal nanomedicine formulations were administered, and therapeutic efficacy was assessed using viability assays.

Result and discussion

The engineered unitary tumor-stroma organoids successfully integrated stromal components, ensuring reproducibility for drug screening. The use of a human-derived collagen matrix allowed for precise modulation of ECM mechanical properties, influencing cellular behavior and drug response. Compared to conventional culture strategies, unitary organoids displayed enhanced structural organization, better recapitulation of the native tumor microenvironment, and a more predictable response to treatment. Liposomal chemotherapy formulations exhibited differential efficacy within the engineered organoids, underscoring the importance of ECM stiffness and stromal interactions in therapeutic response.

Conclusion

This study introduces a bioengineered platform for generating unitary tumor-stroma lung organoids in a tunable human collagen type I matrix. By overcoming limitations of existing models, it enhances biomimicry and reproducibility, offering a more physiologically relevant system for preclinical drug testing.

Tumor Heterogeneity and Immune Modulation in Oesophageal Squamous Cell Carcinoma Characterised by Single-Cell RNA Sequencing Analysis

C. Wong¹, J. Ko¹, H. Ng¹, V. Yu¹, S. Law², M. Lung¹

¹*School of Clinical Medicine, The University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong, China*

²*School of Clinical Medicine, The University of Hong Kong, Surgery, Hong Kong, Hong Kong, China*

Introduction

Oesophageal squamous cell carcinoma (ESCC), the aggressive subtype of esophageal cancer, has a significant cancer-related mortality rate and incident rate in Asia. The current treatment strategy remains challenging as the prognosis of ESCC patients is dismal.

Moreover, immunotherapy treatments showed selective responses in ESCC patients. This could be caused by the complicated immune cell states within the tumor microenvironment, which differs in ESCC patients due to heterogeneity. Therefore, the communication between tumors with tumor-associated stromal and tumor-infiltrating immune components remains unresolved in the complex immune-suppressive ESCC microenvironment. We aim to decipher the ESCC ecosystem to characterize the evolution of the epithelial cells and identify prognostic immune subtypes that could aid the treatment decision.

Material and method

A total of 55 ESCC patients were included in this study. Single-cell RNA sequencing was utilized to explore the cell subtypes from blood samples, tumor tissues, and adjacent normal tissues. All samples were aggregated in cellranger and integrated by harmony. The R program Seurat was used to perform clustering and marker gene identification. The changes in the inferred copy number were visualized with inferCNV, and gene set analysis was conducted with AUCell. Additionally, monocle was used for trajectory analysis to determine the evolution of ESCC immune subgroups, and cellphoneDB was used to analyze the communication between subtypes.

Result and discussion

Six major cell types were identified: T-cells, B-cells, epithelial cells, fibroblasts, endothelial cells, and myeloid cells. For better classification, we reclustered each of the major cell types. The epithelial cells with copy number changes, visualized by inferCNV, were separated from normal epithelial cells. Gene set analysis was performed to characterize the function of different epithelial cell subgroups, such as inflammatory-related, cell cycle-related, RNA-high, and migratory phenotypes. A fibroblast cluster with matrix metalloproteinase marker 11 (MMP) and high expression of the epithelial-mesenchymal transition gene set was found to correlate to progression-free survival. Immune cells that infiltrated tumors were identified by comparing the proportions in tumor tissues and adjacent normal tissues or blood. The TREM2-high macrophages upregulated MMPs and VEGFA, which could assist the migration process. Additionally, the immunosuppressive T-cell subtype expressing PD-1 was identified using cell markers. The trajectory analysis and receptor-ligand interaction are underway to unravel the biological progression of various cell types and how they communicate within the ESCC microenvironment.

Conclusion

Our study broadened our knowledge of ESCC tumorigenesis and ecosystem by revealing the connection between epithelial, stromal, and immune cell subtypes.

Raf Kinase Inhibitor Protein (RKIP) plays a role more than scaffolding protein by modulating cytokines in colorectal Cancer cell lines

M. Rayhan¹, E. Lee², H. Cho², H. Jo², E. Koh², M. Al Mazid¹, M. Kim², B. Choi², H. You²

¹National Cancer Center-Graduate School of Cancer Science and Policy (NCC-GCSP), Cancer Biomedical Science, 323 Ilsan-ro, Ilsandong-gu, Goyang-si Gyeonggi-do, Korea (Republic of)

²National Cancer Center, Cancer Microenvironment Branch, Division of Cancer Biology, 323 Ilsan-ro, Ilsandong-gu, Goyang-si Gyeonggi-do, Korea (Republic of)

Introduction

As a scaffolding protein, raf kinase inhibitor protein (RKIP/PEBP1) binds lots of proteins important for cellular signaling pathways, which are associated with various cellular processes including proliferation, differentiation and cellular motility. Mostly, the expression of RKIP might be important for regulating signaling pathways through its binding capacity, however, some cancers express RKIP proteins more than enough, implying its function in cancers.

Material and method

To investigate RKIP's role in colorectal cancer, we have established two RKIP knockout (KO) cell lines by CRISPR-Cas9 system using HCT116 a human colon cancer cell line, and validated RKIP KO effect on variety of cellular processes including cell proliferation, motility, and aggregation in suspension culture system.

Additionally, to evaluate cytokine expression, we performed a Cytometric Bead Array (CBA) assay using culture supernatants from parental, MOCK, and RKIP KO HCT116 cells.

Result and discussion

As expected, two RKIP KO cell lines, HCT116 RKIP KO#3 and KO#4 showed reduced cell proliferation up to 20 % (significant but not drastic) and aggregation growth in suspension culture, and increased motility compared to HCT116 parental and MOCK cell lines. Transcriptomic profiling showed enriched gene sets associated with cell cycles, motility, and inflammation. Interestingly, cytokines were ranked highly, which led us to consider the possible role of RKIP on cytokine expression through another binding partners beyond nuclear factor-kappa B-NF- κ B pathway through NIK. Thus, we considered TBK1 as a candidate for modulating cytokines and tumor microenvironment. Flow cytometry-based bead array showed measurable interleukin-8 (IL-8) than the others in HCT116 cells, which was much increased by RKIP KO and reversed by recovering RKIP expression significantly. Thus, we further investigated the relationship between RKIP and TBK1 on IL-8 expression and macrophage polarization.

Conclusion

To further delineate RKIP's role in the tumor microenvironment, we are conducting in vivo studies to explore the therapeutic potential of RKIP as a novel target for metastasis intervention in colorectal cancer.

Multiomic profiling of colon cancer sidedness reveals TGF β -driven EMT and Mast cell dynamics as key prognostic factors

B. García-Mico^{1,2}, F. Gimeno-Valiente³, B. Martínez-

Castedo^{1,2}, J. Martín-Arana^{1,2}, D. G. Cambor¹, B. Palomar⁴, M. Cabeza-Segura¹, C. Martínez-Ciaparglini⁴, A. Cervantes^{1,2}, N. Tarazona^{1,2}

¹INCLIVA Biomedical Research Institute, Medical Oncology, Valencia, Spain

²CIBERONC, Instituto de Salud Carlos III, Madrid, Spain

³Cancer Evolution and Genome Instability Laboratory, UCL Cancer Institute, London, United Kingdom

⁴INCLIVA Biomedical Research Institute, Pathology, Valencia, Spain

Introduction

Emerging evidence suggests that tumor sidedness is a key prognostic factor in colorectal cancer (CRC). Left- and right-sided tumors differ in embryonic origin, molecular profile and clinical outcome, with left-sided colon tumors (LT) generally having a better prognosis and right-sided tumors (RT) exhibiting more mutations, often linked to greater aggressiveness. Our aim is to perform a multi-omic analysis of LT and RT in order to optimize personalized therapies.

Material and method

A multiomic profiling was conducted on 61 FFPE tissue samples from CRC patients at the Hospital Clínico Universitario of Valencia, Spain. Samples included 32 RT and 29 LT. Genomic and transcriptomic analyses were performed using whole exome sequencing (WES) and RNAseq. Deconvolution analysis was carried out by CIBERSORT and functional enrichment via GSEA utilized a significance threshold of FDR < 0.05.

Result and discussion

Patients with locally advanced RT exhibited a worse disease-free survival (DFS) than those with LT. However, no statistically significant differences were observed in the early stages. Focusing on stage III tumors, 48% of mutated genes were identified exclusively in RT, of which SOX9, MSH3 and NSD1 were related with a lower DFS; while 22% were identified in LT and none of them were associated with a poorer outcome. Moreover, GSEA in stage III RT showed a mutational enrichment in apoptosis, TGFβ signaling and Wnt β-Catenin pathway that was not found in LT. Selecting the genes from the TGFβ signature, an overexpression of TGFB2 and SKIL was observed in stage III RT compared to LT, highlighting the importance of distinctive TGFβ signaling among RT and LT. As TGFβ signaling promotes epithelial-to-mesenchymal transition (EMT) and immune evasion, differential expression of the EMT pathway and tumor immune infiltration between LT and RT were evaluated. 3 genes of the EMT pathway (ID2, SLIT3 and ANPEP) were found upregulated in stage III RT compared to LT. Besides, when focusing on RT an overexpression in 5 EMT genes was observed in stage III in comparison to stage II, suggesting that the poorer prognosis of RT may be due to the TGFβ-driven EMT. Additionally, stage II RT showed more activated mast cells (MC) and increased inflammatory and TNF-α pathway activity compared to stage II LT and stage III RT, suggesting a pro-inflammatory role for MC in stage II RT. Moreover, when dividing primary tumors into TGFβ-high/TGFβ-low by the median expression of TGFβ pathway, most of TGFβ-high were RT and exhibited a significant lower MC infiltration. This suggest a protective role of MC in

early stages, which is lost as the disease progresses in TGFβ-high RT.

Conclusion

Comprehensive multiomic characterization of LT and RT revealed that the poorer prognosis of patients with locally advanced right colon cancer may be due to the TGFβ-driven EMT and the loss of pro-inflammatory MC, enabling the discovery of new therapeutic targets.

²Liberà Università Vita-Salute San Raffaele, Milan, Italy

³Università di Milano, Milan, Italy

⁴Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Introduction

Colorectal cancer (CRC) is the leading cause of cancer-related deaths. The staging of CRC impacts on patient survival, with prognosis closely tied to diagnosis timing. When metastasis is present, treatments are less effective with mostly poor prognosis. In the transition from non-metastatic to metastatic cancer cells, Reactive Oxygen Species (ROS) play a significant role and are involved in multiple processes. Ion channels' activity is closely linked to ROS balance promoting metastasis. Finding a specific target able to tackle oxidative stress or using antioxidants as N-acetylcysteine and glutathione (GSH) could be the key for CRCs therapies, but it was recently seen that metastatic cancer cells rely on GSH to manage oxidative stress and exogenous antioxidants supports cancer cell metastasis. Moreover, many ion channels involved are fundamental in normal physiology. The transmembrane form of Chloride Intracellular Channel 1 (tmCLIC1) protein supports tumoral ROS over-production. In these cells, CLIC1 undergoes a conformational change that release releases GSH into the cytoplasm. Once in the membrane, tmCLIC1 facilitates ROS overproduction, fostering an aggressive cancer phenotype. The peculiar expression of tmCLIC1 in metastatic CRC cells, and its role in ROS balance, make it a promising target.

Material and method

We evaluated CLIC1 level of expression, its activity as a chloride channel, and its involvement in cancer physiology in several human CRC cells chosen at different cancer stages through western blots, patch clamp experiments, 2D and 3D growth curves, migration and invasion assays. Moreover, invitro data were confirmed in vivo on zebrafish and murine models. In addition, we forced non-metastatic CRCs cells to increase tmCLIC1 activity through the addition of N-acetyl-cisteine, and we followed cells behaviour in vitro and in vivo.

Result and discussion

Our findings show that tmCLIC1 protein correlates with cell aggressiveness and that the inhibition of tmCLIC1

activity results in a downregulation of cellular proliferation, migration, and invasion in vitro and in vivo. Moreover, forcing non-metastatic CRC cells to release GSH using the antioxidant N-Acetyl Cysteine (NAC) enriched cytoplasmic GSH and increased tmCLIC1 expression. This effect, however, was absent in cells where CLIC1 was silenced, proving that GSH release depends on tmCLIC1 activity. These cells were converted from non-aggressive cell lines to metastatic ones in vitro and in vivo.

Conclusion

In the present work, we demonstrate that the translocation of CLIC1 in the plasma membrane has a key role in tumor aggressiveness enhancing the transition from non-metastatic to metastatic cells. These findings challenge the traditional view of antioxidants in cancer treatment, suggesting that tmCLIC1 inhibition could serve as a novel therapeutic strategy against metastatic colorectal cancer, addressing a pressing societal health concern.

³Università degli Studi di Brescia, Molecular and Translational Medicine, Brescia, Italy

⁴Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Experimental Oncology, Bergamo, Italy

Introduction

Bone is a common site of metastases. Breast cancer commonly develops osteolytic bone metastases, in which excessive bone degradation is due to upregulation of the bone-resorbing osteoclasts. Thrombospondin-1 (TSP-1) is a matricellular protein with a complex modular structure, able to interact with multiple ligands thus playing pleiotropic roles in the microenvironment of primary tumors and metastasis. This study aimed at investigating the role of TSP-1 in bone remodeling associated with breast cancer osteolytic bone metastasis.

Material and method

To assess the effect on osteoclastogenesis, the activity of TSP-1 and its recombinant domains on RANKL-induced differentiation of murine bone marrow precursors and monocyte-like RAW 264.7 cells was tested. Binding of TSP-1 to the RANKL-receptor RANK and to osteoprotegerin (OPG) – key factors in osteoclastogenesis – was analyzed by solid phase assays and Surface Plasmon Resonance. To evaluate the activity on bone metastasis, bone tropic breast cancer 4T1.2 cells, transfected to express and secrete the active TSP-1 fragment, were injected in the caudal artery of mice, and the formation of metastasis-associated osteolytic lesions was monitored by microCT.

Result and discussion

We have identified a C-terminal fragment of TSP-1 active in inhibiting RANKL-induced osteoclast differentiation. Cleavage of TSP-1 by proteases produced by mature osteoclasts released a similar fragment, indicating a possible role as a feedback control mechanism. The fragment bound RANK, the RANKL receptor on osteoclast precursors, and impaired early (the MAPKs p38 and JNK) and late (NFATc1) downstream signaling. The fragment also bound osteoprotegerin (OPG), the decoy receptor of RANKL, in this case further potentiating its inhibitory activity on osteoclastogenesis. In an in vivo model of osteolytic bone metastasis, the expression of the TSP-1 fragment by murine breast cancer cells reduced osteolytic lesions and prolonged mice survival, indicating that the C-terminal TSP-1 fragment is active also in vivo and can protect the bone against metastasis-associated osteolysis.

Conclusion

The release of an active TSP-1 fragment in the bone environment can represent a mechanism to control remodeling and protect the bone against degradation associated with breast cancer osteolytic metastasis.

Introduction

Over the past decade, multiple groups have classified colorectal carcinoma (CRC) subtypes based on molecular profiles to explain CRC heterogeneity. Increasing evidence suggests microbial dysbiosis plays a crucial role in CRC development and progression. Our study aimed to identify integrated tumor microenvironmental groups (iTMEg) through multi-omics subtyping based on preselected cancer-related features.

Material and method

Harnessing a unique multi-omics CRC dataset comprising of 6 distinct modalities, we analyzed 138 patients with stage 0–IV CRC (without prior neoadjuvant treatment) using unsupervised consensus clustering of three of the modalities: microbial composition of tumor mucosa, tumor genes expression, and tumor mutational landscape. For further refinement, we studied immune cell fractions inferred from bulk tumor transcriptomics

via xCell, spatial distributions of morphological regions within tumor tissue, and stool-derived microbial and miRNA profiles.

Result and discussion

Through comprehensive multi-omics analysis, we identified 6 distinct iTMEgs, reflecting unique immune, stromal, and microbial compositions. iTMEg 1 (Immune Activated) exhibits an immune-active yet immuno-suppressive microenvironment enriched with oral pathogens such as *Fusobacterium nucleatum*, *Parvimonas micra*; MSI-H status, and BRAF mutations. iTMEg 2 (Immune Desert) represents a CIN-driven, immune-depleted group with low microbial diversity, stromal sparseness, and canonical APC and TP53 mutations. Stromal-enriched tumors divided into two groups: iTMEg 3 (Immune Excluded), showing a desmoplastic phenotype with EMT activity, noncanonical WNT signaling, and NRAS mutations; and iTMEg 6 (Highly Immuno-genic), characterized by active KRAS signaling, *Bacteroides* enrichment, and an immune-activated stromal microenvironment. Mucinous tumors stratified into three groups: iTMEg 1 and iTMEg 4 (Regulated Immunity), both MSI-H, but differing in immune and microbial profiles; and iTMEg 6. iTMEg 5 (Immune Suppressed), in contrast, displays a structured, immune-low profile with complex tubular morphology and PIK3CA mutations. Partial associations of iTMEgs were observed with CMS and iCMS.

Conclusion

Our approach offers a novel, more comprehensive perspective on the tumour microenvironment beyond existing molecular classifications. These groups suggest potential of more targeted therapeutic strategies, including immune checkpoint inhibitors for immune-active groups, stromal modulation for desmoplastic groups, and targeted therapies for CIN-driven tumors.

EACR25-1856

Mouse intraductal model of ER+ breast cancer to study the role of HSF1 in its development

N. Vydra¹, R. Smolarczyk¹, M. Bar¹, K. Mrowiec¹, A. Toma-Jonik¹, P. Janus¹, W. Widlak¹

¹*Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice Branch, Gliwice, Poland*

Introduction

Breast cancer is the most common tumor diagnosed in women. The majority of cases are estrogen receptor α positive (ER+). The lack of relevant *in vivo* models hampers the study of the pathogenesis of ER+ breast cancer cells and the finding of the possible way for drug treatment. The recently developed mouse intraductal (MIND) model, based on the breast cancer cell injection directly into the mouse milk duct system, provides an intraductal microenvironment adequate for ER+ breast cancer cell growth and enables the recapitulation of human disease. We use the MIND model to study the role of HSF1 inhibition in ER+ breast cancer growth. HSF1 plays a key role in the cell response to stress and also supports many aspects of cell metabolism enabling tumor growth. We found that HSF1 is activated by 17 β -estradiol (E2) in ER+ breast cancer cells and gains transcriptional competence to regulate the expression of

several genes associated with E2 signaling. HSF1 deficiency reduces the growth of ER+ cells *in vitro* and may be a potential target for breast cancer treatment.

Material and method

The human breast adenocarcinoma MCF7-Luc2 cells expressing luciferase were knockouted for HSF1 using the CRISPR/Cas9 editing system. The growth of MCF7-Luc2 cells HSF1-deficient or HSF1-proficient was analyzed *in vitro*. Tumor cells were injected into the ductal system of NSG (NOD scid gamma) mice. The tumor growth was monitored through bioluminescence imaging (IVIS system).

Result and discussion

The complete lack of HSF1 led to a substantial loss of heat-inducibility of HSP genes (molecular target of HSF1) and a reduction of the proliferation rate of MCF7-Luc2 cells *in vitro*. After injection of MCF7-Luc2 cells with different HSF1 status into the abdominal mammary gland of adult female NSG mice, they grew without hormonal supplementation for 6 months. *In vivo* monitoring of engrafting mice by luminescence revealed that all cell lines grew exponentially, but the growth of HSF1-deficient MCF7-Luc2 cells was slowed down compared to HSF1-proficient cells.

Conclusion

The MIND model offers the opportunity to study the progression of ER+ breast cancer and the role of HSF1 in its development. It can be used to test new combination therapies targeting HSF1 and estrogen receptors.

The work was supported by the National Science Center, grant no. 2021/43/B/NZ5/01850.

Extracellular Matrix-Based 3D Head and Neck Cancer Model: A Biofabricated Platform for Testing Melatonin Therapy

L. de Lara Peña¹, J. López de Andrés¹, C. Rodríguez Santana², G. Jiménez¹, G. Escamez³, J. Marchal¹

¹*University of Granada, Department of Human Anatomy and Embryology, Granada, Spain*

²*Aarhus University, Department of Biomedicine, Aarhus, Denmark*

³*University of Granada, Department of Physiology, Granada, Spain*

Introduction

Head and neck squamous cell carcinoma (HNSCC) is an aggressive disease with high recurrence rates, partly attributed to the presence of cancer stem cells (CSCs) within the tumor. Melatonin has demonstrated antitumor properties, although its effects on CSCs remain unclear. This highlights the need for models that reproduce tumor heterogeneity to better understand the effects of this molecule. The aim of this study was to develop a tumor model based on decellularized extracellular matrix (dECM) derived from fibroblasts, replicating the tumor microenvironment (TME) of HNSCC, to analyze the antitumor effects of melatonin in a context closer to the native scenario.

Material and method

CSCs were isolated from the Cal-27 cell line using specific culture conditions to form tumor spheres. Stromal cells were obtained with informed consent from healthy skin through enzymatic digestion. For dECM-

based bioinks, human fibroblasts were cultured and induced to produce ECM. This matrix was characterized and combined with alginate and gelatin to generate a hydrogel that mimicked native tumors and allowed the culture of HNSCC CSCs and TME cells.

Result and discussion

The fibroblast-dECM retained the expression of molecules and growth factors similar to those found in native tumors. The model confirmed that melatonin exerts an antiproliferative effect on HNSCC CSCs, reducing markers of tumor invasion and migration, even in a chemoprotective microenvironment. Additionally, it did not show toxicity toward the healthy cells co-cultured in the model.

Conclusion

This 3D model represents an advanced tool for studying HNSCC, integrating CSCs, stromal components, and a biomimetic matrix, allowing for more representative investigations of tumor reality and facilitating advances in precision oncology.

Cellular and molecular features of the aberrant vascularization and mechanisms of TKI resistance in metastatic clear cell renal cell carcinoma

C. Compère¹, V. Rousseau¹, M. Coutelier², C. Raoux², A. Bougoüin¹, L. Roumenina¹, Y. Vano¹, I. Cremer¹, C. Monnot¹

¹*Centre de Recherche des Cordeliers, UMRS1138, Inserm, Paris, France*

²*Institut du Cerveau - Paris Brain Institute - ICM, Paris, France*

Introduction

Clear cell renal cell carcinoma (ccRCC) is one of the most aggressive cancers worldwide, primarily due to its high haematogenous metastatic dissemination. This aggressive behaviour stems from mutations in the Von Hippel-Lindau (VHL) gene, present in approximately 70% of cases, resulting to a pseudo-hypoxic context promoting tumor invasion, angiogenesis and extracellular matrix (ECM) remodelling. Accordingly, ccRCC vasculature displays a higher degree of complexity than the vascular network reported in other solid tumors. In primary tumors and metastases, we recently characterized two types of aberrant endothelial structures exhibiting specific features of dimensions and shapes, distinct from tumor capillaries. Since more than 60% of the metastatic ccRCC patients display poor or no response to anti-angiogenic treatments using tyrosine kinase inhibitors (TKI), we suggest that the vascular architecture complexity may influence the ccRCC clinical outcome. The goal of this study is therefore to deeply characterize the involvement of ccRCC vasculature in tumor development, dissemination and response to treatments.

Material and method

This study was conducted on both cohort of metastatic ccRCC patients and an in vitro 3D model of vascularized micrometastases (VMT). Spatial transcriptomic analyses (Visium & Xenium, 10X Genomics) were performed on ccRCC patients for deciphering transcriptomic profiles

specific of aberrant vascular structures and their close microenvironment.

Result and discussion

Analysis of ccRCC patient cohort allowed us to:

- 1) characterize three distinct patient groups based on the predominant architecture of the vascular network;
- 2) identify the involvement of a specific aberrant structure in the metastatic process. Spatial transcriptomic analyses of these aberrant vascular structures revealed specific profiles of genes related to endothelium development, ECM remodelling and TKI resistance. Using the in vitro VMT model that faithfully recapitulates the ccRCC vasculature, we confirmed that the aberrant structures exhibited distinct sensitivities to TKI treatments.

Conclusion

These combined approaches allowed us to characterize the crosstalk between endothelial and tumor cells potentially contributing to TKI resistance and metastatic dissemination in ccRCC. This project opens promising clinical perspectives for ccRCC patients at advanced metastatic stages, by targeting the aberrant vascular structures involved in tumor dissemination.

Introduction

Trastuzumab is a powerful targeted therapy for HER2 positive breast cancer (HER2+ BC) patients but a consistent percentage of resistant cases are reported. It is well known that miRNAs are involved in a plethora of biological processes, that their dysregulation is a common feature in cancers, and that they can serve both as biomarkers and therapeutic tools. Analyzing tissue samples from NeoALTTO trial, we identified miR-31-3p as negatively associated with pathological complete response upon neoadjuvant trastuzumab. Here we explored the impact of miR-31-3p modulation on HER2+ BC cell response to trastuzumab.

Material and method

MiRNA overexpression and downmodulation were achieved transfecting respectively a miRNA mimic and an LNA-based inhibitor in human HER2+ BC SKBR3 and HCC1954 cells; miRNA and protein levels were assessed by qRT-PCR and Western blot analyses; cell growth was analyzed by 3D assay. In vivo injection of HCC1954 cells was performed in SCID mice and LNA-31-3p was delivered peritumoral 5 times, twice a week; each injection was followed by trastuzumab treatment. RNA-seq analysis was performed in miRNA-over-expressing/inhibited HCC1954 cells treated or not with

trastuzumab. Ingenuity pathway analysis was used to define gene enrichment in RNA-seq dataset. Cytotoxicity ability of natural killer (NK-92) and macrophages (THP1) cell lines, upon their conditioning with miR-31-3p-overexpressing SKBr3 cells supernatant, was assessed by using 51Cr-labelled K562 leukemia cells as target. Correlation analysis between miRNA expression and 60 immune-related metagenes was performed by considering Spearman Corr. coeff. >0.30 in absolute value.

Result and discussion

Overexpression of miR-31-3p upregulates both HER2 levels and activation status in both SKBR3 and HCC1954 cells. These effects are paralleled by increased cell number at baseline and after exposure to trastuzumab. Moreover, miR-31-3p inhibition significantly reduced the in vivo growth of HCC1954 xenografts in trastuzumab-treated mice. Trastuzumab efficacy greatly relies on its ability to trigger an immune response; data from RNAseq analysis of HCC1954 cells revealed that miR-31-3p inhibition induced a significant upmodulation of genes involved in Interferon α/β signaling, regardless of trastuzumab treatment. Moreover, the conditioning of NK-92 and THP1 cells with the supernatant of miR-31-3p-overexpressing SKBr3 cells significantly reduced immune cell cytotoxicity. Accordingly, miR-31-3p expression negatively correlated with the presence of activated immune cell subsets in the NeoALTTO series.

Conclusion

miR-31-3p inhibition holds a promising potential as adjuvant strategy to increase trastuzumab efficacy by simultaneously reducing tumor growth and taming the immune response in HER2+ BC.

Introduction

Chromosomal instability (CIN) is a hallmark of most solid tumors, including colorectal cancer (CRC). CIN arises from errors in sister chromatid segregation and drives tumor initiation, progression, and therapy resistance. However, there is evidence that excessive CIN exerts an oncosuppressive effect, triggering mitotic catastrophe and immune responses. This suggests that neoplasms evolve mechanisms to keep CIN at tolerable levels during their progression. These adaptations may create specific dependencies in CIN tumors, which could be targeted therapeutically.

Material and method

We used CRC patient-derived spheroids (PDSs) and organoids (PDOs) characterized for their genome, transcriptome, genetic instability status and therapy response. We developed multiple experimental strategies to modulate CIN, including the induction of whole-genome duplication (WGD) with antimitotics, followed by limiting dilution to generate clones with redoubled ploidy. Of note, these models enable the study of cell plasticity, as they are enriched for (PDSs), or derived from (PDOs), stem-like cells. To assess transcriptional changes associated with CIN and evaluate chromatin accessibility, we performed RNA-Seq and ATAC-Seq. CIN cell vulnerabilities were investigated through high-throughput drug screening and proteomics studies.

Result and discussion

Transcriptomic profiling of PDSs and PDOs with low vs. high CIN revealed transcriptional rewiring associated with increased CIN, coupled with the overactivation of multiple epigenetic regulators, including histone post-translational modifiers and chromatin remodelers. These analyses also uncovered heterogeneity among CIN cell lines, with a CIN subtype displaying global mitotic deregulation. ATAC-Seq studies confirmed differences in chromatin accessibility between primary CRC cells with distinct CIN levels. To identify specific vulnerabilities of CIN cells, we first performed a high-throughput immunofluorescence microscopy-based screening in CRC cells with low vs. high CIN. The screening led to the identification of some epigenetic drugs including inhibitors of histone ubiquitination/methylation enzymes and chromatin remodelers, which reduce proliferation and viability by disrupting the DNA replication process. In parallel proteomic and functional studies in low vs. high CIN CRC cells, we revealed a role for the mTOR pathway kinase RPS6KB1 in promoting CIN tolerance in CRC while supporting cell plasticity, growth and survival.

Conclusion

In conclusion, using CRC patient-derived models we demonstrated a complex transcriptional rewiring associated with increased CIN, as we identified epigenetic regulators (histone modifiers and chromatin remodelers) and growth signaling regulators (RPS6KB1) as crucial drivers of CRC adaptation to CIN. These findings could pave the way for the development of therapeutic strategies targeting CIN-associated vulnerabilities in CRC.

Harnessing Mechano-Modulation: Enhancing Nano-Immunotherapy Efficacy by Targeting the Tumor Microenvironment in Sarcomas and TNBC

C. Neophytou¹, F. Mpekris¹, A. Charalambous¹, M. Panagi¹, C. Voutouri¹, S. Angelis¹, A. Papouli¹, T. Stylianopoulos¹

¹University of Cyprus, Mechanical and Manufacturing Engineering, Nicosia, Cyprus

Introduction

Nano-immunotherapy has shown significant potential for improving outcomes in cancers such as desmoplastic

sarcomas and triple-negative breast cancer (TNBC), but its effectiveness is limited by the tumor micro-environment (TME), which includes factors such as tumor stiffness, vascular dysfunction and poor drug delivery. Mechanotherapy and ultrasound sono-permeation offer potential solutions to modulate the TME and enhance treatment efficacy. Our study explores the synergy of these strategies to optimize nano-immuno-therapy in sarcoma and TNBC models.

Material and method

In vivo experiments were performed using two murine sarcoma and two TNBC models. First, ultrasound sono-permeation was applied using a clinical devise, with parameters optimized in our study. Mice were treated with the mechanotherapeutic ketotifen, sonopermeation, Doxil nanomedicine, and a cocktail of immune checkpoint inhibitors (ICIs). Tumor stiffness and perfusion were assessed using Shear Wave Elastography (SWE) and Contrast Enhanced Ultrasound (CEUS). Flow cytometry and proteomic analysis were used to evaluate immune response, and machine learning identified the most valuable parameters that can predict treatment efficacy.

Result and discussion

Ultrasound sonopermeation with mechanical index MI = 0.6 and number of cycles NoC = 32 significantly optimized improved tumor perfusion and drug delivery in both sarcoma and TNBC models. Ketotifen further enhanced these effects by reducing tumor stiffness and interstitial fluid pressure. The combination of sono-permeation, ketotifen and nano-immunotherapy (Doxil and ICIs) produced the most significant therapeutic outcomes, including tumor regression and improved survival, leading to complete cure. In TNBC models, this combination improved perfusion, increased immune cell infiltration and elevated the levels of chemokines and cytokines at the tumor site. Machine learning identified tumor stiffness and immune cell profiles as key biomarkers of therapeutic success.

Conclusion

The combination of mechanotherapy and ultrasound sono-permeation effectively modulates the TME, enhancing drug delivery, tumor perfusion, and immune responses. This approach significantly boosts nano-immunotherapy efficacy, offering a promising strategy to overcome treatment barriers in desmoplastic cancers and TNBC, with potential to improve survival in resistant tumors.

Introduction

Breast cancer is one of the leading causes of cancer-related deaths among women worldwide [1]. Traditional 2D cell cultures fail to replicate the 3D architecture of tumors, while animal models often lack translational accuracy [2]. Advanced 3D models, including hydrogels and bioprinted scaffolds, better mimic the tumor's biomechanical and biochemical properties, providing a more reliable platform for studying cancer progression and drug response [3]. The research activities planned within this project focus on the development and biological characterization of biomimetic scaffolds for breast tumor tissue.

Material and method

Four different concentrations of alginate-gelatine (ALG-GEL) hydrogels were prepared. All groups were weighed at various time points, to assess their swelling capacity and examine their subsequent degradation for long time incubation at 37°C. pH variations were monitored for different time points. A morphological investigation of the prepared hydrogels was also conducted using SEM. To assess if the polysaccharide structure of ALG was preserved after the hydrogel formation and to assess the successful incorporation of gelatin in the system, FTIR was performed. Different rheological analyses were performed on all the prepared samples.

Result and discussion

All samples showed high swelling after 2h incubation and a slight degradation trend after 21 days of incubation. FTIR analysis confirmed successful GEL incorporation within the hydrogels preserving the structure of ALG. SEM imaging revealed a uniform reticulation among all the prepared samples. Rheological analysis showed a G' value around 10 kPa, demonstrating a good fitting for mimic breast cancer tumor's mechanical properties. The different hydrogel formulations are under investigation to assess their capability to support the cell viability of breast cancer cells (the MDA-MB-231 cell line) and allow their distribution inside the hydrogel structure.

Conclusion

The results obtained demonstrated that the incorporation of gelatin effectively modulates the mechanical properties of alginate-based hydrogels, allowing for a more accurate replication of breast tumor tissue stiffness. These hydrogels successfully formed 3D structures capable of mimicking the complexity of the tumor micro-environment, making them valuable models for studying breast cancer progression and response to treatments. Future research will focus on optimizing their bio-printability. By incorporating selected cell lines, these bioprinted models could provide a powerful platform for in vitro cancer research, offering new opportunities to investigate tumor behavior, drug responses, and cell-matrix interactions in a controlled and physiologically relevant setting.

⁴ Universidad Complutense de Madrid, Grupo de Física Nuclear, EMFTEL & IPARCOS, Madrid, Spain

⁵ Universidad Complutense de Madrid, Bioquímica y biología molecular, Madrid, Spain

Introduction

Metastatic prostate cancer patients (mPCa) exhibit lower survival rates compared to those with localized tumors. This is mainly due to the complexity of the molecular mechanisms governing malignant cells dissemination, which contributes to the inefficacy of existing treatments. Therefore, to improve the prognosis and diagnosis of mPCa patients, it is essential to elucidate the mechanisms underlying metastases. To address this, our study focuses on the identification of key regulators of mPCa progression using high-throughput CRISPR/Cas9 screenings.

Material and method

To identify novel factors that promote the acquisition of the metastatic phenotype we have developed an in vivo gain of function (GoF) genome-wide screening using orthotopic inoculation of low-metastatic PCa cells (LNCaP) infected with a genome-wide SAM library. Moreover, the temporal and spatial components of metastasis were examined by analysing the detection of gRNAs in 5 tissues (bone marrow, lung, liver, lymph nodes and brain) of the animals at either 4 (early metastasis)- or 6 (late metastasis) weeks post orthotopic inoculation of PCa cells.

Result and discussion

Our findings reveal distinct patterns of key biological processes and pathways involved in dissemination, which vary depending on the target tissue, as well as an enrichment of specific gRNAs in late-stage metastases compared to early metastases. These results highlight the influence of both the microenvironment and time dependent factors on metastatic evolution. The early metastasis analysis identified FGF8 as a common metastatic driver in bone marrow (BM), lymph nodes and liver, while in late metastasis this gene was only significant in BM. FGF8 has been previously described as a metastatic promoter thereby validating our system. BM is the most common metastatic destination in

prostate cancer. By comparing early vs late metastasis BM upregulated gRNAs, we have identified 4 common genes: NELL2, ADAM2, DLG5 and FGF8, of which NELL2, ADAM2 and DLG5 have been exclusively identified in BM. NELL2 and ADAM2 were more enriched in early BM metastasis, suggesting they might be involved in primary metastatic stages like colonization and survival. Conversely, DLG5 and FGF8 were more enriched in late BM metastasis and thus might be regulating proliferation and metastatic outgrowth. Moreover, among the BM exclusive genes we have identified transcriptional repressors ZNF202 and MXI1 as drivers of early and late metastasis, respectively, both with prognostic value in both prostate and breast cancer.

Conclusion

This approach has allowed us to study the whole metastatic cascade in vivo, facilitating the identification of the different tropisms acquired by disseminated tumor cells in response to the host microenvironment, as well as the discovery of new prognostic biomarkers and/or therapeutic targets which could be essential for mPCa treatment.

³ Facultad de Medicina y Ciencias de la Salud, Universitat de Barcelona, Unidad de Biofísica y Bioingeniería, Departamento de Biomedicina, Barcelona, Spain

⁴ Universidad Complutense de Madrid, Grupo de Física Nuclear, EMFTEL & IPARCOS, Madrid, Spain

Introduction

Metastasis is a primary cause of mortality among patients with solid tumors. Disseminated tumor cells (DTCs) migrate to secondary organs, where they enter a reversible quiescent state known as dormancy, before contributing to metastasis. The microenvironment within secondary organs is recognized as a crucial regulator of dormancy. Our research has demonstrated that neural derived molecules such as neuropilin 2 (NRP2), regulate DTCs proliferation in the lung. Additionally, our findings indicate that NRP2 upregulation in lung DTCs is modulated by lung stromal cues such as TGFb1 secreted by lung fibroblasts (LF). Within this framework, we are investigating the lung stroma as a regulator of the transition from dormancy to proliferation in head and neck cancer. Moreover, we are focusing on FGFR2 as a potential mechanism underlying this process, a receptor tyrosine kinase that is frequently mutated in head and

neck cancer and has been described to regulate fibroblasts mediated treatment resistance in breast cancer.

Material and method

To investigate the interaction between LF and DTCs, we utilize healthy LF cell lines and four head and neck cancer cell lines as an *in vitro* dormancy model. These include a primary tumor-derived cell line (T-HEp3), a lung DTC-derived cell line (Lu-HEp3), a bone marrow DTC-derived cell line (BM-HEp3), and a dormant cell line (D-HEp3). Conditioned media (CM) are collected from these models and employed in various functional assays. To assess the role of FGFR2 in DTCs regulation, we use pharmacological inhibitors and have generated FGFR2 knockdown cell lines to examine their phenotype and behavior. Additionally, we employ the chorio-allantoic membrane (CAM) assay to evaluate tumor growth under distinct experimental conditions.

Result and discussion

Our results show that treatment with LF CM promotes Lu-HEp3 cells proliferation both *in vitro* and *in vivo* and activates ERK signaling. Furthermore, treatment of LF with CM from proliferative and dormant cell lines revealed that CM from dormant cell lines induces LF activation, suggesting there is a bidirectional crosstalk between dormant DTCs and LF. Additionally, FGFR2 is overexpressed in Lu-HEp3 cells. Pharmacological and genetic inhibition of FGFR2 induces cell cycle arrest in G1 phase, promotes dormancy markers upregulation and reduces proliferation *in vitro* and *in vivo*. Moreover, in dormant cell lines, FGFR2 inhibition induces apoptosis, suggesting FGFR2 plays a critical role in sustaining dormant DTCs survival.

Conclusion

Our findings suggest that LF, upon activation by dormant DTCs, promote DTCs release from dormancy facilitating metastatic progression in the lung. Moreover, our data indicate that the FGFR2 signaling pathway regulates both DTCs proliferation and survival, highlighting its potential as a therapeutic target in metastatic disease.

EACR25-1968

Mapping of human prostate tumour heterogeneity using AtlasPlex immunofluorescence approach

E. Kuteeva¹, A. Charbonneau², M. Malmqvist²

¹*Atlas Antibodies, Research and Development, Stockholm, Sweden*

²*Atlas Antibodies, Research and Development, Stockholm, Sweden*

Introduction

The progression from normal to neoplastic state is characterized by continuous changes in epithelial cell phenotype and in tissue microenvironment. Detailed characterization of this process is crucial for understanding tumour biology, discovery of novel biomarkers and identification of therapeutic targets. Multiplexed immunohistochemistry/immunofluorescence (mIHC/IF) has been successfully used for studies of tumour biology. However, such studies are often limited by the availability of the primary antibodies from different host species, a need for harsh tissue treatment in between the staining cycles or requirement for complex automated

platforms. In the present study, the newly developed mIHC/IF technology ‘AtlasPlex’ was employed for studies of tumour microenvironment in transition from normal to cancer state in human prostate.

Material and method

AtlasPlex was used to perform mIHC/IF for the evaluation of tissue microenvironment in normal (n = 6), benign hyperplasia (n = 6) and prostate cancer (n = 5) FFPE human tissue sections. KRT5 (HPA059479), TP63 (AMAb91224) and AMACR (HPA019527) were used as markers for normal and neoplastic glands. CD3E (HPA043955), CD8A (HPA037756), and CD68 (HPA048982) were utilized as markers of T cells, cytotoxic T cells, and tumour associated macrophages respectively. The AtlasPlex workflow was as follows: primary antibodies were biotinylated and labeled with HRP. A sequential multiplexed TSA-IF assay was then performed using 2 or 3 epithelial and 1 immune cell markers at a time. MetaSystems slide scanner equipped with epifluorescence and appropriate filters was used for image acquisition.

Result and discussion

Normal and benign hyperplasia prostate glands displayed strong KRT5 and TP63 positivity in the basal cell layer, while cancerous glands were negative. In contrast, AMACR positivity was high in the tumour glands, while normal prostate and benign hyperplasia glands showed negative or occasional weak positivity. Analysis of immune cell count indicated significant increase in number of CD3E-positive T cells in cancer samples (normal 71+/-10 vs cancer 176+/-14 cells), CD8A cytotoxic T-cells (normal 204+/-39 vs cancer 559 +/- 108 cells) and CD68 tumour associated macrophages (normal 97+/-21 vs cancer 269+/-27 cells, assessed per 9 FOVs, 1.4 mm²). Both T-cells and macrophages were observed in close proximity to the cancer glands. No significant changes were observed in benign hyperplasia.

Conclusion

The present study demonstrated how AtlasPlex mIHC/IF could be successfully used to analyse normal and tumour tissue microenvironment in prostate cancer. The AtlasPlex approach to combine the StreptaClick-HRP and the TSA-IF technologies allowed multiplex tissue analysis using the same species primary antibodies, with signal quality and assay sensitivity equal to that of gold standard chromogenic IHC.

Monitoring Lynch syndrome colonic organoid engraftment in mice cecum

M. Ginesta¹, B. Arozamena², S. Crespo¹, M. Torralba¹, M. Diaz², F. Marin¹, M. Pineda¹, J. Guiu², G. Capellá¹

¹*IDIBELL, Hereditary Cancer Program, L'Hospitalet de Llobregat, Spain*

²*IDIBELL, Program for Clinical Translation of Regenerative Medicine in Catalonia, L'Hospitalet de Llobregat, Spain*

Introduction

Lynch syndrome (LS) is a hereditary pan-cancer syndrome caused by constitutional pathogenic variants in DNA mismatch repair (MMR) genes (MLH1, MSH2, MSH6, PMS2). Despite intensive surveillance interval

colorectal Cancers (CRC) are common in LS carriers. In vivo modelling of the early events mechanisms leading to MMR-deficient carcinogenesis may lead to its better understanding critical to improve surveillance strategies. The aim of our study is to assess the feasibility of the engraftment of normal tissue-derived colonic organoids from LS patients implanted in the mouse cecum.

Material and method

Colonic tissue-derived organoid lines were generated from biopsies of normal appearing mucosa of 3 LS carriers (1 MLH1, 2 MSH2) and 1 control without Lynch syndrome. Three of the lines were cultured 3 months (25 passages). Organoids were surgically implanted in the caecal submucosa of immunosuppressed mice ($n = 5-7$ mice/organoid line; total 27) at different passages (2, 7, 11, 17 and 25) as described by Fumagalli et al (PMID 29300390). Mice were sacrificed 4 ($n = 14$), 6 ($n = 7$) and 8 ($n = 6$) weeks after the surgery. Histological characterisation was performed by haematoxylin-eosin (H&E) staining. Expression of anti-human Ku80, MMR (MSH6 and PMS2), Ki67 and MUC2 proteins was assessed by Immunohistochemistry (IHC). In selected cases, PCR amplification of human GAPDH was done.

Result and discussion

Engrafted organoids grew in mice for up to 8 weeks after implantation. H&E staining revealed the presence of rounded structures lined with a thin epithelium growing in the submucosal layer in 24 out of 27 mice (3 cases were non-informative). Their human origin was confirmed by anti-human Ku80 homogeneous staining and amplification of human GAPDH. Expression of MMR proteins was conserved in concordance with the expression observed in paired human biopsies and organoids. Ki67 expression was observed in 30-60% of cells of engrafted organoids while MUC2 was expressed after engraftment *in vivo* while absent *in vitro*.

Conclusion

Normal colonic tissue-derived organoids are able to grow for up to 8 weeks in the cecum of immunosuppressed mice. This tool will be used for the characterization of the early events occurring in MMR-deficient colorectal carcinogenesis.

P-Selectin as a Key Regulator of Lung Cancer Brain Metastasis: Altering the Immunophenotype of the Tumor

Microenvironment

K. Salomon¹, Y. Roth¹, A. Miari¹, I. Kamer², J. Bar², I. Barshack³, R. Satchi-Fainaro^{1,4}

¹Tel Aviv University, Physiology and Pharmacology, Tel Aviv, Israel

²Sheba Medical Center, Institute of Oncology, Ramat Gan, Israel

³Sheba Medical Center, Department of Pathology, Ramat Gan, Israel

⁴Tel Aviv University, Sagol School of Neuroscience, Tel Aviv, Israel

Introduction

Our overarching goal is to understand the molecular and cellular mechanisms by which the P-Selectin/P-Selectin ligand-1 (CD62P/CD162) axis mediates lung cancer

brain metastasis (LCBM) progression. Specifically, we investigate how interactions between lung cancer (LC) cells with microglia polarize their immunophenotype into an anti-inflammatory and pro-tumorigenic state, ultimately remodeling the immune landscape.

Material and method

Multiplex immunofluorescence staining was performed on FFPE tissues from LCBM patients to elucidate CD62P and CD162 localization expression across different cell types. To assess microglia's role in promoting LC cell growth, a 3D organoid model embedded in Matrigel was established, incorporating the entire brain tumor micro-environment (btME) to simulate the clinical scenario. The Transwell migration assay was employed to investigate microglia's role in promoting LC cell migration. A cytokine array assay identified factors that mediate migration through P-selectin interaction in a paracrine model. CD62P's contribution was assessed using either a small molecule inhibitor or a neutralizing antibody.

Result and discussion

Spatial analysis revealed that CD62P and CD162 were significantly overexpressed in LCBM tissues compared to healthy controls. Interestingly, CD62P was found to be positive in astrocytes, microglia, CD8+ T cells, endothelial cells, and LC cells. Moreover, the co-expression of the immune markers, PD-L1 and PD-1, with CD62P-positive cells suggested potential pathways for immune modulation. In spheroids embedded in Matrigel with the whole btME, microglia significantly enhanced LC cell proliferation, migration, and invasion, which were markedly reduced by CD62P inhibition. Transwell migration assays confirmed that soluble CD62P promotes the migration of LC cells toward microglia. Additionally, cytokine profiling confirmed that the paracrine interaction between microglia and LC cells upregulated pro-tumorigenic cytokine secretion. Furthermore, inhibition of CD62P using a neutralizing antibody diminished these effects and altered cytokine profiles.

Conclusion

Inhibiting the CD62P/CD162 axis could reprogram microglia and tumor-associated macrophages from a pro-tumorigenic to an anti-inflammatory state, potentially enhancing the adaptive immune response against LCBM. Further exploration of CD62P/CD162 in LCBM may offer novel strategies to reverse brain immuno-suppression and improve patient outcomes.

EACR25-1976

A Novel Transgenic Mouse Model to Assess On-Target Off-Tumor Toxicities of HER2-Targeted Therapies

S. Duro-Sanchez¹, M. Bort-Brusca¹, M. Roman-Alonso², J. Arribas¹

¹HMRI Barcelona, Barcelona, Spain

²VHIO, Barcelona, Spain

Introduction

HER2-targeted therapies have revolutionized the treatment of HER2-positive tumors. However, these therapies can cause severe toxicities due to HER2 expression in healthy tissues, where it is present at low levels. These on-target off-tumor effects can lead to life-threatening complications particularly with novel therapies in clinical

trials. Therefore, there is a need for preclinical mouse models that faithfully recapitulate human HER2 expression patterns in mice to properly evaluate the safety of HER2-directed therapies before use in humans.

Material and method

Our transgenic mouse model was generated using the embryonic stem (ES) cell method combined with CRISPR-Cas technology. Murine ES cells were modified *in vitro*, selected with antibiotic resistance, expanded and analyzed via Southern blot. Genotyping of mice was performed by PCR with primers specific to the human HER2 and mouse Erbb2 genes. The expression of HER2 and Erbb2 mRNA across different organs was assessed by RT-qPCR. Protein expression of human HER2 was analyzed by western blot and immunofluorescence in various mice tissues.

Result and discussion

We successfully developed a novel transgenic mouse model in which the human HER2 gene is knocked-in under the control of the murine Erbb2 promoter. Genomic validation by southern blot confirmed the successful insertion of HER2 in several mouse ES cells, and both heterozygous and homozygous mice bearing the human HER2 gene were obtained. RT-qPCR analyses revealed tissue-specific expression of human HER2 mRNA in organs like the lungs, kidneys or heart, correlating with murine Erbb2 expression patterns in healthy murine tissues and the presence of the human HER2 protein was confirmed in the lungs and kidneys. As proof of concept, the administration of HER2-targeted murine CAR-T cells in transgenic mice resulted in preliminary evidence of toxicity, consistent with the expected on-target off-tumor adverse effects.

Conclusion

In conclusion, this novel transgenic mouse model represents a valuable tool for the preclinical assessment of HER2-targeted therapies, enabling the study of their on-target off-tumor toxicities before clinical translation. This murine model will facilitate the development of safer and more effective HER2-directed strategies for the treatment of HER2-positive tumors.

EACR25-1983

Exploring tumor-suppressing fibroblast population in ovarian adenocarcinoma

A. Kazakova¹, K. Anufrieva¹, M. Lukina¹, O. Ivanova¹, P. Shnaider¹, V. Shender¹, G. Arapidi¹

¹Lopukhin Federal Research and Clinical Center of Physical-Chemical Medicine of Federal Medical Biological Agency, Moscow, Russia

Introduction

Among the various stromal cell types within the tumor microenvironment, cancer-associated fibroblasts (CAFs) are the predominant component, exhibiting diverse oncogenic functions. Despite their potential as therapeutic targets, no effective strategy exists to neutralize CAF activity due to the lack of specific markers and their heterogeneous nature. Current anti-tumor approaches indiscriminately deplete CAFs, overlooking the existence of both pro- and antitumor subpopulations in the tumor, which makes these therapies toxic to the organism. A more promising strategy

involves reprogramming CAFs into a uniform anti-tumor state, necessitating the identification of CAF subsets with exclusively tumor-suppressive properties, which is the objective of this study.

Material and method

To examine the distinctive features of CAF transcriptome, we integrated multiple public datasets, including 11 scRNA-seq datasets of different tumor tissues, mRNA-seq data from 934 cancer cell lines (CCLE), 10,000 patient tumor samples (TCGA), and 10 scRNA-seq datasets of normal tissues (HPA). Public scRNA-seq data of ovarian adenocarcinoma were analyzed to identify CAF subpopulations and their transcriptomic differences. The effect of IFNγ-pretreated dermal fibroblast secretome on SKOV3 cell migration was assessed using a scratch test. Xenium-based spatial transcriptomics analysis was performed to determine the localization of tumor-suppressive CAFs in ovarian adenocarcinoma.

Result and discussion

Developing a custom marker identification algorithm based on comprehensive bioinformatic analysis of large RNA sequencing datasets allowed us to identify a set of genes specific to CAFs across 11 tumor types. In ovarian adenocarcinomas, we identified a CAF population whose higher abundance correlates with a favorable prognosis. This population specifically expressed genes activated in response to IFNγ, which are upregulated in ovarian tumors compared to normal ovarian tissue. Additionally, we demonstrated that the secretome of IFNγ-pretreated fibroblasts reduces SKOV3 ovarian cancer cell migration *in vitro*. Spatial transcriptomics analysis revealed that these fibroblasts are localized within IFNγ aggregates, enriched with epithelial cells, macrophages, and endothelial cells exhibiting enhanced IFNγ response gene expression, as well as CD8+ T cells.

Conclusion

Our findings reveal the existence of a tumor-suppressive CAF population in ovarian adenocarcinoma, characterized by an IFNγ-associated gene signature and its correlation with favorable prognosis. Additionally, our results provide insights into selecting the most appropriate combination of CAF markers across different tumor types. These findings enhance our understanding of CAF heterogeneity and its role in the tumor microenvironment.

This work was carried out with state funding for the "Immunopeptidome" project, state registration number of R&D 124031200004-7.

ADAR1-Mediated RNA Editing as an Oncogenic Driver in Prostate Cancer

S. Kalogera¹, K. Detkiewicz¹, L. Verk², M. Persson¹, A. Bjartell³, Y. Ceder¹

¹Lund University, Clinical Sciences, Lund, Sweden

²Lund University, Biology, Lund, Sweden

³Lund University, Translational Medicine, Lund, Sweden

Introduction

Prostate cancer (PCa) stands as the second most frequently diagnosed cancer and the second leading cause of cancer-related death in men. The biggest challenge in PCa is treatment resistance and managing metastatic

disease progression. Recent studies have highlighted the role of RNA editing in the pathogenesis of cancer. Adenosine deaminase acting on RNA (ADAR1) binds to double-stranded RNA (dsRNA) and catalyzes the conversion of adenosine to inosine through a process known as A-to-I editing. Previous literature confirmed a role for ADAR1 in multiple cancer hallmarks, but its function in PCa has not been fully elucidated. The aims of this project were to explore the functional role of ADAR1 in PCa as a potential oncogenic driver using *in vitro* assays and the clinical potential of ADAR1 as a biomarker using clinical cohorts.

Material and method

ADAR1 levels were compared among benign prostate tissue, primary tumour, and bone metastatic samples. *In vitro*, the effect of ADAR1 knockdown on proliferation and cell-to-cell adhesion on different PCa cell lines was investigated. Furthermore, tissue microarray cores from radical prostatectomy of 230 patients with PCa were immunostained for ADAR1. ADAR1 levels were compared between cancerous and paired non-cancerous areas, and their association with clinical outcomes was investigated.

Result and discussion

In silico data analysis showed a significant increase of ADAR1 levels in bone metastases compared to the benign and primary group. ADAR1 knockdown significantly reduced A-to-I editing levels and inhibited PCa cell proliferation in different PCa cell lines. On the other hand, ADAR1 knockdown increased cell-to-cell adhesion in different PCa cell lines. Data from the tissue microarray cores showed that ADAR1 expression in the epithelial compartment of cancerous tissue was significantly higher compared to paired non-cancerous areas. Additionally, ROC curve analysis showed that epithelial ADAR1 levels demonstrated a moderate ability to differentiate between benign and cancerous tissues, with an AUC of 0.72. Finally, high ADAR1 expression was associated with an increased risk of biochemical recurrence (BCR).

Conclusion

In conclusion, the findings of this study shed light on the potential role of ADAR1 in PCa progression and its clinical significance, suggesting ADAR1 as a potential target for the development of diagnostic and therapeutic strategies.

EACR25-2010

An mRNA isoform produced by intronic polyadenylation as a new signature in tobacco associated cancers

⁴*Institute for research and innovation in health (i3S), Instituto de Biologia Molecular e Celular (IBMC) and*

Instituto de Ciências Biomédicas Abel Salazar (ICBAS), Universidade do Porto, Porto, Portugal

Introduction

Tobacco smoking is responsible for approximately 2.5 million cancer deaths annually worldwide, being the primary preventable risk factor for lung, bladder, and head and neck (H&N) cancers. The associated burden on health care systems emphasizes the need for a better understanding on how this carcinogen affects our cells, as well as in new therapeutic strategies for these cancers. Cancer cells tend to express mRNA isoforms with short 3'UTRs, by alternative polyadenylation in the 3'UTR (3'UTR-APA) and intronic polyadenylation (IPA), which may affect the function of genes involved in tumorigenic processes, and lead to the dysregulation of important signaling pathways. Here, we investigated whether lung, bladder and H&N cancers present a specific profile of “mRNA signatures”, which may serve as new biomarkers or therapeutic targets for cancers linked to smoking habits.

Material and method

Bioinformatic analysis was performed using TCGA RNA-seq data from lung, bladder and H&N cancers, as well as in-house 3'mRNA-seq of samples obtained by surgery of heavy-smokers with H&N cancers at Institute of Portuguese Oncology (IPO-Porto). The obtained mRNA isoforms were validated by 3'RACE and RT-qPCR, using samples obtained from IPO-Porto of H&N cancer patients. *In vitro* analysis of protein translation was performed using a coupled transcription/translation cell free assay. mRNA stability was analyzed by Actinomycin D assays.

Result and discussion

The mRNA signatures obtained from the analyses of the TCGA data, that are present in smoker patients while absent from non-smoker patients, were intersected with the ones obtained from our in-house 3'mRNA-seq, identifying 9 common smoking-specific mRNA signatures. We decided to further study one of these signatures, an IPA mRNA isoform from PCGF3, as it may produce a new protein with a still unknown function. PCGF3 is known to be a component of Polycomb group multiprotein complex, a complex involved in epigenetic modifications. We validated PCGF3 expression in samples obtained from IPO-Porto of H&N cancer patients showing that this IPA mRNA isoform is upregulated in tumors when compared to normal tissues. *In vitro*, we showed that the truncated IPA mRNA isoform can lead to the production of a protein, even though it loses all the canonical protein domains, crucial for its function. In fact, after translation, this IPA isoform shares only the first 36 amino acids with the canonical PCGF3 protein. Curiously, the mRNA stability of both the canonical and the intronic isoforms, is very similar, despite their inherent differences.

Conclusion

Overall, we have identified an unknown protein, with new functions to unravel and a possible role in smoking-related cancers. By studying this smoking-specific mRNA signature, common to three different types of cancer, we can open new possibilities for innovative therapeutic targets.

Efferocytosis by peritoneal metastasis-associated fibroblasts reprograms the tumour microenvironment to promote cancer progression

C. Zotter¹, C. Ramos¹, T. Weiss², R. Oehler¹

¹Medical University of Vienna, Department of General Surgery, Vienna, Austria

²Medical University of Vienna, Department of Plastic Surgery, Vienna, Austria

Introduction

Anti-cancer therapies, such as chemotherapeutic drugs, function by inducing apoptosis in cancer cells. The clearance of apoptotic cells (ACs) by efferocytosis is essential for maintaining tissue homeostasis and promoting an anti-inflammatory microenvironment. It has been long thought that efferocytosis is primarily carried out by professional phagocytes, such as neutrophils and macrophages. However, emerging evidence arises that also fibroblasts are able to execute this process. In addition, cancer-associated fibroblasts (CAF), a major component of the tumor stroma, are known to acquire distinct polarization status such as myoCAFs or immunomodulatory CAFs contributing to various aspects of tumor progression. In this study, we investigated the efferocytosis capacity of fibroblasts from normal tissue, primary colorectal cancer (CRC) and peritoneal metastasis and explored whether their phenotype polarization is altered upon the engulfment of ACs.

Material and method

Normal fibroblast (NF), CAFs from CRC and metastasis-associated fibroblasts (MAFs) were isolated from healthy and tumour tissues, as well as from the peritoneal fluid of patients with colorectal peritoneal metastases (CPM).

Efferocytosis capacity was assessed using fluorescence microscopy and flow cytometry. Gene expression analysis was performed on efferocytosing MAFs. To examine possible immunomodulatory effects of efferocytosing fibroblasts, MAFs were co-cultured with monocyte-derived macrophages and macrophage polarization was analyzed by flow cytometry. Moreover, tumor growth was assessed by using conditioned media of efferocytosing MAFs.

Result and discussion

MAFs exhibited remarkable higher efferocytosis capacity compared to normal peritoneal fibroblasts and fibroblasts from early-stage colorectal cancer. Efferocytosing MAFs showed increase in immunomodulatory CAF markers and a decrease in myoCAF markers indicating a switch in fibroblast phenotype. Following efferocytosis, MAFs showed increased expression of epidermal growth factors and cytokines. Correspondingly, tumor cell proliferation assays demonstrated an increased growth rate of colorectal cancer cells when cultured with CM from efferocytosing MAFs.

Conclusion

Our study demonstrates that fibroblasts possess the ability to efferocytose apoptotic tumour cells. Particularly, MAFs from peritoneal metastases exhibit a high efferocytosis capacity. After the uptake of apoptotic cell debris MAFs acquire a specific polarization status,

modifying immune cells and tumor cells in their microenvironment. This may contribute to the progression of peritoneal metastasis in CRC.

EACR25-2021

Intratumoral heterogeneity in microsatellite instability status at single cell resolution

H. Anthony¹, C. Seoighe¹

¹University of Galway, School of Mathematical and Statistical Sciences, Galway, Ireland

Introduction

Subclonal diversity within a tumor is highly relevant for tumour evolution and treatment. The cumulative diversity is referred to as intratumoral heterogeneity (ITH) and high ITH can complicate the interpretation of single-test biomarkers. Microsatellite instability (MSI) is one such biomarker, which is used to help guide immune checkpoint inhibitor treatment by classifying samples as either having high microsatellite instability (MSI-H) or as being stable (MSS). Interestingly, one area that has yet to be addressed in depth is whether MSI itself is heterogeneous. To address this question, we collected publicly available single-cell sequencing data that had paired MSI status and developed a computational pipeline to identify MSI-H cells and assess ITH in MSI.

Material and method

We curated a collection of 56 publicly available samples from across 32 individuals that underwent 10X, 3' single-cell RNA sequencing. Data was downloaded in either matrix or BAM format and were then processed with a custom Snakemake pipeline. Briefly, the pipeline identifies clusters of cells using Seurat, distinguishes cancer from normal cells with scATOMIC, and then identifies cells as being MSI-H or MSS with MSIsensor-RNA. Samples are then subset to only cancer cells and are re-clustered. Heterogeneity in a sample is then summarized using the analysis of variance F test statistic based on the MSI scores obtained from each cancer cell cluster. This is complemented by differential gene expression analysis between clusters.

Result and discussion

Our results suggest that heterogeneity in MSI status is more prevalent than has been previously reported. Five of the 32 individuals analyzed showed evidence of divergence in MSI status between distinct clusters of cancer cells ($F > 30$). The individual with the highest level of heterogeneity ($F = 75.2$) had seven distinct cancer cells clusters comprising a total of 779 cells. In contrast, the F statistic of the individual with the lowest level of heterogeneity was 5.1 (based on 6 cancer cell clusters comprising 470 cells). Tukey HSD analysis showed 17 significantly different cluster pairs for the individual with high heterogeneity whereas only five were found for the individual with low heterogeneity. These results are reinforced by differential gene expression between MSI-H and MSS cells. The individual with high heterogeneity had nine differentially expressed genes, whereas the individual with low heterogeneity only had two.

Conclusion

We provide the first single cell resolution analysis of ITB in MSI status. Our results suggest that heterogeneity in MSI is more common than previously reported. Further studies are warranted to determine the frequency of heterogeneity in this biomarker at the population level, and whether the presence of both MSI-H and MSS subclones can have clinical impacts, including the potential to result in more rapid evolution of resistance to treatments for which MSI-H is a biomarker.

ERBB Signalling contributes to immune evasion in KRAS-driven lung adenocarcinoma

S. Laing¹, B. Kruspij¹, R. Shaw², K. Kirschner¹, D. Strathdee², M. Junttila³, E. Roberts², S. Coffelt¹, D. Murphy¹

¹*University of Glasgow, School of Cancer Sciences, Glasgow, United Kingdom*

²*CRUK Scotland Institute, Glasgow, United Kingdom*

³*ORIC Pharmaceuticals, Biology, San Francisco, United States*

Introduction

In lung cancer patients, immunotherapy is now considered a frontline, standard of care therapy. However, the responses seen are varied and often transient, and a deeper mechanistic understanding of tumour:immune interactions and the dynamic immune response to evolving tumours is required. Modelling these processes in GEMMs has proven challenging, primarily due to a low mutation burden and consequent lack of immune visibility of most allelic combinations. APOBEC mutagenesis signatures are prominent in lung cancer and activity is predicted to drive immune visibility through Cytidine deaminase activity and inaccurate DNA-repair response. We have previously shown that initiation and progression of KRAS-driven lung tumours require input from ERBB family receptor tyrosine kinases. Here we utilise the immunogenic KMA model of lung cancer to investigate the immunosuppressive nature of ERBB signalling.

Material and method

Lung tumours were induced in mice carrying conditional alleles *Isl-KRasG12D*, *Rosa26DM.Isl-MYC*, +/- *Rosa26DS.Isl-APOBEC3B*, (KMA or KM respectively) by intranasal inhalation of Adeno-SPC-CRE. Mice were treated with anti-PD1 immune checkpoint blockade and harvested at defined timepoints and analysed by IHC and ScRNA-SEQ. Tumour bearing mice were treated with anti-PD1 +/- a multi-ERBB inhibitor, Afatinib, and examined acutely or monitored for survival benefit.

Result and discussion

Inclusion of the APOBEC allele drove a transiently effective T cell mediated immune response, resulting in extended survival of KMAs compared with KMs. Temporal analysis showed pronounced CD8 tumour infiltration at 8 weeks in KMA lungs but immune exclusion by 12 weeks post induction. PD1 blockade was ineffective, but via a single cell sequencing analysis, we discovered a surprising increase in tumour cell expression of EGFR/ERBB ligands following treatment and present evidence that transient ERBB blockade can restore immune surveillance in KRas mutant lung adeno-

carcinoma and combine effectively with immune checkpoint blockade. We also found additional immune suppressive mechanisms to be upregulated following PD1 blockade, and the potential of these targets will be discussed.

Conclusion

Inhibition of ERBB signalling can combine effectively with immune checkpoint blockade to restore immune infiltration in KRas driven lung adenocarcinoma. We believe the KMA model has the potential to transform our understanding of dynamic anti-cancer immunity and its collapse in lung cancer.

PRMT7 as key driver of metastatic process in prostate cancer

M. Hermosilla-Trespaderne^{1,2}, M. Rodrigo-Faus^{1,2}, A. Gordo-Vega¹, I. de la Guia-Lopez^{1,2}, P. Linzoain-Agos^{1,2}, P. Fernández-Nogueira³, A. M Cuesta^{1,2}, A. Porras^{1,2}, P. Bragado^{1,2}, A. Gutierrez-Uzquiza^{1,2}

¹*Complutense University of Madrid, Farmacy, MADRID, Spain*

²*Health Research Institute of the Clinico San Carlos Hospital, MADRID, Spain*

³*Universitat of Barcelona, Unit of Biophysics and Bioengineering, Department of Biomedicine, BARCELONA, Spain*

Introduction

Prostate cancer (PCa) patients diagnosed with metastasis have a poor survival rate of less than three years, primarily due to the inefficacy of current strategies to inhibit metastatic progression. Therefore, identifying new therapeutic targets is critical to improving the survival of metastatic PCa (mPCa) patients. Our studies using CRISPR/Cas9 screenings have identified PRMT7, a methyl transferase, as a new essential player in mPCa which depletion significantly impairs the invasive capabilities of metastatic prostate cancer (mPCa) cell lines.

Material and method

In order to better understand the molecular mechanism displayed by PRMT7 we have examined the metastatic dissemination of PCa tumor cell in vivo and the viability of cells in circulation. The molecular basis of this mechanism was further explored through proteomic and chromatin analysis.

Result and discussion

Mechanistically, PRMT7 appears to promote metastasis establishment by inducing an adhesion molecule switch in prostate cancer cells, indirectly through the methylation of transcription factors. We have performed orthotopic injections of mPCa cells into the prostate of murine model and observed that cells expressing PRMT7, form larger tumors and disseminate to key metastatic sites, including the liver, lungs, bone marrow, and brain. On the other hand, tumors derived from PRMT7-depleted cells were smaller and exhibited reduced lesions in these metastatic niches. However, cell survival analysis of cell under suspension conditions and circulation was similar in both cells suggesting a main role of PRMT7 in colonization. The results indicate that PRMT7 plays a crucial role in the regulation of RNA splicing through methylation of splicing factors (SF) like

hnRNPA1. Our analysis showed a significant up-regulation of SF in mPCa cells expressing PRMT7 compared to cells depleted of PRMT7. To further investigate its role in alternative splicing, we conducted MAJIC analysis from RNA sequencing data, identifying metastatic relevant genes regulated by PRMT7. Additionally, chromatin accessibility (ATAQ-seq) analysis showed that PRMT7 is essential for chromatin accessibility and expression of splicing factors and adhesion genes.

Conclusion

PRMT7 may serve as a novel biomarker for poor prognosis in PCa patients through the regulation of splicing of metastatic relevant genes. Furthermore, targeting the inhibition of this protein could potentially improve the life expectancy of patients with mPCa.

EACR25-2068

Functional role of unannotated small RNA cluster 1 (smRC1) during hepatocarcinogenesis and angiogenesis

F. Pagani¹, F. Giehren¹, J. Diederichs¹, S. Huber², H. Wege¹, G. Sauter¹, M. Bugatti³, W. Vermi³, R. Ronca³, J. von Felden¹

¹*University Medical Center Hamburg-Eppendorf, I.Medicine, Hamburg, Germany*

²*I.Medicine, Hamburg, Germany*

³*University of Brescia, Molecular and Translational Medicine, Brescia, Italy*

Introduction

Despite the revolution in precision oncology, primary liver cancer lacks early detection biomarkers and actionable mechanisms of carcinogenesis are poorly understood. We previously identified unannotated, small non-coding RNAs (smRCs) from circulating extracellular vesicles and developed a signature for early cancer detection (von Felden et al. Gut 2022).

Material and method

Lentiviral CRISPR/Cas9-mediated genome editing was used to generate clonal smRC1 knockout Huh7 cells and validated by RTqPCR. HUVEC cells were treated with either conditioned medium obtained from the Huh7 clones, or EVs isolated from the medium by size-exclusion chromatography. EVs were labelled using ExoGlow EV-labelling kit and EV-positive cells were visualised with a fluorescence microscope. We performed functional assays on both cell types: proliferation curve, MTT assay, morphogenesis assay on Matrigel®, colony formation assay and cell migration on Transwell® supports. Epithelial-to-mesenchymal-transition markers were quantified by RTqPCR, Western Blot, immunocytochemistry. EGFR pathway activation was measured with Human Phospho-Kinase Array Kit and Western Blot. Angiogenesis markers were quantified by RTqPCR and Human Angiogenesis Array Kit. Apoptosis activation by caspase enzymes was measured using Caspase-Glo® 3/7 assay. RNA sequencing was conducted on smRC1-KO and wildtype control clones followed by differential gene expression analysis (DESeq2 package). Spatial transcriptomic analysis (RNAscope™) was performed on primary HCC tissue.

Result and discussion

To investigate smRC1 functional role in carcinogenesis, we established an in vitro CRISPR/Cas9 model to modulate the expression in HCC cell lines. smRC1 expression was associated with increased tumour proliferation, morphogenesis, clonogenic ability and migration, as well as epithelial-mesenchymal transition, apoptosis and EGFR-pathway activation. Interestingly, genes related to angiogenesis were >2-fold upregulated (FDR<0.05) (e.g. FGF2, FGF18, PDGFB, HDAC9 and TMSB4X). Human Umbilical Vein Endothelial Cells (HUVEC) were treated with smRC1 positive and negative EVs, and conditioned medium, respectively, from the wildtype and knockout HCC clones. First, we confirmed the uptake of fluorescently-labelled EVs by HUVEC cells. Spatial transcriptomic analysis on FFPE tumour slides confirmed smRC1 positive expression in the intra-tumoural vessels. Functionally, EVs and conditioned medium from smRC1 expressing HCC cells led to increased proliferation, migration, morphogenesis, as well as increased expression of endothelial activation markers, such as FGFR1, KDR, PECAM and CHD5, in treated HUVEC cells. In order to confirm these findings *in vivo*, chick chorioallantoic membrane (CAM) assay experiments are planned.

Conclusion

Our data suggest a tumourigenic effect of smRC1 expression in HCC cells as well as pro-angiogenic effect of smRC1 on endothelial cells.

EACR25-2070

Bidirectional interaction between Schwann cells and cancer cells of Hepatocellular carcinoma: implications for tumor progression

Introduction

In cancer research, the role of peripheral nerves has been extensively studied over the past few decades, with increasing attention recently focusing on Schwann cells (SCs), the primary glial cells of the peripheral nervous system. Tumor-activated SCs have been shown to

significantly contribute to cancer progression by modulating the tumor microenvironment (TME) and directly interacting with cancer cells through both paracrine signaling and physical contact. Hepatocellular carcinoma (HCC), the most common primary liver tumor, remains one of the leading causes of cancer-related deaths worldwide. While several studies have highlighted the potential role of autonomic innervation in HCC development and progression, the specific role of SCs in this context remains largely unexplored. To address this gap, we aimed to investigate the biological effects and molecular mechanisms underlying the communication between SCs and cancer cells in the HCC.

Material and method

We decided to focus on the paracrine crosstalk between SCs and HCC cells, employing an *in vitro* approach based on conditioned media (CM), to explore the potential impact of this dialogue on both HCC cells aggressiveness and SCs reprogramming. We used the human hepatoma Hep3B cell line and human SCs, treating each cell type with either control CM (derived from the same cell type) or with CM from the other cell type. The effects of these treatments were assessed through functional assays and analysis of molecular and morphological profiles.

Result and discussion

Our results show that Hep3B cells treated with SCs-CM, compared to those treated with control CM, exhibit more aggressive features associated with tumor spread, including enhanced migration, a doubled capacity for matrigel invasion, changes in the protein levels of epithelial-to-mesenchymal transition markers (N-cadherin, E-cadherin, Vimentin) and structural and topographical alterations evaluated by atomic force microscopy. Concurrently, paracrine signals from Hep3B cells induce a chemotactic response in SCs, promoting processes such as proliferation, migration, matrigel invasion, and the upregulation of repair-related markers (GFAP, N-cadherin), thereby driving their activation.

Conclusion

Overall, our findings demonstrate a bidirectional interaction between SCs and HCC cells, emphasizing the importance of a deeper understanding of the glial component in the TME of HCC, as it could significantly influence tumor progression.

EACR25-2074

Neurosurgery in glioblastoma induces proneural-to-mesenchymal transition, therapy resistance and immunosuppression by ischemic hypoxia

A. Ballestín¹, J. Reveilles¹, C. Pichol-Thievend¹, V. Ribecco¹, A. Thomas¹, F. Roncaroli², J. van Rheenen³, K. Joseph⁴, V. Ravi⁴, G. Seano¹

¹Institut Curie, Tumor Microenvironment Laboratory, INSERM U1339 - CNRS UMR3666, Orsay, France

²Geoffrey Jefferson Brain Research Centre, University of Manchester, Manchester, United Kingdom

³The Netherlands Cancer Institute, Division of Molecular Pathology, Amsterdam, Netherlands

⁴Medical Center - University of Freiburg, Department of Neurosurgery, Freiburg, Germany

Introduction

Glioblastoma (GBM) is the most lethal and prevalent malignant brain tumor, with patients facing a median survival of 8 months and only 6.9% reaching five-year survival. The standard of care includes surgical resection of the tumor, radiotherapy, and concomitant chemotherapy with temozolomide. Despite aggressive multimodal therapy, GBM invariably recurs after surgical resection. However, the immediate impact of surgery on residual tumor biology remains poorly understood.

Material and method

To investigate the impact of surgical resection on residual GBM tumor cell plasticity and TME, we developed sophisticated preclinical neurosurgical oncology models. We used two syngeneic GBM mouse models and one patient-derived xerograph and performed fluorescent-guided neurosurgery of sized-matched GBMs. For clinically relevant rodent models of neurosurgical oncology, we replicated each step of the neurosurgical procedure performed in patients with GBM and we used the same materials. In these models, we employed time-resolved bulk- and single-cell transcriptomics, proteomics, epigenomics, digital pathology, and intravital microscopy. Next, to examine the specific effects of surgical intervention on tumor progression in patients, we assembled an international, multicenter cohort of GBM patients who underwent two surgical procedures within a period of less than 10 days. For these particularly rare samples, we conducted a longitudinal investigation comprising neuropathological analysis, single nuclei and spatial transcriptome.

Result and discussion

In both preclinical and clinical samples, we demonstrated that surgical intervention triggered a rapid cascade of events in the residual GBM. Specifically, surgery induces acute vascular disruption and leakage leading to profound hypoxia, which drives proneural-to-mesenchymal transition and extensive chromatin remodeling in tumor cells. This hypoxic environment fosters a robust immunosuppressive tumor microenvironment, characterized by increased infiltration of hypoxic tumor-associated macrophages, Tregs, and neutrophils, along with diminished antigen presentation. Comprehensive multi-omics inter- and intracellular network analyses demonstrated that postsurgical pathways converge on hypoxia-inducible factor (HIF)-1a as a central node. Critically, these postsurgical alterations confer increased resistance to conventional therapies.

Conclusion

These findings revealed a critical window of vulnerability immediately after surgical resection, suggesting that targeted interventions during this period could significantly improve GBM outcomes.

Introduction

While the interaction among platelets and tumor cells in the circulation has been described several decades ago, whether all tumor cells (TCs) are capable of equally bind platelets remains unclear. We recently highlight that different TCs display different abilities to bind platelets, relying on their contribution in distinct stages of the metastatic progression. Yet, the molecular determinant of such, and downstream consequences, remain unidentified. Here, we identified CD24 as a new TC rheostat regulating platelet binding and their subsequent pro-metastatic function.

Material and method

By screening publicly available databases, we assessed CD24 expression across a collection of murine and human TCs and further confirm its expression by flow cytometry. Based on CD24 expression levels, we selected high CD24-expressing cells (4T1) and low ones (B16F10 and 67NR) for the continuation of the study. These cells were testified for their platelets binding ability by immunofluorescence correlating this data with their CD24 expression. To demonstrate its involvement, we silenced CD24 expression by a shRNA approach generating the shCD24 4T1 cell line. After assessing in vitro their platelets binding abilities, we followed in vivo their metastatic progression in an experimental metastasis model. We also dissected the metastatic immune tumor microenvironment and the local secretome. Thanks to a short TCP regimen, we evaluate the early contribution of platelets to metastatic progression in the same in vivo scheme.

Result and discussion

Across both murine and human TCs, CD24 expression correlates with platelets binding ability. Furthermore, high CD24 expression is a poor prognostic factor in triple-negative breast cancer (TNBC) and, indeed, we observed high CD24 expression in metastatic TNBC cells (4T1) while its expression is reduced in non-metastatic isogenic counterpart (67NR). When CD24 expression is reduced by a shRNA approach (shCD24 4T1 cells), platelets binding abilities reaches levels comparable to the ones of low-binding cells. In vivo, we demonstrated that CD24 expression tunes the metastatic progression, rewiring, at the same time, the immune micro-

environment and the local secretome. By shortTCP regimen, we provide a proof-of-concept that this effect is due to early platelets-TCs interaction in a CD24-mediated fashion.

Conclusion

Overall, our work identifies CD24 to be, in part, responsible, for the differential binding of platelets to TCs and the subsequent pro-metastatic function of platelets. In addition, these findings identify CD24 as a potential druggable target to counteract platelet-TC interaction and metastatic progression, avoiding the collateral hemostatic perturbations of classical anti-platelet agents.

EACR25-2078

Development of a microphysiological system reflecting breast cancer lymph node metastasis

S. Li¹, L. McCarthy¹, L. Lin¹, R. Dwyer¹

¹University of Galway, Discipline of surgery, Galway, Ireland

Introduction

A critical step in disease spread involves the crosstalk between the primary tumour and lymph nodes, which drives remodeling of the pre-metastatic niche and facilitates cancer cell invasion. As the number of involved lymph nodes increases, patient survival decreases. Extracellular vesicles (EVs) play a significant role in this intercellular crosstalk. This study employs a 3D dynamic fluidic in vitro model to study crosstalk between the primary breast tumour and lymph node.

Material and method

MDA-MB-231, a triple negative breast cancer cell line, was transduced with CD63-conjugated green fluorescent protein (MDA-GFP), ensuring any released EVs would also carry GFP. Primary tumour stromal cells (TSCs) and lymphatic stromal cells (LSCs) were isolated from patients' tissue. Multicellular breast cancer (MBC) spheroids were generated using MDA-GFP cells and pre-stained Dil labeled-TSCs. Lymphatic spheroids were formed using LSCs. Spheroids were encapsulated in alginate on day 3 and transferred to inserts lined with Matrigel containing human umbilical vein endothelial cells (HUVECs) or lymphatic endothelial cells (LECs) respectively. Interconnected inserts were introduced to the multi-in vitro organ system (MIVO®) with a pump applied for dynamic flow to mimic blood flow. Confocal microscopy was used to image GFP and Dil and for Live/Dead assays. Embedded spheroids were also sectioned for histology.

Result and discussion

MDA and TSC were successfully labeled with GFP and Dil respectively, and confocal microscopy revealed the cells interspersed and integrated throughout the spheroid. Live/Dead assay showed similar viability in the presence or absence of alginate-encapsulation. Cell death in the spheroid core increased over time. Haematoxylin and Eosin (H & E) staining revealed extracellular matrix (ECM) deposition in the spheroid centers while cells around the periphery were polarized and migratory. In the presence of HUVECs which formed branching tubules in matrigel, tumour spheroids developed

branching smaller spheroids which extended beyond the alginate encapsulation. Migrating cells and small spheroids appeared to align with the net of tubules. Transfer of GFP from the tumour to the lymph node spheroid in the interconnected MIVO system was observed, likely originating from MDA-GFP secreted EVs taken up by the lymphatic spheroid.

Conclusion

The MBC spheroid encapsulated in alginate and co-cultured with HUVECs provides a robust approach to model tumour development. The 3D dynamic fluidic model successfully demonstrates crosstalk between MBC and lymphatic spheroids, offering a promising platform for testing novel therapeutic strategies to impede disease progression.

Introduction

The Androgen Receptor (AR) is a key oncogenic driver in prostate cancer (PCa). As a result, therapies targeting the AR signaling axis, such as androgen receptor signaling inhibitors (ARSI), remain the gold standard for treating advanced PCa. However, resistance to these therapies inevitably develops. One of the primary mechanisms of ARSI resistance is the upregulation of constitutively active AR variants (AR-Vs), with AR-V7 being the most clinically relevant. AR-V7 mRNA contains a distinct 3' untranslated region (UTR) compared to full-length AR (AR-FL) with different single nucleotide polymorphisms (SNPs) and short tandem repeats (STRs), suggesting differences in post-transcriptional regulation. This finding opens up the possibility that micro RNA (miRNA), known to play a role in post-transcriptional regulation, could potentially be therapeutically exploited in a combination therapy with ARSI.

Material and method

To identify ARV7-specific miRNAs that could be affected by the presence of SNPs in the 3' UTR, a bio-informatic pipeline was used. Expression of differentially binding miRNAs was assessed via publicly available datasets (GSE21036 and GSE60117). Five different miRNA/ SNP combinations were selected for further wet lab validation

Result and discussion

miRNA-133b – rs140988926 G/A, miRNA-133a-3p – rs140982926 G/A, miRNA-140-5p – rs5918762 T/C, miRNA-574-5p – rs7065530 A/T, and miR-324-5p –

rs147764148 G/A were selected for validation. From these five miRNAs, only one, miR-574-5p, was found to bind AR-V7 3' UTR in an allele-specific manner, with rs7065530 alternative T allele as preferred allele, as shown in a dual-luciferase assay. Furthermore, transfection of miRNA-574-5p in AR-V7 positive DuCaP and 22Rv1 cell lines led to a decrease of ARV7 expression, while AR-FL expression remained unchanged. ARV7 downregulation was the strongest in 22Rv1. Currently, the effects of miRNA-574-5p on cellular proliferation are evaluated by live cell imaging.

Conclusion

Our study identifies miR-574-5p as a regulator of AR-V7 in an allele-specific manner, preferentially binding the rs7065530 T allele and reducing AR-V7 expression. Differences in binding efficiency between cell lines suggest a potential influence of STR rs760106489. These findings provide new insights into miRNA-mediated AR-V7 regulation and its possible role in ARSI resistance.

EACR25-2107

Genetically modified M1 macrophages secreting IL-12 as a potential melanoma anticancer therapy

D. Sprus-Lipka¹, J. Cieplak¹, J. Czapla¹, A. Drzyzga¹, M. Jarosz-Biej¹, D. Sojka¹, E. Pilny¹, K. Sinek¹, R. Smolarczyk¹, T. Cichoń¹

¹Maria Skłodowska-Curie National Research Institute of Oncology, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland

Introduction

Macrophages are phagocytic cells with remarkable plasticity and heterogeneity that serve a multitude of functions, including tissue homeostasis, regulation of inflammatory responses and have a crucial role in the cancer development. Macrophages undergo different polarization states, pro-inflammatory, anti-cancer M1 phenotype and anti-inflammatory, pro-tumorigenic M2 phenotype. Tumor associated macrophages (TAMs) are responsible for induction of immunosuppression by secreting specific cytokines. Interleukin 12 (IL-12) is a cytokine which activates the effector T-helper 1 cells. The importance of macrophages in the tumor micro-environment (TME) has generated interest in therapeutic approaches. Broadly, the strategies can be divided into two groups: reducing the number of TAMs or altering their functionality within the TME for instance reprogramming TAMs from M2 to M1 phenotype. The aim of the study was development of cell therapy using M1/IL-12/RFP macrophages that destroy tumor cells by secretion of IL-12 protein into TME and transform existing TAM (M2) pro-tumor macrophages into M1 anti-tumor ones. Studies also determined the influence of modified macrophages on the systemic immune response.

Material and method

The experiments were conducted on bone-marrow derived macrophages from C57BL/6NCrl mice. Using adenovirus transduction macrophages were modified to express IL-12 and red fluorescent protein. The efficiency of the transduction was determined by flow cytometry. The amount of IL-12 secreted by modified macrophages was assessed by ELISA. The fluorescence of M1/IL-12/RFP was observed through *in vivo* imaging systems

(IVIS). The M1/IL-12/RFP macrophages were assessed in murine B16-F10 melanoma. Tumor growth was monitored. Parameters of complete blood count in control and M1/IL-12/RFP-treated mice have been analyzed using the hematology analyzer. Additional post-therapeutic analyses were performed to observe changes in the tumor microenvironment.

Result and discussion

Our data show that transduction of primary macrophages depends on multiplicity of infections and cells phenotype. There was noticed that undifferentiated macrophages were more susceptible to transduction than polarized ones. M1/IL-12/RFP macrophages release IL-12 to the medium. In vivo studies showed that M1/IL-12/RFP demonstrate fluorescence after intra dermal injection into mice up to 72h and that second dose prolonged the fluorescence up to 8 days. It has been shown that two doses of M1/IL-12 inhibited B16-F10 tumors growth and increased number of immune cells in mice blood.

Conclusion

The results demonstrate that genetically modified macrophages secrete IL-12 and have influence on tumor growth inhibition and number of the innate and adaptive immune cells. However, further research is needed to investigate their precise effect in the tumor micro-environment.

The work was financed by National Science Center Poland UMO-2021/41/B/NZ5/03245.

EACR25-2113

Cell viscosity influences hematogenous dissemination and metastatic extravasation of tumor cells

J. Goetz¹

¹*INSERM, Strasbourg, France*

Introduction

Metastases arise from a multi-step process during which tumor cells change their mechanics in response to micro-environmental cues. While such mechanical adaptability could influence metastatic success, how tumor cell mechanics directly impacts intravascular behavior of circulating tumor cells (CTCs) remains poorly understood.

Material and method

In the present study, we demonstrate how the deformability of CTCs affects hematogenous dissemination and identify the mechanical profiles that favor metastatic extravasation. Combining intravital microscopy with CTC-mimicking elastic beads and mechanically-tuned tumor cells, we demonstrate that the inherent properties of circulating objects dictate their ability to enter constraining vessels.

Result and discussion

We identify cellular viscosity as the key property that governs CTC circulation and arrest patterns. We further demonstrate that cellular viscosity is required for efficient extravasation and find that properties that favor extravasation and subsequent metastatic outgrowth can be opposite.

Conclusion

Altogether, we identify CTC viscosity as a key biomechanical parameter that shapes several steps of metastasis.

N.B: This study is available on BiorXiv (doi.org/10.1101/2024.03.28.587171) and currently in revision in Nature Materials.

EACR25-2152

xRNA in Ovo: Target Validation and Efficacy Studies Using Chicken Embryo Model (CAM Assay)

X. Rousset¹, Y. Wang¹, C. Prunier¹, E. Dosda¹, S. Roveda¹, C. Rabat¹, J. Viallet¹

¹*Inovotion, La Tronche, France*

Introduction

Recently, the chicken ChorioAllantoic Membrane (CAM) assay has been used as an in vivo model for cancer research. In fact, the CAM assay is a highly vascularized extraembryonic membrane surrounding the embryo, which is a good soil for tumors to grow and provides the condition for studying the tumor metastatic invasion in different organs and tissues. Besides, at the Embryonic Development Day (EDD) 9 when tumor cells are xenografted, the embryo is an “adult” embryo and has all organs formed and functional, including an active immune system. Therefore, this model is suited for the development of different types of anti-cancer therapies. Here we used the CAM assay to investigate the therapeutic activity of different RNA-based approaches.

Material and method

On EDD 9, a small window is made in the eggshell and allows easy access to the CAM. Cancer cell lines are then grafted onto the CAM and allowed to form tumors. From EED10 to EDD18 (end of the experiment) tumors can be treated with RNA-based therapeutics. Different therapeutics approaches have been used in ovo:

- (1) either through cell modification in vitro followed by graft in ovo or
- (2) by treating tumors with RNA directly in ovo.

The effect of RNA mutation (1) or RNA therapeutic’s treatment (2) is evaluated through different parameter: the tumor weight, the histopathological analyses of tumors (classical staining or immunohistochemistry), the immune cell infiltration (by RT-qPCR), the detection of metastases in specific target tissues, the analysis of the angiogenic network surrounding the tumor and the analysis of the toxicity (mortality rate and/or abnormal development of the embryo).

Result and discussion

In the first approach, the efficacy of siRNA, miRNA, RNAi and anti-sens RNA in various cancer types was studied:

- On PC9 non-small cell lung cancer model, the expression of a siEx8 reversed the resistance of tumors to gefitinib by blocking a specific variant of the autophagic gene ATG16L1b.
- On LNCaP prostate cancer model, the miR-135a inhibited ROCK1 expression and led to a significant regression in tumor cell invasion ability. In contrast, the inhibition of mTOR by a combination of 2 RNAi induced an increase in metastatic invasion.
- On A375 melanoma cancer model, the suppressive effect of the anti-sens RNA (LADON) in the TGF β pathway inhibited the cancer cell invasion. In the second approach, the efficacy of miRNAs was evaluated: - On

SK-OV-3 ovarian cancer model, the combination of one miRNA with doxorubicin showed an additive effect of both compounds.

- On BT-474 breast cancer model, the anti-miRNA loaded in lipid nanoparticle shows no effect on tumor, while reduced by 50% the metastatic invasion in the lower CAM.

Conclusion

The CAM model is a relevant alternative *in vivo* model that can be used for evaluating the efficacy of RNA-based therapies, in just a few days, with various interpretations on tumor growth, metastasis and as well as deeper analyses, like transcriptomics or proteomics.

EACR25-2155

Dissecting KRAS G12C inhibitor resistance at the transcriptomic level

P. Lagkada^{1,2}, S. Vietti Michelina¹, D. Caprella^{1,2}, M. Grieco^{3,2}, C. Ambrogio^{1,2}, M. Cereda^{3,2}

¹University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy

²Italian Institute for Genomic Medicine, c/o IRCCS, Candiolo (TO), Italy

³University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy

Introduction

Oncogenic RAS mutations drive approximately 30% of all carcinomas, with KRAS being the most frequently altered isoform. Despite the historical challenge of targeting KRAS due to its structural and biochemical properties, significant progress has been made with the development of KRAS G12C inhibitors, including sotorasib and adagrasib, which are FDA-approved for treating KRAS G12C-mutated Non-Small Cell Lung Cancer. However, the emergence of adaptive and acquired resistance mechanisms limits the long-term efficacy of these inhibitors. These findings underline the critical need for further research to identify novel therapeutic targets to overcome resistance. Here we uncovered adaptive transcriptomic shifts, spanning gene expression and alternative splicing rewiring, linked to resistance against adagrasib and sotorasib, shedding light on the molecular mechanisms driving therapeutic evasion.

Material and method

RAS-less mouse embryonic fibroblasts (MEFs) and human lung cancer cell lines (LUAD: H23, LUSC: CALU1) were engineered to express the KRAS G12C mutation and exposed to escalating doses of sotorasib and adagrasib until resistance emerged. Total RNA sequencing was employed to map transcriptomic adaptations at the gene and exon level. Differential expression and pathway enrichment analyses were exploited to identify significant gene/exon expression dysregulation and pathway activation.

Result and discussion

RNA-seq analysis uncovered distinct transcriptomic reprogramming in response to prolonged treatment, highlighting key pathways implicated in resistance. Epigenetic regulation, alternative splicing, translational control, and epithelial-to-mesenchymal transition (EMT) emerged as significantly altered processes upon sotorasib and adagrasib. MAPK signaling pathway was

significantly dysregulated in both mouse and human cell lines. Interestingly, sotorasib-resistant mouse and human samples showed higher expression of genes associated with metabolic pathways and cell signaling. Strikingly, splicing factors were dysregulated in all resistant cells, with MBNL1 being the strongest candidate. This impacted on the splicing landscape of resistant cells, with differential inclusion of exons in genes contributing to actin cytoskeleton and cell adhesion and potentially impacting EMT.

Conclusion

Our findings pinpoint that cells dynamically rewire their transcriptome upon sotorasib and adagrasib administration through the dysregulation of splicing factors. Adaptive resistance to these KRAS G12C inhibitors converges on MAPK signaling disruption and isoform remodeling in cell plasticity and adhesion pathways. This regulatory shift is conserved across mouse and human cells, with the strongest effects observed under adagrasib treatment. Our results uncover new therapeutic opportunities to overcome KRAS G12C inhibitor resistance by targeting RNA-based mechanisms.

⁶PT Government Associate Laboratory, Guimarães, Portugal

⁷Barretos Cancer Hospital, Molecular Oncology Research Center, Barretos, Brazil

⁸6Barretos School of Health Sciences Dr. Paulo Prata, Barretos, Brazil

Introduction

Liquid biopsy-based biomarkers present a promising approach for non-invasive cancer detection. miRNA and circRNA signatures provide advantages such as high stability, easy accessibility, and sensitivity to tumor microenvironment, making them ideal candidates for early cancer detection. To identify a miRNA and circRNA signatures in sputum and plasma samples as a non-invasive biomarker for early detection of non-small cell lung cancer (NSCLC).

Material and method

A case-control study was conducted with individuals enrolled in the Barretos Cancer Hospital Lung Cancer Screening Program (Brazil). Sputum and plasma samples were collected from high-risk controls (based on NLST and/or PLCO criteria; n=61) and non-metastatic NSCLC patients (n=62), matched for age, sex, and smoking

history. The nCounter HumanV3 miRNA panel (Nanostring™) was used to analyze miRNA expression, with the total counts normalized by the top stable miRNAs, followed by differential expression analysis ($p < 0.05$). The miRNA selection was performed using Random Forest, Boruta and LASSO approaches. Machine learning models (ML) were applied (Azure) to determine lung cancer based on differential miRNA expression between cases and controls, with model performance evaluated using the area under the curve (AUC). For circRNA analysis, plasma samples were obtained from controls ($n = 100$) and NSCLC patients ($n = 86$) from Hospital Universitari Quirón Dexeus (Spain). The nCounter Elements custom panel (Nanostring™) was used to analyze the expression of 74 circRNA, and total counts normalized by housekeeping, followed by differential expression analysis using Random Forest, and Recursive Feature Elimination for model adjustment.

Result and discussion

In plasma, 68 miRNAs were identified as differentially expressed, and 6 miRNAs were selected. The best ML model (Voting Ensemble) for the 6-miRNA plasma signature showed high accuracy (AUC = 0.91; CI 95% 0.86-0.97) in distinguishing cases and controls. In sputum, 46 miRNAs were identified as differentially expressed, and 6 miRNAs were selected. The best ML model (SVD, Logistic Regression) for the 6-miRNA sputum signature demonstrated high accuracy (AUC = 0.92; CI 95% 0.86-0.97) in distinguishing cases and controls. The two defined signatures exhibited no overlap in the miRNAs between the two fluids. Regarding circRNAs, 4 circRNAs were identified with high accuracy (AUC = 0.75; CI 95% 0.83-0.97) and a odds ratio greater than 4 (OR = 4.28, range: 2.32-7.88).

Conclusion

This study identified two distinct miRNA fluid-specific signatures for plasma and for sputum, along with a circRNA-based signature in plasma samples. These signatures have the potential to serve as non-invasive biomarkers for the early detection of lung cancer, enhancing precision-based screening and supporting better clinical decision-making in the management of lung nodules.

EACR25-2173

Histamine dihydrochloride induces myeloid cell production of the anti-metastatic protein thrombospondin-1

N. Issdisai¹, H. Grauers Wiktorin², M. Kaya¹,

K. Hellstrand³, A. Martner¹

¹*Biomedicine, Microbiology and Immunology, Gothenburg, Sweden*

²*Immunology, Genetics and Pathology, Uppsala, Sweden*

³*Biomedicine, Virology, Gothenburg, Sweden*

Introduction

Metastatic disease accounts for the majority of deaths among cancer patients and new anti-metastatic treatment options are thus highly warranted. Thrombospondin-1 (TSP-1) is a natural endogenous angiogenic inhibitor that may suppress metastasis in cancer patients. In addition to reducing angiogenesis, TSP-1 is reported to modulate the tumor microenvironment via effects on macrophage

polarization. Platelets are the main source of TSP-1, but it may also be produced by other cell types, including myeloid cells. In preclinical studies, myeloid-cell-derived TSP-1 was shown to limit the metastatic burden in mice orthotopically injected with metastatic tumor cells.

Material and method

Primary human monocytes and myelomonoblastic PLB-985 cells were cultured in the presence or absence of histamine dihydrochloride (HDC), and supernatants were analyzed for TSP-1 levels. Additionally, TSP-1 production by human monocytes was analyzed following treatment with different cyclic AMP (cAMP) inducers or HDC in the presence or absence of protein kinase A (PKA) inhibitors. In *in vivo* experiments, wild-type (WT) and TSP-1 knock-out (KO) mice received three bi-daily intranasal injections of lipopolysaccharide (LPS) to induce lung inflammation. HDC or vehicle was administered via intraperitoneal (i.p.) injections prior to each LPS dose. Mice were sacrificed one day after the final LPS/HDC administration, and lungs were analyzed for TSP-1, IL-6, and IL-1 β levels by ELISA or Western blot, as well as for myeloid cell infiltration by flow cytometry. Moreover, WT and TSP-1 KO mice were treated systemically with HDC before and after intravenous injection of B16F10 cells, and the number of lung metastases was enumerated three weeks later.

Result and discussion

HDC was found to be a robust inducer of TSP-1 of human and murine myeloid cells *in vitro* and *in vivo*. The TSP-1-inducing effect of HDC was mediated through histamine type 2 receptors via the cAMP/PKA signaling pathway. Systemic administration of HDC suppressed lung metastases from B16F10 melanoma cells in WT mice, but had no effect on metastasis formation in TSP-1 KO mice. Western blot analysis of lung tissues confirmed increased TSP-1 production in HDC-treated WT mice compared to untreated counterparts. In an *in vivo* inflammation model, we found that HDC reduced LPS-induced production of the pro-inflammatory cytokines IL-1 β and IL-6, in the lungs of WT mice. However, this effect was abolished in TSP-1 KO mice.

Conclusion

Together, our findings suggest that HDC stimulates production of TSP-1 from myeloid cells, which may help limit lung inflammation and reduce metastasis formation. Additional studies are however needed to further define the effects of HDC-induced TSP-1 production on neo-angiogenesis, macrophage polarization, and inflammation within the pre-metastatic niche.

EACR25-2176

Spatial profiling of the colonic immune microenvironment reveals modulation by intestinal estrogen receptor beta and sex

M. Holm^{1,2}, L. Stepanauskaitė^{1,2}, A. Bäckström¹,

K. Westberg³, M. Birgersson^{1,2}, L. Lindquist¹,

A. Archer^{1,2}, M. Karlsson³, C. Stadler¹, C. Williams^{1,2}

¹*KTH Royal Institute of Technology, Department of Protein Science, Solna, Sweden*

²*Karolinska Institutet, Department of Medicine, Huddinge, Sweden*

³Karolinska Institutet, Department of Microbiology, Tumor and Cell Biology, Solna, Sweden

Introduction

Inflammation and immune cells in the tumor microenvironment play a critical role in colorectal cancer (CRC) progression. Notably, sex differences exist in CRC incidence, with men at higher risk. Estrogen has protective effects against CRC, and intestinal estrogen receptor beta (ER β) has been shown to reduce colitis and CRC development. However, its role in shaping the colonic inflammatory immune landscape remains unclear.

Material and method

Using the COMET multiplex immunofluorescence platform, we analyzed colonic tissues from wild-type (WT) and ER β KO-Vil mice (N=32) to assess immune cell infiltration with full spatial context. Unsupervised clustering, spatial image analysis (SPIAT), and manual quantification were performed to characterize immune cell populations. Additionally, plasma cytokine assays were used to evaluate systemic immune responses. Macrophage polarization assays were conducted to examine the effects of CRC signaling on macrophage differentiation *in vitro*.

Result and discussion

Our findings reveal that intestinal ER β plays a role in modulating the colonic immune microenvironment under both healthy and inflammatory conditions. Loss of ER β significantly alters macrophage infiltration, with a pronounced effect in males. Furthermore, we observed regional differences in immune cell distribution. ER β KOVil mice exhibited an amplified systemic immune response to colitis and CRC, suggesting a broader regulatory role for ER β in inflammation. *In vitro*, macrophage polarization assay did not show ER β -dependent differences.

Conclusion

These findings highlight the sex-dependent effects of intestinal ER β in shaping the colonic immune landscape. ER β deficiency leads to altered macrophage dynamics and heightened systemic inflammation, particularly in males. This provides novel insights into the sex-specific development of CRC and suggests the possibility of using ER β -selective ligands as immune modulators in CRC.

EACR25-2177

Lysosome Exocytosis Inhibition Impairs Breast Cancer Cell Invasion

A. Rodrigues¹, C. Escrevente¹, T. Barona¹, D. Barral¹

¹NOVA Medical School, Universidade NOVA de Lisboa, iNOVA4Health, Lisbon, Portugal

Introduction

Breast cancer (BC) is the most frequently diagnosed type of cancer and the second leading cause of cancer-related deaths in women, with metastasis being associated with poor prognosis and a decrease in patient overall survival. Metastasis formation requires the acquisition of migratory and invasive capacities by BC cells, allowing them to colonize adjacent tissues and form secondary tumors in distant sites. Previous studies indicate that lysosome exocytosis is upregulated in BC cells, leading to alterations in the tumor microenvironment and

degradation of the extracellular matrix, therefore creating favorable conditions for tumor progression. In this study, we aimed to understand the effect of modulating lysosome exocytosis in BC cell invasion, which can lead to a novel therapeutic strategy to impair BC progression and prevent metastasis formation.

Material and method

To accomplish our goal, we used two BC cell lines: poorly invasive MCF-7 luminal A and highly invasive MDA-MB-231 triple negative BC (TNBC) cells. To modulate lysosome exocytosis, we silenced known regulators of this process, including RAB10 and RAB7A. Additionally, we treated cells with lysosome exocytosis modulatory compounds. Lysosome exocytosis levels were assessed by measuring the release of the lysosomal enzyme β -hexosaminidase, and invasion was evaluated through a transwell assay.

Result and discussion

Our results show that the silencing of RAB7A, an essential regulator of lysosomal trafficking, increases lysosome exocytosis and invasion of MDA-MB-231 BC cells. Conversely, the silencing of RILP, a RAB7A effector that mediates the retrograde transport of lysosomes, as well as late endosome-lysosome fusion, results in decreased lysosome exocytosis and invasion of MDA-MB-231 cells. Similarly, RAB10 silencing leads to a reduction in lysosome exocytosis and impairment of the invasion capacity of this line of TNBC cells. We also employed a drug repurposing strategy and identified two compounds that significantly decrease lysosome exocytosis and invasion of MDA-MB-231 BC cells. Additionally, treatment of MCF-7 cells with ML-SA1, an agonist of the TRPML family of calcium channels, increases both lysosome exocytosis and cell invasion. Overall, our results indicate a direct causal correlation between lysosome exocytosis and BC cell invasion.

Conclusion

Since lysosome exocytosis and BC cell invasion are directly correlated, our study suggests that the inhibition of lysosome exocytosis is a promising strategy to impair BC cell invasion. Furthermore, we identified two compounds that can be used towards this goal, which can lead to the impairment of metastasis formation and improvement of BC patient prognosis and overall survival.

A Vascularized Tumor-on-Chip Model for Patient-Relevant Drug Screening in Non-Small Cell Lung Cancer

S. Zeinali¹, K. Schmid¹, S. Schneider¹, R. Peng^{2,3}, T. Marti^{2,3}, O. Guenat^{1,2,4}

¹Organs-on-chip Technologies Laboratory, ARTORG Center, University of Bern, Bern, Switzerland

²Division of General Thoracic Surgery, Inselspital, University Hospital of Bern, Bern, Switzerland

³Department of BioMedical Research, University of Bern, Bern, Switzerland

⁴Department of Pulmonary Medicine, University Hospital of Bern, Bern, Switzerland

Introduction

The tumor microenvironment (TME) plays a critical role in cancer progression, metastasis, and therapy resistance.

Tumor cells dynamically interact with stromal components and the vasculature, influencing drug responses. While patient-derived xenografts (PDX) are widely used in preclinical research, they lack human immune components and are costly, time-consuming, and poorly scalable. Advanced in vitro microphysiological systems provide an alternative by incorporating patient-derived tumor cells, stromal components, and functional vasculature to better mimic the TME. Here, we developed a vascularized tumor-on-chip model to investigate the influence of microvascular networks on tumor drug response, with a focus on cisplatin treatment in non-small cell lung cancer (NSCLC).

Material and method

A microphysiological system was developed using a microfluidic platform where human endothelial cells and fibroblasts were embedded within a fibrin-based hydrogel to self-assemble into a perfusable microvascular network. NSCLC patient-derived tumor spheroids were placed onto the vascular network to allow integration and vascularization. Cancer-associated fibroblasts (CAFs) were induced from normal fibroblasts using tumor-conditioned medium to enhance stromal interactions. Vascular function was assessed by permeability assays and endothelial marker staining. Tumor responses to cisplatin were evaluated by live-cell imaging, apoptosis assays, and vascular integrity analysis.

Result and discussion

The model successfully established a functional tumor-vascular interface, with tumor spheroids integrating into the microvascular network. VEGF stimulation promoted endothelial sprouting toward tumor spheroids, confirming angiogenic interactions. Chemotherapy response analysis revealed reduced tumor viability and increased apoptosis in vascularized tumors, highlighting the impact of microvascular perfusion on drug delivery. Notably, tumor vascularization influenced cisplatin sensitivity, demonstrating the importance of incorporating functional vasculature in drug testing platforms. The presence of CAFs further modified drug responses, emphasizing the role of stromal interactions in therapeutic outcomes.

Conclusion

This vascularized tumor-on-chip model provides a robust, patient-relevant platform for studying tumor-stroma-vascular interactions and drug responses. By replicating key aspects of the human TME, it offers a scalable and ethical alternative to PDX models, improving the predictive accuracy of preclinical drug screening and paving the way for personalized oncology applications.

EACR25-2191

From genotype to phenotype: how IDH1 mutations alter the landscape of intrahepatic cholangiocarcinoma

A. Seretny¹, L. Böse¹, L. Butthof¹, J. Rückheim¹, P. Macsek¹, K. Volz¹, D. Tschaarganeh¹
¹*DKFZ & Institute of Pathology, University Hospital, Cell Plasticity and Epigenetic Remodeling, Heidelberg, Germany*

Introduction

Mutations in IDH1 confer a gain-of-function neomorphic activity, leading to the accumulation of the onco-metabolite 2-hydroxyglutarate (2-HG). This metabolite induces epigenetic changes that alter gene expression and cellular differentiation. Although IDH1 mutations are frequently observed in intrahepatic cholangiocarcinoma (iCCA), their role in tumor progression, micro-environment remodeling, and immune modulation remains unclear. This study investigates the impact of IDH1 mutations on tumor-stroma interactions, immune cell infiltration, and potential therapeutic targets, including the chemokine CCL17, which recruits regulatory T cells (Tregs) and may contribute to immune suppression.

Material and method

We used a genetically engineered mouse model allowing in vivo introduction of IDH1 mutations alongside iCCA-associated oncogenic events. Tumor burden, survival, and microenvironmental changes were assessed using histopathology, transcriptomics, and proteomics. To evaluate the effects of 2-HG accumulation on extracellular matrix (ECM) composition and immune modulation, we combined multi-omics analysis with immunohistochemistry to perform immunoprofiling, focusing on stromal and immune cell infiltration. Immunogenic peptide screening was conducted to explore mutation-specific vaccination strategies, and CCL17 was investigated as a potential immunosuppressive factor.

Result and discussion

IDH1 mutations significantly reduced survival in tumor-bearing mice. 2-HG accumulation led to epigenetic dysregulation, promoting tumor differentiation and altering ECM and stromal composition. Notably, IDH1-mutant tumors exhibited a desmoplastic phenotype, characterized by excessive ECM deposition and stromal expansion, which may contribute to immune evasion. Immune profiling revealed shifts in T cell populations, suggesting an immunosuppressive microenvironment. Proteomic and transcriptomic analyses identified increased CCL17 expression, supporting its role in Treg recruitment and tumor-driven immune evasion. Targeting CCL17 could provide a therapeutic strategy for overcoming immune suppression. Additionally, an immunogenic peptide was identified, with potential for mutation-specific immunotherapy.

Conclusion

These findings establish IDH1 as a key driver of tumor microenvironment remodeling, differentiation, and immune modulation in iCCA. The pronounced desmoplastic nature of IDH1-mutant tumors suggests a role for stromal expansion in shaping the immune landscape. The observed stromal and immune changes underscore the impact of 2-HG accumulation, while the identification of CCL17 as a Treg-recruiting chemokine highlights a novel immunosuppressive mechanism. Targeting CCL17 or incorporating mutation-specific immunotherapy may offer new strategies for IDH1-mutant iCCA.

EACR25-2214**Targeting tumor hypoxia and immune blockade to improve breast cancer therapy**

L. Svajda¹, S. Surguta², V. Lener³, M. Rezeli⁴, M. Cserepes⁵, J. Tóvári²

¹*Doctoral School of Semmelweis University, National Institute of Oncology and the National Tumor Biology Laboratory, Budapest, Hungary*

²*National Institute of Oncology and National Tumor Biology Laboratory, Budapest, Hungary*

³*KINETO Lab Ltd., Budapest, Hungary*

⁴*Department of Biomedical Engineering, Lund University and BioMS—Swedish National Infrastructure for Biological Mass Spectrometry, Lund University, Lund, Sweden*

⁵*National Institute of Oncology and National Tumor Biology Laboratory, Hungary*

Introduction

Tumor hypoxia is linked to several negative consequences, such as increased metastatic potential, metabolic reprogramming, and angiogenesis via the activation of the hypoxia-inducible factor 1 (HIF-1). It also contributes to immune suppression which induces programmed death ligand 1 (PD-L1) expression, preventing T cell activation. Immune checkpoint inhibitors (ICIs) have significantly advanced cancer therapy by inhibiting immune blockade-generating molecules. However, HIF-1 promotes aberrant vascularization that impedes immune cell infiltration and increases resistance via ATP-binding cassette (ABC) transporter expression. We hypothesize that combining hypoxia-targeting agents with PD-L1 inhibition may improve ICI efficacy. Therefore, this approach was investigated in breast cancer models and clinical samples.

Material and method

Proteomic analysis was conducted via data-independent acquisition mass spectrometry to evaluate the effects of hypoxia and acriflavine. Pathway analysis was performed using DAVID. TCGA breast cancer datasets were examined through UCSC Xena to assess the relationship between HIF-1α and PD-L1 expression and survival outcomes. Immunohistochemistry tumor microarrays were used to validate these findings.

Result and discussion

Survival analysis showed that while HIF-1α expression did not impact survival, a key HIF-1-target gene correlated with worse outcomes. We did not find a significant relationship between HIF-1α and PD-L1 in breast cancer cell lines. However, the clinical sample analysis proved that HIF-1α levels were associated with elevated PD-L1 expression. Proteomic analysis showed that hypoxic treatment upregulated mitochondrial protein degradation, cholesterol biosynthesis, and fatty acid β-oxidation. Acriflavine counteracted these changes by downregulating mitochondrial translation, protein metabolism, and rRNA processing, impairing hypoxia-driven metabolic shifts.

Conclusion

Our findings highlight that co-targeting HIF-1 and PD-L1 could enhance breast cancer therapy by improving ICI efficacy. The next step is developing *in vivo* models to assess this strategy.

This study was funded by the National Tumor Biology Laboratory (2022-2.1.1-NL-2022-00010), the Hungarian Thematic Excellence Program (TKP2021-EGA-44), and NKFIH-OTKA grants K147410 (JT) and PD142272 (MC).

EACR25-2228**Dissecting the role of retinoic acid signaling in human chronic lymphocytic leukemia using novel 3D lymph node-like microenvironments**

Introduction

The microenvironment of secondary lymphoid organs is composed of various cell types, including fibroblastic reticular cells (FRCs), which play a crucial role in providing signals to promote activation and survival of normal and malignant B cells such as in chronic lymphocytic leukemia (CLL). We have discovered a retinoic acid (RA)-dependent FRC-leukemia crosstalk during CLL progression in mice and demonstrated that pharmacological inhibition of the RA pathway reduces tissue infiltration and CLL progression in preclinical models. Here we further explored the role(s) of the RA pathway in human FRC-CLL crosstalk using several approaches, including a newly established humanized lymph node (LN)-like microenvironment suitable for mechanistic studies under more physiological conditions.

Material and method

We used 2D and 3D culture systems of human lymph node fibroblasts and primary human CLL cells; RNA-scope, RNA-seq, western blot, flow cytometry and confocal microscopy.

Result and discussion

Using the RNA-scope, we detected upregulation of genes involved in RA synthesis, RA degradation and RA signaling in human CLL-LN biopsies compared to control tissues. Specifically, we found that the transcription factor Retinoid X Receptor (RXR) alpha, an RA nuclear receptor is overexpressed at mRNA and protein levels in hCLL cells compared to control B cells. Using 2D co-cultures and 3D spheroids, we demonstrated that inhibition of RXR alpha reduces CLL adhesion and prevents CLL cell aggregation and spheroid formation. To further investigate the functional role of RXR alpha

inhibition, we used a 3D lymph node-like microenvironment cultured in a bioreactor and found that inhibition of RXR alpha impaired the interaction of hFRCs and hCLL and promoted the mobilization of leukemic cells from the 3D niche. To study the molecular mechanism underlying this phenotype, we performed bulk RNA-seq on hCLL and hFRCs after treatment with an RXR antagonist and found that RXR alpha inhibition caused deregulation of multiple molecular pathways, including cell adhesion, fatty acid metabolism, and cytokine signaling.

Conclusion

Our results show that the retinoic acid signaling pathway is upregulated in hCLL-LN biopsies *in vivo* and in hCLL cells from the peripheral blood. We demonstrated a functional role of RXR alpha and RA signaling in promoting interactions of hCLL and hFRCs, and hCLL retention within the microenvironment. We are currently investigating the underlying mechanism of RXR alpha overexpression and function.

⁴*INSERM, Paris, France*

Introduction

Clear cell renal cell carcinoma (ccRCC) is the most prevalent form of kidney cancer, characterized by a pseudo-hypoxic state that drives tumor invasion, hypervasculization, and the recruitment of stromal components, including cancer-associated fibroblasts (CAFs) in the tumor microenvironment. CAFs play a pivotal role in promoting aberrant blood vessel formation, epithelial-mesenchymal transition, extra-cellular matrix remodeling, immune evasion, and therapy resistance. Our team recently identified aberrant vascular structures within ccRCC that exhibit dramatic dimensions and irregular morphology, surrounded by thin mural cell layers and strongly differing from the tumor capillaries. The presence of these aberrant structures correlates with patient prognosis and is frequently observed in CAF-rich regions, both within the tumor and in the surrounding peritumoral fibroblastic capsule. Notably, a high intratumoral CAF density has been associated with poor clinical outcomes. This doctoral research aims to decipher the role of CAFs in ccRCC pathogenesis, with a particular focus on their involvement in aberrant vascularization and resistance to tyrosine kinase inhibitors and/or immune checkpoint inhibitors.

Material and method

This study investigates the functional interactions between CAFs, tumor cells, and endothelial cells using a

3D *in vitro* model of vascularized microtumors (VMT) developed by our team. Specifically, fibroblast-mediated paracrine regulation of tumor-endothelial cell interactions supports the formation of aberrant vascular structures within the VMT model, recapitulating key features observed in ccRCC patients. Various 3D *in vitro* models are used to assess the impact of patient-derived or *in vitro* engineered CAFs on tumor invasiveness, formation of aberrant structures, and drug sensitivity. In parallel, the contribution of CAFs to aberrant vascularization will be further elucidated in cohorts of ccRCC patients, using spatial transcriptomic profiling (Visium, 10X Genomics).

Result and discussion

Using 3D *in vitro* models, we demonstrated that ccRCC tumor cells activate fibroblasts through both paracrine regulation and direct interactions, enhancing their invasive capacities and ability to acquire CAF-like features. Additionally, the heterotypic spheroid model reveals that leader CAFs drive the invasion of follower tumor cells. Moreover, the alphaSMA⁺ CAFs and/or mural cells exhibit specific intratumoral patterns in proximity to aberrant vascular structures in the ccRCC patient samples.

Conclusion

This ongoing project characterizes paracrine and direct interactions between CAFs, ccRCC tumor cells, and endothelial cells, using both *in vitro* models and patient samples. The study provides insights into the tumor microenvironment, aberrant vascularization, and treatment resistance, potentially leading to therapeutic combinations with CAF-targeted treatments.

CSF1R Haploinsufficiency in the Tumor Microenvironment and Its Impact on CLL Progression

N. Rosen¹, G. Rodriguez Real¹, N. Reinart¹, P. Nguyen¹, M. Hallek²

¹*University of Cologne, Department I of Internal Medicine, CECAD, Cologne, Germany*

²*University of Cologne, Department I of Internal Medicine, CIO, Cologne, Germany*

Introduction

Chronic lymphocytic leukemia (CLL) is a malignancy that critically depends on its tumor microenvironment for survival and expansion. In particular, monocytes and macrophages play essential roles by providing survival signals and fostering an immunosuppressive niche. The colony-stimulating factor 1 receptor (CSF1R) is a central regulator of these myeloid cells and has recently emerged as a promising target for therapeutic intervention in CLL.

Material and method

In this study, we used mice with a partial knockout of the *Csf1r* gene to simulate the degree of inhibition that could be achieved with therapeutic antibodies. These heterozygous mice were crossed with the well-established Eμ-TCL1 CLL model. Detailed analyses were performed on the myeloid compartments by assessing CSF1R expression on circulating monocytes and tissue-resident macrophages. Disease progression was meticulously monitored over time through serial *in vivo* observations, and *in vitro* migration assays were employed to evaluate

the functional impact of CSF1R reduction on CLL cell motility.

Result and discussion

Our experiments demonstrated that heterozygous mice had a marked decrease in CSF1R expression on circulating monocytes compared to wild-type controls. Despite this reduction, the absolute numbers of monocytes and macrophages in both blood and lymphoid tissues remained largely unaltered, suggesting compensatory mechanisms that maintain myeloid homeostasis. Importantly, *TCL1tg/wt Csflr+/-* mice exhibited a significant yet transient reduction in leukemia burden at approximately 8 months of age. This initial benefit, however, waned as the disease advanced, with overall survival rates eventually aligning with those of mice expressing normal CSF1R levels. Additionally, our *in vitro* migration assays revealed that diminished CSF1R expression impaired the migratory capacity of CLL cells, indicating that CSF1R may be critical for the effective dissemination of malignant cells within the tumor microenvironment. These results underscore the complex interplay between CSF1R-mediated signaling and the dynamic regulation of immune cell functions in CLL, and they highlight the potential limitations of targeting CSF1R as a monotherapy.

Conclusion

The data presented herein suggest that while CSF1R plays a pivotal role in supporting the CLL tumor microenvironment, partial reduction of its expression only modestly delays disease progression. Our findings support the hypothesis that CSF1R-targeted therapies might yield the best outcomes when combined with additional agents that collectively disrupt the supportive interactions between CLL cells and their microenvironment. Further investigations into combination strategies are warranted to fully exploit the therapeutic potential of CSF1R inhibition in CLL.

Decoding Sarcoma Complexity: Harnessing *Xenopus tropicalis* for In Vivo Studies of Liposarcoma, Desmoid Tumors, and Beyond

*M. Boelens^{1,2}, T. Naert^{1,2}, W. Houbart^{1,2}, D. Tulkens¹,
S. Demuyncck¹, D. Creytens³, K. Vleminckx^{1,2}*

¹Ghent University, Department of Biomedical Molecular Biology, Ghent, Belgium

²Cancer Research Institute Ghent (CRIG), Ghent, Belgium

³Ghent University Hospital, Department of Pathology, Ghent, Belgium

Introduction

Sarcomas constitute a heterogeneous group of mesenchymal malignancies with diverse genetic drivers and clinical manifestations—from benign lesions and locally aggressive forms such as desmoid tumor, to malignant entities like liposarcoma. The complexity of these tumors underscores the high need for robust *in vivo* animal models to unravel their underlying biology and to identify novel therapeutic targets.

Material and method

In this study, we leverage the genetic amenability of

Xenopus tropicalis, whose large brood size, external development, and high genomic synteny with humans enable rapid generation of high-penetrance cancer models. Utilizing CRISPR/Cas9-based genome editing tools, we create F0 mosaic mutants (crisprants) to inactivate key tumor suppressor genes and test candidate co-drivers in sarcoma development. Our comprehensive downstream analyses combine targeted amplicon deep sequencing, single-cell RNA sequencing (scRNA-seq), immunohistological profiling, and three-dimensional imaging to thoroughly characterize these cancer models.

Result and discussion

We are investigating two distinct sarcoma models in *Xenopus tropicalis*. Desmoid tumors (DT) were obtained by targeting *apc* with a single guide RNA, creating a genetically straightforward, Wnt-driven model. The clear genetics of our model enables us to focus on tumor behavior; we hypothesize that DTs are immunologically cold—potentially due to diminished immune cell infiltration and/or a physical barrier from extensive collagen deposition. To investigate this, we are spatially mapping the cellular and extracellular tumor microenvironment using cell marker analysis coupled with 3D whole-mount light-sheet imaging. In contrast, our liposarcoma (LPS) model manifests as a paradigm for cancers with more complex genetics and poor therapeutic opportunities. Here, a multiplex CRISPR/Cas9 approach targeting the *p53* and *retinoblastoma* pathways simultaneously generated a mixed well- and dedifferentiated LPS subtype (i.e. WDLPS and DDLPS). Given the poor outcome of this cancer, we employ comprehensive transcriptomic profiling to identify co-driver genes, particularly those involved in the dedifferentiation process toward the more aggressive DDLPS phenotype.

Conclusion

Collectively, these findings illustrate the power of *Xenopus tropicalis* as a versatile *in vivo* platform for modeling sarcoma subtypes. Future investigations are warranted to clarify the molecular mechanisms driving liposarcoma dedifferentiation, refine immunomodulatory strategies in desmoid tumors, and extend these approaches to additional sarcoma subtypes, thereby advancing our understanding and treatment of these challenging malignancies.

ETV6::JAK2 fusion promotes central nervous system invasion in murine B-cell acute lymphoblastic leukemia

*T. Costa^{1,2}, T. A. Catarino¹, I. Pacheco-Leyva¹,
N. R. dos Santos¹*

¹i3S – Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal

²ICBAS – Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto, Portugal

Introduction

Acute lymphoblastic leukemia (ALL) is the most frequent pediatric malignancy and remains an important cause of mortality and morbidity in all ages. A subgroup of B-cell precursor ALL (BCP-ALL) patients with bad prognosis carries specific genetic alterations, including JAK2 fusions or mutations and CDKN2A deletions.

Disease relapse in these patients is often associated with central nervous system (CNS) invasion.

Material and method

To study the impact of constitutively active JAK2 kinase signaling in CNS involvement by B-ALL, we generated mice expressing an ETV6::JAK2 fusion in the lymphoid lineage, in a leukemia-prone genetic background (Rag2 and Cdkn2a deficiency).

Result and discussion

Indeed, in comparison to Rag2^{-/-};Cdkn2a^{-/-} littermates, ETV6::JAK2;Rag2^{-/-};Cdkn2a^{-/-} mice exhibited earlier onset of B-ALL and presented more frequent CNS invasion (e.g., paraparesis/paraplegia of hind limbs). Immunohistochemical analyses of diseased ETV6::JAK2;Rag2^{-/-};Cdkn2a^{-/-} and Rag2^{-/-};Cdkn2a^{-/-} mice revealed leptomeningeal invasion by B220+PAX5+ cells expressing phosphorylated STAT5, a JAK kinase substrate. In vitro treatment of primary leukemic cells with AZD1480 (JAK2 inhibitor) significantly impaired the survival of ETV6::JAK2;Rag2^{-/-};Cdkn2a^{-/-} cells but not Rag2^{-/-};Cdkn2a^{-/-} cells. To assess JAK2 signaling dependency in vivo, Rag2^{-/-};Il2rg^{-/-} mice injected intravenously with ETV6::JAK2-driven B-ALL cells were treated for four days with FDA-approved JAK1/JAK2 inhibitor Ruxolitinib (50 mg/kg/daily) upon detection of > 1% peripheral B-ALL blasts. Ruxolitinib-treated recipients exhibited a significant reduction in circulating B-ALL cells and concomitant increased number of cleaved caspase 3-labeled apoptotic cells in the spleen, in comparison to vehicle group. Moreover, to grasp the dynamics of CNS invasion by B-ALL, we infused CD45.2-expressing ETV6::JAK2;Rag2^{-/-};Cdkn2a^{-/-} and Rag2^{-/-};Cdkn2a^{-/-} cells in Rag2^{-/-};CD45.1+ recipients and detected leukemic cells in the cerebrospinal fluid (CSF) at different timepoints, via flow cytometry analysis. Mice injected with ETV6::JAK2-driven B-ALL presented earlier and significant higher invasion of CSF by CD45.2+B220+ cells compared to recipients transplanted with Rag2^{-/-};Cdkn2a^{-/-} leukemia, but similar tumor burden in the bone marrow.

Conclusion

In conclusion, the ETV6::JAK2 fusion promotes leukemia survival, accelerates disease development, and confers increased neurotropism to leukemic cells.

EACR25-2285

Charting the immune landscape and communication axes in metastatic colorectal cancer with spatial transcriptomics

Introduction

Colorectal cancer (CRC) globally ranks among malignancies with highest incidence and recurrence rates, afflicting almost one million subjects each year. Despite the wealth of studies carried out in CRC correlating the degree and type of immune infiltration with invasive capability, spatial relationships governing the interplay between immune and tumor cells in the CRC tumor microenvironment (TME) have been thus far explored at coarse-grained scale. In this work, we employ spatial profiling technologies to investigate the cellular ecosystem of metastatic and non-metastatic CRC, providing a comprehensive picture of the spatial architecture of immune cell responses at play and elucidating their role in the progression towards an invasive cancer phenotype.

Material and method

To identify links between spatial determinants of the CRC ecosystem and the process of tumor metastasization, we assembled an initial retrospective cohort of primary tumor FFPE samples from 16 CRC patients with either overt or undetectable metastases after surgery. Samples were processed for targeted spatial transcriptomics with the latest version of the CosMx™ SMI platform, profiling the expression of ~6,000 different genes in situ resulting in a comprehensive collection of more than 2.2 million single-cell transcriptomes coupled to their spatial location.

Result and discussion

Leveraging a large-scale scRNA-seq cohort, we uncover the transcriptional diversity of malignant cells across more than 100 CRCs at single-cell resolution. Notably, cancer cells exhibited a state marked by features of TNF signaling and hypoxia response, active in primary tumors prone to form metastases. This transcriptional state also correlated with increased IFN response, inflammation and EMT programs, suggesting an intimate link between the metastasization potential of these cells and immune compartments of the CRC TME. Integrating spatial information with the depth provided by scRNA-seq data facilitated cell type annotation and the identification of malignant cell states directly in situ, revealing how metastatic CRC spatially orchestrates expression of these gene programs. To further connect features of the CRC TME with the development of pro-metastatic cancer cell states, we correlated the abundance of local ligand-receptor interactions in the CRC TME with the activity of transcription factors linked to the emergence of invasive cancer cell states.

Conclusion

By combining large-scale scRNA-seq data and targeted spatial approaches we gathered an unbiased look into the molecular and physical architecture of metastatic and non-metastatic CRC. Cancer cells displayed gene programs which are intimately linked to the surrounding composition of the tumor bed they reside in. Ultimately, this work provides initial mechanistic insights into how TME signals drive metastatic potential in CRC.

Introduction

Gastric cancer represents a poor prognosis disease. Indeed, the 5-year survival rate in Europe is 32%. The heterogeneity of the disease represents a major issue. Molecular profiling studies have revealed the existence of four main different subtypes highlighting different targets for personalized medicine. Currently, chemotherapy is the standard-of-care for this disease, but its high heterogeneity and the discovery of new targets for personalized medicine calls for an urgent need for patient-derived preclinical models aimed at the fast identification of individualized combination therapies to improve clinical outcomes and avoid undesired side effects. The present project is aimed at generating a platform to test drug combinations active in gastric cancer. It is based on the setting-up of Gastric Cancer derived Organotypic Cultures (GC-OC) that retain the main characteristic of the primary tumour.

Material and method

We took advantage of two syngeneic mice models of gastric cancer, YTN3 and YTN16 that differ in drug sensitivity. To generate GC-OC, tumors were subjected to mild dissociation followed by serial filtration. The obtained organotypic spheroids (40-100 µm) were then seeded in a miniaturized microfluidic device to generate 3D-collagene embedded cultures in an appropriate medium. Flow cytometry and immunofluorescence analysis were performed to analyze GC-OC cell composition. Cell viability was evaluated by Acridine Orange (AO)/ Propidium Iodide (PI) staining and confocal imaging of 3D cultures. Cell number was monitored by staining of the nucleus via Hoechst.

Result and discussion

We generated GC-OC as spheroids that keep neoplastic and stromal cells in their original matrisome, maintaining their spatial and functional organization. Immunofluorescence analysis of cell composition confirms the presence of the main components of the tumor microenvironment (e.g. cancer cells, immune cells, endothelial cells and fibroblasts) in the generated GC-OC. Immune cell composition was further investigated in the tumor and spleen of the mouse models leading to the identification of G-MDSC (Granulocyte-Myeloid Derived Suppressor Cell) as the main immune subpopulation that was retained by the GC-OC. Drug effects on cancer cell viability were also assessed, revealing differences in drug sensitivity with respect to the classical 2D culture.

Conclusion

Altogether, the data obtained in our lab has allowed the setting-up of a 3D cell culture system that is expected to result in the generation of tumor in-vitro-twins, a phenocopy of the patient tumor and its microenvironment. These in-vitro-twins could be exploited for therapy identification of effective personalized drug combinations in the clinical setting. Moreover, the eventual application of omics strategies will help to

define the features of the tumors and its microenvironment representing novel drug vulnerabilities.

Unveiling the role of Sialyl-Tn in pancreatic cancer progression and therapy

I. Ribeiro¹, A. Soares¹, M. Barbosa¹, M. Castillo-Martin², P. Videira³

¹UCIBIO-Applied Molecular Biosciences Unit, NOVA School of Science and Technology, Universidade NOVA de Lisboa, Department of Life Sciences, Caparica, Portugal

²Fundação Champalimaud, Molecular and Experimental Pathology Laboratory, Lisboa, Portugal

³UCIBIO-Applied Molecular Biosciences Unit, NOVA School of Science and Technology, Universidade NOVA de Lisboa, Department of Life Sciences, Caparica, Portugal

Introduction

Pancreatic cancer (PC) is a major cause of cancer mortality, with pancreatic ductal adenocarcinoma (PDAC) comprising ~90% of cases. PDAC exhibits extensive desmoplasia, immunosuppression and treatment resistance. While immunotherapy shows promise, current approved therapies for PDAC target PD-1 and are restricted to high microsatellite instability tumors (~2% of cases). Understanding the mechanisms of PDAC pathogenesis is crucial to identify better and more targeted therapeutics. Aberrant glycan expression drives cancer progression. A frequently expressed aberrant glycan is sialyl-Tn (STn), a truncated O-glycan modifying proteins like mucins. STn is linked with immunosuppression, poor survival and metastasis in other cancers[1]. We hypothesize that STn drives PC progression, and its targeting may hinder tumor development. Our study assesses STn and its main carrier protein's role in PC progression, clinical correlation, and immunotherapeutic potential.

Material and method

A cohort of 185 formalin-fixed paraffin-embedded (FFPE) samples, including precursor lesions, PDAC and metastases, was analysed by immunohistochemistry (IHC) for STn expression. Quantification used the H-score, considering luminal and cytoplasmic staining intensities. H-score was calculated based on the intensity of staining (0-3) and the percentage of stained cells. Two independent evaluators, including a pathologist, performed the scoring. Statistical comparisons were made between precursor lesions, PDAC, and metastases.

Result and discussion

STn was absent in healthy tissue and was present in precursor lesions and PDAC samples. STn levels were different across different precursor lesion types. Intestinal and pancreaticobiliary-type IPMNs (Intraductal Papillary Mucinous Neoplasms) had higher STn levels, likely due to differential mucin expression. The intestinal and pancreaticobiliary-type IPMNs express MUC2 and 1, respectively, both reported as STn carriers. STn expression in PDAC was heterogeneous (H-score between 0-260) with a non-significant trend toward reduction in post-chemotherapy. A significant increase in STn expression was found in untreated PDAC and

metastases in relation to low-grade IPMNs, and in metastases against high-grade IPMNs. These findings suggest that STn has a role in PC progression.

Conclusion

The results highlight that STn is tumor-specific and mainly expressed in later PDAC stages, particularly in metastases. These findings suggest STn plays a role in PC progression. Ongoing studies are exploring STn-associated immune phenotypes, STn carriers, immune checkpoints, and inflammation markers in the same cohort, alongside in vitro studies in PDAC cell lines overexpressing STn to further elucidate its role in disease progression.

EACR25-2296

Impact of Brain-Derived Neurotrophic Factor (BDNF) on Tight Junction (TJ) Proteins and Cell Adhesion and Migration in Breast Cancer: Implications for Brain Metastasis

M. Eshmela¹, W. Jiang¹, L. Ye¹, T. Martin¹

¹*Cardiff University, CCMRC, School of Medicine, Cardiff, United Kingdom*

Introduction

Brain-Derived Neurotrophic Factor (BDNF) plays a significant role in the modulation of tight junction-(TJ)-proteins and influences cell adhesion and migration, which are essential for both cancer metastasis and blood-brain-barrier (BBB) integrity. This study investigates the effects of BDNF on the expression of TJ proteins and the functional consequences on cell adhesion and migration in breast cancer cells and brain endothelial cells.

Material and method

Following treatment with BDNF, changes in the expression of TJ proteins including Claudins, Occludin, ZOs, JAMs, MAGIs and Nectins were assessed using quantitative PCR (qPCR) at different time points (30 minutes, 60 minutes, 2 hours, 4 hours, and 24 hours) with a baseline control (0-time point) in both MDA-MB-231 (breast) and HMECD3 (endothelial) cell lines. BDNF knockdown models were created using anti-BDNF siRNA to assess the functional consequences of BDNF signalling on cell adhesion and migration using Electric Cell-Substrate Impedance Sensing (ECIS).

Result and discussion

qPCR results indicated dynamic alterations in the expression of multiple TJ proteins, suggesting a regulatory role for BDNF in the maintenance of cell-cell adhesion and barrier integrity in both cell types.

Additionally, BDNF knockdown resulted in a significant decrease in cell adhesion and migration, highlighting the importance of BDNF in promoting the migratory behaviour of cancer cells and in maintaining BBB integrity.

Conclusion

These findings suggest that BDNF is a key regulator of cell adhesion, migration, and TJ proteins expression, implicating its role in cancer metastasis. Targeting BDNF/TrkB could provide a novel therapeutic strategy to

inhibit cancer cell migration and stabilize BBB integrity, preventing brain metastasis from breast cancer.

EACR25-2317

Epitranscriptional interplay of FOXA1 and MYC impact prostate cancer progression

M. Grieco^{1,2}, A. Avon², S. Sinha², F. Lazzaro³, M. Muzi Falconi³, M. Cereda^{1,2}

¹*University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy*

²*Italian Institute for Genomic Medicine, c/o IRCCS Candiolo, Candiolo (TO), Italy*

³*University of Milan, Department of Biosciences, Milan, Italy*

Introduction

FOXA1 and MYC oncogenes cooperate to drive prostate cancer (PCa) progression by remodeling chromatin and rewiring alternative splicing (AS) landscape. FOXA1 promotes splicing factors' expression to modulate AS, while MYC governs RNA processing machinery. Both regulations impact patient prognosis. While MYC's role in post-transcriptional regulation is well established, FOXA1's contribution remains less understood. Their interplay and overlapping influence on RNA processing is still under investigation, but their convergence in transcriptional control unveils new therapeutic opportunities to target PCa at the RNA level.

Material and method

AR-independent PCa cells (PC3) were depleted of either FOXA1 or MYC using siRNA. Nanopore direct mRNA and Illumina totalRNA libraries of 14 replicates (siFOXA1:4, siMYC:3, siCTRL:7) were sequenced. PC3 transcriptome was reconstructed. Differential analyses of isoform expression, usage, m6A methylation, and polyA tail length were conducted across conditions. To validate FOXA1-mediated m6A methylation, MeRIP-seq was performed on FOXA1 depleted and control samples. To evaluate RNA stability, FOXA1-depleted and control cells were treated with actinomycin D. Total RNA was collected at five time points (0-8 h) and Illumina sequenced. Differential expression and pathway analyses were performed. Finally, 10x-Visium spatial transcriptomic data from five sections of a PCa were analyzed for clustering and transcriptomic signature identification.

Result and discussion

We found that FOXA1 and MYC orchestrate a dynamic regulatory network influencing isoform expression in AS, RNA methylation, and localization. These TFs specifically remodel m6A modifications on isoforms linked to AS and RNA localization. Transcriptional blockade experiments confirmed that FOXA1 enhances mRNA stability of isoforms implicated in RNA processing. Both TFs govern polyA tail selection favouring short tails to increase expression of isoforms. Spatial analyses corroborated FOXA1- and MYC-mediated RNA processing regulation in distinct tumor clones. Network analyses pinpointed candidate splicing and RNA processing factors under FOXA1/MYC control, including SRSF7.

Conclusion

Our data highlight a central role of FOXA1 and MYC interplay in controlling co- and post-transcriptional

programmes of PCa. These TFs fine-tune the production of isoforms involved in AS and RNA localization enhancing their expression, reshaping their m6A methylation, shortening their polyA tails. Our comprehensive catalogue of full-length isoforms, driven by these oncogenic TFs, offers new means to tackle PCa progression.

EACR25-2332

Single-cell transcriptomics identifies vulnerabilities of osimertinib ex-vivo persister cells

F. Calero-Nieto¹, S. Talbot¹, L. Bradshaw¹, R. Miragaia¹, A. Koers¹, C. Rands¹, A. Hughes¹, S. D'Arcy¹, L. Magiera¹, N. Floc'h¹

¹AstraZeneca, Cambridge, United Kingdom

Introduction

Persister cells arise upon chronic treatment and constitute the origin of resistant cells. Understanding the biology and heterogeneity of persister cells is essential for the design of future treatment approaches. However, the study of persister cells has been strongly limited by our capacity to analyse small numbers of cells ex-vivo.

Material and method

PC9 drug-tolerant/persister (DTP) cells were characterised at single cell resolution in vivo. To this end, PC9 cells were implanted in the flank of female mice. Once tumours acquired the desired volume, mice were orally administered osimertinib daily at a dose of 25 mg/kg for 14 days. Vehicle-treated samples were used as a reference. Tumours were then dissociated and processed for single-cell RNA-seq using the 10X Genomics reagents or for single-cell protein analysis using CyTOF.

Result and discussion

Our results showed that the resulting osimertinib DTP population is transcriptionally heterogeneous. The comparison of the different transcriptional states identified a putative target which was confirmed at protein level using CyTOF. Further in vivo studies in PC9 cells using an antibody-drug conjugate (ADCs) against the identified putative target in combination with osimertinib resulted in ablation of a specific subpopulation of DTPs.

Conclusion

Our single-cell RNA-seq analysis of osimertinib-treated tumours highlighted that it is essential to investigate therapeutic response at single-cell resolution. The understanding of cellular heterogeneity is key to better understand combinatorial treatments. In our preclinical model, a specific subpopulation of DTPs was eliminated by combinatorial treatment which resulted in reduction in the heterogeneity of the resulting DTP population and ultimately in delayed re-growth of tumours.

Therapeutic Potential of miR-379 through modulating Breast Cancer Stem Cells via HSPA5-TGF β Axis

L. Lin¹, E. McCarthy², K. Wynne³, R. Dwyer²

¹University of Galway, School of Medicine, Galway, Ireland

²University of Galway, School of Medicine, Galway,

Ireland

³University College Dublin, School of Medicine, Dublin, Ireland

Introduction

Breast cancer (BC) remains a leading cause of mortality, with cancer stem cells (CSCs) driving tumour progression, therapy resistance, and metastasis.

MicroRNAs are key regulators of CSC dynamics. This study investigates miR-379, a tumour-suppressive miRNA in breast cancer. Using an *in vivo* proteomic approach, target prediction analysis and functional studies, this study aimed to identify the mechanism of action of miR-379 in BC.

Material and method

A 4T1 murine BC model with stable miR-379 enrichment (4T1-379) or control (4T1-NTC) was established. Tumour tissues were analyzed using liquid chromatography-tandem mass spectrometry (LC-MS/MS) for proteomic profiling. Bioinformatic prediction of miR-379 targets was conducted using TargetScan, miRDB, and miRTarBase. miR-379 enriched HCC1954, MDA-MB-231, and 4T1 BC cells were employed in functional studies. Mammosphere formation assays evaluated tumour initiation and self-renewal capacity. TGF- β 1 secretion in media was quantified by ELISA. Immunohistochemistry (IHC) assessed CD44 expression *in vivo*. Flow cytometry analysis targeting the stemness related panel CD24/CD44/CD90 was also performed.

Result and discussion

Six hundred differentially expressed proteins (DEPs) were identified, with 11 significantly downregulated and 43 significantly upregulated in miR-379 enriched tumours. HSPA5 was a DEP and a predicted target of miR-379 identified through multiple platforms.

Functional annotation using GO and KEGG analysis highlighted that miR-379-HSPA5 interactions regulate TGF- β production and signalling. First-generation mammosphere formation, an indicator of tumour-initiating activity, was significantly reduced in miR-379-enriched cells. This inhibitory effect persisted in second-generation mammospheres, an indicator of self-renewal ability, demonstrating that miR-379 impairs both tumour initiation and self-renewal capacity of BCSCs. This mirrored *in vivo* findings, where miR-379 suppressed tumour growth. ELISA revealed a significant reduction in TGF- β 1 secretion by miR-379-enriched cells. IHC analysis of miR-379-enriched tumours *in vivo* revealed downregulation of CD44, a key BCSC marker and downstream effector of TGF- β signalling. These results demonstrate that miR-379 inhibits stemness of BC by downregulating HSPA5, thereby suppressing the TGF- β 1-CD44 axis. Furthermore, flow cytometry analysis revealed that miR-379 increased the mesenchymal CD90+CD24+CD44+ cell subset, accompanied by a decrease in the less mesenchymal CD90+CD24+CD44- subset. This suggests that miR-379 alters BCSC heterogeneity by shifting cellular states towards a mesenchymal phenotype.

Conclusion

Our study establishes miR-379 as a potent suppressor of BC stemness by targeting the HSPA5-TGF- β 1 axis. By disrupting BCSC-associated pathways, miR-379 emerges as a promising RNA-based therapeutic candidate.

EACR25-2346**A uveal melanoma murine model which faithfully recapitulates organotropism and dormancy**

L. Isenegger¹, L. Palanga¹, S. Pant², Z. Maliga², A. Nirmal³, M. Karg⁴, S. Rodig⁵, P. Sorger², B. Ksander⁴, R. Haq¹

²Harvard Medical School, Laboratory of Systems Pharmacology, Boston, United States

³Brigham and Women's Hospital, Department of Dermatology, Boston, United States

⁴Massachusetts Eye & Ear Infirmary, Schepens Eye Research Institute, Boston, United States

⁵Brigham and Women's Hospital, Department of Pathology, Boston, United States

Introduction

Uveal melanoma (UM) is the most common intraocular malignancy, affecting more than 2,500 adults yearly in the United States. When confined to the eye, UM is often successfully treated with radiation or surgery. However, nearly half of the patients eventually develop metastatic disease, in some cases decades after primary diagnosis. Metastatic UM is highly resistant to current treatments, resulting in a very poor prognosis, with a mean overall survival of less than two years. The liver is nearly always the initial site of metastases. The preferential dissemination to the liver raises the possibility that hepatic microenvironmental factors contribute to metastatic progression and the resistance of UM to available treatments. However, the identification of such factors is limited by the lack of UM preclinical models that exhibit liver metastasis. We aim to elucidate the mechanisms underlying the characteristic hepatotropism in order to develop strategies to intercept metastatic progression and improve therapeutic options for metastatic UM.

Material and method

Here, we present a metastatic UM model using intraocular, intravenous and subcutaneous injection of patient-derived primary human UM cell lines (MP41 and Mel202) in immunocompromised mice. We performed CycIF (Cyclic Immuno-fluorescence) and scRNASeq on two metastatic sites to evaluate transcriptional differences between the tumor cells deriving from the liver and the lung. Additionally, this model enables in vivo studies of candidate targeted drug treatments such as the PKC inhibitor darovasertib, currently in clinical trial. A parallel approach of in vitro and in vivo CRISPR screens in three cell lines, or mice harboring xenografts respectively, treated with the kinase inhibitor is currently being validated through single gene knockout and mechanistical experiments.

Result and discussion

We describe a novel UM model whose metastasis closely resembles metastatic patterns observed in patients. After a latency of two to four months, we consistently see liver macrometastases irrespective of injection site.

Surprisingly, we observe single cells in non-hepatic sites such as the lung. Using highly multiplexed spatial profiling (CyCIF tissue imaging), we have further

defined the proliferation, dormancy, and oncogenic signaling in the two metastatic sites. Transcriptomic profiling and CRISPR screening of metastatic cells is currently being analyzed.

Conclusion

This model faithfully represents a unique opportunity to dissect the pathways that lead to UM hepatotropism and an extrahepatic dormancy-like phenotype as well as the opportunity of developing more effective therapeutic options in order to improve patient outcomes.

EACR25-2356**Genetic deconstruction of prostate cancer heterogeneity through a unique preclinical mouse modelling platform (ProMPt)**

N. Pandell¹, M. Tartagni¹, F. Gabel¹, R. Rota¹, A. Thankamony¹, E. Flittner¹, M. Bezz¹

¹Institute of Cancer Research, Cancer Biology, London, United Kingdom

Introduction

Prostate cancer is among the leading causes of cancer related death in men. An unmet need is the availability of genetically complex preclinical models to study disease development and response to therapy. The Prostate Cancer Preclinical Mouse Modelling Platform (ProMPt) utilizes a biobank of prostate cancer organoids that covers 150 genetically unique combinations as seen in patients. An exploratory characterization of 20 models is presented to showcase this platform and investigate the genetic basis of therapeutic response to androgen deprivation therapy (ADT).

Material and method

Mice harbouring inducible alterations for PTEN, TP53, MYC, TMPRSS2/ERG, RB1, and APC were bred to achieve 20 genetically unique models. Prostatic organoids were generated from these models and this syngeneic biobank has been characterized through bulk RNA sequencing and mass cytometry by time of flight (CyTOF) for phenotypic alterations in response to androgen deprivation therapy. Permutation of organoid culture media in combination with ADT revealed upregulation of druggable pathways that have been assessed through targeted drug screens in vitro and ProMPt mouse models.

Result and discussion

Viability assessment revealed varied response to long term ADT exposure across 20 genetically unique organoid models, with resistant lines harbouring 3 or more genetic alterations. To investigate the influence of culture media on response to therapy, organoids were deprived of EGF, Noggin, R-Spondin1, and A83-01 in combination with ADT prior to CyTOF data collection. A striking response was seen between EGF removal and increased sensitivity to ADT in a genotype dependant manner when focused on alterations in a Pten and P53 deleted background. Overexpression of MYC rescued this sensitivity and CyTOF analysis revealed Pten-P53-MYC organoids maintain upregulation of phosphorylated 4E-BP1 in EGF null and ADT conditions, indicating a cell autonomous mode of survival. These results were

translated to a targeted drug screen where ErbB, AKT, MAPK and translation inhibitors were assessed in multiple combinations in conjunction with ADT. Homoharringtonine, an FDA approved translation inhibitor, showed exceptional results in reducing viability when used in combination with ErbB inhibitors. This effect is currently being assessed *in vivo* against a Pten-MYC and Pten-P53-MYC model of prostate cancer.

Conclusion

ProMPt allows for rapid *in vitro* and *in vivo* modelling that can be used to investigate many aspects of prostate cancer biology. To demonstrate the platform, the therapeutic response of 20 unique prostate cancer organoids were assessed at the proteomic level. Vulnerabilities were further highlighted through permutation experiments which have been translated to active preclinical *in vivo* trials. ProMPt will soon be publicly available, providing a novel catalogue of prostate cancer material.

EACR25-2377

Microfluidic System for Tumor Microenvironment Investigation

W. Losa^{1,2}, R. Smolarczyk³, M. Milewska^{4,2}, S. Student^{1,2}
¹Silesian University of Technology, Department of Systems Biology and Engineering, Faculty of Automatic Control, Electronics and Computer Science, Gliwice, Poland

²Biotechnology Centre, Silesian University of Technology, Gliwice, Poland

³Maria Skłodowska-Curie National Research Institute of Oncology, Gliwice, Poland

⁴Silesian University of Technology, Department of Organic Chemistry, Bioorganic Chemistry and Biotechnology, Faculty of Chemistry, Gliwice, Poland

Introduction

Microfluidics offers a transformative approach to biological experimentation by providing precise fluid control and high throughput. The miniaturized scale of these devices makes them especially suitable for investigating the tumor microenvironment (TME). Integrating microfluidic technologies with hydrogels, that can mimic extracellular matrix enables more accurate simulation of *in vivo* condition.

Material and method

A microfluidic device was designed and fabricated using a combination of materials, primarily PMMA, a specialized membrane, and PDMS. The system comprises several distinct elements joined by an adhesive tape: a glass base serves as the support, overlaid by a main culture chamber with an upper membrane. Above this chamber, a medium channel is integrated with a PDMS barrier that permits gas exchange with the external environment. Thermoresponsive microgels based on poly(N-isopropylacrylamide) were used to create an artificial extracellular matrix. At 25 °C, these microgels form a stable colloid in the culture medium, allowing for the cell suspension and introduction to microchip. Upon heating to physiological temperature, microgel colloid undergoes a phase transition, gelling to form macroscopic physical hydrogel with an interconnected porous structure.

Result and discussion

Experiments with cancer cell lines demonstrated that the microfluidic platform supports long-term cell culture while enabling continuous microscopic observation. The device maintained cell viability and proliferation under dynamic conditions, highlighting its capability to replicate essential TME characteristics. The controlled modulation of matrix properties and flow dynamics further allowed for detailed investigations into cell-matrix interactions and potential therapeutic strategies.

Conclusion

The developed microfluidic system provides a robust and versatile platform for TME studies. The integration of multi-material microchip and thermogelling hydrogel enables a close simulation of *in vivo* microenvironment, offering significant potential to advance cancer biology research and therapeutic development.

EACR25-2378

Engineered 3D osteosarcoma microenvironment model: Bridging *in vitro*- *in vivo* gap in cancer research and anticancer drug screening

J. Stojkovska¹, I. Banicevic¹, M. Pavlovic¹, M. Milivojevic², R. Jankovic³, B. Obradovic¹

¹University of Belgrade, Faculty of Technology and Metallurgy, Belgrade, Serbia

²University of Belgrade, Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia

³University of Belgrade, Faculty of Medicine, Belgrade, Serbia

Introduction

Current treatments for osteosarcoma typically include surgical excision followed by neoadjuvant and adjuvant chemotherapy. Research attempts to streamline and improve these treatments, but progress is slow mostly due to limited translation of *in vitro* to *in vivo* studies. The aim of this work was to develop and validate an engineered three-dimensional (3D) osteosarcoma model based on macroporous composite scaffolds, as cell carriers, and biomimetic perfusion bioreactor for osteosarcoma research and anticancer drug screening.

Material and method

The scaffolds (4 mm thick discs, 9 mm in diameter) were produced by controlled gelation of hydroxyapatite (HAP) suspension in Na-alginate solution (2 wt.% alginate and 2 wt.% HAP) followed by freeze-drying and rehydration in the culture medium. Murine osteosarcoma K7M2-wt cells were seeded onto the scaffolds (15x106 cells cm⁻³ scaffold volume) and cultivated for 7 days in "3D Perfusion" bioreactors under continuous medium superficial velocity of 40 µm s⁻¹, while static cultures served as a control. To evaluate this model for anticancer drug screening, bioreactor cultures were treated with doxorubicin (1 µg cm⁻³), on day 1 (first study) or on day 7 (second study) and lasted for 1 day, while untreated bioreactor culture served as a control. The scaffolds were assessed regarding the cell metabolic activity by MTT, morphology and distribution by histological and scanning electron microscopy analyses. Masson-trichrome and reticulin staining were used for extracellular matrix (ECM) analysis, while quantitative real-time PCR (qRT-PCR) assessed osteosarcoma marker expression.

Result and discussion

After short-term cultures, biological assessment showed that the cells stayed viable and metabolically active, produced ECM, expressed osteosarcoma markers and spontaneously formed aggregates under both culture conditions. However, cells in the bioreactor culture exhibited higher metabolic activity, while the cell aggregates were slightly larger (~1.2-fold), more compact with higher amounts of reticular fibers, more numerous and more uniformly distributed throughout the scaffold compared to the static culture. These results could be explained by positive effects of flow on cells due to enhanced mass transport and adequate hydrodynamic shear stresses. Evaluation of the model for anticancer drug screening has shown a negligible effect of doxorubicin on individual cells as well as cell aggregates implying that the developed model more closely mimics *in vivo* drug responses than 2D cultures.

Conclusion

This study has shown potentials of engineered 3D osteosarcoma microenvironment model based on macroporous composite scaffolds, and perfusion bioreactor for relevant and reliable osteosarcoma research and anticancer drug screening.

EACR25-2403

Doxorubicin-induced Cardiotoxicity represents a Risk Factor for Lung Metastasis in Osteosarcoma

G. Sampaio-Ribeiro¹, T. Martins-Marques¹, H. Girão¹, C. Gomes¹

¹Univ Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR), Faculty of Medicine, Coimbra, Portugal

Introduction

Osteosarcoma is the most common primary malignant bone tumor in children and adolescents, with lung metastasis remaining the leading cause of mortality. Doxorubicin (DOX), a cornerstone chemotherapeutic agent, is widely used due to its efficient antitumor activity; however, its cumulative dose-dependent cardiotoxicity significantly limits its therapeutic potential. Moreover, emerging evidence suggests that chemotherapy may inadvertently promote metastasis, raising concerns about its long-term impact on disease progression. Herein, we investigate whether DOX-induced cardiotoxicity, with a focus on cardiac fibroblasts, promotes a pro-metastatic lung microenvironment in osteosarcoma.

Material and method

Cardiac fibroblasts were first exposed to DOX for 24 hours and then maintained in a DOX-free medium for 48 hours. Fibroblast activation status and fibrotic and inflammatory profiles were assessed by RT-qPCR, western blot and immunofluorescence. Senescence was evaluated by β-galactosidase immunostaining, p38/NF-κB signaling and SASP factors. A co-culture model was used to mimic the paracrine signaling of DOX-treated cardiac fibroblasts on lung fibroblasts, which are the most abundant stromal cells in the lung. Swiss nude mice

were pre-treated with DOX or PBS (control), followed by intravenous injection of 1×10^6 143B-luciferase osteosarcoma cells and monitored for lung metastasis formation by optical imaging. Heart and lung tissue were collected for analysis.

Result and discussion

Upon exposure to DOX, cardiac fibroblasts acquire a myofibroblast-like phenotype, with a marked expression of α-SMA, FAP, and PDGFR, along with upregulation of fibrotic (LOXL2, SPARC, CTGF, and Galectin-3), ECM remodeling markers (periostin and MMPs) and of pro-inflammatory cytokines TNF-α, IL-6, and IL-1β. Phalloidin staining revealed an increase in cell size, indicative of senescence, confirmed by the activation of p38, NF-κB, and the upregulation of SASP-related genes. Paracrine signaling from DOX-treated cardiac fibroblasts in co-cultures induced a pro-fibrotic and inflammatory phenotype in lung fibroblasts, resembling cancer-associated fibroblasts. *In vivo*, pretreatment with DOX, induced cardiac fibrosis and accelerated the formation of lung metastasis.

Conclusion

Our findings identify DOX-induced cardiotoxicity as a potential risk factor for lung metastasis and unveiled the role of cardiac fibroblasts in inducing a profibrotic premetastatic niche favorable to tumor cell seeding and outgrowth. Mitigating DOX-induced cardiac remodeling may represent a preventive strategy to reduce metastatic progression in osteosarcoma.

EACR25-2406

Extracellular Vesicles from Melanoma-Associated Fibroblasts Promote Pro-Tumourigenic Changes in Brain Endothelial Cells

M. Shelton¹, C. Anene², J. Nsengimana³, W. Roberts², J. Newton-Bishop⁴, J. Boyne²

¹University of Nottingham, Nottingham, United Kingdom

²Leeds Beckett University, Leeds, United Kingdom

³Newcastle University, Newcastle, United Kingdom

⁴University of Leeds, Leeds, United Kingdom

Introduction

Melanoma frequently metastasizes to the brain, where it is associated with poor survival and limited treatment options. While cancer-associated fibroblasts (CAFs) are known to support melanoma progression, their role in brain metastasis remains poorly understood. Small extracellular vesicles (sEVs) are key mediators of cell-cell communication within the tumour microenvironment, and CAF-derived sEVs may contribute to changes in brain endothelial cells that support metastasis.

Material and method

A melanoma-educated CAF model was developed *in vitro*, and sEVs were isolated and characterised using nanoparticle tracking analysis, electron microscopy, and western blotting. Proteomic and RNA sequencing were performed to profile sEV cargo. Functional assays assessed the effects of CAF sEVs on melanoma cell behaviour and brain endothelial remodelling, including invasion, migration, and vascular permeability.

Result and discussion

CAF-derived sEVs were taken up by melanoma cells and brain endothelial cells, promoting invasive behaviour in melanoma and altering endothelial cell morphology and function. Proteomic and RNA analyses identified sEV cargo linked to TGF β signalling and endothelial-mesenchymal transition. Blocking sEV secretion reduced these effects, suggesting a role for CAF sEVs in shaping the pre-metastatic niche.

Conclusion

These findings indicate that CAF-derived sEVs influence both melanoma cells and brain endothelial cells, potentially contributing to metastasis. Targeting CAF sEV pathways may offer new therapeutic approaches for patients with melanoma brain metastases.

EACR25-2417

Self-assembling peptide hydrogels as animal-free models of the tumour microenvironment

V. Erdelyi¹, M. Shelton¹, J. Ashworth², C. Merry², J. Curd¹

¹PeptiMatrix Limited, Nottingham, United Kingdom

²University of Nottingham, Nottingham, United Kingdom

Introduction

Current 3D in vitro models for studying development and disease often rely on animal-derived matrices, which suffer from ill-defined composition, batch-to-batch variability, and poor representation of human biology. These limitations contribute to the high attrition rate of new drugs transitioning from the lab to the clinic, particularly in oncology. Consequently, there is growing interest in synthetic alternatives that offer greater control over mechanical and biological properties to better replicate human tissues.

Material and method

We have developed a novel, animal-free 3D cell culture platform using a simple self-assembling peptide hydrogel (SAPH) to overcome the limitations of existing in vitro models. This SAPH is chemically defined, exhibits minimal batch variability, and can be tailored to mimic the mechanical and biological characteristics of specific tissues more accurately than traditional animal-derived matrices.

Result and discussion

Our platform has successfully modeled various tissue types, including breast cancer, glioblastoma, colorectal cancer, hepatocellular carcinoma, and acute myeloid leukemia. By tuning the SAPH's mechanical and biological properties, we have enhanced cell viability and in vivo-like behaviors, demonstrating its potential for both mechanistic studies and drug screening.

Conclusion

This chemically defined, animal-free 3D culture platform presents a viable alternative to Matrigel® and other animal-derived matrices. However, further research is needed to optimize matrix properties for specific cell lines and applications, ensuring robust and reproducible in vitro models for drug development and disease modeling.

²Universidade de Aveiro, Medical Sciences, Aveiro, Portugal

³Portuguese Oncology Institute of Porto, Porto Comprehensive Cancer Center Raquel Seruca, Porto, Portugal

⁴Institute of Experimental Biology and Medicine, Buenos Aires, Argentina

⁵University of Buenos Aires, IFIBYNE, Buenos Aires, Argentina

⁶University of Aveiro, iBIMED - Medical Sciences, Aveiro, Portugal

Introduction

RNA-binding proteins (RBPs) regulate gene expression post-transcriptionally, and their dysregulation can amplify cancer driver effects, stimulate tumor progression, and increase aggressiveness. TDP-43, an RBP involved in mRNA metabolism, is known for its role in neurodegenerative diseases (NDs), such as frontotemporal dementia and amyotrophic lateral sclerosis, but recent evidence implicates it in cancer. In triple-negative breast cancer, TDP-43 upregulation drives alternative splicing promoting tumor progression. Here, we investigated TDP-43 expression and function in estrogen receptor-positive (ER+) breast cancer.

Material and method

TDP-43 expression was assessed via Western blot in soluble and insoluble fractions of MCF-7 cells. Cells were treated with IC50 doses of 17 β -estradiol (E2), 4OH-tamoxifen (TAM), or fulvestrant (FUL). After 24 hours, confocal microscopy determined the subcellular localization of TDP-43 and ER α . TDP-43 was knocked down with a siRNA cocktail; after 24 hs, cells were processed for RNA sequencing or exposed to E2/anti-estrogens for 3 days before quantifying proliferation. Additionally, TDP-43 expression was examined in a small cohort of paired ER+ breast cancer samples ($n = 16$, pre- and post-neoadjuvant antiestrogen treatment) from the Portuguese Oncology Institute (CES IPO: 369/2017). Expression associations in the luminal TCGA and CPTAC datasets were analyzed using cBioPortal.

Result and discussion

RNA sequencing identified 17 upregulated and 14 downregulated genes (\log_2 fold change >2 or <-2 , FDR < 0.01). Upregulated genes related to cell cycle arrest, mitotic disruption, apoptosis, and altered cell adhesion/cytoskeletal integrity, while downregulated genes were involved in cell adhesion, extracellular matrix interactions and cytoskeletal organization. In the TCGA and CPTAC datasets, low TDP-43 expression associated with genes in innate immunity, cell adhesion, and lipid metabolism, whereas high TDP-43 expression correlated with genes related to transcription, spliceosome function, and DNA repair. Following TDP-43 knockdown, a 40% reduction in cell number and Ki67 expression were observed after 3 days. Moreover, TDP-43 knockdown abrogated E2's mitogenic effects and amplified growth

inhibition by TAM and FUL. Notably, ER inactivation with TAM or FUL increased TDP-43 insolubility promoted its nuclear translocation and reduced co-localization with ER α . In breast cancer tissues, TDP-43 showed cytoplasmic mislocalization, normalized to nuclear localization after endocrine therapy. CPTAC protein expression correlation analysis further indicated a significant association between TDP-43 and key ER-regulated genes.

Conclusion

This study is the first to demonstrate TDP-43's impact in ER+ breast cancer, suggesting a functional crosstalk of relevance to endocrine therapy and the need for further mechanistic research.

EACR25-2433

3D Patient-Derived Tumor Microtissues: Next Level In Vitro Model for Scalable and Reliable Preclinical Drug Testing

C. Veser¹, M. Rudnik¹, M. Zbinden¹, A. Pawlowska¹, S. Hutter¹, T. Issa¹, I. Agarkova¹, B. Ulmer¹, N. Goedecke¹, L. Ligeon¹

¹InSphero, Schlieren - Zürich, Switzerland

Introduction

Recent advancements in tumor biology have significantly deepened our understanding of the tumor microenvironment, enabling the development of innovative therapies. However, the majority of oncology drug candidates still fail during clinical trials due to inadequate preclinical models that do not sufficiently replicate tumor complexity and heterogeneity. These shortcomings limit the ability to predict therapeutic efficacy and resistance mechanisms. To address this issue, we have developed a refined preclinical model based on 3D patient-derived tumor microtissues.

Material and method

Our 3D InSight™ Primary Tumor platform preserves essential components of the patient tumor microenvironment while offering scalability for high-throughput screening and validation of therapeutics. Unlike other 3D in vitro and ex vivo models, including patient-derived organoids, PDX-derived organoids, and organotypic slice cultures, our platform uniquely retains the structural integrity and heterogeneity of the original tumor. Cellular composition was assessed using flow cytometry following tissue dissociation, while treatment responses to standard-of-care chemotherapeutics were evaluated

Result and discussion

Our findings confirm that 3D patient-derived tumor microtissues maintain key physiological traits of their original tumors. Flow cytometry analysis demonstrated that crucial tumor and stromal cell populations were preserved, highlighting the model's ability to reflect patient-specific tumor heterogeneity. Using fresh colorectal and breast cancer tissue samples, we successfully established uniform 3D microtissues with a 70% success rate. Additionally, exposure to chemotherapeutic agents produced responses consistent with those observed in clinical settings, underscoring the platform's translational relevance. By providing a model that mirrors tumor complexity, this system enables a

more accurate assessment of therapeutic responses and resistance mechanisms.

Conclusion

The 3D InSight™ Primary Tumor platform presents a robust and scalable approach for preclinical drug development. By maintaining the structural and cellular diversity of tumors, it offers an effective system for evaluating novel therapeutics in a clinically relevant manner. This high-throughput model facilitates the development of personalized oncology treatments, ultimately contributing to improved patient outcomes and advancing precision medicine.

EACR25-2438

Androgen Receptor Loss Drives Nuclear Instability in Cancer-Associated Fibroblasts: A Novel Mechanism of Tumor-Stroma Remodeling

S. Ghosh¹, P. Dotto²

¹Birla Institute of Technology and Science (BITS), Pilani, Department of Biological Sciences, Pilani, India

²University of Lausanne, Immunobiology, Lausanne, Switzerland

Introduction

Cancer not only mutates its own cells but also hijacks its surrounding microenvironment to support its growth. Cancer-associated fibroblasts (CAFs), the dominant stromal players, actively remodel the tumor niche. While nuclear abnormalities are well-documented in cancer cells, their role in CAFs remains largely unexplored. Here, we uncover a striking discovery: the loss of androgen receptor (AR), an early event in CAF activation, triggers nuclear instability – disrupting nuclear architecture, increasing micronuclei formation, and promoting nuclear envelope ruptures.

Material and method

Using primary human dermal fibroblasts (HDFs) and patient-derived CAFs from skin squamous cell carcinoma (SCC), we examined the effects of AR depletion on nuclear integrity. Genetic AR overexpression and pharmacological activation with the synthetic AR agonist ostarine were used to rescue nuclear abnormalities. AR silencing in melanoma cells was performed to assess whether this mechanism extends beyond fibroblasts. Chromatin immunoprecipitation (ChIP) and protein interaction studies were conducted to uncover lamin-associated transcriptional regulation and nuclear structural changes.

Result and discussion

Loss of AR in fibroblasts resulted in severe nuclear abnormalities, a phenotype mirrored in SCC-derived CAFs, which naturally exhibit reduced AR expression. Restoration of AR – either genetically or pharmacologically – rescued these defects, directly linking AR function to nuclear stability. Similar nuclear abnormalities were observed in AR-silenced melanoma cells, suggesting a broader role beyond fibroblasts. Mechanistically, AR loss disrupted the interaction between lamin A/C and the nuclear protein phosphatase PPP1, leading to increased lamin A/C phosphorylation at Ser 301 – a defining characteristic of CAFs. Strikingly,

phosphorylated lamin A/C at Ser 301 bound to the regulatory regions of CAF effector genes associated with the myofibroblast subtype, amplifying their activation. ChIP analysis revealed increased lamin A/C association with chromatin, directly influencing CAF gene expression. Furthermore, AR was identified as a key lamin A/C interactor, and its depletion led to persistent lamin A/C phosphorylation, depolymerization, and nuclear instability.

Conclusion

This study uncovers a previously unrecognized AR-lamin axis that safeguards nuclear integrity in the tumor microenvironment. The accumulation of phosphorylated lamin A/C and nuclear abnormalities in SCC and melanoma stroma suggests that AR loss drives CAF activation through lamin-mediated chromatin remodeling. By weakening stromal resilience and promoting tumor-supportive CAFs, AR depletion fuels tumor progression. Targeting AR signaling could offer a novel therapeutic strategy to restore nuclear stability and disrupt CAF-driven tumor support, potentially dismantling cancer's protective fortress.

EACR25-2449

Spatial mapping of breast cancer highlights discrete tumour microenvironments and differences in spatial tumour architecture between Black British and White British women

J. Haj-Shomaly¹, E. Heylen¹, K. Baird¹, E. Maniati¹, I. Wall², J. Wang³, A. Grigoriadis², L. Jones³, G. D'Amico¹, K. Hodivala-Dilke¹

¹BCI-QMUL, TME, London, United Kingdom

²KCL, London, United Kingdom

³QMUL, London, United Kingdom

Introduction

Breast cancer presents with earlier onset and more aggressive progression in certain ethnic populations, yet these groups remain underrepresented in clinical trials. Standard therapies are largely based on responses observed in Caucasian populations, often failing to adequately address the unique biological characteristics of breast cancer in diverse ethnic backgrounds women. Understanding the ethnic-specific biology of breast cancer by investigating the spatial architecture of the breast tumour microenvironment (TME) is crucial for developing more effective, tailored therapeutic approaches that improve outcomes across all populations.

Material and method

We set to investigate the biological drivers for ethnicity associated early onset of breast cancer by using a British patient cohort comprised of 45 Black British and 45 White British patients. These groups were matched for age, breast cancer subtype and disease stage, with all patients being treatment naïve. To capture spatial tumor heterogeneity, two tumor cores were obtained per patient: one from the tumor centre and one from the tumor leading edge. GeoMx spatial transcriptomics and Cell DIVE hi-plex immunostaining were employed to identify and validate differentially expressed genes and proteins within the tumor and TME.

Result and discussion

Through spatial mapping of the TME, our findings indicate significant transcriptional differences arise mainly in the immune and αSMA-positive stromal compartments of Black British and White British women. Interestingly, we identified significant alterations of hallmark pathways including ECM and immune related pathways across distinct tumour areas (centre vs edge) from these different ethnic groups. Additionally, Cell DIVE analysis reveals cellular phenotypic architectural and difference according to ethnicity.

Conclusion

Overall we show that breast cancer biology is differentially regulated in various ethnic backgrounds and lays the foundation for a deeper understanding of potentially identifying ethnically relevant treatment strategies for breast cancer.

EACR25-2454

Targeting RNA splicing as a novel therapeutic strategy in ovarian high-grade serous carcinoma

Y. Xu¹, Y. Ma¹, C. Wickremesinghe¹, A. Cheesman¹, I. McNeish¹, C. Fotopoulou¹, P. Cunnea¹, H. Keun¹, A. Nijhuis¹

¹Imperial College London, United Kingdom

Introduction

Ovarian High-grade Serous Carcinoma (HGSC) is the predominant ovarian cancer subtype and a leading cause of cancer mortality in women. Although new therapies such as PARP inhibitors have improved treatment options for some homologous recombination deficient (HRD) patients, disease progression is characterised by cycles of relapse, and inevitably, resistance to therapy. Thus, there is a clinical unmet need to address the lack of therapies available for these patients. Alternative splicing of RNA is a key mechanism for phenotypic diversity and splicing variants, and important in tumour progression and drug-resistance. Aryl-sulfonamides such as indisulam are molecular glue degraders that inhibit RNA splicing via protein degradation of RNA splicing factor RBM39. This leads to genome-wide RNA splicing defects such as intron retention and exon skipping that we hypothesise generate opportunities for combination therapy.

Material and method

We use comprehensive transcriptomic and proteomic analyses including long-read sequencing to elucidate functional consequences of RNA splicing interference. We employ 2D, 3D, and in-vivo models of ovarian HGSC for experimental validation and conduct drug library and CRISPR/Cas9 screens to identify new drug combinations and genetic dependencies for PARP inhibitors.

Result and discussion

Exposure to indisulam leads to large scale RNA splicing defects that are not random and enriched for cell cycle and DNA damage repair pathways. Consequently, indisulam increases the sensitivity to platinum and PARP inhibitors drug-resistant models in-vitro and in-vivo. Combination drug library and CRISPR/Cas9 knockout screens in therapy-resistant models have identified new combination therapies and additional RNA splicing modulators as dependencies for PARP inhibitors. Finally, proteogenomic approaches combining long-read

sequencing with mass-spec have demonstrated that indisulam produces aberrant transcripts that are translated into detectable peptides that may be targetable with immunotherapy.

Conclusion

RNA splicing interference with molecular protein degraders offers new strategies to sensitise to therapies in resistant ovarian HGSC through a dual action of targeting DNA damage repair and splicing-derived neoantigens.

EACR25-2464

ADAMTS1 orchestrates cell state dynamics in muscle regeneration and rhabdomyosarcoma

C. Berthelot¹, A. Bertrand¹

¹INSERM U1052 CRCL, Lyon, France

Introduction

Rhabdomyosarcoma (RMS) is the most frequent form of pediatric soft-tissue sarcoma and remains a medical challenge. RMS shares histological features with cells of the muscle lineage and this cancer is thought to arise from malignant transformation of myogenic precursors. It has been proposed that some early steps of myogenic differentiation are blocked in RMS, and that understanding how the normal process has gone awry could help to decipher the biological underpinnings of tumorigenesis and tumor escape.

Material and method

Here, we combine the use of murine transgenic and xenograft models, in vitro tools including organoids, and integrative multi-omic bulk and single-cell data analyses, to define the function of ADAMTS1 in muscle pathophysiology.

Result and discussion

Our results show that a matrix protein with hitherto unknown function, ADAMTS1, is involved in skeletal muscle regeneration, via modulation of focal adhesion pathway activity. We demonstrate that ADAMTS1 is a good prognosis factor in Fusion Positive-RMS (FP-RMS). In FP-RMS, ADAMTS1 drives a phenotypic switch that modifies invasion potential of tumor cells, suggesting that it may constitute a new therapeutic target.

Conclusion

Our results identify ADAMTS1 as a new prognostic marker in FP-RMS and underlies the need to characterize in depth the crosstalk between matrix and tumor cells, as a new putative lever to impact tumor aggressive cell state.

EACR25-2472

m6A epitranscriptome landscape in bladder tumors: translational impact in patients' prognosis and treatment outcome

⁴Biomedical Research Foundation Academy of Athens, Athens, Greece

Introduction

Bladder cancer (BlCa) exhibits a highly heterogeneous molecular landscape, resulting in non-personalized prognosis and treatment decisions. N6-methyladenosine (m6A) represents the most prevalent RNA modification, regulating RNA biology/metabolism and cellular homeostasis. Herein, we have profiled mutations/copy number variations (CNVs) and expression of m6A RNA machinery genes as well as m6A epitranscriptome in bladder tumors and healthy urothelium, and assessed their clinical relevance in BlCa patients.

Material and method

DNA-seq (MGI Tech) was performed in 96 bladder specimens (tumors: n = 87; normal urothelium: n = 9) using a custom-designed panel of enrichment probes (Agilent) for m6A writers (METTL3, METTL14, METTL16, VIRMA, WTAP, RBM15, RBM15B, ZC3H13), erasers (FTO, ALKBH5) and readers (YTHDF1, YTHDF2, YTHDF3, YTHDC1, YTHDC2, IGF2BP1, IGF2BP2, IGF2BP3). m6A-seq/MeRIP-seq (MGI Tech) was performed in 55 bladder specimens (tumors: n = 50; normal urothelium: n = 5) following m6A RNA immunoprecipitation. m6A writers and erasers expression quantified by RT-qPCR in a screening cohort of 213 patients. The UROMOL (n = 535) was analyzed as validation cohort for non-muscle-invasive BlCa (NMIBC), while the TCGA-BLCA (n = 412) and Mariathasan et al. (n = 348) cohorts were analyzed for muscle-invasive BlCa (MIBC). Colorimetric ELISA-like assay using m6A Abs performed for %m6A quantification. Disease relapse/progression for NMIBC and patients' mortality for MIBC were used as clinical endpoints for survival analysis.

Result and discussion

Deleterious mutations in m6A writers were highlighted in ~30% of tumors (25/87), compared to m6A erasers (3.2%) and readers (5.3%). Moreover, CNVs were detected in ~60% of the patients (52/87), with ~22% gain/amp of VIRMA in NMIBC. MIBC patients with deleterious mutations in m6A writer's complex presented higher progression risk ($p = 0.036$) and worse survival ($p = 0.010$). Moreover, VIRMA gain/amp was associated with higher %m6A levels and short-term relapse ($p = 0.019$) in NMIBC. Finally, reduced METTL3 expression correlated with higher risk for short-term relapse ($p = 0.004$) and progression ($p = 0.013$) of superficial (TaT1) to muscle-invasive (T2-T4) tumors, as well as with worse survival of MIBC patients ($p = 0.027$). Consistently, validation cohorts confirmed the poor treatment outcome of the patients with METTL3 loss, while METTL3-fitted multivariate models improved risk-stratification compared to clinical established markers.

Conclusion

Overall, genomic variations in m6A machinery and METTL3 expression regulation emerge as modern molecular markers to address BlCa clinical heterogeneity and guide personalized prognosis and treatment.

Unveiling the influence of Citrate on Prostate Carcinoma Tropism to Bone by a microfluidic model of bone metastasis

S. Avnet¹, A. Pasquarelli¹, M. Lipreri², G. Di Pomo², E. Boanini¹, M. Montesissa², N. Baldini¹

¹University of Bologna, Bologna, Italy

²Istituto Ortopedico Rizzoli, Bologna, Italy

Introduction

Prostate cancer (PCa) exhibits distinct metabolic traits – including unique citrate metabolism, high lactate production – and a pronounced affinity for bone. While bone's mineralised matrix, rich in citrate, mirrors healthy prostate tissue, PCa's reliance on bone-trapped citrate and its interplay with lactate in the metastatic niche remain poorly understood. Conventional 2D models inadequately replicate the 3D stromal-metabolic crosstalk critical to tumour progression.

Material and method

To dissect citrate's role in PCa bone tropism, we engineered a 3D microfluidic bone-on-a-chip model. This system integrates Osteocytes (citrate-secreting MLO-Y4 cells), a collagen type I matrix mineralised with hydroxyapatite nanoparticles (HA-NPs) synthesised with or w/o citrate, and physiologically tunable citrate gradients. Metastatic (PC3) and less metastatic (LNCaP) PCa cells were tested for chemoattraction toward citrate-enriched HA-NPs versus HA-NPs alone. Post-seeding, we quantified spheroid formation, viability, clonogenicity, metabolic adaptations (e.g., lactate production), cytotoxic effects on osteocytes, and osteogenic activity.

Result and discussion

The model replicated osteocytes' 3D dendritic network and bone metabolic dynamics. Citrate-enriched HA enhanced PCa chemoattraction, particularly in bone-metastatic PC3 cells, and increased spheroid formation without compromising viability. While tumour cell metabolic activity remained stable, citrate and HA buffered microenvironmental acidification during proliferation of highly glycolytic PCa cells, correlating with elevated clonogenicity. Notably, PCa-derived lactate triggered osteocyte apoptosis and stimulated citrate release, suggesting a feedforward loop where tumour-driven bone remodelling enriches citrate deposits, potentially fuelling metastatic growth.

Conclusion

Our 3D model uncovers a bidirectional interplay between PCa and bone: citrate enhances tumour aggressiveness, while tumour-derived lactate promotes osteocyte death and citrate-enriched bone formation, creating a vicious cycle. These findings advance physiologically relevant metastasis models and identify citrate-bound hydroxyapatite as a therapeutic target to disrupt PCa-bone crosstalk.

miR-214 Modulates Pigmentation and Therapy Resistance in Cutaneous Melanoma

E. Andreucci¹, A. Biagioni¹, M. Pinto², N. Di Menna², E. Gambale³, S. Pillozzi¹, L. Antonuzzo³, C. Talamonti⁴, M. Mangoni⁵, L. Papucci¹

¹University of Florence, Department of Experimental and Clinical Biomedical Sciences, Florence, Italy

³Careggi University Hospital, Clinical Oncology Unit, Florence, Italy

⁴Careggi University Hospital, Medical Physics Unit, Florence, Italy

⁵Careggi University Hospital, Radiotherapy Unit, Florence, Italy

Introduction

Despite significant advances in cutaneous melanoma (CM) treatment, particularly with immune checkpoint inhibitors (ICI), resistance remains a major challenge, necessitating innovative therapeutic strategies. Melanin plays a crucial role in CM progression, with hyperpigmentation correlating with therapy resistance, including resistance to ICI. While melanin primarily protects against light-induced damage by scavenging reactive oxygen species (ROS), it can also act as a photosensitizer and pro-oxidative agent, depending on its type and intracellular redox state. Its ROS-scavenging activity largely depends on its ability to chelate metal ions, particularly iron, which paradoxically induces melanogenesis due to its high ROS-generating activity. Experimental evidence suggests that miR-214 is a key player in melanoma hyperpigmentation and therapy resistance. This study aims to elucidate the interplay between miR-214 and resistance in CM and to identify potential molecular targets for restoring therapy sensitivity.

Material and method

Melanoma cells were stably transfected to overexpress miR-214 (miR-214+) using the PiggyBac transposon system. Intracellular melanin content was quantified by spectrophotometry, melanosomes were visualized via transmission electron microscopy, and key melanogenic proteins were analyzed through western blot. ROS levels were assessed by flow cytometry, and intracellular iron content was measured using a colorimetric assay.

Therapy response was evaluated in bi- and three-dimensional experimental settings, prevalently using MTT assay, live/dead flow cytometry dye, and colony formation assay. Melanogenesis inhibitors (e.g., the tyrosinase inhibitor deoxyarbutin and the iron chelator pyridoxal isonicotinoyl hydrazone) were used to confirm the role of pigmentation in the acquisition of resistance. Similarly, miR-214-3p/5p mimics were used to ensure the role of miR-214 in pigmentation and therapy resistance of melanoma cells. Serum levels of miR-214

were quantified by droplet digital PCR in CM patients treated with ICI.

Result and discussion

miR-214+ melanoma cells exhibited increased pigmentation, deregulated iron metabolism, and elevated ROS levels accompanied by reduced antioxidant response. These hyperpigmented cells displayed reduced responsiveness to chemo-, targeted-, radio-, and immunotherapy *in vitro*, but sensitivity was restored upon inhibition of miR-214 signaling and melanogenesis. Significantly higher levels of miR-214 were found in the serum of metastatic patients, and within the metastatic setting under ICI treatment, an increasing expression trend was observed in non-responders compared to responders.

Conclusion

miR-214 drives the development of hyperpigmented, resistant melanoma phenotypes. A deeper understanding of its molecular network is crucial for identifying novel therapeutic targets to overcome resistance in non-responsive CM patients.

EACR25-2491

Impact of obesity on the interaction between stem cells and cancer cells in ovarian cancer

A. Cortez^{1,2}, A. Wilk^{1,3}, K. Kujawa², M. Olbryt², S. Student³, T. Soley⁴, A. Klopp⁴, P. Jakubowska², K. Lisowska²

⁴*The University of Texas, MD Anderson Cancer Center, Division of Radiation Oncology, Houston, United States*

Introduction

With obesity considered a global pandemic and one of the major health concerns, it is important to understand the impact of body fat levels on other diseases, such as cancer. Adipose tissue is an active secretory organ influencing a number of metabolic processes. It comprises various cell types, including stem cells, which may play a role in cancer development, progression, and metastasis. In ovarian cancer obesity is considered as both a risk factor and negative prognostic factor. As our earlier study on the interaction between omental derived adipose stem cells (O-ASC) and ovarian cancer cell lines suggested some BMI-dependent differences in gene expression, we aimed to further investigate this relation.

Material and method

We used three ovarian cancer cell lines (OVCA433, OVCA429, and SKOV3) and three O-ASC lines derived from patients with varying body mass index (BMI) (O-ASC1, O-ASC4, and O-ASC15; in the increasing donors BMI order). Cancer and O-ASC cells were cultured in Boyden chambers (cell culture inserts with 0.4 µm pores) to enable paracrine communication without direct contact

(co-culture), or alone (control). Total RNA was isolated and used for gene expression profiling with Affymetrix Human Gene 1.0 oligonucleotide microarrays. After initial pre-processing and exploratory analysis, interaction models were applied to identify genes whose expression changes between control and co-culture differed according to BMI. For O-ASCs, additional filtering was performed to ensure monotonic changes with increasing BMI.

Result and discussion

Gene expression profiles of both the ovarian cancer cells and O-ASCs were affected by inter-cellular interactions. For cancer cell lines, we identified 504 genes that differ in expression level between co-culture and control and depending on the O-ASC cell line (22 of them with $|\log_{2}FC| > 0.5$). In O-ASCs, principal component analysis revealed correlation between gene expression levels and BMI of the donor. Additionally, the effect of interaction with cancer cells varied depending on BMI – we found a signature of 36 genes whose expression in co-culture vs control consistently increased (in case of some genes) or decreased (in case of other genes) along with increasing BMI.

Conclusion

Obesity may influence the gene expression profile of O-ASC and ovarian cancer cells interacting with one another, as well as to modulate the strength of these interactions, particularly in genes related to proliferation and migration. These results, encourage to further study these interactions on the proteome and metabolome level. They also suggest O-ASC – ovarian cancer cell interactions as potential therapeutic target, and highlight the importance of weight management in patient care.

Simple and cost-effective cancer diagnosis in liquid biopsy through native tRNA sequencing

O. Begik¹, X. Katopodi¹, L. Llovera¹, C. Pauli², C. Müller-Tidow³, E. Novoa⁴

¹*Centre for Genomic Regulation, Genome Biology, Barcelona, Spain*

²*DKFZ, Heidelberg, Germany*

³*University of Heidelberg, Heidelberg, Germany*

⁴*Centre for Genomic Regulation, Genome Biology, Bar, Spain*

Introduction

Every year, 20 million people are diagnosed with cancer, and 10 million people die due to this complex and heterogeneous disease. Early cancer diagnosis is highly correlated with good prognosis and higher survival rates. For example, patients diagnosed with stage IV lung cancer have 1-year survival rates of only 15–19 %, whereas stage I patients show 81–85 % 1-year survival rates. Screening liquid biopsy (LB) samples has been proposed as a promising approach to diagnose cancer in earlier stages, since it is a minimally invasive approach that can be applied to the whole population. The discovery of relatively stable, extracellular RNAs in blood plasma has generated much interest in their potential use as non-invasive biomarkers. Most efforts have so far focused on miRNAs or lncRNAs as potential

biomarkers. By contrast, tRNAs remain unexplored as potential biomarkers, despite their information-rich nature – abundances and modifications – and their well-documented dysregulation in cancer samples. This is mainly due to the lack of a simple, fast and cost-effective approach to quantify them. Indeed, current approaches to study tRNAs require steps that introduce bias in the process of quantification, are lengthy and laborious, and have very high costs. Thus, the high costs of existing diagnostic tests, the lack of adequate biomarkers and the inability to capture RNA modification information using next-generation sequencing (NGS) technologies have hindered the development of tRNA-based screening tests for early cancer detection, and the use of tRNA molecules as biomarkers.

Material and method

Here we propose to take advantage of a recently developed sequencing technology, native RNA nanopore sequencing, to quantify small RNA abundances and modifications in liquid biopsy samples. More specifically, we will employ our recently established Nano-tRNAseq method, which we have patented, to sequence information-rich circulating tRNA molecules to profile their abundance and modification dynamics. We will then couple this method with artificial intelligence to predict:

(i) whether the sample is “normal”, “cancerous”, or “metastatic” based on the profiles we build from training samples, as well as
(ii) the cancer tissue of origin.

Result and discussion

Our preliminary experiments demonstrate that Nano-tRNAseq captures human tRNA dynamics across cell lines, tissues and nutrient statuses, confirming their potential as biomarkers. Moreover, using tRNA abundance and modification data from paired lung normal and tumor tissues, we were able to distinguish their disease state. Notably, we have also been able to isolate and quantify small RNAs from human plasma samples with high quality.

Conclusion

In this study, we aim to fully validate our approach for the differential analysis of low-input RNA amounts in liquid biopsy samples.

EACR25-2505

Studying glioblastoma-associated blood vessel changes across tumor progression to improve targeted therapies

M. Jaraiz-Rodríguez¹, L. García-Vicente², A. Alvarez-Vázquez², R. Flores-Hernández², A. Tabernero²

¹*Universidad de Salamanca, Instituto de Neurociencias de Castilla y León, Salamanca, Spain*

²*Universidad de Salamanca, Salamanca, Spain*

Introduction

Glioblastoma is the most common and aggressive primary brain tumour and despite current treatments that combine chemo- and radiotherapy with surgery, recurrence is overwhelmingly inevitable for most of the patients. Importantly, treating glioblastoma is particularly challenging as it requires crossing the blood-brain barrier and reaching the tumor cells within the heterogeneous brain microenvironment. In addition, tumour micro-

environment shifts as the tumour progresses hindering therapy efficacy. Thus, understanding the biological influence of the tumor on the blood brain barrier and its response to therapies as glioblastomas develop is key to engineer the most effective and personalized targeted therapies. In this work, we investigated the changes in tumor-associated endothelial cells (ECs), the first component of the blood brain barrier, at different stages of a mouse model of glioblastoma.

Material and method

To decipher changes in ECs across tumor progression, single-nucleus RNA sequencing of GL261 tumour-bearing mice was performed at early and late stages of tumour development and upon treatment with temozolamide (TMZ), the standard of care for glioblastoma, and with a promising cell-penetrating peptide that inhibits the oncoprotein Src, TAT-Cx43266-283.

Result and discussion

By comparing the vascular landscape from tumors at their final stages with early stages, we observed that ECs acquired a more activated phenotype, as seen by the increase in the adaptive immune response and antigen presentation; and a relevant boost in translation by the increase in ribosome assembly or protein folding that may underlie cell growth; and metabolic pathways that may fuel these processes, such as fatty acid metabolism and regulation of lipid transport. TMZ treatment, however, reduced the inflammatory response, and increased the regulation of calcium and ion transmembrane transport, both essential for barrier function. Interestingly, ECs from early tumor stages treated with TAT-Cx43266-283, compared with TMZ, showed a decrease in pro-migratory pathways, such as cell adhesion mediated by integrins; and important pro-angiogenic pathways such as WNT, suggesting a delay in the onset of the glioblastoma-associated proangiogenic vascular phenotype.

Conclusion

In conclusion, this work shows that glioblastoma triggers a more complex blood vessel machinery than just an angiogenic response, and that a deeper insight into the phenotypic changes induced by both tumors and therapies is needed. Understanding the tumor and therapy-associated microenvironment changes will improve the current knowledge on the vascular response that may influence the prospects of the disease.

EACR25-2507

High-throughput Bioprinting of Physiomimetic Tumor-Stroma Microenvironment 3D Models for Screening Therapeutics

M. Monteiro¹, L. Ferreira², J. Mano³, V. Gaspar³

¹*University of Aveiro, Department of Chemistry, Aveiro, Portugal*

²*Cellularis Biomodels, Ilhavo, Portugal*

³*University of Aveiro and Cellularis Biomodels, Aveiro, Portugal*

Introduction

Engineering tumor microenvironments (TMEs) with cancer-associated fibroblasts (CAFs) has emerged as a powerful tool for screening chemotherapeutics and nano-

therapeutics. The TME plays a crucial role in tumor progression, drug resistance, and therapeutic efficacy, yet conventional two-dimensional (2D) models fail to replicate its complexity. Herein we bioengineered three-dimensional (3D) TME model incorporating CAFs to improve drug screening and enhance translational relevance. The models are generated as high-throughput platforms using superhydrophobic surfaces and our automated technique - FLORE (Flow-On-Repellent) bioprinting. This approach enables the rapid, automated fabrication of cancer-on-a-bead models, providing a scalable and reproducible system for preclinical drug evaluation. Additionally, the models are embedded within tissue-specific decellularized extracellular matrix (dECM) to better mimic the native tumor microenvironment and enhance physiomimetic relevance.

Material and method

We developed a 3D tumor-CAF co-culture system using patient-derived cancer cells and CAFs within a biomimetic, tissue-specific dECM scaffold. The system was fabricated using FLORE bioprinting on superhydrophobic surfaces to enable high-throughput generation and ensure reproducibility and scalability. The dECM was derived from decellularized tissue to retain key biochemical and structural cues. High-content imaging and viability assays were conducted to assess cancer-stromal cells spatial distribution and drug responses.

Result and discussion

Our engineered TMEs demonstrated enhanced recapitulation of *in vivo* tumor-CAF interactions compared to traditional models. CAFs influenced drug responses by modulating extracellular matrix composition and secreting key cytokines. The use of tissue-specific dECM provided a more physiomimetic environment, supporting cellular organization and enhancing drug response predictability. The integration of FLORE bioprinting and superhydrophobic surfaces ensured high-throughput and reproducible screening, highlighting the necessity of incorporating CAFs and dECM in preclinical drug testing to improve the predictive accuracy of such tumor microenvironment surrogates.

Conclusion

The engineered 3D tumor-CAF model represents a significant advancement in preclinical drug screening by providing a more physiologically relevant, high-throughput platform to assess chemotherapeutics performance. By leveraging FLORE bioprinting and tissue-specific dECM, this approach enhances biomimicry and predictive accuracy, paving the way for more effective drug development and personalized treatment strategies. *This work was developed within the framework of EU INSPIRE project (grant ID: 101057777 a Cluster 1 - Health).*

EACR25-2508

Impact of preoperative treatment on the tumor microenvironment of liver metastases from colorectal cancer

N. Molina¹, M. Bañuls², N. Ruiz³, L. Lladó³, K. Mills³, D. García Molleví²

¹*Bellvitge Biomedical Research Institute (IDIBELL), Hospitalet de Llobregat, Spain*

²*Catalan Institute of Oncology, Hospitalet de Llobregat, Spain*

³*Hospital of Bellvitge, Hospitalet de Llobregat, Spain*

Introduction

Colorectal cancer (CRC) often spreads to the liver (LM-CRC). While surgery can be curative for some patients, most receive preoperative chemotherapy. Chemotherapy alters the tumor microenvironment (TME). Understanding this could uncover therapeutic targets, resistance mechanisms, and new treatment vulnerabilities. This study aims to investigate the influence of FOLFOX-based chemotherapy on the TME of LM-CRC.

Material and method

The human HSC line LX-2 was treated with FOLFOX for six cycles, mimicking clinical protocols. Conditioned media and cell lysates were collected, and proteomic analysis was performed. Functional assays, including immune cell recruitment, tumor proliferation, and migration, were done using treated and untreated LX-2 cells. RNA sequencing was performed on co-cultures of LX-2 cells, THP-1, and SW620 tumor cells. Tissue microarrays from chemotherapy-naïve and FOLFOX-treated patients were used for validation.

Result and discussion

Proteomic analysis revealed carbonic anhydrase 9 (CA9) as the most significantly upregulated protein in treated LX-2 cells compared to untreated controls. CA9 overexpression was confirmed by Western blot, immunofluorescence, and immunohistochemistry in TMA. IPA analyses reported a metabolic shift from oxidative phosphorylation to glycolysis, being HIF-1α and STAT3 upstream regulators of the enriched pathways in treated HSC. Western blot revealed HIF-1α overexpression in treated cells. Control cells displayed a more HSC-quiescent state, involving the metabolism of fatty acids, lower proliferative rate, and organization of the actin filament bundle. The proinflammatory profile of treated-LX-2 was also observed in the analyses of the analytes in the conditioned media where IL-4, IL-1β, CCL2, CCL4, CCL20 and M-CSF were overexpressed in treated-LX-2 in comparison to non-treated ones. Also, other factors such as HGF, VEGF, PAI-1, COL1A1, and COL4A1 were upregulated. RT-PCR and protein levels showed an overexpression of FAP and Periostin in treated LX-2 compared to chemonaive. Analyses of 3D cocultures displayed enrichment of interferon pathways activation in LX-2 T cells, as well as in co-cultured SW620 and THP-1 cells, relative to untreated controls. THP-1 cells co-cultured with LX-2 T cells exhibited enrichment in proliferation-related pathways. Untreated LX-2 cells displayed enrichment in cholesterol and oxidative phosphorylation metabolism pathways, and co-cultured tumor cells showed enrichment in proliferation pathways. Functional assays demonstrated differential effects of the treatment on immune cell recruitment, tumor growth modulation, and tumor cell migration. Galectin 9 is tested as a surrogate marker of IFN response between chemonaive and FOLFOX-treated samples.

Conclusion

FOLFOX-activated HSC displayed transcriptomic, proteomic, and metabolic changes that impact in the TME, including tumor cell responses and immune modulation.

EACR25-2517

Neuroendocrine plasticity diversity in prostate cancer: role of redox state

S. Alcón Rodriguez¹, D. Hevia¹, P. González Menéndez¹, J. Mayo¹, R. Sainz¹, I. Quirós González¹

¹University of Oviedo, Morphology and Cell Biology, Asturias, Spain

Introduction

Neuroendocrine (NE) plasticity contributes to prostate cancer progression affecting both tumour cell and its microenvironment, however, NE phenotypes display strong variability. Some factors involved in prostate cancer risk such as inflammation or therapy, such as androgen deprivation strategies are able to initiate NE plasticity. In these work we study diversity of NE plasticity to clarify what aspects truly contribute to disease progression.

Material and method

In vitro NE plasticity is induced in androgen-dependent human adenocarcinoma LNCaP Cells by androgen deprivation (Ad), increase levels of cAMP, Interleukine-6 and the redox-hormone Melatonin (MEL). Conditioned media were used to evaluate pro-angiogenic activity (HUVEC matrigel assay and VEGF secretion), pro-fibrotic activity (Collagen production in 3T3 cell culture) and growth proliferation (PC-3 cell culture). Survival to Chemotherapy (Etoposide and Docetaxel) and Prostate Specific Antigen (PSA) secretion was also studied. Androgen Receptor (AR) protein levels were measured by IHC and Mitochondrial Superoxide Dismutase (MnSOD/SOD2) levels were studied by western blot and enzymatic activity gel. DFC, MitoSOX and H2O2 secretion by amplex red were used to monitorize redox state. The following animal models of prostate cancer were used: Transgenic Prostate Cancer (TRAMP)-WT and triploid for SOD2 allele. Xenograft of LNCaP alone or in combination with NE-LNCaP.

Plasticity of NE in human prostate cancer was inquired by using Hyperion Spatial Proteomics System (EACR-Fluidigm Grant).

Result and discussion

Substantial differences in all the progression features studied were observed in the different NE groups, AR expression levels, survival to Chemotherapy treatment, PSA production, angiogenesis or fibrosis. NE plasticity induced by Ad and MEL showed similar features with increase of paracrine effect on PC-3 growth or decrease in VEGF secretion. All the NE-stimuli however, showed a significant increase in MnSOD levels and activity, together with a general decrease in redox state especially in Ad group. Consistently, TRAMP triploid for SOD2 showed significant less VEGF in the prostate tissue and higher rates of NE plasticity in response to surgical castration. Antioxidant treatment is able to change in vitro fibrosis and VEGF production in cAMP, IL-6 and MEL but the effect in Ad were the redox levels were already very low is modest. In xenograft models when LNCaP cells are administered together with NE-LNCaP cells, tumours are much less haemorrhagic and exhibit a non-collagenous extracellular matrix. Antioxidants prevent partially the NE-characteristics in the TME and delays tumour onset. In patient tissue, NE-plasticity only shows

impact in TME in those tissue with substantial levels of MnSOD.

Conclusion

NE plasticity caused by Ad has the strongest impact in TME. NE plasticity occurs together with a rearrangement in redox state which contributes to TME effects.

EACR25-2524

3D Cell-derived ECM Production for Humanized Lung Cancer in vitro Model Development

L. Ferreira¹, P. Rodrigues¹, E. Oliveira¹, V. Gaspar², J. Mano³

¹Cellularis Biomodels, R&D, Ilhavo, Portugal

²Cellularis Biomodels, CEO, Ilhavo, Portugal

³University of Aveiro, Chemistry, Aveiro, Portugal

Introduction

Despite significant advances in the development of 3D in vitro tumor models, the majority still fails to recapitulate the complexity of the lung tumor microenvironment (TME) extracellular matrix (ECM). Instead of applying microenvironment rich in tissue-specific ECM components, most common approaches rely on the application of singularly isolated ECM components, or complex non-tissue specific hydrogels, that do not recapitulate the specificity of lung-tumor ECM. Cell-Derived Matrixes (cdECM) offer an alternative pathway to address the need for tissue and tumor specific ECM biomaterial production. However, conventional methodologies of cdECM production are recognizably associated with small biomaterial yields, making the application of these matrixes in the context of high-throughput model production challenging.

Material and method

To address this limitation, we developed a bioreactor-based approach for large-scale production of human lung cancer ECM by assembling and maturing 3D tumor microtissues composed of A549 lung adenocarcinoma cells and MRC-5 lung fibroblasts in dynamic stirring conditions. Moreover, MRC-5 cells were stimulated with different biochemical cues (i.e., TGF-β1 and Ascorbic acid) to induce their activation into cancer-associated fibroblast (CAF)-like phenotypes. Obtained matrixes were fully decellularized, and posteriorly characterized with recourse to previously established approaches, and proteomic characterization.

Result and discussion

Structural SEM and biochemical quantification analyses of ECM main components confirm the development of a tumor-relevant ECM composition, providing a biomimetic scaffold that could then be processed into workable hydrogels. These lung specific cdECM are expected to enhance the physiological relevance of in vitro lung cancer models. This stimulated ECM deposition and remodeling, mimicking the stromal adaptations observed in lung tumors.

Conclusion

Our study systematically optimizes key culture parameters, including cell ratios, biochemical stimulation, and maturation time, to maximize ECM production while preserving tissue-specific characteristics. Structural SEM and biochemical quantification analyses of ECM main components confirm the

development of a tumor-relevant ECM composition, providing a biomimetic scaffold that could then be processed into workable hydrogels. These lung specific cdECM are expected to enhance the physio-logical relevance of in vitro lung cancer models. By establishing guidelines for ECM-enriched microtissue production, this work presents a robust framework for generating humanized 3D tumor models with improved fidelity to in vivo conditions, advancing their applicability in preclinical research, drug screening, and personalized medicine.

Pancreatic Ductal Adenocarcinoma on Chip for Therapy Screening

M. Bento¹, M. Cipriano², P. Loskill³, H. Florindo¹

¹*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal*

²*Department for Microphysiological Systems, Institute of Biomedical Engineering, Eberhard Karls University Tübingen, 72074 Tübingen, Germany, Tübingen, Germany*

³*Department for Microphysiological Systems, Institute of Biomedical Engineering, Eberhard Karls University Tübingen; NMI Natural and Medical Sciences Institute at the University of Tübingen; 3R-Center for In vitro Models and Alternatives to Animal Testing; Eberhard Karls University Tübingen, Tübingen, Germany*

Introduction

Pancreatic Ductal Adenocarcinoma (PDAC) is one of the most aggressive cancers, hallmark by an immuno-suppressive tumor microenvironment (TME) enriched with cancer-associated fibroblasts (CAF), pro-tumoral macrophages (TAM), and abnormal vasculature. This complexity hinders therapeutic efficacy, highlighting the urgent need for advanced preclinical models. Here, we developed a PDAC-on-chip model incorporating pancreatic cancer cells, immune cells, and stromal components, enabling a more accurate high-throughput characterization of tumor-immune cell interactions.

Material and method

A polymethylmethacrylate (PMMA)-based chip was designed with media and tissue channels separated by a semi-permeable membrane. PANC-1 spheroids were loaded in the chip containing a hydrogel with fibroblasts and lymphatic endothelial cells (LECs). CD14+ monocytes from peripheral blood mononuclear cells (PBMCs) were differentiated into macrophages and integrated into the hydrogel. Labeled T cells were perfused through the chip to assess infiltration under different treatments. Microvascular endothelial cells (MVECs) were seeded onto the chip's membrane to simulate vascular perfusion [1]

Result and discussion

The PDAC-on-chip sustained long-term cell culture for over a week, enabling continuous monitoring of tumor spheroid growth, drug response and immune cell dynamics. To validate the model, we confirmed:

- (i) CAF marker expression, including αFAP, Podoplanin, and Vimentin;
- (ii) the formation of a stable MVECs monolayer

facilitating functional vasculature-like perfusion;

- (iii) integration of LECs in the stroma, forming vessel-like structures;
- (iv) incorporation of macrophages expressing pro-tumoral markers; and
- (v) perfusion of monocytes and T-cells through flow, allowing a semi-quantitative assessment of tissue penetration in response to pharmacological treatment.

Conclusion

The PDAC-on-chip successfully replicates tumor-stroma-immune cell interactions, offering a physiologically relevant model for immunotherapy screening [5]. Additionally, this platform enables the testing of nanotherapies targeting fibroblasts, macrophages, or vascular components, providing new insights into overcoming PDAC's immunosuppressive TME. These findings contribute to cancer research, paving the way for innovative strategies to improve patient outcomes.

[1] The use of human-derived cells was approved by the Ethical Committee of the Eberhard Karls University Tübingen.

Spatial Profiling of Exhausted T cells Using High-Plex Imaging Mass Cytometry

M. Klug¹, T. Pfister², J. Chwee², Q. Raza², D. Howell², N. Parsotam², L. Lim², C. Loh²

¹*Standard BioTools, Berlin, Germany*

²*Standard BioTools, Markham, Canada*

Introduction

The spatial organization and cellular composition of the tumor microenvironment (TME) has the potential to inform clinical and translational researchers about mechanisms of disease progression and therapeutic success. Of particular interest are immune cells, especially T cells, which can become exhausted due to chronic stimulation. This poses a significant challenge in cancer therapy as exhausted T cells have reduced effector functions and sustained expression of inhibitory receptors such as PD-1 and CTLA-4, resulting in failure to effectively eliminate tumor cells. Imaging Mass Cytometry™ (IMC™) technology is a high-plex imaging technique that enables deep characterization of the heterogeneity and complexity of the TME. The Hyperion™ XTi Imaging System utilizes IMC technology to provide signal intensities over a wide dynamic range and entails one-step detection of 40-plus markers without issues of tissue autofluorescence, making it ideally suited for spatial biology applications. Whole slide imaging modes and an automated slide loader function enable a streamlined, versatile scalable workflow for high-throughput analysis.

Material and method

We used IMC technology to characterize immune cell populations and the spatial distribution of T cell exhaustion markers across various cancer types. We applied a 40-plus-marker IMC panel by integrating the Human Immuno-Oncology IMC Panel with the Human T

Cell Exhaustion IMC Panel to study the TME of multiple human tissues.

Result and discussion

IMC analysis revealed striking heterogeneity with distinct tumor and immune-rich niches in the TME. In colon adenocarcinoma, we detected functional effector T cells and multiple tertiary lymphoid structures (TLSs). In contrast, we observed fewer TLSs and more T cells expressing PD-1 and TIM-3 at the tumor periphery in the urothelial carcinoma tissue, suggesting that they are in advanced exhaustion stages. We also observed expression of PD-L1, IDO and VISTA in the tumor cells. t-SNE and PhenoGraph clustering analysis of Cell Mode data segregated and spatially resolved the T cells into effector and exhausted T cell subpopulations, which were mapped back to the segmented cell masks. Unsupervised pixel clustering and analyses of Tissue Mode data further delineated distinct tumor areas based on the presence of infiltrating immune cells, tumor replicative activity and spatial proximity to stromal components.

Conclusion

This work characterizing T cell exhaustion markers in multiple cancers showcases the capabilities of IMC technology and establishes it as a reliable highplex, high-throughput spatial biology imaging platform. IMC technology is ideally suited for developing future translational and clinical applications and has the potential to help guide personalized therapeutic strategies for cancer treatment. For Research Use Only. Not for use in diagnostic procedures.

³*University of Antioquia-UdeA, Chemistry of Colombian Plants Group, Medellín, Colombia*

⁴*Pontifical Bolivarian University, Medicine Faculty, Medellín, Colombia*

Introduction

Colorectal cancer (CRC) is a prevalent malignancy, often diagnosed at advanced stages. 5-fluorouracil (5FU) is a common chemotherapeutic agent for CRC but is limited by toxicity, variable responses, and resistance. Thus, alternative preventive and therapeutic strategies with proven in vivo antineoplastic activity are essential. Hybrid molecules, such as the 5FU-curcumin conjugate, combine the 5FU pharmacophore with curcumin, an antioxidant pigment, to enhance efficacy and reduce adverse effects.

Material and method

A colorectal cancer (CRC) model induced by azoxy-methane (AOM) and dextran sodium sulfate (DSS) was standardized in Balb/c mice, evaluating two induction protocols: protocol 1 (AOM + 1 cycle of DSS) and protocol 2 (AOM + 2 cycles of DSS), selecting the optimal one through histopathological analysis. Then, treatment was administered using 5-fluorouracil (control) and the 5-fluorouracil-curcumin hybrid in two periods (weeks 3 to 7 and weeks 5 to 10). Positive (CRC-AOM/DSS) and negative controls were included. After euthanasia, the colon was extracted for methylene blue staining and histopathological analysis. The study was approved by the bioethics committee (Act No. 114/2017, UdeA).

Result and discussion

A single DSS cycle (protocol 1) did not induce tumors in all animals, whereas two cycles (protocol 2) did after week 10. Wilcoxon test analysis showed no significant sex differences, confirming that the AOM/DSS CRC model in BALB/c mice replicates the adenocarcinomatous process and is applicable to both sexes with one AOM dose and two DSS cycles. Preneoplastic lesions appeared in week 3, progressing to tumors by week 12. Dysplasia was observed from week 2, preceding neoplastic proliferation and infiltration. Fibrosis developed in response to inflammation detected in week 2. Both 5FU and 5FU-curcumin delayed lesion progression, with mild to moderate histopathological alterations compared to the positive control. However, tumor growth resumed by week 12. Mice treated with 5FU experienced up to 40% mortality and weight loss, whereas those receiving 5FU-curcumin did not, indicating lower toxicity. Histopathological analysis confirmed reduced tissue damage, as ulceration levels were lower in the 5FU-curcumin group than in 5-FU alone.

Conclusion

The AOM/DSS system effectively replicates colorectal cancer progression in humans and is useful for evaluating chemopreventive strategies.

- The model can be applied to both male and female mice.
- The 5FU-Curcumin hybrid slightly delays tumor progression, but its effect is insufficient after treatment discontinuation.
- Unlike 5FU alone, the 5FU-Curcumin hybrid showed no toxicity and slightly reduced tissue damage.
- Hybrids like 5FU-Curcumin could be a promising strategy for colorectal cancer chemoprevention.

⁵Broad Institute of MIT and Harvard, Cambridge, United States

Introduction

Human tumors are difficult to treat owing to their unique tumor microenvironment (TME) in which stromal cells foster drug resistance, leading to the inefficacy of current treatments. In this focus, the urgent need for predictive and accurate preclinical models has motivated researchers to explore new strategies for recapitulating the native TME for preclinical drug screening. Cryobioprinting, which integrates 3D bioprinting with cryopreservation methods, offers a promising approach for generating on-demand 3D tumor models at a relevant scale. Aiming to fabricate storable tumor-stroma models, that capture native TME elements and key tumor signatures, with potential for predictive screening of new therapies, here we take advantage of 3D cryobioprinting technique. The optimization of a tissue-specific de-cellularized extracellular matrix (dECM)-based bioink, comprising tumor-associated cells and optimal cryoprotective agents (CPAs) was conducted aiming to generate a cryoprotective bioink that protects cells during the cooling, storage and thawing process. The ability of the cryopreserved tumor platforms to reproduce key hallmarks as found *in vivo* was evaluated followed by its suitability to screen anti-cancer therapeutics.

Material and method

Two distinct bioinks were formulated:

- (i) the tumor bioink comprising lung cancer or pancreatic cancer cells, lung or pancreas dECM precursor hydrogel solution, and a combination of CPAs (i.e., melezitose + glycerol or DMSO); and
- (ii) the stroma bioink composed of cancer-associated fibroblasts (CAFs), dECM-HA-Tyr precursor hydrogels, and a combination of CPAs (melezitose + glycerol or DMSO).

The emulation of key biomarkers including tumor fibrosis was then characterized so as to address the potential of the cryobioprinted systems. Additionally, the biofabricated models were used for screening the anti-tumoral agents, in order to demonstrate the screening functionality of storable platforms.

Result and discussion

The formulated bioink-cryoprotectant combinations using tissue-specific dECM has enabled the cryofabrication of tumor models and the recapitulation of its TME. The discovered CPA combination of melezitose-glycerol ensured cellular viability after 3D tumor models cryobioprinting and cryopreservation, in comparison to the conventionally used CPAs (i.e., DMSO- melezitose), demonstrating the potential of this cryoprotective formulation to establish off-the-shelf tumor models. The cryopreserved 3D models also showed preclinical drug screening functionality, exhibiting no major differences in terms of response to standard-of-care chemotherapeutics, when compared to non-cryopreserved controls.

Conclusion

Overall, the herein cryobioprinted tumor-stroma models represent a significant advancement in cancer research and drug screening, offering the ability to fabricate shelf-ready biomimetic tumor models with screening functionality.

⁴Silesian University of Technolog, Department od Systems Biology and Engineering, Faculty of Automatic Control, Electronics and Computer Science, Gliwice, Poland

Introduction

MicroRNAs (miRNAs) are short single-stranded RNA molecules that play a key role in gene expression regulation. MiRNAs can be located in introns and exons of protein-coding or noncoding genes as well as in intergenic regions. Biogenesis of miRNAs is a multi-step process that starts in the nucleus, where the primary miRNAs (pri-miRNAs) are transcribed, processed to precursor miRNAs (pre-miRNAs), which are transported to the cytoplasm for further processing to mature miRNAs. MiR-155 is crucial for B-cell lymphoma development. It is also a well-known oncogenic miRNA considered a therapeutic strategy for miR-155-expressing leukemias. miR-155 originates from the MIR155HG gene. The MIR155HG gene can also generate other functional products: long non-coding RNA 155 (lncRNA-155, also known as BIC) and the micropeptide miPEP155.

Material and method

Our aim was to develop a mathematical model for the biogenesis of miR-155 and other MIR155HG products under oxidative stress conditions. First, we examined the impact of ionizing radiation (IR) on miR-155 biogenesis in Burkitt's lymphoma (BL) cell lines: ST486, and DG75.

Result and discussion

Small RNA-seq performed 4- and 12-hours (h) post 4Gy of IR revealed that miR-155 levels increased at least 1.5-fold in DG75 and ST486 cell lines. By qRT-PCR, we showed that pri-miRNA-155 levels increased within 1–4 h post-IR preceding the increase in miR-155 levels at 12 h post-IR, suggesting that IR transcriptionally activated MIR155HG. Additionally, we showed that expression of spliced transcript/lncRNA155, and not unspliced BIC was upregulated after IR. We used the experimentally obtained data to develop a mathematical model describing interactions between unspliced and spliced MIR155HG transcripts, miR-155, and miPEP155. Our preliminary model defines five variables representing MIR155HG products and identifies parameters of biogenesis from MIR155HG.

Conclusion

Our findings indicate that IR affects miR-155 biogenesis by transcriptional activation of MIR155HG in BL cells. The mathematical model we developed provides a

framework for understanding the complex interactions between MIR155HG-derived products and their potential role in lymphoma pathogenesis. Model improvement and experimental validation are ongoing.

Tracking neuroblastoma-derived small extracellular vesicles: uptake and functional impact in the tumor microenvironment

A. Scott¹, O. Piskareva¹

¹Royal College of Surgeons in Ireland, Anatomy and Regenerative Medicine, Dublin, Ireland

Introduction

Neuroblastoma (NB) is a rare, yet aggressive pediatric cancer often resulting in poor prognosis. Small extracellular vesicles (sEVs) have gained scientific interest due to their ability to transfer genetic cargo between cancerous and non-cancerous cells. Understanding how sEVs influence tumor progression is critical for elucidating their role within the tumor microenvironment (TME). Notably, sEVs have the ability to induce pre-metastatic niche formation through oncogenic cargo transfer. This study utilizes a 2D co-culture model to visualize the transfer of sEVs from NB to non-NB cells, further providing insights into their potential impact on recipient cells.

Material and method

Human NB cell lines Kelly and SKNAS, fluorescently labeled with green fluorescent protein (GFP), were co-cultured with a human non-NB cell line, HS-5, using a hanging well insert model. The insert contained a porous membrane with seeded NB cells, preventing direct cell contact and allowing sEV transfer. Following a 7-day incubation period, fluorescence microscopy confirmed the uptake of sEVs in HS-5 cells. Downstream analysis, including cell proliferation using a PicoGreen assay, cell viability using Cell Titer-Glo assay and confocal microscopy, elucidated the influence of sEV interactions.

Result and discussion

HS-5 cells had successful sEV uptake from NB cells based on their exhibited GFP fluorescence. During the first 4 days of incubation, there was minimal fluorescence observed. By the final incubation day, 80% of the HS-5 cell population was fluorescent. These results demonstrate the ability of NB-derived sEVs to transfer cargo to non-NB recipient cells without direct cell contact. Preliminary observations of cell proliferation and cell viability suggest NB sEV transfer affects HS-5 cell behavior, resulting in increased cell proliferation, without negative impacts on cell viability. Ongoing work includes characterizing the impact of sEV interactions on HS-5 cells before and after exposure to NB-derived sEVs through gene expression profiling using RT-qPCR.

Conclusion

This study provides direct visualization of sEV-mediated communication between NB and non-NB recipient cells. Further reinforcing the hypothesis that sEVs contribute to

modification of the TME. Future work will focus on translating the 2D co-culture model to the Rastrum™ 3D bioprinter to study NB-derived sEV transfer in a physiologically relevant model that mimics the TME. A new understanding of sEV influence in the TME may improve our knowledge of NB progression as well as ultimately reveal new therapeutic targets.

⁴Ipatimup, Porto, Portugal

⁵INEB, Lisbon, Portugal

Introduction

For many years, colon cancer has been studied and treated as a unique entity, however, it is now well-known that left and right colon tumors have distinct embryologic origins, mutational signatures, microbiota, immune infiltrates and exhibit different responses to therapy, with impact on patients' prognosis. Although many cell studies have been performed to dissect the basis of these differences, the potential role of the Extracellular matrix remains unexplored.

Material and method

In this study, using paired tumor and normal matrices, derived from colorectal cancer patients surgical resections, we unveiled the major biomechanical and biochemical differences between right and of left tumors and appointed sidedness unique proteins that may constitute targets of future therapeutic strategies.

Result and discussion

Microscopic and rheological analysis revealed that both ECM fiber density and stiffness were enhanced in tumors compared to adjacent normal tissues. These differences were side-dependent being observed only on left-sided tumors. Analysis of the ECM protein signature revealed that tumor matrices exhibited increased ECM collagens, glycoproteins, secreted factors, and inflammation-associated proteins and lower expression of proteoglycans. Despite similar number of differentially abundant proteins were observed, between tumor and normal decellularized tissues in both right and left sides, altered signaling pathways differed. Proteomic analysis further showed that left-sided tumors are enriched in proteins related to elastic fiber formation and TGF-β signaling. Specifically, ADAMTS1, PLXDC2, and WNT11 were identified as tumor-specific proteins across both sides, while SPARC and TIMP1 were elevated exclusively in left-sided tumors, potentially associated to its fibrotic and stiffer properties.

Conclusion

These findings suggest that ECM composition differs significantly between tumor and normal tissues in a side-dependent manner, with left-sided tumors displaying unique characteristics that may contribute to their distinct disease profiles and clinical outcomes. To our

knowledge, this is the first study to identify a sidedness signature in the ECM of colon tumors, and rising the enthusiasm for its biomarker and therapeutic significance.

EACR25-2569

characterization of murine bone marrow derived macrophages (BMDM) following Interleukin 6 treatment in two mice

strains: C57BL/6 and Balb/c

E. Pilny¹, J. Czapla¹, A. Drzyzga¹, D. Sprus-Lipka¹, R. Smolarczyk¹, S. Matuszczak¹, B. Łasut-Szyszka¹, M. Jarosz-Biej¹, T. Cichon¹

¹*Maria Skłodowska-Curie National Research Institute of Oncology, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland*

Introduction

M2 macrophages facilitate wound healing, tissue remodeling, and resolution of inflammation. The M2 phenotype is subdivided into several subsets: M2a, M2b, M2c, M2d, each with distinct functions in immune regulation. M2d macrophages, also known as tumor-associated macrophages (TAMs), are induced by the TLR antagonists or IL-6. The activity of IL-6 in the stimulation of M2d macrophages has been confirmed by *in vitro* studies. However, the characterization of macrophages after IL-6 treatment is still poorly understood. The aim of these work was to characterize murine bone marrow derived macrophages (BMDM) following Interleukin 6 treatment in two mice strains: C57BL/6 and Balb/c.

Material and method

Bone marrow was collected from femurs and tibias of 6–10 weeks of age C57BL/6 or Balb/c mice. Isolated cells were differentiated into macrophages using M-CSF for 7 days. After one week, BMDM were incubated for 48h with IL-6, IL-4 (to obtain control M2a macrophages), IL-10 (to obtain control M2c macrophages) and IFN- α (to obtain control M1 macrophages). Additionally, the combination of IL-6 with IL-4 or IL-10 were tested. Unstimulated cells were control macrophages - M0. Characterization of the obtained macrophages were performed by flow cytometry and western blot analysis. Cell migration was determined by wound healing assay and Boyden chambers. The amount of cytokines released by macrophages was assessed using the bead-based multiplex assay.

Result and discussion

IL-6 enhances the stimulation of isolated macrophages to the M2 phenotype (CD206+) in Balb/c mice strain, as well as IL-4. Combination of IL-4 and IL-6 increased the expression of CD206 antigen and the viability of BMDM in both mouse strains. IL-4 and the combination of IL-6 with IL-4 increased the level of arginase protein. Only IL-4 increased the phagocytic properties of BMDM. The combination of IL-6 with IL-4 increased the migration of macrophages in wound healing assay in both mice strains compared to cytokines used individually. The combination of IL-6 with IL-4, as well as cytokines used individually increased the migration of macrophages towards the media containing chemotactic factors

secreted by endothelial cells in Balb/c mouse strain. The greatest activation of the STAT3-6R pathway was observed in BMDM following treatment with IL-6 and IL-6 with IL-10. The main cytokine secreted by macrophages stimulated with IL-6, IL-10 and combination of IL-6 with IL-4 was Interleukin 6.

Conclusion

The obtained results provide new information on the properties of M2 macrophages cultured with the addition of IL-6 and its combination with IL-4 or IL-10. Effective reprogramming of macrophages using the tested cytokines may contribute to achieving better efficacy of anticancer therapies by the tumor microenvironment repolarization.

This study was financed by National Science Centre, Poland, grant No. UMO-2018/29/N/NZ4/01689.

High-Throughput Biofabrication of Unitary Lung Tumor Organoids in Superhydrophobic Surfaces

F. Correia¹, M. Henriques-Pereira¹, B. Cardoso², L. Ferreira³, M. Monteiro⁴, J. Mano⁵, V. Gaspar⁵

¹*Cellularis Biomodels, Ilhavo, Portugal*

²*University of Aveiro, Aveiro, Portugal*

³*Cellularis Biomodels, Aveiro, Portugal*

⁴*Cellularis Biomodels, ilhavo, Portugal*

⁵*University of Aveiro and Cellularis Biomodels, Aveiro, Portugal*

Introduction

Lung cancer remains one of the most aggressive and lethal malignancies, necessitating the development of advanced *in vitro* tumor models that better recapitulate the *in vivo* tumor microenvironment, in order to effectively understand tumor biology and test new nanomedicines. Conventional 2D culture models fail to mimic the spatial complexity and cellular interactions of native tumors. Tumor organoids offer a promising alternative, however, existing methods often lack reproducibility and high-throughput capabilities. Herein, a novel biofabrication approach for generating physiomimetic unitary lung tumor organoids using superhydrophobic surfaces is presented. The technology is leveraged to generate new Organoid-on-hydrogel bead models that provide biological cues that are relevant in the tumor microenvironment.

Material and method

The HuLu051421 lung cancer cell line was cultured in suspension to generate tumor organoids, which were subsequently processed to obtain unitary organoids with defined size. To enhance biomimicry, these organoids were co-cultured with cancer associated fibroblasts and embedded in a gelatin/hyaluronan photocrosslinkable hydrogel, with a bioprinting-assisted deposition. The generated unitary tumor-stroma organoids were characterized through immunohistochemistry, proteomics, and live-cell imaging to assess cellular composition, ECM deposition, and tumor-stroma architecture. To evaluate the model's suitability for drug screening, different standard-of-care chemotherapeutics were administered, and therapeutic efficacy was assessed using viability assays and bioimaging analysis.

Result and discussion

The biofabricated lung tumor organoids successfully recapitulated key aspects of the native tumor microenvironment, including the presence of heterogeneous cell populations and ECM. The integration of cancer-associated fibroblasts within the hydrogel matrix led to enhanced stromal remodeling and the secretion of tumor-promoting factors (i.e., PDGFB, FGF and TGF-B1). Immunohistochemical analysis revealed distinct cellular organization patterns and proteomic analysis confirmed the upregulation of lung cancer protein signatures, supporting the model's physiomimetic relevance. Drug screening assays demonstrated differential responses to chemotherapeutics, with tumor-stroma organoids displaying increased resistance compared to standalone models.

Conclusion

Overall, the generated organoid-on-a-bead models demonstrate that the inclusion of stromal components and ECM mimetic hydrogels contributed to a higher resistance profile, reinforcing the necessity of tumor-stroma interactions and of ECM components inclusion in preclinical drug response studies.

Acknowledgments: This work was developed within the framework of EU INSPIRE project (grant ID: 101057777 a Cluster 1 - Health).

EACR25-2580

circRNAs-miRNAs-mRNAs regulatory axis of genes associated with hereditary prostate cancer: in silico analyses for screening potential biomarkers

I. Araujo Vieira¹, A. Fuentes², K. Nishino Miyamoto¹, M. Fontes-Dutra¹

¹*Universidade do Vale do Rio dos Sinos (UNISINOS), Health School, São Leopoldo, Brazil*

²*Universidade do Vale do Rio dos Sinos (UNISINOS), Biomedicine Undergraduate course, São Leopoldo, Brazil*

Introduction

Given that prostate tumors often develop asymptotically, the search for new biomarkers for early detection or improved prognosis evaluation of this type of tumor is essential. However, to date, a limited number of studies have explored circular RNAs (circRNAs), a class of long noncoding RNAs that are covalently closed loops and may function as microRNAs' (miRNAs) sponges, as potential biomarkers of prostate cancer (PCa), especially in the hereditary context (HPCa). This study aimed to analyze the set of miRNAs and circRNAs that regulate the expression of main genes associated with the occurrence of HPCa (HPCa-associated genes) through in silico analyses.

Material and method

The set of HPCa-associated genes was selected from a commercial genetic testing panel (Invitae) previously validated from the literature and widely used in clinical practice. To search comprehensively regulation of these HPCa-associated genes by miRNAs and circRNAs, three tools were used to gather experimentally validated miRNA-target (mRNA) and circRNA-miRNA interaction data: MirTarBase Release 9.0 beta, Tarbase-v9.0, and circRNADisease v2.0.

Result and discussion

Among the remarkable findings, 11 genes were reported as strongly associated with HPCa: ATM, CHEK2, BRCA1, BRCA2, MLH1, MSH2, MSH6, PMS2, EPCAM, HOXB13, and TP53. From the bioinformatics approach, TOP13 miRNAs over-represented as regulators of the genes of interest were identified: hsa-miR-18a-5p, hsa-miR-26a-5p, hsa-miR-19b-3p, hsa-miR-484, hsa-miR-15a-5p, hsa-miR-16-5p, hsa-miR-21-5p, hsa-miR-26b-5p, hsa-miR-19a-3p, hsa-miR-27a-3p, hsa-miR-454-3p, and hsa-miR-454-3p. Furthermore, four (4) specific circRNAs (hsa_circ_SMARCA5, hsa_circ_LARP4, hsa_circAGO2, and hsa_circ_PRKCI) were identified with significantly deregulated expression in biological samples (tumor tissues, cell lines, and xenograft models) related to prostate tumors and which regulate several of the TOP13 miRNAs found in the previous analysis. Importantly, upregulation of hsa_circ_PRKCI (also named circ_0081234) has been previously reported to promote migration, invasion, and epithelial-mesenchymal transition of PCa cells, through regulation of the miR-1/MAP3K1 axis.

Conclusion

Taken together, these in silico findings highlight 13 miRNAs and 4 circRNAs as important modulators of expression of HPCa-associated genes, which represent promising candidates for future experimental validation of their role as a putative set of biomarkers for early diagnosis and prognostic assessment in the CaPH context.

EACR25-2582

Drugable oncofetal RBP Musashi-1 provides a novel Approach for Therapy in immunologically cold High-grade Serous Ovarian Cancer Tumors

R. Rolnik¹, N. Bley¹, A. Rausch¹, M. Glaß¹, S. Hüttelmaier¹

¹*Martin-Luther-University Halle-Wittenberg, Institute of Molecular Medicine, Halle, Germany*

Introduction

High-grade serous ovarian cancer (HGSC) remains one of the most devastating female gynecological cancerous diseases. Characterization of gene expression patterns gave rise to four molecular subtypes (C1, C2, C4 and C5) with subtypes C1 (mesenchymal) and C5 (proliferative, immune evasive) being associated with the worst prospects of therapy. Despite minor advancements, effective therapy remains a challenge.

Material and method

In earlier work from our group using bulk RNA sequencing and siRNA screening of suitable C5-like cell lines, MSI1 emerged as a significant factor in modulating the landscape of immune-regulating tumor cell surface receptors, notably the expression of PD L1. Employing molecular in vitro binding studies, reporter and turnover assays, FACS and live cell imaging, we investigated the mechanisms through which MSI1 post-transcriptionally influences the fate of the PD-L1 mRNA and unfolds other oncogenic functions in suitable ovarian cancer cell models. Furthermore, known small molecule MSI1-Inhibitors Gossypol, Luteolin and R08-2750 were used

for in vitro compound testing to assess their therapeutic potential in HGSC.

Result and discussion

Here we report compelling evidence that MSI1 acts as a molecular oncogenic driver in the context of ovarian cancer, influencing proliferation and invasiveness. Additionally, high expression of MSI1 leads to an increase of PD-L1 presentation on the surface of C5-like HGSC tumor cells, unbalancing the delicate composition of activatory and inhibitory immune checkpoint receptor. This perturbation possibly substantially contributes to the immune desert phenotype of C5 HGSC tumors, diminishing T-cell infiltration and activation. The mechanism of this regulation is dependent on the 3'UTR of the PD-L1 mRNA, which contains six potential binding sites for MSI1. Whether or not this post-transcriptional control is achieved via enhancing translation, increasing transcript stability or other means remains elusive. MSI1-Inhibition using Gossypol, Luteolin and R08-2750 revealed promising micro-molecular effective concentrations in vitro, hopefully paving a road to novel therapy approaches.

Conclusion

Targeting oncofetal RBP MSI1 with small molecule inhibitors could complement established therapeutic regimes for treatment of HGSC tumors, possibly even enhancing efficacy of immune checkpoint therapies.

Cellular Model of Giant Cell Tumor of Bone: Insights from In Vitro and In Vivo Studies

P. Chlapek^{1,2}, V. Knechtová^{1,2}, I. Staniczkova Zambo^{2,3}, D. Zoufalý³, J. Neradil^{1,2}

¹*Masaryk University, Department of Experimental Biology, Faculty of Science, Brno, Czech Republic*

²*St. Anne's University Hospital, International Clinical Research Center, Brno, Czech Republic*

³*St. Anne's University Hospital and Faculty of Medicine, 3) First Pathology Department, Brno, Czech Republic*

Introduction

Giant cell tumor of bone (GCTB) is a disease mainly affecting epiphyses and metaphyses of long bones. Although GCTB is primarily benign, the choice of the correct treatment prevents recurrence and transformation into malignant disease. GCTB is specific for the presence of two cell types, neoplastic stromal cells and osteoclast-like giant cells. Although a cell model composed of such distinct populations is not easy to establish, its existence is important for studying the efficacy of combination treatment approaches.

Material and method

Tumor models were established by co-culturing GCTB-derived cell lines with macrophages. GCTB-derived cell lines were used as a source of stromal cells. The THP-1 human monocyte cell line was used as a source for the formation of macrophages. Both in vitro and in vivo mouse co-cultivation models were established.

Expression of selected markers was analyzed in cells of these models by immunocytochemistry and immunohistochemistry.

Result and discussion

The ability to co-culture both cell types under 2D and 3D conditions was demonstrated. In addition to the detection of specific markers (H3.3G34W, CD68, and CD163) lines tagged with GFP and RFP were also used to correctly distinguish the origin of the cell populations. Only 3D aggregates formed from both cell line types showed tumorigenic potential in the mouse model. However, the in vivo model showed limited efficiency of the originally expected differentiation of monocytes into osteoclast-like cells. The tumor mass from the in vivo model showed neither osteoclasts nor stromal cells but was composed mainly of "histiocyte-like" cells.

Conclusion

To date, efforts to establish a cellular model of GCTB have explored several possibilities. The integration of osteoclasts, respectively the full differentiation of monocytes into osteoclasts, still represents a current challenge. Focusing on the properties of the extracellular matrix and its resemblance to bone represents a promising strategy.

This study was supported by project no. NU22-10-00054 from the Ministry of Healthcare of the Czech Republic and by the project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102)—Funded by the European Union—Next Generation EU.

Hijacking cerebral blood vessels: therapy-induced transcriptomic reprogramming of vessel co-opting glioma cells

N. Bauer¹, F. Görtler², A. Joshi², F. Kiefer¹

¹*University of Münster, European Institute for Molecular Imaging, Münster, Germany*

²*University of Bergen, Computational Biology Unit, Department of Biological Sciences, Bergen, Norway*

Introduction

Glioblastoma (GBM) patients are suffering from poor prognoses and therapeutic responses to the only few treatment options. After initial remission in response to the standard treatment of newly-diagnosed GBM, the tumor recurs in 90% of patients within two years. For recurrent GBM, anti-angiogenic combination therapy is considered the most promising intervention. Although anti-angiogenic therapies (AATs) may achieve progression-free survival temporarily, most patients die within one year after tumor recurrence. Cellular mechanisms underlying this initial therapy responsiveness followed by an aggravated lethal progression remain unclear. Vessel co-option (VCO), the hijacking of cerebral blood vessels (BVs) by tumor cells, which escape the central tumor mass, forms a potential mechanism of GBM to escape AAT. However, a lack of knowledge concerning the drivers and cellular mechanisms of AAT-driven VCO prevents specific targeting of therapy escape mutants and thus, addressing the aggravated lethal progressions in patients.

Material and method

We performed lightsheet fluorescence microscopy (LSFM) of intact murine brain hemispheres carrying

hypoxia-reporter (HRE-dUnaG3ALFA) expressing human GBM xenografts, which enabled the 3D-visualization of tumoral BV networks and oxygenation patterns in their entirety. Here we observed hypoxia-inducible transcription factor (HIF)-stabilizing vessel co-opting GBM cells that hijacked cerebral BVs in response to AAT with Bevacizumab. To identify drivers of this GBM sub-population, we isolated and RNA bulk sequenced these tumor cells to screen for differentially expressed genes.

Result and discussion

LSFM of GBM xenografts revealed a tumor cell sub-population that vessel co-opted cerebral and apparently well-perfused BVs in response to AAT. These cells activated a hypoxia-responsive element (HRE)-dependent hypoxia-reporter, potentially by non-canonical HIF stabilization. Consistent with our observation, hypoxia and HIF-signaling have been proposed to fuel VCO in various tumor types. Our RNA bulk sequencing approach revealed a differential transcriptomic profile of this perivascular/HRE-active sub-population in comparison to cells isolated from the central tumor of AAT-treated mice or vehicle-treated tumors. In particular, candidate genes associated with cancer cell stemness and epithelial-to-mesenchymal transition (EMT) were significantly upregulated and might present as potential drivers of VCO.

Conclusion

VCO as an escape mechanism to AAT might contribute to the aggravated lethal progressions in recurrent GBM patients. So far, there is no therapeutic strategy available to target vessel co-opting therapy escape mutants. Here, we identified differentially expressed genes that were specifically upregulated in vessel-co opting GBM cells during AAT and might act as drivers of VCO in AAT-induced therapeutic escape.

³Hospital Universitario Alcorcón-Universidad Rey Juan Carlos, Department of Urology, Alcorcón, Madrid, Spain

Introduction

Cellular heterogeneity is the major obstacle to cancer cure. Despite the development of available anti-tumour therapies, resistance and recurrence are common, reflecting their ineffectiveness against all tumour cell phenotypes. The dynamic interactions between the tumour microenvironment and cancer cell plasticity drives intratumor phenotypic heterogeneity that promotes disease progression and underpins therapy resistance, representing an attractive therapeutic target. It has recently emerged that bi-directional interactions between cancer cells and adipocytes drive fatty acid uptake from

the microenvironment and represent a major factor in disease progression in cancer. Previous data of the group reveal the capacity of melanoma and colorectal cancer cells to induce lipolysis and fatty acid release from human adipose tissue in a phenotype-specific manner, the fatty acid uptake by tumoral cells, and the subsequent impact of fatty acids in invasiveness and metastatic dissemination in 2D models. It is essential to develop new in vitro three-dimensional models that more accurately mimic tumour structure and extracellular matrix (ECM) to study the role of the environment in tumour progression and to dissect the implicated molecular mechanisms. The aim of this work is to develop new in vitro three-dimensional models to study tumour-stroma signalling and therapeutic efficacy.

Material and method

Primary and metastatic melanoma and colorectal cancer cells and human preadipocytes were used to generate 3D multicell type spheroids. Standard cell biology techniques were used to characterise the spheroids.

Result and discussion

We have developed a simple scaffold-free protocol to generate human tumour/adipocyte 3D models. This method allows full differentiation of adipocytes in vitro, resulting in larger lipid droplets and increased lipid content of melanoma cells. We have optimised the culture conditions to avoid dedifferentiation of adipocytes, one of the main problems of in vitro adipocyte culture. Our model presents a complex extracellular matrix that closely resembles that of in vivo adipose tissue.

Conclusion

Our mixed spheroid model provides an improved culture system to study the molecular mechanisms involved in the contribution of adipose tissue to melanoma metastasis and acquisition of therapeutic resistance. This model could be used to study multiple tumours, as we demonstrate with colorectal cancer.

Pan-cancer analysis of successive whole genome duplication in the 100,000 Genomes Project

E. Smyth¹, A. Hawari², C. Wirth², D. Wedge², M. Ní Leathlobhair³

¹Trinity College Dublin, School of Genetics and Microbiology, Dublin, Ireland

²University of Manchester, Manchester Cancer Research Centre, Manchester, United Kingdom

³Trinity College Dublin, School of Genetics and Microbiology, Dublin, Ireland

Introduction

Whole genome duplication (WGD), involving the doubling of a complete set of chromosomes, is a pivotal evolutionary event in cancer that contributes to accelerated cancer genome evolution, increased tumour cell diversity, and poorer prognosis as well as exhibiting tissue-specific patterns. While the impact of a single WGD event is well-documented, the role of successive WGD (WGDX2) in driving cancer evolution remains underexplored. This study develops a consensus method for identifying WGDX2 events, integrating multi-faceted

genomic analyses to elucidate their impact on tumour progression and clinical outcomes.

Material and method

Whole-genome sequencing data from the Genomics England 100,000 Genomes Project, encompassing 9,420 tumour samples spanning 60 histologies, were analysed. Five distinct methods of WGDX2 detection were implemented: loss of heterozygosity and ploidy regression, allele-specific counts, average chromosome number calculation, phylogenetic tree reconstruction (MEDICC2) and subclonal mutational timing analysis (ParallelGDDetect). Samples were categorised as WGDX2 based on the agreement of three or more methods. Mutation timings were determined using MutationTimeR and evolutionary trajectories of WGDX2 samples were reconstructed using PlackettLuce Timer.

Result and discussion

WGDX2 was observed predominantly in specific tumour types, including breast, lung, colorectal, hepatopancreatobiliary, and upper-gastrointestinal cancers. Survival analysis revealed significantly poorer outcomes for WGDX2 tumours compared to WGD and diploid groups, with a higher prevalence of metastatic and recurrent disease in WGDX2 cases.

Conclusion

This study establishes a robust consensus framework for WGD+ detection, highlighting its association with aggressive tumour phenotypes and worse clinical outcomes. The findings underscore the importance of WGDX2 in shaping tumour evolution and progression. Understanding WGDX2 may reveal new therapeutic vulnerabilities and improve prognostic stratification in cancer.

Barcode-Based Approach Reveals Clonal Heterogeneity in Response to Combinatorial Treatment

D. Ngandiri^{1,2}, D. Lucarelli¹, D. Wellappili^{1,2}, C. Schneeweis^{1,2}, P. Putze^{1,2}, D. Saur^{1,2}

¹*Institut of Translational Cancer Research and Experimental Cancer Therapy, TranslaTUM, University Hospital Rechts der Isar of the Technical University of Munich, Munich, Germany*

²*German Cancer Consortium (DKTK), partnersite Munich, a partnership between DKFZ and University Hospital rechts der isar of the Technical University of Munich, Munich, Germany*

Introduction

Combination therapy has emerged as a promising strategy for treating pancreatic ductal adenocarcinoma (PDAC). Our previous findings show that combination therapy can reprogram immunosuppressive mechanisms, particularly in the mesenchymal PDAC subtype. Specifically, the novel combination therapy (trametinib + nintedanib, T/N) induces immunomodulatory chemokine secretion, promotes cytotoxic T-cell infiltration, and sensitizes mesenchymal PDAC to PD-L1 inhibition (Falcomatà et al., 2022). To map therapy-induced changes in the tumor microenvironment (TME) landscape, we conducted a time-course experiment examining T/N combination with immune checkpoint

blockade in vivo and in vitro. To assess dynamic transcriptional changes between the tumor cells and their TME in response to treatment, we employed lineage and RNA recovery (LARRY)-based barcoding.

Material and method

To investigate the characteristics of resistant and sensitive clones, we barcoded mesenchymal PDAC clones using the LARRY barcode and characterized their genomic features with low-coverage whole-genome sequencing (lcWGS). A pool of 40 distinct clones was orthotopically implanted into mice. We divided the cohorts into two experimental arms: control and treated (T/N + anti-PD-L1). Mice were sacrificed at specific time points, and in vitro samples were collected simultaneously. Samples were analyzed using Chromium 3'-scRNA-seq, FFPE-based Flex gene expression, and Xenium. To enable barcode detection with Flex, we designed specific probes for each clone.

Result and discussion

We successfully detected tumor barcodes using both 3'-scRNA-seq and Flex, thus allowing a clear distinction between tumor and non-tumor populations. Barcode analysis identified several treatment-resistant clones. Notably, two distinct populations emerged, including highly proliferative tumor cells with high Avil expression, predominantly composed of myc-amplified clones, and low-proliferative tumor cells with high Bgn expression, which showed more resistance to therapy. This analysis revealed gene signatures linked to resistance mechanisms against combinatorial therapy and immune checkpoint blockade.

Conclusion

Barcode-based tumor detection offers a powerful approach for tracking clonal dynamics, identifying resistant populations, and uncovering molecular mechanisms of therapy resistance in PDAC.

EACR25-0646

Unveiling the heterogeneity of pancreatic cancer initiation: a novel perspective on normal-mutant cell-cell Interactions

E. Reed¹, J. Morton², P. Acedo Nunez³, C. Hogan¹, B. Salvador Barbero¹

¹*Cardiff University, European Cancer Stem Cell Research Institute, Cardiff, United Kingdom*

²*CRUK Scotland Institute, Preclinical Pancreatic Cancer Lab, Glasgow, United Kingdom*

³*University College London, Institute for Liver & Digestive Health, London, United Kingdom*

Introduction

Pancreatic cancer (PC) is a devastating disease with abysmal survival rates, due to late diagnosis and early metastasis. Understanding PC development is crucial to identify biomarkers of early disease and prevent its progression. In most cases, PC initiates from KRAS mutant cells. These cells induce permanent acinar-to-ductal metaplasia (ADM). KRAS mutant cells drive the progression of ADM to pancreatic intraepithelial neoplasias (PanINs). Accumulation of other genomic alterations drive PanINs progression to invasive carcinoma. Our preliminary data, using a mouse model that more accurately mimics sporadic disease by

activating KRas mutations only in few cells of the pancreatic epithelium, unearthed the presence of non-mutant cells in PC initiation. This suggests a collaboration between non-mutant and KRas mutant cells in PanINs and tumours.

Material and method

FLASH tissue clearing was used to process banked mouse tissue samples, enabling 3D visualization of KRas mutant and non-mutant cell distribution in tumours and PanINs. BaseScope Duplex Assay *in situ* hybridization identified cells carrying the three most common point mutations in the KRas oncogene (G12D-40% of cases, G12V-35%, G12R-20%) and wildtype sequence in mouse and human samples.

Result and discussion

By analysing banked mouse tissue, we demonstrated how the 3D distribution of KRas mutant cells changes through neoplastic lesion development and tumour progression, unveiling mixed populations of mutant and non-mutant cells within PanINs and tumours. We observed an increase in the % of RFP+ cells overtime, with full RFP+, full RFP-, and mixed PanINs found. The transition from low-grade to high-grade PanIN is accompanied by an increase in non-mutant cells neighbouring mutant cells, suggesting a dynamic interplay between the two is required for tumour progression. We also unravel the heterogeneity of KRas wildtype and mutant cells in the same neoplastic lesion using BaseScope, confirming the presence of both KRas mutant and non-mutant cells. We observed that whilst some cells remain wildtype, others acquire KRasG12D, KRasG12V, and KRasG12C mutations.

Conclusion

To conclude, this work has highlighted the heterogeneity of PanINs and tumours in both a mouse model of sporadic disease and human tissue. The observed mixture of KRas mutant and non-mutant cells suggests a dynamic interplay between the two, and that KRas mutant cells may recruit non-mutant cells to PanINs to utilise them as support for lesion development. By beginning to understand this interplay further, we can begin to identify novel therapeutic targets and develop strategies for early detection and prevention of pancreatic cancer.

Development of an innovative microdissection platform to study tumor spatial heterogeneity

M. Golias^{1,2,3}, Z. Krupova¹, P. Defrenaix¹,

M. Heymann^{2,3}, D. Heymann^{2,3}

¹*Exclone, Elancourt, France*

²*Nantes Université, CNRS, UMR 6286, US2B, Nantes, France*

³*Institut de Cancérologie de l'Ouest, Tumor Heterogeneity and Precision Medicine Lab., Saint Herblain, France*

Introduction

The intrinsic heterogeneity of tumors makes the study of the underlying mechanisms of tumor spread and molecular diagnosis a real challenge. Therefore, it is of great interest to identify and understand these mechanisms in order to determine the most appropriate treatment for each patient.

Material and method

Here, we describe an innovative microdissection platform called MiniPunch®. Based on the use of 200µm diameter and depth controlled single-use needles, this system is able to collect samples automatically in formalin-fixed paraffin-embedded (FFPE) blocks. Sampling of specific areas is enabled by the use of artificial intelligence that allows automatic alignment between the annotated virtual slide and the original FFPE block. A high sampling rate (~40 sec/sample) facilitates its routine use.

Result and discussion

Our work aims to demonstrate the relevance of this technology for the study of intrinsic tumor heterogeneity. To this end, after validating the applicability of the technology, we performed RNA-seq on MiniPunch® samples obtained from human tumors. We were able to show variations in transcriptome expression with respect to both location and stage of disease. We also demonstrated the potential of this technology for molecular diagnosis by comparing it with routine techniques. The results showed increased sensitivity with MiniPunch® samples and access to critical information on intra-tumor heterogeneity that can improve the accuracy of established diagnosis.

Conclusion

This platform, capable of investigating tumor heterogeneity, will contribute to a better understanding of the complex mechanisms involved in tumor evolution. In this way, by improving molecular diagnosis, this system will contribute to the global development of precision medicine and thereby improve patient care worldwide.

EACR25-0834

Barcode-based lineage tracing to track breast cancer clonal evolution

C. Merle¹, I. Di Terlizzi², M. Huyghe¹, S. Rulands³, S. Fre¹

¹*Institut Curie, Paris, France*

²*Max Planck Institute, Dresden, Germany*

³*Ludwig Maximilian University, Munich, Germany*

Introduction

Despite significant progress in understanding tumor phylogeny through whole-genome sequencing, the cellular origins of breast cancer and their dynamic clonal evolution remain poorly understood. By integrating barcode-based *in vivo* lineage tracing with single-cell RNA sequencing, we aim to delineate the hierarchical organization of tumor cells and uncover the molecular dynamics driving tumor progression and metastatic dissemination.

Material and method

We utilize a novel mouse model that enables *in vivo* labeling of individual cells with a highly diverse set of genetic barcodes, allowing precise lineage tracing throughout tumor development and metastasis. Clonal tracking is performed in the MMTV-PyMT mammary tumor model at both pre-neoplastic and advanced tumor stages. This approach enables us to simultaneously assign each cell to a specific clone and determine its transcriptional signature.

Result and discussion

Our analysis reveals two distinct transcriptomic trajectories leading to EMT states. These trajectories are

associated with divergent molecular programs: one linked to an injury-associated state and the other to differentiation toward an alveolar lineage. Notably, these EMT trajectories correlate with distinct prognostic outcomes in human breast cancer, underscoring their potential clinical relevance.

Conclusion

By leveraging a novel lineage-tracing strategy, our findings provide fresh insights into the role of EMT in tumor heterogeneity and cancer progression. This study highlights the diverse transcriptional landscapes shaping breast cancer evolution and offers a framework for understanding how EMT contributes to metastatic potential.

EACR25-0879

Characterising the immunogenetic heterogeneity in liver cancer to understand the varied responses to immunotherapy, with a focus on multifocal disease

A. Connor¹, L. Chang², K. Scott¹, F. Ismail¹, E. West¹, D. Newton¹, A. Samson¹

¹*University of Leeds, Leeds Institute of Medical Research, Leeds, United Kingdom*

²*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Introduction

Liver cancer is the third-leading cause of cancer-related death worldwide. It arises in the context of a diseased liver, linked to alcohol, obesity or hepatitis viruses. Patients with advanced hepatocellular carcinoma are all offered the same standard-of-care immunotherapy, a combination of anti-VEGF and anti-PD-L1 monoclonal antibodies, but just a third of patients experience a slowing of tumour growth. Understanding what makes these patients different to each other is crucial in understanding how we can stratify them for treatment and identify opportunities for novel therapeutic strategies. These patients often present with multiple tumors at the same time, providing a unique opportunity to study this heterogeneity at both the inter- and intra-patient level.

Material and method

56 paired formalin-fixed, paraffin-embedded background liver and tumour samples were obtained from the National Health Service. DNA was extracted for Whole Exome Sequencing and a subtractive analysis was performed to identify tumour-specific variants. Sections were cut from the same samples and stained for proliferation (Ki-67) and immune cell (CD4, CD8, FoxP3) markers, using Immunohistochemistry. Stained images were quantified automatically using QuPath.

Result and discussion

Tumour mutation burden analysis for this cohort confirmed a low average value, compared to other tumour types, but a large range was seen. Genetic patterns were observed between different aetiological groups, with genes mutated at differing frequencies. Ki-67 staining revealed that the proliferation rate is significantly higher at the tumour periphery, compared to the core. This suggests that the tumours could align with

a 'boundary-driven' growth pattern that has been observed in other tumour types. When compared to background liver, the frequency of CD4+ and CD8+ immune cells was not significantly increased in the tumours and was highly variable. However, the frequency of regulatory FoxP3+ T cells was significantly increased, overall indicating a suppressive immune environment. In multifocal patients, the mutational data indicated a range of tumour relatedness and evolution contexts. Interestingly, many tumours with genetic similarity appear in separate lobes of the liver. The immune cell frequencies were often found to be highly variable, even in apparently metastatic tumours.

Conclusion

Immunogenetic profiles were found to be highly heterogeneous, both between separate patients and within the same patient. The finding that many tumours do not have an increase in CD4+ and CD8+ T cells, compared to the paired healthy liver samples, supports a mechanism whereby an initially 'immune cold' tumour immune microenvironment limits the benefit of immune checkpoint blockade. This suggests that a tumour-targeted treatment approach would be efficacious for many patients, with the genomic data providing strong rationale for personalisation within aetiological groups.

EACR25-1033

Patient-derived tumor xenografts as models of acquired chemoresistance – studying melanoma, renal cell carcinoma and non-small cell lung cancer

M. Cserepes¹, C. Szarvas^{1,2}, Á. Juhász^{3,2}, J. Tóvári¹

¹*National Institute of Oncology, Department of Experimental Pharmacology and National Tumor Biology Laboratory, Budapest, Hungary*

²*Semmelweis University, Doctoral school, Budapest, Hungary*

³*National Institute of Oncology, Pharmacy, Budapest, Hungary*

Introduction

Cancer therapy was revolutionized in the last two decades by molecularly targeted therapies. However, in many cases, the efficient and manageable treatment declines within months or few years due to repopulation of the tumor with resistant cells, which leads to progression and metastasis – the two major factors of cancer mortality. Cell line model treatments can show individual cell changes following treatment, but found targets usually are failing to be translatable to clinics. Patient-derived tumor xenograft (PDTx) models are resembling heterogeneity, structure, plasticity of the tumors more than cell lines. Therefore, we wanted to see if resistance evolution in PDTx models assimilate to those in cell lines, or can reveal novel pathways of interest.

Material and method

We performed long-term treatment on melanoma (MM), renal cell carcinoma (RCC), and non-small cell lung cancer (NSCLC) with the respectively approved targeted drugs: vemurafenib, sunitinib and erlotinib. NOD-SCID mice used have limited timespan for the experiment, thus

tumors were serially transplanted and treated again. This fashion enabled us to collect flash-frozen samples from each generation of mice. The samples were either analyzed using mRNA-seq to show genetic background and changes in the landscape during treatment, or possible suspects were further confirmed by rt-pcr, western blot or immunohistochemistry.

Result and discussion

In melanoma, BRAF V600E mutation specific inhibitor usually is reported to enhance MAPK or AKT pathway activities, as well as loss of the mutation, or enhancement of CRAF. Intriguingly, none of these changes were recorded in PDTX resistance model, whilst upregulation of multidrug resistance determinant ABCB1, immune checkpoint stimulator CD27, or interferon inducible protein IFI27. In our RCC models, two different resistance strategies were identified, one described by the overexpression of MAPK pathway, the other by silencing cell cycle and apoptosis, generating the tumors from a slower, mesenchymal, motile cell phenotype. In NSCLC, the resistance mutation of EGFR was identified in one case, while altered MAPK and PI3K signaling in case of the other model.

Conclusion

Our PDTX resistance experiments show clear evidence that previously published resistance mechanism share role with unknown, patient-specific resistance strategies. With an increasing number of such model experiments, typical background landscapes might be identified to propose and intervene probable drug tolerance in solid tumors.

EACR25-1093

HPMA-based polymeric conjugate bearing derivative of HIV protease inhibitor lopinavir successfully reverses P-gp mediated multi-drug resistance in vitro and in vivo

D. Starenko¹, L. Kostka², K. Běhalová¹, L. Kotrčová², J. Kovářová¹, V. Šubr², J. Kousalová², T. Etrych², M. Kovář¹

¹*Institute of Microbiology of the Czech Academy of Sciences, Laboratory of Tumor Immunology, Prague, Czech Republic*

²*Institute of Macromolecular Chemistry of the Czech Academy of Sciences, Department of Biomedical Polymers, Prague, Czech Republic*

Introduction

Multi-drug resistance (MDR) is a common phenomenon in cancer. It may occur after several courses of chemotherapy (i.e. induced MDR) or could be an innate feature of some cancer types (i.e. natural MDR). MDR is often caused by overexpression of P-glycoprotein (P-gp), a member of ABC-transporter family, enabling cancer cells to efflux structurally unrelated anti-tumor drugs. Here we introduced a derivative (5-methyl-4-oxohexanoic acid ester) of HIV protease inhibitor lopinavir (LD) possessing high inhibitory potential for P-gp as well as STAT3 signaling covalently bound to N-(2-hydroxypropyl) methacrylamide (HPMA)-copolymer-based carrier (P-LD). We tested this conjugate in combination with similar conjugates bearing some conventional cyto-

static drugs in several cancer cell lines to evaluate its ability to overcome MDR in these lines and sensitize them to the drug action in vitro and in vivo.

Material and method

P388/MDR murine monocytic leukemia cell line with induced MDR and CT26 murine colon carcinoma as well as SCC7 murine head and neck squamous carcinoma with natural MDR were main model cancer cell lines used in this study. BALB/c, DBA/2 mice and NSG immunodeficient mice were used for in vivo testing. We used Real-Time PCR to assess relative P-gp expression in cancer cell lines. For evaluation of P-gp and STAT3 inhibitory activity of LD and P-LD calcein efflux assay and western blotting (as well as ELISA) were used, respectively. [3H]-thymidine assay and annexin V assay together with caspase-3 activity assays were used to determine cytostatic and cytotoxic activities of tested compounds. In vivo experiments involved treatment of tumor-bearing mice with polymeric conjugate combinations with subsequent monitoring of tumor growth, survival and body weight.

Result and discussion

Both LD and P-LD demonstrated potent P-gp inhibition. LD was confirmed to inhibit STAT3 signaling pathway. We also proved that tested compounds possess synergic cytostatic and cytotoxic effects in cancer cell lines in vitro when applied in combination with polymeric conjugates bearing several conventional cytostatic drugs (doxorubicin, mitoxantrone and docetaxel). In vivo experiments demonstrated an ability of combined treatment to slow down tumor growth and prolong survival in the models of cancer with both induced and natural MDR.

Conclusion

P-LD has a good potential as safe and effective P-gp inhibitor able to boost efficacy of anti-tumor drugs in P-gp expressing tumors. Further in vivo evaluation is required to ensure the best combination and application scheme for maximal efficacy of treatment using the compound.

The study was supported by the project National Institute for Cancer Research (Programme Exceles, ID Project No.LX22NPO5102) – Founded by the European Union – Next Generation EU and by the grant NU21-03-00273 from the Czech Health Research Council.

Unraveling Breast Cancer Heterogeneity: Microfluidic Sorting and Bioassay-Based Functional Analysis

E. Yilmaz¹, Z. Fan², J. Beech¹, V. Swaminathan², J. Tegenfeldt¹

¹*Lund University, Physics, Lund, Sweden*

²*Lund University, Medicine, Lund, Sweden*

Introduction

The metastatic potential of cancer cells is closely linked to their mechanical properties, which evolve with cancer progression and heterogeneity. However, characterizing these properties requires robust tools for sorting and analysing distinct subpopulations. Small and large tumor cells play different roles, with smaller cells exhibiting higher proliferative potential and initiating new tumors, while larger cells may be more differentiated or adapted to specific microenvironments. This study presents a

deterministic lateral displacement (DLD)-based microfluidic device for the label-free sorting of MDA-MB-231 metastatic breast cancer cells into sub-populations based on morphological differences. We investigate the impact of sorting on cell behaviour and assess bio-functional heterogeneity using proliferation, migration and biomarker assays.

Material and method

A microfluidic device with three inlets and three outlets was utilized to fractionate breast cancer cells into sub-populations: small, medium and large. The sorting efficiency is validated using inverted microscopy and post-sorting behaviour is analysed through long-term culturing and functional assays. To assess the biological differences between subpopulations, we perform: Cell proliferation kit to monitor growth rates over one week. Cell migration assays to examine motility differences across subpopulations. Holographic microscopy for long-term tracking of cellular dynamics and their role in metastasis. Biomarker assays (Ki67 and YAP) to further explore differences in proliferation and mechanical signaling.

Result and discussion

Homogeneous subpopulations of small, medium and large cells were successfully isolated. All subpopulations demonstrated continued proliferation from day 0 to day 6. Large subpopulations exhibited significantly higher motility than small and medium subpopulations, suggesting that cell size influences metastatic potential. This is in line with previous reports highlighting the role of cytoskeletal adaptations in invasion dynamics. YAP labeling revealed that small cells experienced more mechanical stimulation than the larger groups, suggesting enhanced mechanotransduction pathways. This may indicate increased responsiveness to extracellular matrix stiffness, which could contribute to their invasive potential. The observed differences in migration, proliferation, and mechanotransduction highlight the functional heterogeneity of breast cancer subpopulations.

Conclusion

This study demonstrates the power of DLD-based microfluidics as a high-throughput, label-free approach for studying cancer heterogeneity. Future work will focus on generating 3D spheroid models from sorted subpopulations to further investigate their role in tumor progression, drug resistance and invasion mechanisms, ultimately aiding in the development of more targeted therapies for aggressive breast cancer.

The nucleolus connects inflammation and tumor cell plasticity in colorectal cancer

J. Pelletier¹, A. Tocaccet², X. Hernando-Momblona³, E. Batlle³

¹*University of Barcelona / IDIBELL / IRB Barcelona, Physiological Science, Hospital de Llobregat, Spain*

²*University of Barcelona / IDIBELL, Physiological Science, Hospital de Llobregat, Spain*

³*IRB Barcelona, Colorectal Cancer Laboratory, Barcelona, Spain*

Introduction

Colorectal cancer (CRC) is a major health problem and economic burden worldwide. The tumor micro-environment and cell heterogeneity are well-established determinants of cancer progression and an important cause of resistance to chemotherapies. Tumor hierarchies are fueled by a small population of self-renewing cancer stem cells (CSCs), reminiscent of the intestinal epithelium. Recent studies have uncovered the existence of zonations of biosynthetic active cells in defined niches of the tumors, with hyperactive ribosome biogenesis and protein synthesis defining cancer stem cells properties, whereas tumor cells undergo a progressive loss of their biosynthetic capacity during differentiation. We hypothesized that loss of ribosome biogenesis could act as a driver of differentiation in colorectal cancer.

Material and method

We used patient-derived organoids (PDOs) and preclinical models of CRCs including subcutaneous PDXs and liver metastasis derived from intrasplenic PDOs injection, in which we inhibited ribosome biogenesis by several approaches amongst which pharmacological inhibitors of RNA polymerase I.

Result and discussion

We showed in PDOs and PDXs that inhibition of ribosome biogenesis induces a reversible differentiation transcriptional program. We performed single cell RNA sequencing in PDOs which revealed that cell-autonomous inflammation programs are activated in response to ribosome biogenesis inhibition, suggesting a role in CRC differentiation plasticity. We then performed a 3D-HTS drug screening of 264 anti-inflammatory drugs in PDOs, and identified drugs, that in combination with ribosome biogenesis inhibition leads to terminal differentiation.

Conclusion

These findings show that:

- (i) ribosome biogenesis and translational control regulate CRC cell differentiation, and
- (ii) cell-autonomous inflammation contributes to CRC plasticity, opening an avenue to novel differentiation therapies in colorectal cancer.

EACR25-1414

Investigating Clonal Dynamics and Drivers of Oxaliplatin Resistance in Colorectal Cancer Using Cellular Barcoding Technology in SW480 Cell Line

O. Basar¹, G. Yilmaz¹, K. Yilmaz¹, A. Acar¹

¹*Middle East Technical University, Ankara, Turkey*

Introduction

Chemotherapy resistance in colorectal cancer (CRC) is a multifaceted process driven by the diverse contributions of individual cancer cell clones. The presence of cancer cell clone subpopulations with varying sensitivities to therapy allow resistant clones to survive and expand, ultimately reducing treatment efficacy and contributing to disease progression or recurrence. To investigate the mechanisms underlying this resistance, we established oxaliplatin-resistant SW480 cells and employed cellular DNA barcoding technology to track their clonal evolution. Our approach also aimed to identify drivers of

oxaliplatin resistance and to uncover secondary drug vulnerabilities to counteract resistance.

Material and method

We used cellular DNA barcoding technology to track SW480 individual clones during the resistance process. All analyses were performed in three drug resistant replicates and control groups. Using amplicon sequencing, we analyzed the barcode distributions across oxaliplatin-resistant and control groups. Whole-exome sequencing (WES) was employed to uncover genomic alterations that may have a pivotal role in resistance mechanisms. Additionally, a secondary drug screen of a 50-compound library was performed to explore therapeutic possibilities.

Result and discussion

We used amplicon sequencing to identify barcode distributions, and the pre-existing vs de novo nature of clones selected through the resistance generation process. Whole-Exome Sequencing (WES) was employed to uncover the genomic make-up of oxaliplatin resistance, highlighting the differences in mutational landscapes of the resistant groups. Finally, a secondary drug screening was performed using a 50-compound drug library, for an ultimate aim to exploit therapeutic vulnerabilities arising from oxaliplatin resistance.

Conclusion

To conclude, this study underscores the utility of cellular DNA barcoding as a powerful tool for dissecting the complex evolution of chemotherapy resistance in cancer. Our findings provide critical insights into the clonal dynamics and molecular drivers of CRC drug resistance, paving the way for targeted approaches to overcome resistance and improve treatment outcomes.

EACR25-1510

Homopolymer diversity at ultrafast evolving loci accurately reflects tumour mutation rate in mismatch repair-deficient (MMRd) CRC

L. McKenzie¹, W. Cross¹, H. Kayhanian¹, M. Jansen¹

¹UCL Cancer Institute, Cancer Biology & Pathology, London, United Kingdom

Introduction

Mismatch repair-deficiency (MMRd) occurs in approximately 15% of colorectal cancers (CRC). Extensive mutational damage fuels tumour growth but also increases neoantigen burden, rendering these cancers vulnerable to attack by the immune system. Recent work in our lab has uncovered a novel mechanism whereby coding homopolymers in the minor MMR genes, MSH3 and MSH6, are repurposed by MMRd tumours as cellular ‘gear switches’ to adapt mutation rates to immune selection (Kayhanian et al., 2024). Spontaneous mutation and reversion within these repetitive tracts modulates subclonal mutation rate, mutation bias and clonal HLA diversity during MMRd cancer evolution, accelerating immune escape. Building on this concept, our goal was to design a method to comprehensively map evolving genomic mutation rates in MMRd CRCs.

Material and method

Owing to their hypermutable nature, microsatellites are widely used to assess the tempo and mode of genomic

evolution. MMRd tumours exhibit elevated population heterogeneity, reflected by greater microsatellite length diversity, as well as an increased exonic mutation burden. Therefore, we reasoned that coding microsatellites in MSH3/MSH6-deficient clones undergo faster erosion than in their MSH3/MSH6-proficient ancestor lineages, allowing the derivation of a small targeted sequencing panel of homopolymers that together act as a proxy for tumour mutation rate. The final panel design consisted of coding microsatellites responsive to changes in mutation rate, alongside non-coding microsatellites included as an internal control. To quantify genomic diversity at these loci, we performed high-depth (1000x) sequencing of multi-region FFPE resection samples and derived ecological diversity indices, including the Shannon diversity index (SDI) and Jensen-Shannon distance (JSD).

Result and discussion

Preliminary results indicated that SDIs and JSJs across responsive loci strongly correlated with MSH3/MSH6 mutation status, with increased SDIs in MSH3/MSH6-deficient compared to MSH3/MSH6-proficient clones (i.e. regions of high and low mutation rates, respectively). Non-coding control loci showed no difference in SDIs or JSJs between tumour regions, and this was reproducible across all patient samples. Both intra-patient and inter-patient differences in SDIs and JSJs were observed across the cohort, with reconstructed phylogenies accurately reflecting the relationship between normal, MSH3/MSH6-proficient and MSH3/MSH6-deficient tumour samples.

Conclusion

Our findings suggest that genomic diversity at key ultra-fast evolving microsatellite loci can be used to infer genome-wide mutation rate. The small genomic footprint of the targeted panel enables affordable high-depth sequencing to reveal clonal diversity from small amounts of FFPE archival material. Further work is needed to validate our methodology in larger cohorts and explore its clinical application in MMRd CRC management.

EACR25-1606

Exploring the role of intratumor heterogeneity and tumor microenvironment crosstalk in the acquisition of cisplatin resistance in High-Grade Ovarian Carcinoma models

L. Perotti¹, E. Capellini¹, L. Guarnera¹, I. Craparotta¹, M. Barbera¹, A. Vallerga¹, C. Grasselli¹, M. Bolis¹, F. Ricci¹

¹Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Experimental Oncology, Milan, Italy

Introduction

Ovarian cancer is the fifth leading cause of cancer-related deaths, affecting ~100,000 women annually. High-grade serous ovarian carcinoma, the most common histotype has a 5-year overall survival rate of around 35%.

Although most patients respond to first-line therapy, 70% relapse within 3 years with a resistant disease. Tumor heterogeneity has been described as a hallmark of cancer progression, impairing the efficacy of cancer therapy.

Material and method

Single-cell technologies were used on a patient-derived xenograft ovarian cancer model (MNHO124), well-representing the clinical setting of the evolution of platinum resistance. MNHO124 subcutaneously transplanted nude mice were randomized and treated or not with cisplatin (5 mg/kg q7dx3). Whole tumor masses were excised from euthanized mice at: 1) "Random Time" before treatment; 2) "Best Response" when tumor reaches about 90% of regression; 3) "Regrowing", when the tumor mass re-enters a proliferative state. Tumor samples ($n = 4$) were processed following 10x Genomics® protocols. RNA sequencing was performed by Illumina® technology. The bioinformatic analysis carried out with Seurat v5.

Result and discussion

Cells sequenced at the three time points were plotted in a Uniform Manifold Approximation and Projection (UMAP), and the clusters of the tumor and of the murine component were observed. The analysis on the human component has identified a total of 12 clusters. Some of these were predominantly composed of cells from a specific time point, leading us to classify them as time-point-specific. To identify their unique gene expression signatures, we performed differential gene expression and pathway enrichment analysis both for the top-expressed and downregulated genes. Signatures specific to the clusters associated with the "Regrowing" timepoint in the tumor component (e.g., DNA damage response, mitochondrial metabolism) are currently being validated using different molecular assays on different ex vivo and in vitro models, to understand if the mechanisms highlighted can represent a target of interest. The UMAP of the murine component revealed 13 distinct clusters, whose representation was uneven across the three timepoints. Both an automated and manual annotation of the murine component clusters are being performed to characterize the main populations composing the tumor microenvironment at the different timepoints and to investigate their evolution over time and their crosstalk with the human compartment.

Conclusion

These results provide new evidence on the role of tumor heterogeneity in the development of resistance to cisplatin in ovarian cancer. The scRNA sequencing analysis enabled the identification of distinct cell clusters, whose transcriptional signatures are still under investigation, and revealed potential markers and pathways involved in tumor progression and therapeutic response.

EACR25-1677

In Vivo, Time-Dependent Metabolic Flux Analysis of Normal and Tumor Tissue Using MasSpec Pen Technology

M. Tuck¹, Y. Shanneik¹, H. Janakiraman¹, Z. Gao¹, F. Jackobs¹, T. Godfrey¹, E. Camp¹, L. Eberlin¹

¹Baylor College of Medicine, The Michael E. DeBakey Department of Surgery, Houston, Texas, United States

Introduction

Pancreatic ductal adenocarcinoma (PDAC) is the most common and aggressive form of pancreatic cancer, accounting for ~90% of cases. It is a particularly lethal

disease, with a five-year survival rate of ~10%. Alterations in metabolic pathways are key to tumor growth, disease progression, and response to therapy. Metabolic flux analysis is a technique to quantify the rates of metabolic activity via isotopically labeled substrates. These assays are commonly performed on excised tissues with liquid chromatography mass spectrometry (MS). Here, we provide direct MS analysis of PDAC tissue using the handheld MasSpec Pen (MSPen), establishing the potential for *in vivo*, time-dependent metabolic flux analysis.

Material and method

KPC cell line-derived syngeneic orthotopic PDAC mouse model undergoes surgery for the implantation of tumor cells into the pancreas. Tumors grow for 4 weeks without treatment. Metabolic flux analysis is performed by injecting peritoneally 1.4 mg/g [$^{13}\text{C}_6$] glucose and sacrificing at 0.5h, 1h, 1.5h, and 3h for each respective mouse. Organs are harvested and flash-frozen in liquid N₂ for mass spectrometric analysis by the MSPen. Desorption electrospray ionization MS imaging was also obtained. This work led to *in vivo* tissue analysis under anesthesia (2% isoflurane 0.2 L/min in 100% oxygen), providing real-time temporal insight into the fate of 13C-glucose and its transformations in a live mouse.

Result and discussion

On *ex vivo* tissue, varying degrees of labeling for metabolites, such as glutamic acid and pyroglutamic acid were found by MSPen analysis. The brain was the most metabolically active organ, with enrichment of glutamic acid over 40% for the M+1 and M+2 isotopologues compared to the theoretical and a 12C-glucose control animal. Interestingly, while labeled alanine was detected, labeled pyruvate was not detected at the sampled timepoints. DESI-MSI of the brain shows the localization of glutamic acid in matching M+1 and M+2 isotopologues. Significant enrichment was also detected in other organs, such as the kidney and liver, between 6 to 10%. For example, pyroglutamic acid in the kidney peaked at 1 h and 1.5h, then dropped precipitously at the 3 h timepoint. For pancreatic cancer models, we analyzed n = 3 animals at 4 timepoints and 8 organs, including the tumor. An *in vivo* analysis was performed by anesthetizing a mouse isoflurane. Analysis during surgery with the MSPen revealed higher levels of enrichment *in vivo* at comparable timepoints, particularly for the higher isotopologues, M+3 and M+4.

Conclusion

Overall, the direct, longitudinal, and *in vivo* metabolic flux analysis in a single animal model we describe here may impact many areas of cancer research.

EACR25-1755

Characterizing polyp heterogeneity to identify those at higher risk of progressing to colorectal cancer

L. Bassaganyas¹, C. Júlia², T. Lahoul¹, J. Bourgaux³, J. Camps², J. Pannequin¹, C. Bonnans¹

¹Institut de Génomique Fonctionnelle, Univ. Montpellier, CNRS, INSERM, Montpellier, France

²Autonomous University of Barcelona (UAB), Cell Biology and Medical Genetics Unit, Department of Cell

Biology, Physiology and Immunology, Faculty of Medicine, Bellaterra, Spain

³*Centre Hospitalier Universitaire, Nîmes, France*

Introduction

Colorectal cancer arises from precancerous lesions called polyps, most of which are benign, but some have the potential to progress to cancer. Early detection and polypectomy significantly reduce colorectal cancer incidence, but risk-based patient stratification could help avoid unnecessary and costly surveillance colonoscopies. Identifying high-risk polyps is therefore crucial, particularly through the identification of transcriptomic biomarkers, which may pave the way for predictive blood-based markers. Tumor microenvironment (TME) is a complex and dynamic ecosystem that is heterogeneous even at the earliest stages of tumorigenesis. In an Apc-mutated mouse model of intestinal tumorigenesis, we previously identified two distinct types of polyps, one of which exhibited a transcriptomic signature associated with immune infiltration. Given that inflammation is known to drive genomic instability, proliferation, and tumor progression, we aim to investigate whether this immune signature is also present in human polyps and whether it is linked to an increased risk of malignant transformation.

Material and method

Bulk RNA sequencing was performed on a distinct transgenic mouse model and on a human cohort, including 20 intestinal adenomas from Apc-mutated mice and 42 patient-derived samples comprising 21 advanced adenomas and 21 adenocarcinomas. To classify these lesions, unsupervised clustering and nearest-template prediction analyses were applied using our previously defined immune signature. Additionally, single-sample Gene Set Enrichment Analysis and multiple deconvolution approaches were used to characterize immune cell composition and functional cancer-related states.

Result and discussion

In both mice and humans, adenomas can be broadly classified into two main groups (~50%) based on the immune transcriptional profiles. The “immune-up” lesions showed heterogeneity in immune cell composition and activation, but B cells and myeloid cells appeared to be consistently present in contrast to the other immune cell types such as NK and CD8+ T cells. Importantly, “immune-up” polyps share transcriptomic profiles more closely resembling those of adenocarcinomas, with significant enrichment of signatures of hypoxia, invasion, differentiation, and EMT.

Conclusion

Our study reveals a transcriptional dichotomy among polyps in both a well-established mouse model and human patients, suggesting a subset of immune-enriched lesions that may share molecular features with adenocarcinomas. Given their similarity to malignant tumors, these lesions may represent high-risk polyps with an increased likelihood of progression to colorectal cancer.

EACR25-1808

Selective Inter-clonal Interaction is Crucial for the Metastatic Phenotype of BRAF-inhibitor Resistant Melanoma

S. Bhowmik¹, S. Murukute¹, S. Badajena¹, A. Goyal¹, R. Virutkar¹, P. Mohapatra¹

¹*NIPER Guwahati, Biotechnology, Guwahati, India*

Introduction

Intra-tumoral heterogeneity is the major cause of therapy failure in malignant melanoma patients. Under chemotherapy pressure, the emergence of diverse drug-resistant clonal subpopulation and their intricate cooperation could contribute to a higher drug resistance, elevated tumorigenicity and metastasis. Multi-clonal interactions in tumors are very challenging to study, which demands relevant in vitro or in vivo models to investigate these events. Here we have shown how selective clonal interactions of BRAF-inhibitor resistant melanoma clones are crucial for melanoma progression and metastasis

Material and method

We have used a BRAF mutant malignant melanoma cell model, A375 and made them resistant towards the BRAF-inhibitor, Vemurafenib. The resistant cells were named A375VR. We have isolated three different clones (A375VR-C2, A375VR-C7, A375VR-C11), characterized them through whole exome sequencing, cell viability assays and ERK-activation analysis by western blotting. The clonal interaction was studied using 2D migration, spheroid expansion and in vivo CDX experiments (NIPER/BT/2022/2023). Signaling pathways involved with clonal interaction were evaluated by immunoblotting.

Result and discussion

Our results indicated that the A375VR cells comprised of multiple sub-populations of cells with different degrees of resistance towards Vemurafenib. Interestingly, our sequencing data revealed that the clones have different mutational spectra in the WNT and JAK/STAT3 genes and in addition, the metastatic signaling regulators of WNT and STAT3 cascades are variably expressed in these clones. As WNT and JAK/STAT signaling regulators significantly contribute to the metastatic phenotype of BRAF-inhibitor resistant melanomas, these molecular drivers could be involved with intra-clonal interaction driven tumorigenicity in BRAF-inhibitor resistant melanomas. Indeed, when the clones were grown in a co-cultured setup for cell migration and spheroid expansion studies, we observed that a few selective clones are positively interacting to increase coordinated migration or cell shedding from the spheroid. Our results showed that the clone A375VR-C11 interacts positively with clones A375VR-C2 and A375VR-C7 to increase migration. Based on these results, we conducted in vivo experiments and revealed that the combination of A375VR-C7 and A375VR-C11 induced higher tumorigenesis in animals compared to the individual clones. Altogether we have shown that selective clonal interactions in a heterogeneous tumor microenvironment are crucial for BRAF-inhibitor-resistant melanoma progression.

Conclusion

We have demonstrated a novel strategy to reveal the significance of clonal interaction and signaling involved during resistant melanoma progression. Similar approaches could be adopted to understand the clonal interaction driven metastasis in aggressive cancers and help formulating new therapeutic interventions.

Clonal evolution of metastasis in ovarian and colorectal cancers

S. Klokkerud¹, I. Eilertsen², B. Johannessen², O. Sjo³, K. Lassen⁴, S. Yaqu⁴, A. Nesbakken⁵, R. Lothe¹, A. Sveen¹

¹Oslo University Hospital and University of Oslo, Department of Molecular Oncology, Oslo, Norway

²Oslo University Hospital, Department of Molecular Oncology, Oslo, Norway

³Oslo University Hospital, Department of Gastrointestinal Surgery, Oslo, Norway

⁴Oslo University Hospital, Department of Hepato-Pancreato-Biliary Surgery, Oslo, Norway

⁵Oslo University Hospital and University of Oslo, Department of Gastrointestinal Surgery, Oslo, Norway

Introduction

Metastasis is the main cause of death from cancer. Patients with ovarian cancer (OVCA) and colorectal cancer (CRC) commonly develop metastases, resulting in a poor prognosis. Usually, OVCA disseminate early and directly into the peritoneal cavity, while CRCs most frequently disseminate to the liver through the portal vein. These different routes to metastasis are likely to impact the subclonal development of the cancers. Both cancer types have substantial tumor heterogeneity, and understanding the evolutionary processes is an important step in combating drug resistance and relapse. In light of this, we reconstructed the evolutionary trajectories to compare the modes and molecular determinants of dissemination in the two cancer types.

Material and method

Patients treated by debulking surgery for disseminated OVCA ($n = 23$) or resection of primary CRC and liver metastases ($n = 45$) at Oslo University Hospital were analyzed. Whole-exome sequencing was performed on a median of 5 samples from 2–3 tumor sites from each patient with OVCA (total $n = 104$), and a median of 4 samples per patient with CRC, including primary tumor and liver metastasis samples (total $n = 232$). The prevalence of different cancer cell populations was modeled based on the variant allele frequency of detected mutations, and adjusted for the DNA copy number at the mutated locus and tumor purity of the samples using PyClone. Phylogenetic relationships and subclonal ordering were inferred with ClonEvol. The data from OVCA have previously been published and analyses of CRCs are ongoing.

Result and discussion

Mutations in TP53 and BRCA1/2, as well as mutation signatures associated with homologous recombination deficiency, were predominantly clonal across OVCA. Similarly, mutations in CRC-critical genes such as APC, TP53 and KRAS were clonal and found across all cell subpopulations in the affected CRCs. The OVCA had particularly complex dissemination patterns with polyclonal dissemination in 73% of patients, including polyphyletic seeding of subclones with a branched evolutionary lineage in 23% and examples of bi-directional seeding. Preliminary analyses show that multiple modes of dissemination occur also in CRC,

including cases of monoclonal and polyclonal dissemination.

Conclusion

In conclusion, OVCA have complex evolutionary dissemination trajectories, consistent with frequent and a predominantly passive dissemination mechanism in the abdomen. Preliminary results from CRCs confirm that cases of polyclonal dissemination occur also in this cancer type, although the level of complexity has yet to be determined.

EACR25-1911

Metabolic and Tumor Heterogeneity-Driven Strategies to Overcome Platinum Resistance in Ovarian Cancer

E. Capellini¹, L. Perotti¹, L. Guerrera¹, I. Craparotta¹, R. Jacobs², C. Grasselli¹, M. Vats², M. Vandebosch², G. Damia¹, F. Ricci¹

¹Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Experimental Oncology, Milan, Italy

²Maastricht University, The Maastricht MultiModal Molecular Imaging (M4I) Institute, Division of Imaging Mass Spectrometry-IMS, Maastricht, Netherlands

Introduction

Platinum resistance remains a major challenge in the treatment of this pathology, highlighting the urgent need for innovative therapeutic strategies. Preliminary results suggest the possibility to delay the development of resistance by adding metformin (MET) to cisplatin (DDP) in an upfront therapy setting in ovarian cancer PDXs. Our research focuses on the design of new strategies overcoming and preventing DDP resistance through metabolic interventions and the characterization of the evolution tumor heterogeneity during drug treatment.

Material and method

To reproduce our *in vivo* preliminary results in an *in vitro* setting, starting from sensitive (S) ID8 F3 murine ovarian cancer cells, we developed DDP-resistant (R) cells with multiple treatments. ID8 F3 cells were also treated with a combination of DDP and MET (SDM) to assess the possibility to delay the onset of resistance also *in vitro*. Metabolic profiling and molecular characterization were performed by Seahorse® flux analyzer on the S, R, and SDM cells, and samples derived from PDXs models. Single-cell RNA sequencing (scRNA-seq) was performed by 10X Genomics® technology on a S PDX (MNHOC124) at DDP different treatment stages to characterize tumor heterogeneity: Random time (untreated tumors); Best response (at the maximum of tumor regression after treatment); Regrowing (regrowing tumors after therapy challenge). The bioinformatic analysis was done with Seurat.

Result and discussion

Through multiple DDP treatments, we obtained a DDP-resistant cell line (R), showing an increase of 5 times of the IC50 respect to the parental one (S). As observed *in vivo*, the addition of MET to DDP was able to prevent the development of resistance, showing an intermediate IC50 (SDM cells). Through Seahorse assays we observed that the development of resistance in the ID8 R was associated with a metabolic rewiring, that included a

major use of OXPHOS as energy fuel. Similar results were observed in ex-vivo cultures derived from S, R and SDM PDX models. In the ID8 cells, the addition of MET was able to counteract the metabolic rewiring observed in the R cell line, and restore a more glycolytic phenotype in the SDM as the S cells. The scRNA-seq analysis identified 12 tumor clusters, with specific representation for each timepoint. Differential expression analysis revealed upregulation of genes involved in ribosomal function, mitochondrial metabolism, and DNA repair in clusters most represented at the regrowing timepoint.

Conclusion

Our findings underscore the critical role of tumor metabolism and heterogeneity in platinum resistance. The DDP+MET combination appears to delay resistance emergence, highlighting metabolism-targeting strategies as a potential preventive approach. Ongoing research on scRNaseq experiment and spatial omics aims to refine these strategies and analyse the murine tumor micro-environment contribution, to identify specific therapeutic targets within resistant subpopulations.

Longitudinal Dynamics of Transcriptome and Chromatin Accessibility in Ovarian High-Grade Serous Carcinoma

D. Afenteva¹, P. Rodríguez-Mier², L. Fei³, K. Zhang¹, E. Valkonen⁴, J. Saez-Rodríguez², J. Hynninen⁴, A. Virtanen¹, B. Sahu³, S. Hautaniemi¹

¹University of Helsinki, Helsinki, Finland

²Heidelberg University, Heidelberg, Germany

³University of Oslo, Oslo, Norway

⁴University of Turku and Turku University Hospital, Turku, Finland

Introduction

Ovarian high-grade serous carcinoma (HGSC) remains a leading cause of gynecological cancer mortality due to its marked heterogeneity and propensity for resistance to platinum-based therapies. Understanding the evolution of HGSC requires a comprehensive view of transcriptomic and epigenetic alterations that occur over time and across anatomical sites. Here, we present an integrated analysis that combines longitudinal bulk RNA-seq and single-cell multiome (snATAC-seq and snRNA-seq) data to delineate the dynamic landscape of HGSC.

Material and method

We analyzed 1,006 bulk RNA-seq samples from 308 HGSC patients enrolled in the prospective, multi-region DECIDER trial (NCT04846933). Samples spanned three treatment phases (treatment-naïve Tn, neoadjuvant-treated T, and relapse R) and represented multiple anatomical locations (adnexal, intra-abdominal tumors, and fluid metastases). Gene expression data was modeled with mixed scaled Poisson distributions and solved using expectation maximization, enabling to decompose expression profiles into patient-, tissue-, and treatment-specific components. In parallel, we generated single-cell multiome data from 16 samples from 6 HGSC patients, including Tn-T and Tn-R pairs, to capture epigenetic dynamics that underlie the transcriptomic changes under the treatment pressure.

Result and discussion

Adnexal sites, which included sites-of-origin, exhibited high proliferation potential, evidenced by a pre-dominance of the proliferative subtype, and marked patient specificity. We quantified intra-patient heterogeneity at diagnosis and found that 23% of patients exhibited homogeneous primary samples harboring a single transcriptomic subtype, and this was associated with poorer overall survival (log-rank p = 0.006) compared to patients with heterogeneous subtype profiles. Moreover, the mesenchymal subtype in adnexal tumors at diagnosis correlated with a worse prognosis (log-rank p = 0.026), an effect not observed in intra-abdominal tumors, where this subtype was more frequent (Fisher's exact test p = 2.6e-08). Using the Corneto pipeline for network inference, we identified key deregulated pathways that differentiate R from Tn samples and T from Tn samples based on transcription factor and pathway activities. Preliminary analysis of the 16 snATAC+snRNA multiome samples yielded distinct cell type-specific chromatin accessibility clusters on the UMAP, suggesting that integrated chromatin accessibility and transcriptomic profiling will further elucidate the regulatory mechanisms driving treatment response and disease progression in HGSC.

Conclusion

We evaluated intrinsic and acquired molecular heterogeneity in longitudinal HGSC samples. Our findings underscore the importance of dissecting spatial and temporal heterogeneity in HGSC to explain regulatory mechanisms driving resistance to chemotherapy.

EACR25-1970

Tumor subclonal heterogeneity as a cause of drug resistance in ovarian cancer

S. Holmström¹, G. Micoli¹, J. Oikonen¹, K. Lavikka¹, M. Nguyen¹, Y. Li¹, G. Marchi¹, J. Hynninen^{2,3}, S. Hautaniemi¹

¹University of Helsinki, Research Program in Systems Oncology, Faculty of Medicine, Helsinki, Finland

²Turku University Hospital, Turku, Finland

³University of Turku, Department of Obstetrics and Gynecology, Finland

Introduction

Ovarian high grade serous carcinoma (HGSC) is the most lethal gynecological malignancy. A key contributor to the high lethality is the resistance to treatment, which we aim to understand better by investigating the tumor subclonal composition. We previously showed that patients classify into 3 different evolutionary states based on the subclonal composition of their tumors at pretreatment and that these evolutionary states were significantly associated with treatment outcome. Integrating relapse samples to our previous results, and particularly focusing on the differences between primary and relapse, enhances our understanding of the mechanisms behind drug resistance. We hypothesize that greater tumor heterogeneity gives the cancer higher phenotypical plasticity, meaning the phenotypical changes caused by genomic aberrations are not the only cause of drug resistance. In this project we wish to quantify tumor heterogeneity, find clinically relevant heterogeneity trajectories between primary and relapse samples, and find explanation for drug resistance

other than the theory of a bottle neck effect, where resistance is solely based on acquisition of genomic aberrations.

Material and method

We are using primary and relapse tumor samples, ctDNA samples, and clinical data from 214 patients that are part of the DECIDER study [1]. The samples are collected from multiple anatomical sites, and the sampling is done longitudinally spanning years for most patients. Through whole genome sequencing we obtain copy number information and single nucleotide variants (SNVs) used to infer tumor subclones and phylogenetic trees.

Classifying the patients based on their heterogeneity trajectories over the course of their disease and combining with their clinical and transcriptomic information we aim to find patterns explaining treatment response.

Result and discussion

The set of phylogenetic trees based on primary and relapse samples will alone be among the largest and most comprehensive of its kind. In part of the patients we already see that a high heterogeneity in all treatment stages is associated with a poor treatment outcome. This supports the hypothesis of phenotypic plasticity being at least partly accountable for drug resistance, providing novel insight in our understanding of the resistance mechanisms in HGSC.

Conclusion

Our study provides compelling evidence of how tumor subclonal heterogeneity and evolutionary dynamics shape treatment resistance in ovarian HGSC. These findings support the existence of resistance mechanisms beyond the bottleneck theory.

[1] Multi-Layer Data to Improve Diagnosis, Predict Therapy Resistance and Suggest Targeted Therapies in HGSC; ClinicalTrials.gov identifier NCT04846933

EACR25-2014

Rhabdomyosarcoma tumours undergo endothelial trans-differentiation to evade treatment

J. Wragg¹, F. Mueller¹, S. Gatz¹

¹*University of Birmingham, Department of Cancer and Genomic Sciences, Birmingham, United Kingdom*

Introduction

Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in children and adolescents. It arises from cells of mesenchymal origin across multiple organs where either a gene fusion of PAX3/7-FOXO1 (Fusion positive RMS [FP-RMS]) or RAS pathway mutations (Fusion negative RMS [FN-RMS]) drive aberrant myogenic developmental programs. In the relapse setting RMS is a tumour high unmet need with few treatment options. It is also noted for its plasticity with research focussed on modulation of the myogenic signature. We have identified an alternative avenue of plasticity, whereby RMS cells activate an endothelial developmental program, concurrent with the formation of vessel-like structures (vascular mimicry [VM]). We have shown this switch to be driven by anti-angiogenic receptor tyrosine kinase inhibitor (RTKI) treatment and strongly linked to therapy resistance in pre-clinical testing.

Material and method

Cells from 10 RMS tumour lines (RD, SMS-CTR, JR1, Rh36, T174, RMS01, Rh30, Rh4, Rh41, RMS01) were profiled for vascular mimetic capacity by in vitro Matrigel tube formation assays and in vivo imaging of tumour cell-derived conduits in transparent zebrafish xenografts. Response to regorafenib treatment was assessed by MTS and fluorescent tumour growth assessment assays. Matched transcriptomic (RNA-seq) and secretomic (proteome profiler) profiling was performed to identify markers of VM in RMS, which were validated by immunofluorescent imaging of cells and tissues. A VM gene expression signature based on co-expression of endothelial and tumour markers, was used to dissect VM niches from sc-RNA-seq data from 21 RMS clinical tumour samples.

Result and discussion

We have developed techniques to stratify RMS tumour samples by vessel forming / VM capacity both in vitro and in vivo and found the niche to be marked by the haematopoietic marker CD34 as well as the endothelial specific marker VE-cadherin at cell-to-cell junctions upon vessel maturation. Identification and profiling of the VM niche in sc-RNA data from 21 RMS clinical samples revealed it to be enriched in high-risk metastatic tumours and those that have relapsed from treatment. Profiling of In vitro and in vivo tumour response to the MRTKI regorafenib treatment, revealed VM capacity to be strongly and positively linked to resistance with treatment driving both haematopoietic and myogenic trans-differentiation in distinct tumour cell sub-populations.

Conclusion

Vascular mimicry in RMS provides a potential route towards uncoupling the tumour from dependence on traditional vascularisation, allowing for the greater level of aggression and treatment resistance that we see in our analyses. Some clinically used therapeutics, including regorafenib, can drive this behaviour. There is therefore an urgent need to better understand RMS endothelial plasticity and VM, to stratify patients and avoid detrimental therapeutic regimens, but also to investigate avenues for specific targeting.

EACR25-2144

Investigating the Role of Chromosomal Instability in Colorectal Cancer Drug Resistance Development

A. Gallagher¹, S. McClelland¹, M. Guscott¹, N. Mon Pere¹, A. Lumeau¹, I. Nichols¹, N. Shaikh¹, A. Malling Anderson²

¹*Barts Cancer Institute, QMUL, Centre for Cancer Evolution, London, United Kingdom*

²*Barts Cancer Institute, QMUL (previous), Centre for Cancer Evolution (previous), London (previous), United Kingdom*

Introduction

Chromosomal Instability (CIN) is the rate at which ongoing segregation errors occur over consecutive cell divisions, which can lead to significant genomic changes. While typically harmful to cells, CIN and its subsequent genomic reshuffling is thought to help cancer cells adapt to selection pressures, such as chemotherapy treatment.

Colorectal cancer (CRC), a leading cause of cancer-related deaths, frequently exhibits CIN – which is linked to poorer prognosis and drug resistance in this cancer. However, the exact mechanisms remain unclear. This study investigates the role of CIN in resistance to a key chemotherapy drug, fluorouracil (5'FU), in a CRC cell line.

Material and method

First, a chromosomally unstable CRC cell line was exposed to various 5'FU drug regimens, either as a population of cells or as isolated single cells (clonal outgrowth). Long-term IncuCyte proliferation imaging was used to track clonal outgrowth of single cells. A drug sensitivity screening was subsequently performed using cell proliferation assays, and rates of CIN were estimated by measuring segregation error rate in mitotic cells via immunofluorescence. Single cell DNA sequencing (scDNaseq) was used to compare genomic changes between drug-resistant vs non-resistant cells.

Result and discussion

A model of 5'FU-specific drug resistance has been developed in a chromosomally unstable CRC cell line. Interestingly, only 5'FU-resistant populations showed increased segregation error rate, when compared with control and non-resistant cells. Genomic changes in 5'FU-resistant vs non-resistant single cells have been characterised, showing some unique copy number alterations in drug-resistant cells. Clonal outgrowth experiments showed that single cells, grown into populations under 5'FU treatment, display various growth patterns and rates across treatment regimens; paired scDNaseq of these clones provides insight into clonal evolution, as well as genomic heterogeneity within and between 5'FU-resistant and non-resistant clonal populations.

Conclusion

This work highlights the propensity of a chromosomally unstable CRC cell line to adapt and develop resistance to the major CRC chemotherapy drug, fluorouracil. The rate of CIN shows a positive correlation with 5'FU resistance development in these cells, with future experiments underway to understand whether CIN is causative of this resistance. Cell-cell heterogeneity within and between 5'FU-resistant and non-resistant populations is highlighted by scDNaseq data, which indicates changes that may be key to 5'FU resistance. Given that CIN is present in 60-80% of cancers, understanding its contribution to cancer drug resistance is crucial to addressing the mortality caused by this drug resistance.

EACR25-2259

Elucidating the molecular mechanisms of whole genome doubling in PDAC

D. Wellappili^{1,2}, C. Falcomata¹, A. Rajamani¹, D. Saur^{1,2}

¹*Institute of Translational Cancer Research and Experimental Cancer Therapy, TranslaTUM, University Hospital Rechts der Isar of the Technical University of Munich, Munich, Germany*

²*German Cancer Consortium (DKTK), partnersite Munich, a partnership between DKFZ and University Hospital rechts der isar of the Technical University of Munich, Munich, Germany*

Introduction

Genomic instability is a hallmark of pancreatic ductal adenocarcinoma (PDAC), driving tumor evolution, treatment resistance, and disease progression. One consequence is whole-genome doubling (WGD), leading to aneuploidy and chromosomal aberrations that fuel intratumoral heterogeneity. These genomic alterations play a critical role in shaping tumor evolution by generating genetic diversity, facilitating adaptation to selective pressures, and promoting metastatic potential. WGD and aneuploidy may also contribute to immune evasion and therapy resistance, making them key factors in PDAC progression. However, the mechanisms governing ploidy changes and their impact on tumor evolution remain poorly understood. Here, we investigated ploidy status and genomic alterations in genetically engineered mouse model (GEMM)-derived PDAC primary cell lines to elucidate their contribution to the evolution of aneuploidy in PDAC.

Material and method

We analyzed PDAC primary cell lines derived from GEMMs using flow cytometry and metaphase spreads to determine ploidy status. Whole-genome sequencing (WGS) was performed to characterize chromosomal alterations and structural variants associated with genomic instability. Additionally, phosphoproteomic analysis was conducted using mass spectrometry to investigate alterations in signaling pathways associated with ploidy changes.

Result and discussion

Whole-genome doubling was identified in all PDAC cell lines, though to varying degrees. As expected, cell lines with genomic loss of p53 correlated with higher rates of WGD and increased chromosome numbers. However, in contrast to established models, we also observed cell lines with p53-independent increases in chromosome numbers, driven by genomic activation of Kras and PI3K signaling pathways. Phosphoproteomic analysis revealed distinct differences in kinase activity profiles between PDAC cell lines with varying ploidy levels. Notably, key kinases regulated by PI3K signaling were differentially phosphorylated in high-ploidy cell lines, suggesting a potential role in maintaining genomic instability and tumor evolution.

Conclusion

Our study provides novel insights into aneuploidy and genomic instability in PDAC. The identification of both p53-dependent and p53-independent occurrences of WGD challenges current models and highlights the role of Kras and PI3K signaling in driving chromosomal instability. Further studies into early evolutionary mechanisms during tumor development could provide a more mechanistic understanding of whole genome doubling in PDAC.

EACR25-2327

Characterization of breast cancer tumoroid subclones by proteomics for personalized medicine

A. Raffo Romero¹, L. Lagache¹, M. Duhamel², I. Fournier¹, M. Salzet¹

¹*Laboratoire de Protéomique, Réponse Inflammatoire et Spectrométrie de Masse (PRISM), Villeneuve D'Ascq, France*

²Laboratoire de Protéomique, Réponse Inflammatoire et Spectrométrie de Masse (PRISM), France

Introduction

Introduction: Breast cancer (BC) is the most common cancer among women causing the highest number of cancer-related deaths. Currently, BC research is mainly conducted using 2D cultures or mouse models. Both have proven to have limitations: 2D culture lacks cell-cell or cell-matrix interactions and mice are associated with ethical problems and poorly mimic the human diseases. There is an unmet need to develop novel more accurate, realistic, standardisable and robust experimentation models.

Material and method

Methodology: We have developed BC tumoroids made from a mixture of tumor cells isolated from human and canine BC tissues. In the tumoroid model, we conducted studies to isolate tumoroid-derived subclones with heterogeneous profiles. We analyzed these subclones using proteomics and mass spectrometry imaging to compare them with their parent tumoroids. Our goal was to determine whether the study of these subclones could lead to a more comprehensive treatment strategy that targeting all subclones, potentially reducing post-treatment resistance compared to standard hospital treatment.

Result and discussion

Results: Our results show that intratumoral heterogeneity is maintained in the tumoroid model. While many tumoroids exhibited a homogeneous profile, others showed heterogeneity within tumoroids derived from the same patient, which is critical for recapitulating in vivo drug responses. This led us to investigate different subclones within the tumoroids that represent intra-tumoral heterogeneity. We isolated different sub-populations and used mass spectrometry imaging to demonstrate their similarities to the parent tumoroids. Additionally, proteomic profiling revealed distinct differences between the subclones. Finally, we showed that not all subclones grow and respond uniformly to treatments. The next step is to propose new treatments based on our proteomics analysis that can affect all subclones, thereby preventing relapse in patients.

Conclusion

Conclusion: Our knowledge of biology, combined with our skills in proteomics and mass spectrometry imaging helped us to better understand the BC tumoroids and to study the different intratumoral populations that are so problematic today.

⁵NCT/UCC Dresden, a partnership between DKFZ, Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, and Helmholtz-Zentrum Dresden-Rossendorf (HZDR), National Center for Tumor Diseases (NCT), Dresden, Germany

Introduction

Gastric cancer remains a major clinical challenge, with its incidence and mortality predicted to increase significantly by 2040. Currently ranked fifth globally in both incidence and mortality, the disease is characterised by rising case numbers and inherent heterogeneity.

Gastric cancer exhibits molecular heterogeneity driven by diverse oncogenic drivers and clinical heterogeneity influenced by anatomical location, highlighting the critical need for personalised treatment strategies.

Material and method

To study tumour heterogeneity in gastric cancers, patient-derived organoids (PDOs) were established from multiple locations of treatment-naïve tumours. Morphological assessments were performed to evaluate intra-patient heterogeneity. Drug response studies were conducted on at least three PDOs per patient to assess their reactions to the standard-of-care chemotherapy FLOT (5-Fluorouracil, Leucovorin, Oxaliplatin, and Docetaxel) as well as to alternative therapies, including targeted drugs.

Additionally, sequencing analyses were performed to examine mutational differences between PDOs from the same patient.

Result and discussion

PDOs demonstrated significant intra-patient heterogeneity in their morphology. While most PDOs from the same patient exhibited similar responses to FLOT chemotherapy, distinct responses were observed when exposed to alternative therapies, including targeted drugs. Sequencing data further revealed mutational differences among PDOs derived from the same patient, providing insights into tumour heterogeneity and its impact on therapy resistance.

Conclusion

The use of multiple PDOs per patient highlights the intra-patient heterogeneity of gastric cancer and its influence on therapy responses. This approach enhances our understanding of primary and secondary resistance mechanisms, driven by tumour heterogeneity, and may facilitate the identification of alternative treatment strategies targeting specific oncogenic pathways. These findings underscore the potential of PDO models to inform personalised treatment decisions for gastric cancer patients.

Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Naples, Italy

Introduction

Glioblastoma (GBM) is the most aggressive primary brain tumor, with a median survival of 8–14 months after diagnosis. Its treatment failure is mainly due to two factors: high heterogeneity, which hinders the identification of effective molecular targets, and strong invasiveness, leading to frequent recurrences observed in over 90% of patients. To migrate efficiently, GBM cells mostly exploit the abluminal surface of the blood vessels, which is particularly enriched in laminin, and the white matter tracts. In this study, we present a biomimetic approach based on gridded micropatterns to controllably recapitulate the surface and the topology of blood vessel walls, aiming to differentiate distinct inter- and intra-patient motility behaviours and link them to specific molecular signatures.

Material and method

We developed an analytical platform called SP2G (SPheroid SPreading on Grids) to investigate the motility of patient-derived GBM cells. Tumor spheroids were seeded onto laminin-coated micropatterns mimicking the structure of the brain vasculature, and analyzed using a semi-automated Fiji-based toolkit. This approach allows precise measurements of migratory parameters and enables to distinguish the most invasive clones from the less motile ones, highlighting differences which can be potentially linked to molecular signatures.

Result and discussion

GBM cell analysis revealed significant variability in migration patterns among different patients. Three different patient-derived cell lines already known for their diverse motility modes were tested and confirmed in term of distinct migratory behaviours, with the most aggressive one spreading further away compared to the others. SP2G also showed to be sensitive to drug assays and variations in laminin concentration, confirming the bona-fide of the assay. Intra-patient heterogeneity was also tested with five clones coming from the same tumor. Once again, SP2G revealed differences in migratory behaviours, identifying three motile and two non-motile clones. These differences were further confirmed by molecular signatures showing the motile clones to be enriched in specific integrins compared to non-motile ones. Most interestingly, SP2G also revealed spreading diversity of motile clones between each other, grouping them in two categories which were further confirmed by Principal Component (PC) and Gene Set Enrichment (GSE) analysis.

Conclusion

SP2G has proven to be an effective tool for characterizing the migratory diversity of GBM cells, providing a fast, simple and reproducible approach to identify invasive subpopulations. It may be used to for motility screenings, in order to correlate cell migration with

cancer dissemination, being potentially extendable also to pan-spheroids analysis.

Comprehensive molecular landscape of acquired resistance to sotorasib in pancreatic cancer

A. Ariwoola¹, R. Megid¹, I. Faria², R. Reis², R. Oliveira³

¹*Barretos Cancer Hospital, Molecular Oncology Research Center, Barretos, Brazil*

²*Barretos Cancer Hospital Research Center, Molecular Oncology Research Center, Barretos, Brazil*

³*Barretos Cancer Hospital Research Center, Molecular Oncology Research Center, Brazil*

Introduction

Sotorasib, a KRASG12C inhibitor, represents a breakthrough in treating pancreatic ductal adeno-carcinoma (PDAC); however, acquired resistance limits its clinical efficacy.

Material and method

To investigate resistance mechanisms, we generated a sotorasib-resistant MIA PaCa-2 (KRASG12C) cell line through progressive sotorasib exposure (2–512 nM) and isolated resistant clones via single-cell sorting. Phenotypic changes were assessed using proliferation, migration, and invasion assays, while molecular alterations were analyzed via the PanCancer NanoString panel, protein arrays, western blotting, and fluorescence microscopy.

Result and discussion

Following the resistance induction protocol, 33 of 400 clones remained viable after re-exposure to sotorasib (512 nM). Clone E9 was selected for further analysis due to its higher IC₅₀, elevated levels of active endogenous Ras post-sotorasib treatment, and a protein expression profile indicative of KRAS signaling bypass. In the absence of treatment, the resistant cell line exhibited downregulation of 15 genes, including growth factors (e.g., FGF2), cytokines (e.g., CSF3, IL1A), and genes associated with proliferation (e.g., RAC2, PAK7, MET), cell signaling (e.g., LRP2, PRDM1, GAS1, SOCS3, NFKBIA, KLF4), and gene regulation (e.g., DTX4, JAG2, RPS6KAS). Conversely, the resistant line showed upregulated expression of 5 genes: JAG1 (Notch signaling), IL1R1 (inflammatory response), RUNX1 (hematopoiesis and gene regulation), DDIT4 (stress response and mTOR modulation), and XRCC4 (DNA repair). Protein analysis identified elevated phosphorylation of insulin receptor, IGF-1R, Axl, and mTOR, confirming KRAS signaling bypass. Computational modeling demonstrated that combining sotorasib with mTOR inhibitors restored sensitivity in resistant cells.

Conclusion

These findings elucidate the molecular mechanisms underlying sotorasib resistance in PDAC and provide a rationale for developing combinatorial therapies to overcome resistance, offering new hope for patients with KRASG12C-mutated pancreatic cancer.

Spontaneous telomere dysfunction promotes acrocentric chromosome arm

fusions and aneuploidy in cell cycle checkpoint impaired human astrocytes

Y. Hao¹, T. Ranallo-Benavidez¹, N. Fukushima¹, O. Mbegbu¹, M. Kyriakidou¹, A. Guaracino², E. Garrison², P. Cosper³, F. Barthel¹

¹*The Translational Genomics Research Institute, Phoenix, United States*

²*University of Tennessee Health Science Center, Memphis, United States*

³*University of Wisconsin School of Medicine and Public Health, Madison, United States*

Introduction

Telomere dysfunction (TD) is considered to be a potent mutator mechanism in cancer and a driver of aneuploidy and structural variation (SV). However, it is unclear which SVs are a consequence of TD and which are simply bystanders to other mutational processes. We sought to investigate how TD reshapes cell cycle checkpoint impaired human astrocytes over time using an *in vitro* model system.

Material and method

Normal human astrocyte (NHA) cells were transduced with retroviral vectors containing HPV-18 E6/E7 to impair cell cycle checkpoints. Limited dilution cloning was used to isolate single cells that were independently cultured alongside bulk cultures and grown over six months to induce telomere attrition. Representative clones were selected for short-read genome sequencing and copy number profiling. M-FISH karyotyping was performed to assess genome structure. Immunofluorescence (IF) microscopy was used to quantify metaphase and anaphase defects. Primary NHA cells and a selected bulk and single-cell clone of E6E7-transduced samples with unique copy number profiles were further analyzed using Hi-C, Oxford Nanopore ultra-long and Pacific Biosciences HiFi long-read sequencing. Diploid phased genome assembly was performed on all long-read sequenced samples to determine the full-length chromosome sequences. Pangenome graphs were constructed from assembled genomes to evaluate large-scale structural variation.

Result and discussion

NHA cells began showing aneuploidy after 42 doublings following transduction with E6/E7 (82 days in culture). In particular, we observed partial deletions of all acrocentric chromosome arms (13, 14, 15, 21 and 22) independently in several single cell and bulk clones, most prominently affecting the small arm of chromosome 13, progressing to a complete del(13) after 60–70 doublings. Long read data showed telomere attrition, initially 12 Kb in NHA primary cells and dropping to 6 and 4 Kb at 42 and 70 doublings after E6/E7 transduction, respectively. M-FISH karyotyping showed significant chromosomal abnormalities in every cell examined, including t(2,13) in 40%, del(13) in 30%, t(1,21) in 20% of cells analyzed. Conversely, no chromosomal abnormalities were observed in primary NHA cells. IF showed anaphase bridges in 30% of cells, further implicating TD as the root cause of the observed phenotypes. Long-read sequencing and genome assembly of primary NHA cells produced a diploid genome assembly comparable in quality with the HG002 diploid genome assembly from

the Human Pangenome Reference Consortium. Genome graph-derived and haplotype-specific variant calling confirmed an elevated number of SVs in E6/E7 transduced cells compared to primary NHA cells. Intriguingly, we observed an enrichment of SVs with telomeric sequence at the breakpoint junction, reaffirming TD as the causal mechanism of SV.

Conclusion

Our results suggest that telomere dysfunction promotes fusions involving acrocentric chromosome arms.

TRIB1 leads to M2 skewing of macrophages in LUSC

D. Lu¹, L. Zhang¹, J. Liao², Y. Du³

¹*Technical University of Munich, Department of Otorhinolaryngology, Head and Neck Surgery Molecular Oncology Labor, Munich, Germany*

²*Deyang People's hospital, Intensive Care Unit, Deyang, China*

³*Duijiangyan People's hospital, Department of Oncology, Duijiangyan, China*

Introduction

Building upon the bioinformatics insights, this study aims to delve into the role of tribbles pseudokinase 1 (TRIB1) in M2 macrophages in the context of lung squamous cell carcinoma.

Material and method

M0 macrophages were prepared and co-cultured with LUSC cells, after which the M2-polarized macrophages and the associated markers were analyzed. The proliferation and mobility of the co-cultured LUSCs were analyzed via functional experiments. Loss- or gain-of-function assays of TRIB1 and its putative regulator KLF transcription factor 6 (KLF6) were conducted to analyze their impacts on M2 phenotype shift of macrophages and the malignancy of tumor cells. A mixture of macrophages and LUSC cells was injected into immunocompromised mice for *in vivo* assays.

Result and discussion

Co-culturing with LUSC cells led to an M2 shift of macrophages, accompanied by an upregulation of TRIB1. Knocking down of TRIB1 suppressed this M2 polarization, and it inhibited proliferation and mobility of the co-cultured LUSC cells. The aberrant upregulation of TRIB1 in M2 macrophages was induced by the loss of KLF6, which binds to the TRIB1 promoter for transcriptional repression. Artificial upregulation of KLF6 similarly reduced M2 macrophages and the LUSC cell malignancy, and it weakened tumor growth and dissemination in mice. However, these effects were counteracted by TRIB1 upregulation.

Conclusion

This research suggests that the TRIB1 upregulation upon KLF6 leads to M2 shift of macrophages and LUSC progression.

Introduction

RNA editing is one of the most prevalent post-transcriptional modifications observed in normal physiological processes. Many studies have suggested that widespread RNA editing is an important factor in the occurrence and development of cancer. However, the value of RNA editing in the development and prognosis of bladder cancer has not been clarified.

Material and method

BLCA RNA-seq data and RNA editing data were downloaded from the TCGA database and synapse database to find prognostic signature RNA edits by single/multi-factor Cox analysis and to perform prognostic risk model construction. Differentially expressed genes (DEGs) were screened from high and low risk groups based on the risk scores of the prognostic risk model and subjected to functional and pathway enrichment analyses. In addition, survival analysis, ROC analysis, independent prognostic analysis, ADAR gene correlation analysis, and nomogram curves were used to test the prognostic model effects. RNA editing gene differences, immune infiltration analysis, and immuno-therapy response analysis were used to investigate in depth the mechanisms by which RNA editing leads to poor prognosis.

Result and discussion

Univariate/multivariate Cox analysis was performed to construct prognostic risk models for nine RNA edits. Survival analysis and independent prognostic analysis showed that risk model scoring was an independent prognostic factor in predicting the survival of BLCA patients. In addition, the calibration curves showed high agreement between actual survival and predicted rates, and the ROC curves further demonstrated the model's good predictive ability. Meanwhile, ADAR gene expression and risk score showed a positive correlation, and the 2 RNA edits in the model also differed significantly between the tumor and normal groups. In particular, there were differences in immune cell infiltration in patients with high and low expression of GM2A (dist = 1596), SLC36A3 (dist = 4377) |chr5: 150651549, and different immunotherapy responses.

Conclusion

In short, we have developed a new prognostic model of bladder cancer, which may be helpful for personalized counseling and treatment of BLCA, and is expected to bring a new direction to bladder cancer research.

EACR25-0071

Intra-tumoral bacteria in high grade serous ovarian carcinoma

O. Krami Senhajil¹, S. Saqib², A. Virtanen³, U. Haltia³, A. Färkkilä³, A. Salonen³, L. Kauppi³

¹University of Helsinki, Medicine, Helsinki, Morocco

²University of Helsinki, Medicine, Helsinki, Pakistan

³University of Helsinki, Medicine, Helsinki, Finland

Introduction

While tumors were once thought to be sterile, it has now been shown that many cancers, including high-grade serous ovarian cancer (HGSOC), contain microbiota. Importantly, tumor-resident bacteria could be a potential source for DNA damage that may contribute to more aggressive tumor behavior, such as resistance to chemotherapy and immunochemotherapy, and metastatic potential. Little is known about the interplay of these factors, especially for ovarian cancer. To provide better understanding of this aspect of disease biology, and ultimately to develop better targeted treatments for better outcomes, we investigate in this project the HGSOC microbiome and its link with treatment response.

Material and method

Clinical HGSOC samples (n = 80) were collected as part of the ONCOSYS-OVA prospective study. To investigate the microbiome of each HGSOC tumor, we use three independent approaches: immunofluorescence (IF), DNA amplification-based methods, and amplicon sequencing. Gram-positive and -negative bacteria are detected in formalin-fixed, paraffin-embedded (FFPE) tumor samples by IF. Total bacteria present in our fresh frozen tumor samples are quantified using nested qPCR and digital PCR (dPCR). From the same samples we also have estimates of DNA damage as well as DNA repair capacity (homologous recombination scores). Bacterial identification and diversity assessment is done by high-throughput sequencing. Filters are put in place to eliminate common environmental contaminants, with the help of including positive (fecal sample), negative controls (blood samples), and non-template controls (NTC), with the addition of normal healthy tissue samples in order to differentiate between the healthy tissue microbiome and the tumor specific resident bacteria.

Result and discussion

Preliminary findings indicate that individual HGSOC samples contain different levels and composition of bacteria compared to positive and negative controls and NTCs. These findings were concordant with IF staining results, showing presence of Gram positive and negative bacteria, from the same samples. Next, we performed high-throughput sequencing to identify which bacterial species are present in these samples. The results showed that most samples harbor various bacterial species at different levels of positivity, confirming the previous findings we obtained using IF, nested PCR and dPCR.

Conclusion

Our results so far suggest that most HGSOCs contain bacteria. Our future work is to expand the analysis to include more samples to assess the diversity of tumor-resident bacteria, and its putative direct impact on DNA damage, DNA repair and treatment resistance.

New mouse models to define the function of CCR7+ dendritic cells in anti-tumour immunity

M. Koufaki¹, E. Bonavita¹, A. Moeini¹, E. Richardson¹, M. Russo¹, C. Earnshaw¹, S. Chiang¹, C. Bell¹, N. Moncaut², S. Zelenay¹

¹*CRUK Manchester Institute, University of Manchester, Cancer Inflammation and Immunity, Manchester, United Kingdom*

²*CRUK Manchester Institute, University of Manchester, Genome Editing and Mouse Models, Manchester, United Kingdom*

Introduction

Conventional dendritic cells (cDCs) constitute crucial orchestrators of adaptive immune response against tumours. Recent single-cell transcriptional analyses have unraveled an activation state of tumour-infiltrating cDCs (referred to herein as actDCs a.k.a. CCR7+ DCs, mregDCs, or cDC3s) derived from both cDC1 or cDC2 subsets. Their transcriptional profile suggests putative opposing T cell-stimulating or inhibitory roles, and due to their intratumoural scarcity and lack of experimental tools, the actual contribution of actDCs to tumour immunity remains unknown.

Material and method

Exploiting in-house scRNAseq data of tumour-infiltrating immune cells and intersectional genetics, we here developed new genetically engineered mouse models to conditionally and selectively track, isolate or deplete actDCs. We also devised a primary bone marrow culture system to develop actDCs *in vitro*. We employed our novel actDC reporter to separate actDCs from their resting counterparts and performed tumour antigen presentation assays. We further used our new mouse model for targeted actDC depletion to evaluate their contribution to T cell-mediated tumour control and the response to dual αPD-1/αCTLA-4 blockade or CD8+ T cell adoptive transfer.

Result and discussion

We show that the ability of cDCs to promote CD8+ T cell activation in response to tumour antigens is confined to the actDC state. Mechanistically, actDC1s cross-present, and actDC2s cross-dress tumour-derived material to CD8+ T cells in a tumour cell-type dependent manner. Crucially, we demonstrate that specific and acute depletion of actDCs impairs T cell priming and tumour eradication *in vivo*. Moreover, we show that actDCs are necessary for a successful response to both antibody-mediated and cell-based immunotherapy.

Conclusion

Overall, our work formally establishes an essential, non-redundant contribution of actDCs to T cell-mediated, anti-cancer immunity.

Prognostic role of Immunoscore in colon cancer

Y. Iliev¹, V. Andonov², E. Poryazova³

¹*University hospital Pulmed, Medical oncology, Plovdiv, Bulgaria*

²*Medical University of Plovdiv, University hospital Kaspela, Gastroenterology, Plovdiv, Bulgaria*

³*Medical University of Plovdiv, University hospital Pulmed, Pathology, Plovdiv, Bulgaria*

Introduction

CRC is world-leading health problem. Treatment of CRC is based on TNM classification. For patients with stage 1 disease treatment is well established, but for patients with stage 2 and 3 there are controversies about need of post-operative chemotherapy. We need more prognostic factors which patients are in high risk and which are in low risk. Immunoscore is method based on density of CD3+ and CD8+ TILs in tumor and its invasive margin. It makes quantitative evaluation and results are converted in five predefined threshold from Immunoscore 0 to Immunoscore 4. Several trials are establishing its value as prognostic factor in CRC. This is first retrospective trial studying role of Immunoscore in Bulgarian population of CRC patients.

Material and method

This is single center retrospective analysis of 35 patients with stage II and stage III CRC. All of them have undergone radical surgery in period 2016-2021. Immuno-score analysis is done to tumor samples from each patient. Data from each patient demographics, tumor characteristics and DFS were collected.

Result and discussion

There were patients in all categories of Immunoscore from 0 to 4. The most prevalent were patients with Immunoscore 2 and the patients in highest and lowest values were minority. There were 14 women and 21 men. Distribution of Immunoscore is similar in both sexes. Median result in women is 2.07 and in men 2.10. The study finds no significant differences in Immunoscore distribution between genders. The number of patients in stage II was 20 and in stage III was 15. Results of Immunoscore were similar between both groups- 2.0 in stage II and 2.1 in stage III. There is no significant correlation between age and Immunoscore, and the distribution of Immunoscore is similar in both stage II and III patients. The patients with left side tumors have median three years DFS 33,43 months and these with right sided tumors have DFS 33,36m. It is observed significant difference in results of Immunoscore in patients with left and right sided tumors. The patients with left location have median IS 1,90, but these with right location have median IS 2,36. This difference remains valid when compared according to stage and gender. The results show that patients with a high Immunoscore have best disease-free survival rates. After four years surveillance there are no progression in this group(median DFS-48months). While those with low or intermediate Immunoscore have a higher risk of disease progression. The worst result are for men with right sided tumors and IS-2, which have median DFS of 20 months.

Conclusion

The study concludes that Immunoscore is a valuable prognostic tool independent of tumor stage and could potentially guide decisions on adjuvant chemotherapy. High Immunoscore correlates with excellent survival rates, independent of the tumor stage and location. There is significant difference in Immunoscore for left and right sided tumors. This could be one of explanations for different prognosis according to sidedness.

EACR25-0131**Glucocorticoids trigger CD8+ T cell-dependent tumour control**

Introduction

Melanoma is the deadliest form of skin cancer. Treatment with immune checkpoint blockade (ICB) has transformed outcomes. However, half of melanoma patients do not derive long-term benefit, and improved understanding of this is required to identify novel mechanisms of resistance and treatment. We screened a range of topical treatments, used in non-melanoma skin diseases, for anti-cancer activity in an ICB-refractory murine melanoma model.

Material and method

We used an intradermal melanoma model that we found to be fully unresponsive to the dual combination of anti-PD1 and anti-CTLA4 to assess the effects of topical imiquimod, 5-fluorouracil, diclofenac and glucocorticoid (GC) treatment. Multiparametric flow-cytometry, immunofluorescence and whole transcriptome and single-cell RNA sequencing of mouse tumours were used to assess the effects of GCs in the tumour micro-environment (TME). Bioinformatic analysis of publicly available datasets and IHC of in-house patient samples was employed for human analysis.

Result and discussion

Of all topical treatments tested, only topical GCs resulted in acute tumour growth inhibition. After just two doses, GC-treated tumours shrank, whereas control-treated tumours doubled in volume. Intriguingly, this effect was lost in Rag1^{-/-} mice (deficient in B and T cells) or in mice depleted of CD8+ T cells, uncovering a key role for T cells in GC-induced tumour growth control. Of 8 cancer models tested for GC-responsiveness, half experienced immune-dependent control, and half did not. Genetic ablation of the glucocorticoid receptor in tumour cells, but not in immune cells, abrogated this effect, suggesting GCs act directly on tumour cells to stimulate anti-tumour immunity. Analysis of cancer patient transcriptomic datasets showed melanoma patients with high GC receptor expression, signalling and activation have better overall survival than those with low expression. GC treatment spared CD8+ T cells in the TME, but reduced the presence of conventional and regulatory CD4+ T cells. Sequencing, genetic knockout and targeted mutagenesis experiments revealed GCs downregulated the expression of GARP on the surface of melanoma cells. This reduced TGFβ signalling, allowing CD8+ T cell tumour killing. Supporting this, in single-cell RNA sequencing analysis of human patients, tumours with high glucocorticoid receptor expression had lower TGFβ signalling in tumour infiltrating CD8+ T

cells. Of the 8 tumour models tested, only GC-responsive tumours also responded to TGFβ inhibition, suggesting that GCs triggered immune-dependent tumour control when tumours are reliant on TGFβ signalling for immune evasion.

Conclusion

We discover a paradoxical immune-dependent shrinkage induced by GCs in certain tumour models. Given the widespread use of GCs in patients receiving ICB, these unexpected findings may have significant clinical impact.

EACR25-0154**Five dominant amino acid substitution signatures shape tumour immunity**

S. Juhász¹, B. Papp¹, A. Fülop¹, Z. Farkas¹, D. Gyémánt¹, D. Kókai¹, B. Koncz¹, P. Burkovics², C. Pál¹, M. Manczinger¹
¹*HUN-REN Biological Research Centre, Institute of Biochemistry, Szeged, Hungary*
²*HUN-REN Biological Research Centre, Institute of Genetics, Szeged, Hungary*

Introduction

Numerous mutational mechanisms are identified in cancer, but their functional impacts are unclear. We hypothesize that certain mutation sources preferentially generate amino acid substitutions that are unlikely to produce immunogenic neopeptides, leading to immune-cold tumours regardless of origin or mutation burden.

Material and method

To test the hypothesis, we studied characteristic patterns of amino acid substitution in 9300 cancer exomes and derived a map of functional associations between environmental mutagens, therapeutic agents, and deficiencies in DNA repair mechanisms.

Result and discussion

Despite the immense diversity of mutational sources, only five primary amino acid substitution signatures emerged, with major differences in their functional properties. One notable signature, AAS4, primarily linked to alkylating agents and mismatch repair deficiency, is especially prevalent in kidney and liver cancers. AAS4-type tumours are less likely to accumulate hydrophobic amino acids, leading to lowered neoantigen immunogenicity. These tumours typically exhibit immune-desert microenvironments and respond poorly to immune checkpoint therapies. However, we identified certain combinations of HLA class I variants and mutational processes which are prime spots for immune response. For instance, HLA-B*07:02, a common variant in European populations with atypical peptide binding can uniquely induce T-cell proliferation in AAS4-type cancer cells.

Conclusion

In summary, our findings indicate that the quality of neo-antigens, rather than their quantity, is a key determinant of cancer immunity. Our study helps explain why mismatch repair-deficient tumours fail to respond to immunotherapy despite having a high mutational burden, and highlights the need to use amino acid substitution patterns to improve predictive biomarkers and therapeutic strategies.

EACR25-0183**Interleukin-15 signaling in
Immunosurveillance**

Introduction

IL-15 is one of the most promising candidate in cancer immunotherapy due to its ability to promote the proliferation and cytotoxicity of Natural killer (NK) and CD8+ T cells. The mode of action of IL-15 is very special: IL-15 signals through a heterotrimeric receptor complex composed of three subunits, the α chain (IL-15R α), the β chain and the common γ chain. During biosynthesis, IL-15 associates with IL-15R α and is transported to the cell surface where IL-15R α ‘presents’ IL-15 to target neighboring cells expressing the β chains, referred as ‘trans-presentation’ (mostly known to occur in lymphoid cells). However, in myeloid cells, IL-15 is presented to its receptor on the same producer cell, known as ‘cis-presentation’. Our group previously showed that ‘trans-presentation’ by IL-15R α is dispensable in early innate immune responses to infections. We hypothesize that IL-15 signaling occurs in ‘cis’ via the IL-15R $\beta\gamma$ c complex independently of IL-15R α and is critical for tumor immunosurveillance.

Material and method

Spontaneous fibrosarcomas were induced with Methylcholanthrene in WT, II15-/- and II15ra-/- mice. Tumor development was monitored, and tumor samples were assessed for histopathological, immunological and proteomic features. Cell lines derived from MCA-induced tumors in WT, II15-/- and II15ra-/- mice were established.

Result and discussion

Tumor incidence is reduced in II15ra-/- ($n = 10/50$) compared to II15-/- ($n = 14/34$) and WT ($n = 16/47$) mice. Histologically, tumors from the three mice groups look comparable but we observed reduced NK and CD8+ T cells in II15-/- and II15ra-/- tumors. The proteomic data analyses show that antigen processing and presentation and cellular responses to Interferons are differentially regulated in II15ra-/- compared to II15-/- tumors.

Established cell lines from MCA-induced fibrosarcomas of WT, II15-/- and II15ra-/- mice express MHC-I, PD-L1 and have comparable proliferation rates in vitro.

Following implantation in WT mice, WT, II15-/- and II15ra-/- tumor cell lines do not show any significant differences in the growth. These observations suggest that IL-15 signaling does not play a significant role in tumor immune surveillance. Nonetheless absence of IL-15 ‘trans-presentation’ reduces the incidence of spontaneous tumors.

Conclusion

Our work highlights the subtleties of IL-15R α -independent IL-15 signaling in early innate immune response in immunosurveillance.

EACR25-0261**Immunosurveillance shapes the genetic landscape of intestinal tumors in replication error-deficient mice**

Introduction

Carcinogenesis is normally suppressed by cancer immunosurveillance, a crucial defense mechanism in which the immune system identifies and eliminates neoplastic cells, by negatively selecting the ones presenting immunogenic peptides. However, neoplastic cells eventually devise immune evasion strategies, enabling their progression into detectable tumors. This emphasizes the importance of identifying and understanding the precise mechanisms underlying cancer cell recognition and evasion.

Material and method

Our study employed a mouse model of intestinal carcinogenesis with replication error deficiency (RER+), in immunocompetent (IC) and immunodeficient (ID) backgrounds. Whole-exome sequencing (WES) was performed to compare the tumor genetic landscape and determine distinctive attributes, either positively or negatively selected by the adaptive immune system. Preclinical findings were validated through a mutational screening performed in a cohort of human RER+ intestinal tumor samples. Immunogenicity of mutation-derived peptides was measured by IFN γ production upon co-culture of splenocytes from peptide-vaccinated mice with peptide-loaded murine dendritic cells.

Result and discussion

ID mice exhibited a higher incidence of cancer, an increased number of intestinal lesions, and a shorter lifespan compared to IC mice. Additionally, tumors from ID mice displayed a greater somatic mutation burden, unique mutation profiles, and an enrichment of specific mutations. These mutations occurred in genes commonly altered in human RER+ intestinal tumors. In vivo experiments confirmed the immunogenic potential of specific mutations identified in ID mice tumors.

Conclusion

Our findings suggest that immunosurveillance actively influences intestinal carcinogenesis, possibly through selective immune-mediated editing of the tumor genetic landscape, with elimination of cells presenting specific immunogenic mutations. It might be thus important to consider such mutations for the design of novel therapeutic approaches.

EACR25-0277**Small cell lung cancer evades immune surveillance through an ERBB2-dependent mechanism**

L. Meder¹, C. Orschel², C. Bouchez², D. Stahl², R. Gholamipoorfar², J. Brägelmann³, N. Abedpour², R. Büttner⁴, H. Reinhardt⁵, R. Ullrich²

⁴*University of Cologne, Faculty of Medicine and University Hospital Cologne, Institute for Pathology, Cologne, Germany*

⁵*University Hospital Essen, Department of Hematology and Stem Cell Transplantation, Essen, Germany*

Introduction

Small-cell lung cancer (SCLC) is characterized by systemic metastases and its high aggressiveness, therefore SCLC is frequently identified at an advanced stage, making treatment and prognosis extremely difficult. Chemotherapy, radiotherapy, and immunotherapy are the current treatment options for SCLC but research on targeted treatment options is still proceeding. Immune checkpoint blockage targeting programmed cell death-1 (PD-1) or programmed death-ligand 1 (PD-L1) plus chemotherapy has shown promise in extending overall survival of SCLC patients. However, SCLC cells develop resistance and the capacity to evade immune surveillance.

Material and method

We examined molecular profiles of matched primary and metastatic SCLC samples obtained from patients and an autochthonous SCLC mouse model using phosphokinase arrays, proteomics and immunohistochemistry. We used CRISPR-Cas9 knock-outs to functionally confirm MHC-I and ERBB2-dependent effects in vivo and in co-culture assays. Lastly, we examined the therapeutic potential in mice by combining PD-1 and ERBB2-blockade and analyzed tumor cells and T cells extensively using flow cytometry, scRNA and TCR sequencing.

Result and discussion

MHC-I expression was decreased in matched SCLC metastases. We found that SCLC metastases enhanced ERBB2 signaling, which suppressed MHC-I expression by a STING-dependent mechanism in SCLC cells and stimulated immune modulating gene expression. Combining ERBB2 inhibition with anti-PD-1 immune checkpoint blockade in the autochthonous SCLC mouse model resulted in an improved survival rate by stimulating an anti-tumor T-cell response and clonal expansion.

Conclusion

Our results address the unmet need to identify targetable mechanisms that govern tumor immune evasion in SCLC and clearly show that combined inhibition of ERBB2 and PD-1 represents a valid therapeutic approach to enhance outcomes for SCLC patients.

Introduction

Accumulating evidence has clarified that gut dysbiosis is involved in lung cancer development and progression. Although the relationship between tumors and gut microbiota has been extensively studied using clinical samples, no studies have examined the association between mutant EGFR-induced lung carcinogenesis and dysbiosis in gut microbiota. Therefore, we investigated the gut microbiota profiles in stool samples from human lung-specific conditional EGFR-mutant transgenic mice during lung tumor carcinogenesis.

Material and method

Stool samples were collected before tamoxifen treatment (V1) and at each time point following mutant EGFR expression in lung tissue (V2) and lung tumor appearance (V3). Fecal 16S rRNA taxonomy was analyzed to assess microbial diversity, composition, and dynamic changes at each time point.

Result and discussion

We found that microbiota richness and diversity were significantly elevated when tumors developed and grew in the lung. Phylogenetic analysis of the microbial community revealed that Lachnospiraceae, Ruminococcaceae, Porphyromonadaceae, Rhodospirillaceae, Odoribacteraceae, and Desulfovibrionaceae showed a significant increase at the V3 stage compared to the V1 stage at the family level. In contrast, Lactobacillaceae, Bacteroidaceae, Muribaculaceae, Coriobacteriaceae, and Rikenellaceae significantly decreased at the V3 stage compared to the V1 stage. Furthermore, Lactobacillus species, also known as SCFA-producing bacteria, were relatively abundant at the V1 stage but were depleted with the occurrence of lung tumors at the V3 stage.

Conclusion

Changes in gut microbiota, such as Lactobacillus species, may be a predictive factor for the emergence and progression of tumors in an animal model of lung adenocarcinoma induced by mutant EGFR.

EACR25-0344**Tumor-associated *Staphylococcus* spp. and its potential role in breast cancer progression**

G. Bernardo¹, V. Le Noci², M. Anselmi², T. Triulzi², C. Ciniselli³, P. Verderio³, E. Tagliabue², S. Pupa², M. Sommariva^{1,2}, L. Sfondrini^{1,2}

¹Università degli Studi di Milano, Dipartimento di Scienze Biomediche per la Salute, Milano, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Dipartimento di Oncologia Sperimentale, Milano, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Dipartimento di Epidemiologia e Data Science, Milano, Italy

Introduction

Recent research has unveiled a compositional change of bacteria residing in the mammary tissue in the presence of a growing tumor, suggesting their potential role in tumor progression. We recently demonstrated that oral antibiotic administration in 4T1 mammary tumor-bearing mice significantly reduced tumor growth and enhanced anti-tumor immunity by locally depleting *Staphylococcus epidermidis*. Herein, we investigated the presence of DNA from *Staphylococcus* genus (spp.) and its association with outcome in breast cancer (BC) patients, and analyzed the impact of *Staphylococcus* spp. on tumor-infiltrating immune populations.

Material and method

The presence of *Staphylococcus* spp. was investigated by RT-PCR on already available DNA from tumor tissues of a BC patient cohort (n=45), consecutively collected in 2010 at our Institute. The survival analysis was performed by stratifying patients into positive and negative groups according to bacterial presence, using Kaplan-Meier curves. Tumor-infiltrating immune cells were investigated via CIBERSORTx deconvolution analysis of tumor gene expression data. A standard curve in a 2-fold series was set up by qPCR on DNA extracted from 4T1 mammary tumor-isolated *S. epidermidis*. Conditioned medium from *S. epidermidis* isolated from murine mammary tumors was used to evaluate the induction of regulatory T cells (Tregs) from spleen-derived naive CD4+CD25- T cells and polarization of macrophage derived from bone marrow cells of healthy mice by flow cytometry and RT-PCR.

Result and discussion

The presence of *Staphylococcus* spp. in BC specimens was associated with significantly worse relapse-free survival ($p=0.04$, log-rank test). *Staphylococcus*-positive tumors exhibited higher T reg infiltration and increased M1/M2 macrophage ratio. To correlate *Staphylococcus* DNA quantity to patients' outcomes in a second independent BC patient cohort, we set up a q-PCR and analyses are in progress. Conditioned medium of *S. epidermidis* culture induced FoxP3+ T cells differentiation and promoted a mixed macrophage phenotype, characterized by upregulated IL12b, IL1b, IL10 and IL6 expression. These results are indicative of an association between the bacterium and the enhanced immunosuppressive tumor microenvironment. To validate these observations, a study on mice injected into the mammary fat pad with 4T1 tumor cells is ongoing to

determine whether there is a causal link between the progressive accumulation of *Staphylococcus* spp. during mammary tumor growth, the increased Treg infiltration and the acquisition of a pro-tumor phenotype by tumor-associated macrophages.

Conclusion

Our findings suggest that breast cancer-associated *Staphylococcus* may contribute to an immunosuppressive tumor microenvironment by promoting Treg expansion and macrophage polarization. Further investigation is needed to fully evaluate the potential of *Staphylococcus* as a biomarker for predicting patient outcomes.

EACR25-0399**PTP1B inhibition in tumour cell-conditioned macrophages promotes breast cancer by modulating tumour-promoting genes**

N. Read¹, M. Mesiarikova¹, S. Berry¹, M. Delibegovic¹, G. Murray¹, V. Speirs¹, H. Wilson¹

¹University of Aberdeen, Institute of Medical Sciences, Aberdeen, United Kingdom

Introduction

In breast cancer, tumour associated macrophages (TAMs) are the most abundant immune cells, accounting up to 50% of the tumour mass. Due to their highly immunosuppressive phenotype, TAMs are the major promoters of tumour growth and high infiltration is linked to resistance to immune checkpoint inhibitors and chemotherapy. This study aims to determine whether TAMs are re-programmed to adopt an anti-tumour phenotype using a PTP1B inhibitor, which has already been shown to reduce breast cancer progression through its effects on cancer cells.

Material and method

Human monocyte-derived macrophages (hMDM) were conditioned to TAM-like cells by co-culture with T47D (ER+, PR+) and triple negative breast (TNBC) cancer cell line MDA-MB-231. Effects of PTP1B inhibition of T47D and MDA-MB-231 conditioned TAMs on mammosphere growth were examined by area and viability measurements. Mechanisms by which cancer cell conditioning and PTP1B inhibitor treatment affect macrophage phenotype and mammosphere growth were assessed by gene expression arrays.

Result and discussion

Tumour cell-conditioned macrophages significantly decreased T47D mammosphere area by $19 \pm 6.4\%$ but did not affect MDA-MB-231 mammosphere growth. In contrast, PTP1B inhibitor treatment of tumour cell polarised macrophages enhanced the growth of both T47D and MDA-MB-231 mammospheres by $80 \pm 13.5\%$ and $8 \pm 4.1\%$ respectively. Gene expression arrays revealed T47D mammospheres, generated following co-culture with TAMs downregulated the expression of distinct cancer promoting genes including TGF β , HIF1 α and vimentin. MDA-MB-231 mammosphere generated following co-culture with TAMs downregulated expression of the same cancer promoting genes in addition to Snail2 and STAT5A. PTP1B inhibitor treatment of TAMs upregulated expression of these

cancer promoting genes in both T47D and MDA-MB-231 mammospheres formed post co-culture. PTP1B inhibitor treatment of tumour polarised hMDM enhanced expression of genes including PPAR- γ and IL-10 that result in tumour promoting macrophages which consequently contributed to the increased mammosphere growth.

Conclusion

Therapeutics based on PTP1B inhibition may lose efficacy for treatment of those breast cancers with high infiltration of macrophages (e.g. TNBC) by polarizing macrophages to a more tumorigenic phenotype which drives breast cancer progression.

EACR25-0418

Distinct bladder tumor microbiome profiles between responders and non-responders to intravesical Bacillus Calmette-Guérin therapy in high-risk non-muscle invasive bladder cancer

K. Kim¹, J. Ku², H. Ha¹, C. Choi³

¹Pusan National University Hospital, Department of Urology, Busan, Korea (Republic of)

²Dongnam Institute of Radiological & Medical Sciences Korea Cancer Center Hospital, Department of Urology, Busan, Korea (Republic of)

³Hallym University Dongtan Sacred Heart Hospital, Hallym University College of Medicine, Hwaseong, Korea (Republic of), *

Introduction

Intravesical Bacillus Calmette-Guérin (BCG) therapy is a cornerstone treatment for high-risk non-muscle invasive bladder cancer (HR-NMIBC). BCG functions by stimulating the host's immune system. Increasing evidence suggests that bladder microbiome interacts with the host immune system and may impact the efficacy of BCG therapy. We compared the bladder tumor microbiome profiles between responders and non-responders to BCG therapy.

Material and method

We used taxonomic classification tools, Kraken2 and Bracken, to generate a microbiome counts matrix from RNA-sequence data of HR-NMIBC tissue samples naïve to BCG therapy, obtained from the Gene Expression Omnibus series accession number GSE176178. We conducted alpha and beta diversity analyses on responders and non-responders, followed by differential analysis using ANOVA-Like Differential Expression tool (ALDEx2).

Result and discussion

In the study of bladder tumor microbiome profiles in HR-NMIBC naïve to BCG therapy, significant differences were found between responders and non-responders in microbial diversity and composition. In responders, alpha diversity indices, including the Chao1 and Shannon scores, which measure microbiota richness and evenness, were significantly lower than in non-responders ($p = 0.035$ and 0.038 , respectively), indicating reduced microbiota richness and evenness. For beta diversity, multi-dimensional scaling revealed distinct microbiome compositions between the two groups ($p = 0.001$). Stacked bar charts highlighted the differences in the top

12 genera and 19 species for each group, showing the variations in relative abundance of the microbiome at the genera and species levels between responders and non-responders. Differential analysis using ALDEx2 identified 10 species predominant in either group: *Curtobacterium flaccumfaciens*, *Bacillus velezensis*, *Bacillus cereus*, and *Plasmodium yoelii* in responders, versus *Actinoplanes* sp. OR16, *Neurospora crassa*, *Ascochyta rabiei*, *Malassezia restricta*, *Purpureocillium takamizusanense*, and *Streptomyces tanashiensis* in non-responders.

Conclusion

Our findings revealed significant differences in the bladder tumor microbiome composition between BCG responders and non-responders in the HR-NMIBC. While microbiota richness and evenness were significantly lower in BCG responders compared to non-responders, certain species were still more predominant in responders. These results suggest that the bladder tumor microbiome may influence treatment outcomes, underscoring its potential as a predictive biomarker for BCG therapy.

EACR25-0441

Starch degrading bacteria and prebiotic diet synergistically promote anti-tumor immune microenvironment and response to Immune Checkpoint Blockade

A. Iervolino¹, M. Costa¹, A. Ceccarelli², I. Simeone³, E. Bianchino¹, F. Caraglia⁴, D. Bedognetti⁵, J. Roelands⁶, M. Ceccarelli⁷

⁵Sidra Medical, Tumor Biology and Immunology, Doha, Qatar

⁶Leiden University Medical Center, Department of Pathology, Leiden, Netherlands

⁷University of Miami, Department of Public Health Sciences, Miami, United States

Introduction

Emerging evidence indicates that the gut microbiota plays a critical role in shaping antitumor immune responses, offering an innovative avenue for enhancing Immune Checkpoint Blockade (ICB) efficacy. Recent multi-omics profiling of a large cohort of patients with primary colon cancer revealed that a specific consortium of bacteria known to degrade resistant starch was associated with improved survival and a tumor-suppressive microenvironment (Roelands et al. Nat. Medicine 2023). Here, we validated the immunomodulatory effects of these bacteria, specifically *Ruminococcus bromii*, and dietary interventions with castalagin, a microbiota-modulating compound, in shaping tumor microenvironment and response to ICB.

Material and method

To assess the impact of gut microbiota and microbial interventions on tumor immune response, C57BL/6 mice

received a five-day antibiotic treatment (Day -19 to -14) via oral gavage to deplete microbiota, followed by a washout period. They underwent fecal microbiota transplantation (FMT) or received a vehicle control, either with or without *R. bromii* colonization. On Day 0, MC38 tumor cells were injected, and received anti-PD1/CTLA4 therapy. A subset received daily castalagin gavage. Fecal samples were collected at multiple time points. Mice were sacrificed on Day 17. Gene expression and 16S profiling were performed for four tumors per treatment group ($n = 20$).

Result and discussion

Four treatment regimens were considered: aPD1/aCTLA4 (ICB), ICB+castalagin, ICB+*R. bromii*, ICB+*R. bromii* and castalagin-enriched diet. Gene expression profiling and immunohistochemistry showed that microbiota remodeling enhances the immune response to ICB by increasing CD8+ T-cell infiltration and up-regulation of immune-related genes. We observed a higher estimated proportion of CD103+ dendritic cells and a reduction of the immuno-suppressive myeloid compartment. Supplementation with *R. bromii* alongside ICB significantly reduced tumor growth compared to checkpoint blockade alone. The combination of ICB, *R. bromii*, and castalagin diet leads to the most substantial suppression of tumor growth.

Conclusion

Our findings suggest a synergistic effect between microbiota modulation and immune checkpoint blockade, and that gut bacteria's degradation of resistant starch induces beneficial metabolic alterations that activate anti-tumor immune responses.

EACR25-0462

Prognostic Significance of NK-T Cell Differentiation in Oropharyngeal Squamous Cell Carcinoma: A Transcriptomic Analysis

L. Minarik¹, B. Benzon¹, M. Glavina Durdov²

¹*University of Split School of Medicine, Department of Anatomy, Histology and Embryology, Split, Croatia*

²*University Hospital Center Split, Department of Pathology, Forensic Medicine and Cytology, Split, Croatia*

Introduction

Checkpoint inhibitors have recently been introduced for the treatment of advanced oropharyngeal squamous cell carcinoma (OPSCC), with treatment decisions guided by the combined score of PD-L1 expression in cancer cells and the tumour immune microenvironment (TIM). However, a transcriptome compared with other parameters of OPSCC could provide additional criteria and indicate novel therapeutic targets. This study aimed to compare the transcriptome of OPSCC with clinicopathological findings and signalling pathways of TIM cells.

Material and method

Clinicopathological data and OPSCC transcriptome of 81 patients were collected from cBioPortal and compared with single-sample Gene Set Enrichment Analysis (ssGSEA), using the GenePattern online platform.

Survival analysis was performed for each selected signalling pathway connected to B cells, T cells, neutrophils, NK cells and NK-T cell activation, differentiation, and proliferation. Statistically significant pathways were associated with clinicopathological data. Statistical significance was set at $p < 0.05$.

Result and discussion

Patients with a higher enrichment score for NK-T cell differentiation had better survival outcomes than those with a lower enrichment score, with a median of survival 5.62 years compared to 4.68 years ($p = 0.015$). NK-T cell differentiation enrichment was negatively correlated with alcohol consumption ($p = 0.0202$), and positively correlated with clinical stage ($p = 0.011$) and tumour grade ($p = 0.0079$). Further investigation of this pathway highlighted three key genes: ATF2, ITK, and ZNF683. Higher Z scores for these genes were associated with improved survival, with ITK showing the strongest association.

Conclusion

Our findings suggest that NK-T cell differentiation might have a significant role in OPSCC prognosis, with higher enrichment scores and gene expression being associated with improved overall survival. Further studies are needed to explore the role of NK-T cell function in OPSCC progression and to evaluate its potential as a potential therapeutic target.

⁶*Servier, Quantitative Pharmacology, Gif-sur-Yvette, France*

⁷*Université Catholique de Louvain, Pôle oncologie, Brussels, France*

Introduction

Squamous cell carcinoma of the head and neck (SCCHN) arises from the epithelium of the oral cavity, oropharynx, hypopharynx and larynx. Most patients present with locally advanced disease, but less than 60% of the patients remain free of cancer at 3 years. Recurrent and/or metastatic (R/M) SCCHN has poor prognosis, with a median overall survival of 10–17 months. While large-scale multimodal studies have characterized primary treatment-naïve SCCHN, the molecular and immune landscape of R/M SCCHN remains under-explored.

Material and method

We analyzed 253 R/M SCCHN patients (57% with at least 2 lines of treatment in the R/M setting prior to sampling) using the IMMUCAN multimodal-omics workflow, which integrates molecular and immune profiling. More specifically, we used Whole Exome Sequencing (WES), bulk RNA sequencing (RNAseq), multiplexed immunofluorescence (IF) and expression of tumor markers by Imaging Mass Cytometry. We extracted features from these modalities, encompassing mutations and copy number alterations (WES); deconvolution results, pathway activation scores and unsupervised gene modules (RNAseq), and cell proportions in the tumor and stroma compartments (IF).

Result and discussion

Our findings indicate that HPV status, primary tumor site, substance abuse, relapse pattern, and systemic treatments significantly influence tumor biology. Specific genomic alterations were observed in laryngeal cancer and non-smokers/non-drinkers. HPV-positive tumors retained a strong genomic and transcriptomic identity, but showed no difference in immune infiltrate, immune activity or prognostic benefit compared to HPV-negative tumors. 11q13.3 amplification was more frequent in HPV-negative metastatic tumors and hypopharyngeal cancer, and the genes in this region exhibited two different patterns of expression. HPV-negative SCCHN with locoregional recurrence showed elevated EGFR and CXCL12 pathway activity, and EGFR activity correlated to EGFR ligand expression but not EGFR copy number. Systemic therapy led to a decrease in immune features, such as lymphocyte infiltration (IF) and interferon gamma activity (RNAseq). TGF β pathway activation was specifically linked to patients prior to any R/M treatment line. High expression of genes involved in cell migration and adhesion correlated with poor survival, while B and CD8+ T cell infiltration predicted improved survival. Furthermore, prognostic factors were dependent on the specific R/M SCCHN pattern, with important dichotomies observed between distant metastatic and locoregional prognostic features.

Conclusion

This study highlights the heterogeneity of R/M SCCHN, provides deeper characterization of tumor biology at this stage and finds potential biomarkers for novel therapies.

EACR25-0561

Genome-wide CRISPR screens identify N-glycosylation as regulator of T cell:tumor cell interactions

Z. Huinen¹, A. de Groot¹, D. Peepo¹

¹The Netherlands Cancer Institute, Molecular Oncology and Immunology, Amsterdam, Netherlands

Introduction

The efficacy of immunotherapy fundamentally depends on effective T cell:tumor cell interactions. However, the molecular determinants orchestrating this engagement remain incompletely understood. Understanding the regulatory mechanisms of these interactions is crucial for optimising T cell-mediated cytotoxicity in cancer treatment.

Material and method

To systematically map and perturb key regulators of the functional T cell:tumor cell interactome, we employed

two innovative cell:cell interaction assays. Using these assays, we conducted genome-wide CRISPR screens to identify genes critically required for both physical and functional interactions between T cells and tumor cells. Additionally, we utilised TurboID proximity labeling and T cell-tumor cell conjugates to investigate the molecular landscape influencing these interactions.

Result and discussion

Our study identified the complex N-glycan biosynthesis pathway as a crucial regulator of T cell:tumor cell interactions. Given the known role of N-glycans in protein trafficking and surface retention, we further explored their impact using cell surface proteomics and TurboID-based interactome profiling. These analyses revealed increased expression of cell adhesion and co-stimulatory molecules in complex N-glycan-deficient T cells. Functionally, T cells with perturbed N-glycans exhibited a shift towards an effector memory phenotype, characterized by elevated granzyme and integrin expression. Moreover, both genetic and pharmacological interventions reducing complex N-glycans enhanced intra-tumoral infiltration of T cells *in vivo*, supporting their role in modulating T cell effectiveness in tumor environments.

Conclusion

This study provides a comprehensive functional atlas of molecules modulating T cell:tumor cell interactions. Our findings highlight the complex N-glycan biosynthesis pathway as a key regulatory mechanism and a potential therapeutic target to enhance T cell-mediated cytotoxicity in cancer immunotherapy.

EACR25-0571

Bacteroides Ovatus Is Associated with Clinical Response to Cancer

Immunotherapy in Renal Cell Carcinoma

Y. Yu¹, J. Xu², K. Ma¹, Z. Yao¹, H. Liu¹, T. Chen¹, J. Zheng¹, W. Zhai¹

¹Renji Hospital, Shanghai Jiao Tong University School of Medicine, Department of Urology, Shanghai, China

²Run Run Shaw Hospital Affiliated to Medical College of Zhejiang University, Department of Urology, Hangzhou, China

Introduction

Renal cell carcinoma (RCC) is an immunogenic malignancy responsive to immunotherapy, but durable responses and predictive biomarkers remain insufficient. The gut microbiota influences cancer progression and immunotherapy efficacy, yet its role in RCC is unclear. This study explores microbiome-based insights to enhance treatment prediction and overcome resistance in advanced RCC (aRCC) by profiling gut microbiota after immunotherapy, analyzing its correlation with outcomes, and identifying key microbes influencing treatment response.

Material and method

Study Cohort We conducted a baseline follow-up of 28 aRCC patients receiving immunotherapy combined with targeted therapy and collected their fecal samples. Treatment response was assessed at 12 months using iRECIST. Tumor Model SPF mice pretreated with antibiotics received a cocktail (metronidazole, vancomycin, ampicillin, neomycin) in drinking water for one

week. Renca cells were subcutaneously injected into BALB/c mice, followed by intraperitoneal PD-1 blockade or isotype control twice weekly. For targeted therapy experiments, axitinib or sunitinib was administered daily. *Bacteroides ovatus* (B.o, ATCC-8384) was orally administered (1×10^8 CFU) twice weekly.

Result and discussion

We categorized 28 patients receiving immunotherapy combined with targeted therapy into responders (n=20) and non-responders (n=8) based on iRECIST criteria, and analyzed their post-treatment fecal metagenomes. LEfSe identified B.o as enriched in responders. Cox regression revealed a significant negative correlation between high B.o abundance and post-treatment progression; patients with higher B.o abundance had improved PFS. Oral B.o administration enhanced anti-PD-1 mAb efficacy in tumor-bearing mice, an effect lost upon B.o clearance with metronidazole. However, B.o failed to improve targeted therapy efficacy. Only live B.o and conditioned media treatments showed comparable immunotherapeutic efficacy. Untargeted LC-MS/MS identified arginine as a key B.o-derived metabolite influencing immunotherapy response, further validated by colorimetric assay and HPLC. Previous studies suggest that B.o enhances immunotherapy by increasing arginine levels and CD8+ T cell activity. Flow cytometry of tumor tissues from PD-1 mAb-treated mice confirmed this, showing higher CD8+ T cell numbers and increased GZMB and TNF α expression in the B.o-treated group.

Conclusion

Our study reveals a strong correlation between increased gut B.o and enhanced immunotherapy response in aRCC. B.o promotes progression-free survival by modulating immune responses through arginine secretion. Mouse models confirm its role in augmenting PD-1 blockade efficacy, with elevated arginine levels enhancing CD8+ T cell function. These findings highlight B.o and its metabolites as potential adjuncts to improve immunotherapy outcomes in aRCC, supporting their clinical application.

⁴*Biomedical Sciences, Pieve Emanuele (MI), Italy*

⁵*Biomedical Sciences, Pieve Emanuele (MI), Italy*

Introduction

Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer-related mortality worldwide. Despite recent advancements, treatment approaches including those based on immune checkpoint blockade (ICB) therapy remains largely ineffective in HCC patients.

Given the need for alternative or complementary strategies, we propose that enhancing conventional dendritic cell (cDC) function could potentiate anti-tumor immunity. However, cDCs are often dysfunctional in cancer, leading to impaired immune recognition and response. Therefore, restoring cDC function is a promising strategy to improve anti-tumor immunity. Evidence from our lab reveals that activated/mature cDCs (mDCs) within tumor tissue exhibit elevated expression of IL2ra (CD25), the α -subunit of the IL-2 receptor, but lack the signaling component IL2rb. The role of CD25 in mDC-mediated anti-tumor responses, however, remains unexplored. Therefore, our study aims to define the contribution of CD25 to cDC effector functions in HCC.

Material and method

Hypotheses regarding CD25 contribution in cDC effector functions have been tested using either subcutaneous or orthotopic injection of syngeneic the liver cancer cell line HepG2. To analyze CD25 function in primary liver cancer, mice have been challenged with chemical-induced carcinogenesis through diethyl-N-nitrosamine (DEN) treatment. We have recently generated a Clec9acexII2rafl/fl mouse model to specifically target CD25 in cDCs and assess its role in liver cancer progression and response to ICB. A bone marrow-derived cDC (BMDC) in vitro differentiation protocol enabled exploration of mDC crosstalk with T cells and NK cells, as well as IL-2 trans-presentation.

Result and discussion

In our chemically induced HCC model, we observed a significant reduction in CD25 expression on cDCs during tumor progression, accompanied by impaired NK cell infiltration. Similarly, in our Clec9acexII2rafl/fl mouse model, we found decreased infiltration of cytotoxic CD11b $^{+}$ NK cells and activated T cells, along with a delayed rejection of highly immunogenic tumors. Furthermore, bone marrow-derived cDCs from Clec9acexII2rafl/fl mice exhibited defective maturation/activation, characterized by reduced expression of key cDC markers, including CD40, CD86, MHC-II, and PD-L1. CD25-deficient cDCs also displayed impaired antigen presentation to both CD8 $^{+}$ and CD4 $^{+}$ T cells, leading to diminished activation and proliferation. In contrast with previous evidence that describes CD25 as an immune regulatory molecule, our results support CD25 anti-tumor function in cDCs, suggesting novel therapeutic opportunities for HCC patients.

Conclusion

Collectively, our findings suggest that CD25 is crucial for cDC effector functions and the coordination of anti-tumor immunity, particularly by influencing NK and T cell responses in liver cancer.

Introduction

Medulloblastoma (MB) is the most common malignant brain tumor in children, with approximately 650 new cases being diagnosed annually in the European Union. It is classified by the World Health Organization as a grade 4 malignancy and divided into four molecular subgroups: WNT, SHH, Group 3, and Group 4. Current standard treatment causes severe and long-lasting side effects, which makes urgent the need for novel therapeutic strategies, such as immunotherapy. Our group previously characterized the immune profile of MB, identifying low expression of CD274 and CTLA4, and identified elevated expression new putative immune targets CD24 and CD276, in a large cohort of patients. Nonetheless, there is a lack of standardized preclinical models for immuno-oncology research, and the tumor microenvironment (TME) of existing models remains poorly understood. To address this gap, we characterized the immune profile of the Math1-cre:Ptch1lox/lox mouse model of SHH-MB.

Material and method

RNA was isolated from FFPE samples of normal cerebellum ($n=9$) and tumors ($n=14$) from mice of different ages (P21, P42, and P56). The expression of 561 immune-related genes was analyzed using the NanoString® Immunology Panel, and candidate genes were further validated by RT-qPCR. Additionally, a multiplex cytokine/chemokine array, assessing 111 analytes, was performed using protein extracted from fresh tissue of normal cerebellum ($n=4$) and MB tumors ($n=4$) from mice aged P42.

Result and discussion

Transcriptomic analysis identified 329 differentially expressed genes between normal cerebellum and MB. Consistent with human MB data, Cd24a, Cd276, Cxcl1, Cxcr4, and Tgfb2 were significantly upregulated in tumor samples. Notably, Cd24a and Cxcr4 were the most differentially upregulated genes in the tumor samples. Immune checkpoint analysis revealed low expression of Pdcd1, Cd274, and Ctla4, suggesting an immuno-suppressive TME. Immune cell infiltration estimates showed reduced T cells, CD8+ T cells, and B cells in MB, with myeloid cells being the predominant immune population, mirroring the immune landscape of human MB. Furthermore, publicly available single-cell RNA-seq data analysis showed that Cd24 expression was restricted to tumor cells in both human MB and a comparable SHH-MB mouse model. Proteomic analysis via multiplex array revealed decreased levels of TF, FGF1, CX3CL1, and AHSG, while CHI3L1, ICAM-1, IGFBP-2, LYX, and MPO were upregulated in MB. Functional enrichment analysis linked these proteins to pathways involved in the acute inflammatory response, regulation of AKT signaling, and ERK1/2 cascade modulation.

Conclusion

In conclusion, the immune profile of our SHH-MB mouse model mirrors the immune landscape of human MB, further supporting CD24 as a potential immunotherapeutic target. This preclinical model provides a valuable platform for advancing immuno-oncology research and the development of novel immunotherapies for MB.

Oncogenic MYC depletes amino acids from the tumor microenvironment to foster immune evasion in PDAC

B. Krenz^{1,2}, T. Kannan¹, G. Mattavelli², A. Gebhardt-Wolf³, W. Schmitz¹, S. Cavicchioli⁴, M. John², M. Väth⁴, A. Riedel², M. Eilers^{1,5}

³*University of Kiel, Institute of Biochemistry, Kiel, Germany*

⁴*Julius Maximilian University Würzburg, Würzburg Institute of Systems Immunology, Max Planck Research Group, Würzburg, Germany*

⁵*University Hospital Würzburg, Comprehensive Cancer Center Mainfranken, Würzburg, Germany*

Introduction

Treatment of pancreatic ductal adenocarcinoma (PDAC) has seen only marginal improvements over recent decades, resulting in a dismal 5-year survival rate of merely 11%. A significant obstacle in tumor therapy is the insufficient infiltration with cytotoxic lymphocytes. PDAC stands as a paradigm example of a human tumor characterized by dysregulated expression of the MYC oncogene. Genetic depletion of MYC in an orthotopic transplant model of PDAC induces T cell-mediated tumor regression (Krenz et al., 2021, Gaballa et al., 2024). While the intracellular functions of MYC proteins are well-characterized, the molecular intricacies of MYC's non-cell-autonomous role in promoting immune evasion remain to be elucidated.

Material and method

To unravel the underlying interaction networks within the tumor ecosystem, we employed a multi-faceted approach to investigate orthotopically transplanted murine PDAC tumors after depletion of MYC. Our methodology encompassed bulk RNA sequencing, multi-color flow cytometry and immunofluorescence, single-cell sequencing, mass spectrometry, and spatial transcriptomics.

Result and discussion

Single-cell sequencing of murine PDAC tumors unveiled that infiltrating T cells exhibit attenuated activation, particularly in translation and rRNA biogenesis pathways, which is reversed following MYC depletion. These tumor ecosystems are characterized by severe amino acid scarcity. This is alleviated upon MYC depletion, since MYC depletion curtails the expression of metabolic enzymes and solute carriers in PDAC tumor cells both in vivo and in vitro. In culture experiments mimicking these metabolic conditions demonstrate that increasing amino

acid availability promotes activation of the PI3K/AKT/mTOR pathway and upregulates granzyme expression in effector T cells. Notably, selective inhibition of amino acid uptake by tumor cells *in vivo* elevates their levels in the interstitial fluid, reinvigorating immune surveillance. This triggers rapid and sustained regression of PDAC tumors in our aggressive orthotopic transplant model. The MYC oncogene drives cell-autonomous growth of tumor cells with heightened nutrient demands, particularly amino acids. This creates a nutrient-depleted environment that renders T cells in PDAC ecosystems dysfunctional. Corroborating these findings, retrospective analysis of human single-cell sequencing data reveals that the T cell signature from our nutrient-replete PDAC ecosystems bears closer resemblance to T cells in healthy tissue than those within the tumor ecosystem.

Conclusion

Our findings highlight the potential of selectively targeting tumor cell metabolism as a promising therapeutic strategy for pancreatic ductal adenocarcinoma (PDAC). Moreover, they also emphasize the critical role of amino acid uptake by lymphocytes, underscoring the need for drugs that can more selectively deplete nutrients in tumor cells while sparing immune cells.

EACR25-0722

Impact of smoking status on microbiome diversity and taxonomic shifts in bladder cancer

K. Kim¹, J. Ku², H. Ha¹

¹Pusan National University Hospital, Department of Urology, Busan, Korea (Republic of)

²Dongnam Institute of Radiological & Medical Sciences Korea Cancer Center Hospital, Department of Urology, Busan, Korea (Republic of)

Introduction

Smoking, as a key risk factor for bladder cancer, causes tobacco-derived carcinogens to accumulate in the bladder via urine. Emerging research suggests a significant role of the microbiome in bladder cancer, with distinct microbial profiles identified in cancer tissues. While smoking is known to alter microbiomes in the gut and other tissues, its effects on the microbiome of bladder cancer remain underexplored. This study investigates the influence of smoking status on the composition, diversity, and distribution of specific bacterial taxa within bladder cancer tissues.

Material and method

RNA expression profiles and associated clinicopathological data of bladder cancer samples were obtained from the TCGA database, a publicly available cancer genomics resource [1]. Samples from 399 bladder cancer patients were included in this study. We calculated Chao1 and Shannon indices to assess richness and evenness, respectively. Beta diversity was analyzed using multidimensional scaling (MDS), with p-values determined via the Adonis test. Differential abundance (DA) analysis was conducted using ANOVA-Like Differential Expression tool (ALDEEx2).

Result and discussion

Analysis of alpha diversity metrics, including the Chao1 and Shannon indices, revealed no statistically significant

differences in species richness or evenness among current smokers, former smokers, and non-smokers (all $p > 0.05$). Similarly, beta diversity analysis using MDS showed no significant clustering or compositional differences between these groups (all $p > 0.05$), suggesting that smoking history does not markedly influence the overall microbiome diversity in bladder cancer tissues. However, taxonomic-level analyses revealed notable patterns. At the phylum level, variations in the relative abundance of Firmicutes, Bacteroidetes, Actinobacteria, and Proteobacteria were observed, with a significantly higher abundance of Proteobacteria in current smokers compared to non-smokers and former smokers, particularly those with a cessation period of over 15 years. At the class, order, family, and genus levels, distinct shifts were identified, including a reduced abundance of Bacilli, Lactobacillales, Lactobacillaceae, and Lactobacillus in current smokers. In contrast, Proteobacteria-related taxa such as Enterobacteriaceae and Pseudomonas were more prevalent in current smokers, indicating smoking-induced alterations in specific microbial taxa within bladder cancer tissues.

Conclusion

These findings suggest that while smoking status does not significantly impact overall microbiome diversity in bladder cancer tissues, it induces specific taxonomic shifts, particularly affecting Lactobacillales and Proteobacteria. These microbiome alterations may contribute to the understanding of microbiome-mediated mechanisms underlying smoking-related bladder cancer development.

Cancer vaccines target to a disintegrin and metalloprotease domain (ADAM) could induce anti-tumor immunity

S. Liu¹, W. Wu¹, W. Huang¹, Y. Sher²

¹National Health Research Institutes, National Institute of Infectious Diseases and Vaccinology, Miaoli County, Taiwan

²China Medical University, Institute of Biochemistry and Molecular Biology, Taichung, Taiwan

Introduction

Immune modulation in cancer is a critical strategy aimed at enhancing the immune system to combat tumors and reduce metastasis. One promising approach is immune checkpoint blockade, particularly focusing on the activation of CD8+ T cells. Our research investigates the molecular mechanisms of the metastatic-associated gene, a disintegrin and metalloprotease domain 9 (ADAM9), in regulating the immune response within the tumor microenvironment and its role in cancer progression. ADAM9 overexpression is linked to poor outcomes in cancer patients, specifically in lung and breast cancers.

Material and method

Through RNA-seq analysis comparing control and ADAM9 knockout (KO) lung tumors, we identified genes influenced by ADAM9 that contribute to immune suppression. ADAM9 appears to impact immune cells by modulating cytokine production, interferon response, and lymphocyte activation, thereby influencing the tumor microenvironment and facilitating tumor growth and

metastasis. Additionally, we generated recombinant ADAM9 to assess its therapeutic potential.

Result and discussion

Our findings showed that knocking out ADAM9 in lung cancer cells alters cytokine profiles, reduces neutrophil infiltration, increases CD8+ T cell presence, and enhances the interferon-gamma (IFN- γ) pathway activity. These changes may explain the smaller tumor sizes and decreased metastasis observed in syngeneic mouse tumor models. Remarkably, the recombinant protein ADAM9 with adjuvants completely inhibited tumor growth in our models, highlighting ADAM9's significance in tumor progression and its potential as a candidate for cancer vaccine development.

Conclusion

In summary, our research underscores the critical role of ADAM9 in shaping the immune landscape of tumors. Targeting ADAM9 may provide new therapeutic approaches, enhancing the effectiveness of existing cancer treatments.

POSTER IN THE SPOTLIGHT

COX-2/PGE2 Activity in Cancer Cells: A Key Driver of Metastasis via Immune Escape

M. Russo¹, L. Nebot-Bral², S. Chiang², A. Pidoux², M. Koufaki², C. Earnshaw², S. Zelenay²

¹*Cancer Research UK Manchester Institute, Cancer Inflammation and Immunity group, Manchester, United Kingdom*

²*Cancer Research UK Manchester Institute, Cancer Research UK Manchester Institute, Manchester, United Kingdom*

Introduction

Metastasis, the leading cause of cancer-related deaths, remains a significant clinical challenge due to the lack of effective therapies. A critical question that remains unanswered is why some tumours evade immune control and metastasise, while others do not. Our previous work demonstrated that COX-2/PGE2 activity in cancer cells promotes progressive tumour growth through immune escape in preclinical models of primary tumours.

Building on this, we explored the role of this inflammatory pathway in regulating the immune response to metastasis.

Material and method

We evaluated the metastatic potential of breast, pancreatic, and renal cancer cells following orthotopic transplantation or intravenous injection into immune-competent wild-type mice or genetically engineered to lack specific immune cells or inflammatory signalling pathways. We used bioluminescent cancer cells to explore the steps of the metastatic cascade influenced by cancer cell-COX2/PGE2 activity. Furthermore, we conducted antibody-mediated depletion of specific immune cells to assess their functional contribution to metastasis.

Result and discussion

Using loss- and gain-of-function approaches, we show that cancer cell COX-2 expression is both necessary and sufficient to drive metastatic dissemination across

multiple cancer models. Mechanistically, we found that PGE2 supports metastatic colonisation by enabling cancer cells to escape NK and T cell recognition.

Interestingly, in contrast to primary tumours, we provide evidence that neutrophils play a central role in facilitating metastasis by COX-2-expressing cells. This highlights the distinct immune microenvironmental interactions between primary and metastatic tumours.

Conclusion

Our findings establish PGE2 production by cancer cells as a critical mediator of neutrophil-driven pro-tumorigenic activity and immune escape. In addition, they suggest that targeting the COX-2/PGE2 axis could offer a therapeutic strategy to enhance the efficacy of immunotherapies for patients with metastatic cancer.

Observational study comparing sequential boost versus SIB

chemoradiotherapy induced toxicity and its association with oral candidiasis in Head and Neck Cancer Patient

R. Chourasia¹, T. Selvaraju², G. Gayathri³

¹*Vels Institute of Science, Technology ,and Advanced Studies (VISTAS), Microbiology, Chennai, Tamil Nadu, India*

²*Barpeta Cancer Centre, Radiation Oncology, Barpeta, Assam, India*

³*Vels Institute of Science, Technology ,and Advanced Studies (VISTAS), Microbiology, Chennai, Tamil Nadu, India*

Introduction

Radiotherapy for LAHNC has changed considerably over the past two decades with the advent of conformal radiotherapy techniques. Whereas these techniques differ in treatment related outcomes including survival, however the toxicity remains unanswered. Our objective of this study was to compare the sequential versus SIB chemoradiotherapy induced toxicities and their association with the oral candidiasis in HNC patients.

Material and method

A single institutional prospective observational data on histologically proven squamous cell LAHNC treatment with definitive chemoradiation 66-70 Gy was done. Treatment was delivered via sequential boost using IMRT/VMAT/IGRT. Sequential Arm was delivered in 3 Phases, Phase I- 46-50 Gy, Phase II- 10-14 Gy, and Phase III- 10 Gy, while SIB Arm with 66 Gy (High risk), 60 Gy (Intermediate risk), and 54 Gy (Low risk) was given. Both arms received concurrent chemotherapy with weekly injection of Cisplatin 40 mg/m². Toxicity was graded weekly during treatment and a three monthly follow-ups.

Result and discussion

With both the Arms of our study, the oropharynx was the most common subtype followed by the larynx and hypopharynx. Most of the patients had good performance score with ECOG 0-1 and 70-75% of patient were locally advanced with the stage IVA and stage IVB. More than 70-75% of the patient consumed tobacco/ tobacco related products and 70-75% of patients received chemotherapy in both sequential and SIB Arms. In terms of toxicity,

there were no treatment-related deaths in either cohort. Grade III dermatitis occurred in 40% vs 50% of patients receiving sequential vs SIB chemoradiotherapy respectively while Grade IV dermatitis was observed in 2% vs 20% of the cases receiving sequential boost vs SIB treatments. Likewise, Grade III mucositis was observed in 60% vs 55% with sequential vs SIB treatments while Grade IV mucositis was found in 5% vs 25% of cases with sequential vs SIB treatments. Grade IV dysphagia occurred in 0% of cases with sequential treatment compared to 15% with SIB. These toxicity profiles suggest that the Grade III/IV dermatitis and dysphagia were higher in SIB Arm in comparison with the sequential boost arm. Grade III/IV mucositis associated with the oral candidiasis was more common in the SIB arm compared to the sequential arm. Among the Candida species, *Candida albicans* outnumbered the non-albicans *Candida*. Overall, we find that these techniques appear equivalent with respect to treatment outcomes though sequential boost using Rapid Arc/IMRT technique is associated with some improvement in rates of acute toxicity.

Conclusion

There was no difference in the disease related outcomes between the two treatment delivery approaches. A higher rates of acute toxicity with Grade III/IV RT dermatitis, mucositis, dysphagia and associated oral candidiasis were observed to be higher in SIB arm compared to sequential arm.

EACR25-0801

Reprogramming and therapeutic relevance of immunosuppressive cells in the process of prostate cancer metastasis

V. Cid¹, I. Hermanova², J. Auzmendi¹, M. Piva¹

¹CiCBioGune, Derio, Spain

²Center for Cooperative Research in Biosciences, Basque Research and Technology Alliance (BRTA), Derio, Spain

Introduction

Prostate Cancer is the most cancer diagnosed worldwide being the second cancer-cause of death. Although 90% of prostate cancer have good prognosis, 20-10% of the prostate cancer cases are early diagnosed metastatic prostate cancer(mTNPC) which only 50% of these patients survive. Thus, it's important the understanding of the mTNPC immune landscape to develop new immunotherapies to improve the patient's survival rate.

Material and method

The Lab developed an animal model which mimics the aggressiveness and metastatic capacity of mTNPC. This animal model consists of the complete knock out of PTEN and LKB1 tumor suppressors generating tumors within 3-5 months.

Result and discussion

This genetic model showed high infiltration of MDSC cells and low lymphocytes infiltration, compared to different genetic mouse models with different degree of aggressiveness (PTENpc-/- LKB1pc+/-, PTENpc-/- LKB1pc+/-). The dissociation of the PTENpc-/- LKB1pc-/- tumors and reinjecting them in the ventral prostate of the C57bl/6 mice produced a fast-growing tumor, within 15-20 days, maintaining the same

metastatic capacity to lungs and lymph nodes. Furthermore, the reinjected tumors present the same immune cells infiltration of the genetic model. This reinjected model when treated with androgen deprivation therapy responded but expressed resistance at the end of the experiment. Also, immunotherapy against MDSCs, anti-GR1, seemed to reduce the metastasis and the infiltration of pro-tumoral immune cells. We generated a cell line from one of these reinjected tumors, the T051 cell line. This new line, having the genetic model genotype and AR expression, was injected in mice obtaining more aggressive tumors with a higher dissociation capacity to several organs than reinjected tumors. When treating mice-bearing T051 subcutaneous tumors with anti-PD1 as a single agent and in combination with Androgen Deprivation Therapy, tumor growth is partially controlled with an improvement in T-Cell response. Furthermore, the T051 tumors presents high infiltration of MDSCs as well as the genetic model. Thus, this model allows to test different therapeutic strategies to reduce MDSC functions and improve treatment response.

Conclusion

In conclusion, these new animal models and the cell line having an aggressive immune landscape, capacity to metastasize and responding to different therapies will help us to get a deeper knowledge of mTNPC.

EACR25-0829

The role of immune checkpoints interplay in modulating NK cell activity in ovarian cancer environments

A. Pawłowska-Lachut¹, W. Skiba¹, P. Pieniądz-Feculak^{2,1}, A. Ignatowicz³, J. Lyczba⁴, J. Kotarski⁵, M. Bilska⁴, J. Tomaszewski⁵, R. Tarkowski⁶, I. Wertel¹

⁵St. John's Center of Oncology of the Lublin Region, Lublin, Poland, Second Department of Gynecological Oncology, Lublin, Poland

⁶Medical University of Lublin, Poland, I Chair and Department of Gynaecological Oncology and Gynaecology, Lublin, Poland

Introduction

Ovarian cancer (OC) is the most lethal gynaecological malignancy. To date, there are no screening methods or biomarkers to diagnose the disease at an early stage. NK cells play a pivotal role in antitumor immunity in OC. Their activity is modulated by activating and inhibitory signals, including the programmed death pathway (PD-1/PD-L1/PD-L2) and TIGIT/CD155/DNAM-1 axis. DNAM-1 acts as a co-stimulatory receptor. After binding to ligands such as CD155, it enhances NK cytotoxicity, while TIGIT has an inhibitory effect. Moreover, these

two pathways work synergistically, leading to immune evasion in the ovarian tumor microenvironment (TME). In this study, we compared the distribution of NK cells with DNAM-1, TIGIT, and PD-1 expression in different OC environments.

Material and method

The study group consisted of 34 patients with histopathologically confirmed OC. Mononuclear cells (MNCs) were isolated from three OC environments, i.e. peripheral blood (PB), peritoneal fluid (PF), and tumor tissue (TT), using density gradient centrifugation. The isolated MNCs were stained with specific monoclonal antibodies (anti-CD3, anti-CD16+56, anti-DNAM-1, anti-PD-1, anti-TIGIT) and analyzed by flow cytometry. The percentages of the NK cells in different environments were compared using the Wilcoxon paired test.

Result and discussion

The highest %NK cells was detected in PB in comparison to PF (median 14.88% vs. 4.90%; $p < 0.001$), and TT (median 14.88% vs. 3.06%). We observed the highest %NK cells with TIGIT expression in PF in comparison to PB (median 90.15% vs. 75.86%; $p < 0.01$) and TT (median 90.15% vs. 64.19%). Similarly, we found the highest percentage of NK cells with DNAM-1 expression in PF in comparison to PB (median 69.76% vs. 60.86%) and TT (median 69.76% vs. 48.13%); however, the differences did not reach the statistical significance ($p > 0.05$). We also found higher percentage of PD-1 positive NK cells in TT than PB (median 41.01% vs. 21.43%; $p < 0.05$) and PF (median 41.01% vs. 26.44%). The accumulation of NK cells with TIGIT expression in PF may create an immunosuppressive microenvironment, facilitating immune evasion and metastatic spread. The accumulation of PD-1 positive NK cells among OC infiltrating cells suggests that NK cells may be chronically exhausted within TME. The highest percentage of TIGIT or DNAM-1 positive NK cells in PF may indicate that NK cells' activity is dependent on the availability of the ligands in the environments. Moreover, TIGIT has a higher affinity to CD155 than DNAM-1, which promotes immunosuppression within TME.

Conclusion

The high accumulation of NK cells with TIGIT expression in PF indicates that PF is a strongly immunosuppressive environment. The high %NK cells with PD-1 expression among OC infiltrating cells may be related to NK cell exhaustion within the ovarian TME.

EACR25-0866

Advancing treatment in high-grade serous ovarian cancer through targeting of RNA splicing

*A. Cheeseman¹, Y. Xu¹, I. McNeish¹, H. Keun¹, A. Nijhuis¹,
¹Imperial College London, London, United Kingdom*

Introduction

The RNA binding protein RBM39 regulates alternative splicing and is targeted by the small aryl sulphonamides E7070 (indisulam) and E7820. These molecules display strong anticancer activity by acting as a molecular glue between RBM39 and the E3 ubiquitin ligase DCAF15, leading to the polyubiquitination of RBM39 and

ultimately resulting in defects in RNA splicing. Ovarian high grade serous carcinoma (HGSC) is the most prevalent, as well as the most aggressive and lethal subtype of ovarian cancer. Current standard therapeutic options include cytoreductive surgery and chemotherapy, however, even patients who initially respond well to treatment are likely to develop recurrence. Ovarian HGSC tumours are highly heterogeneous lesions traditionally categorised as 'immune-cold' due to the low immune infiltrate observed. Given the challenges in treatment arising from the high heterogeneity and low immune infiltrate observed, as well as the frequent late-stage diagnosis of ovarian HGSC, the development of new treatment regimens is essential. Previous studies have shown that depletion of RBM39 via indisulam treatment gives rise to highly immunogenic neoepitopes capable of increasing the response to immunotherapy in murine models of neuroblastoma. Additionally, in house data has shown that RNA-splicing derived neopeptides are expressed in ovarian cancer models in vitro. Based on this data, I hypothesise that RBM39 depletion via molecular glue indisulam modulates the tumour immune microenvironment by generating neoepitopes capable of eliciting an immune response in ovarian HGSC models.

Material and method

The tumour immune microenvironment was profiled in vivo following indisulam treatment via flow cytometry and immunohistochemistry.

Result and discussion

These results show an increase in the level of specific immune cell populations including conventional dendritic cells or tissue resident macrophages. An increase in the levels of conventional dendritic cells (cDCs), a type of antigen-presenting cell, as well as macrophages, could suggest an increase in immune activation as well as tumour immunogenicity potentially due to the presence of novel immunogenic neoepitopes.

Conclusion

An increase in antigen-presenting cells (APCs) such as cDCs may reflect a rise in neoantigens available for identification, aligning with our hypothesis. Overall, these results could suggest a complex immuno-modulatory effect following RBM39 depletion, which could potentially benefit patients receiving immunotherapies.

An integrated organoid and stool-derived culture platform for investigating microbiota-driven metabolite effects in colorectal cancer

N. Bodenstein¹, V. Brunner¹, E. Diogenes², F. Springer³, G. Zeller³, K. Kleigrewe⁴, D. Saur¹, M. Tschartschenthaler¹

¹Technical University of Munich, Center for Translational Cancer Research, Munich, Germany

²Federal University of Ceará, Department of Pathology and Forensic Medicine, Fortaleza, Brazil

³European Molecular Biology Laboratory, Heidelberg, Germany

⁴Technical University of Munich, Bavarian Center for Biomolecular Mass Spectroscopy, Freising, Germany

Introduction

Colorectal cancer (CRC) progression is influenced by the gut microbiome via direct bacteria–host interactions, secretion of metabolites/toxins, and immune cell recruitment that drives pro-inflammatory signalling. Yet, the impact of microbiome-derived metabolites on tumour progression remains poorly understood. Previous studies examined single bacterial or metabolite species, overlooking the complexity of community dynamics. To address this, we developed and validated a novel platform to assess community-culture derived bacterial metabolite supernatants on CRC adenoma and carcinoma organoid models.

Material and method

Matched caecal content from tumour-bearing mice with mutations in *Apcfl/fl*, *BrafV637E*, *KrasG12D* and *Pik3caH1047R* was collected at humane endpoint for whole metagenome sequencing and targeted and untargeted metabolomics. Linear discriminant analysis of the metagenomic dataset identified genotype-specific bacterial species signatures with differential abundance relative to controls. Stool-derived *in vitro* communities (SICs) were also established from the caecal content of tumour-bearing and wild-type mice, with their species composition validated by 16S-rRNA analysis. Finally, the bacterial metabolite supernatants were integrated with the colorectal cancer organoid models *in vitro*, with viability being assessed by CellTiter Glo® assays.

Result and discussion

Metabolomic and untargeted metagenomic data of matched samples reveal that driver mutations shape gut microbiota composition and tumour progression. We identified species signatures uniquely linked to each genotype, showing either enrichment or reduction relative to wild-type. Remarkably, these signatures persisted in SICs as confirmed by 16S-rRNA analysis. Moreover, *BrafV637E*, *KrasG12D*, and *Pik3caH1047R* organoids exhibited enhanced, disease-state-specific survival when treated with matched-genotype SIC metabolites versus wild-type. This confirms that microbiome changes generate genotype-specific pro-oncogenic niches that support tumour progression.

Conclusion

Key mutations in colorectal cancer – *Apcfl/fl*, *BrafV637E*, *KrasG12D* and *Pik3caH1047R* – drive changes in gut microbiome composition that promote tumour cell survival and progression. These alterations also drive notable modifications in the secretory metabolite profile, affecting the biochemical environment and metabolic interactions within the ecosystem. Our platform reintegrates these metabolites with colorectal cancer organoids *in vitro*, enabling study of their functional implications. Additionally, our findings suggest that bacterial metabolites from healthy donors may complement current therapies, improving patient outcomes.

Introduction

Breast Cancer (BC) subtypes with poor prognosis are often associated with tumor microenvironments (TMEs) rich in myeloid immune cells. Cumulating evidence points to their role in promoting pro-tumorigenic immunosuppressive (IS) TMEs. Immunotherapies targeting immune suppression, typically cytokine signaling, have been proposed. Yet they faced challenges due to signaling redundancy and compensatory mechanisms, hampering clinical success. Recent findings emphasize the role of myeloid lectins, immune-modulating carbohydrate receptors that recognize aberrant glycans on tumor cells, in sustaining IS TMEs. As such, lectins are proposed as potential targets for immunotherapies, but the systematic characterization of their expression pattern remains underexplored. In this work, we profiled the lectin landscape of the BC myeloid cell population to identify potential targets to block myeloid-mediated immunosuppression.

Material and method

We analyzed an RNA-Seq dataset and classified samples as IS and Non-IS, by applying a published classifier gene panel [1]. We then combined differential gene expression analysis (DGEA) of the lectins in the IS vs Non-IS group with analysis of the top 25% over-expressed lectins in the myeloid cells of a single-cell RNA-Seq cohort [2]. For biological validation of the identified lectins, we employed a BC human 3D cell model (3D-3) using alginate microencapsulation and agitation-based cultures [3]. Both stromal (fibroblast) and immune components (blood-derived monocytes) were co-cultured with spheroids of BC cell lines MDA-MB-231, HCC1806 & BT474. The lectin subset was probed in the 3D-3 model of BC by flow cytometry. Top hits were validated for clinical outcome in patient tumor samples.

Result and discussion

Bioinformatic analysis of 3207 patients [4] revealed HER2 overexpressing and Triple Negative tumors overrepresented in the IS group (44%), associated with decreased overall survival and relapse-free survival. DGEA identified 13 lectins of interest enriched in the IS myeloid subset. Along 1 week of culture, an IS TME was acquired depicting cancer-associated fibroblasts and tumor-associated macrophages (TAM) phenotype. Probed lectins showed differential protein expression upon TAM polarization (CD163+CD206+) and the top hits correlated with clinical outcome. Functional validation by CRISPR gene knockout and evaluation of the impact on TAM polarization is ongoing.

Conclusion

In sum, we deliver a comprehensive characterization of the lectin landscape of myeloid cells within IS TME in BC, with putative targets to tackle IS, rendering tumors sensitive to novel immunotherapies.

Osteopontin reprogrammes macrophages to a dysfunctional state in intrahepatic cholangiocarcinoma for patients with longer survival outcomes on chemotherapy

M. Gabriel¹, C. O'Rourke¹, C. Braconi², J. Andersen¹

¹University of Copenhagen, Biotech Research and Innovation Center, Copenhagen, Denmark

²University of Glasgow, Glasgow, United Kingdom

Introduction

Heterogeneous benefit from chemotherapy in intrahepatic cholangiocarcinoma (iCCA) stems from differences in tumour and systemic biology. Previously, using pre-treatment biopsies, we identified the RPLS transcriptomic signature which distinguishes patients who would become rapid progressors (RP) from long survivors (LS) on chemotherapy. These differences predominantly originate from altered tumour-macrophage dynamics which remain to be mechanistically tested.

Material and method

We transcriptionally annotated iCCA cell models as RP-like (HUCCT1, KKU213, HUH28) or LS-like (KMCH1, CCLP1, SNU1079, YSCCC). To generate tumour-educated macrophages, conditioned media transfer was performed from these iCCA cell lines to THP1-derived and primary macrophage models. THP1 cells and primary monocytes were differentiated into macrophages by phorbol 12-myristate 13-acetate and colony stimulating factor 1, respectively. THP1 macrophages were further polarized into M1 (using interferon gamma and lipopolysaccharides) or M2 (using interleukin-4 and interleukin-13) states. Secreted proteins in conditioned media were profiled by NULISA-seq (200-plex inflammation panel). Macrophage phenotypes were assessed by viability (WST-1), morphology (IncuCyte® live cell imaging), phagocytosis (Zymosan substrate colorimetric assay), and transcriptional reprogramming (RNA-seq). The impact of recombinant osteopontin (SPP1) treatment on macrophage phenotypes was further evaluated.

Result and discussion

Conditioned media from RP-like iCCA cell lines contained a higher abundance of 52 extracellular proteins linked with pro-inflammatory signalling. Exposure of THP1-macrophages to RP-like media led to increased viability and altered morphology (more elongated and amoeboid-like shape) without any effect on their phagocytic capacity. Contrasting with these observations, conditioned media transfer from LS-like iCCA more extensively reprogrammed the transcriptomes of THP1- and primary macrophages. This suggested either a greater immunostimulatory effects of secreted proteins in LS-like conditioned media or greater immunosuppressive effects of secreted proteins in RP-like conditioned media.

Importantly, SPP1 was the only higher abundant protein in LS-like conditioned media. Recombinant SPP1 treat-

ment decreased viability and the phagocytic capacity of M0 THP1-macrophages (but not M1 or M2).

Conclusion

LS-like iCCA secrete higher amounts of SPP1, directly compromising the immune functions of macrophages in the M0-state. These data support a unique immune evasion strategy employed by a subset of tumours associated with better outcomes on chemotherapy. Understanding these cellular dynamics may offer insights into potential immunodulatory effects of SPP1 and its role in the tumor-macrophage-mediated iCCA progression.

Sympathetic-β2 adrenergic receptor drives the formation of pro-metastatic niche in liver metastasis

Y. Zhang¹, J. Zhou¹

¹The Chinese University of Hong Kong, School of Biomedical Sciences, Hong Kong, Hong Kong, China

Introduction

Liver is the most common site for cancer metastases, which may be attributed to the hepatic immuno-suppressive microenvironment. Recent studies have highlighted the immunomodulatory of innervation in various cancers. Given that the liver is richly innervated, we aimed to investigate their possible involvement in the metastatic-prone liver microenvironment.

Material and method

Integrative single-cell RNA sequencing (scRNASeq) and multiplex immunofluorescence (mIF) analysis in patients with colorectal cancer (CRC) liver metastasis (CRLM) was utilized to profile the expression patterns of neurotransmitter receptors. Orthotopic CRLM mouse models, high-dimensional flow cytometry, spatial transcriptomics, β2-adrenergic receptor (β2-AR) blocker and chemical sympathectomy were applied to investigate the functional roles and possible molecular mechanisms of β2-AR in CRLM.

Result and discussion

Our integrative analysis uncovered that β2-AR, the receptor of norepinephrine, was significantly upregulated in myeloid cells from patients with CRLM. Using our established spontaneous CRLM mouse models, we found that the upregulation of β2-AR was restricted to hepatic neutrophils, induced by the existence of primary CRC tumors and correlated with tyrosine hydroxylase (TH)+ sympathetic nerve fibers in the liver. Most importantly, blockade of sympathetic-β2-AR via β2-AR blockers or chemical sympathectomy in CRC-tumor bearing mice showed a potential to reduce liver metastatic incidence without suppressing primary CRC. Mechanistically, β2-AR activation may upregulate the expression of S100a8/9 to enhance the immunosuppressive activity of hepatic neutrophils via regulating neutrophil degranulation, thereby promoting CRC liver metastasis.

Conclusion

Our findings reveal the potential of targeting β2-AR signaling for the prevention and treatment of liver metastasis.

EACR25-0944**Translation Dysregulation In Cancer as a Source for Targetable Antigens**

Introduction

Recent clinical successes of cancer immunotherapies have highlighted the importance of identifying cancer neoantigens – novel epitopes of self-antigens that derive from mutant proteins – for anti-tumor immunity. Indeed, identifying neoantigens derived from tumor-specific somatic mutations has enabled the advent of personalized therapeutic cancer vaccines. However, these immunotherapies are still limited to certain cancer types and are seldom curative. A major contributing factor to this limitation is the scarcity of identified targetable antigens. Thus, expanding the neoantigen search to non-mutational sources could greatly increase immunotherapy applications. This can be achieved by exploiting antigens derived from dysregulated protein synthesis in malignant cells.

Material and method

To investigate the role of translational dysregulation in immunological tumor control, we disrupted translation fidelity by deleting tRNA- γ W synthesizing Protein 2 (TYW2) in human and murine tumor cells and characterized the downstream impact on translation fidelity and immunogenicity using immunopeptidomics, genomics, and functional assays.

Result and discussion

Our analyses revealed that TYW2-KO cells generate immunogenic out-of-frame peptides. Furthermore, Tyw2 loss increased tumor immunogenicity and Tyw2 KO tumor-bearing mice exhibited a superior response to immune checkpoint blockade (ICB) therapy compared to Tyw2 WT tumor-bearing mice, indicating involvement of antigen-specific anti-tumor responses. Importantly, stimulation of T cells from ICB-treated Tyw2 KO tumor-bearing mice with out-of-frame peptides induced antigen-specific proliferation and activation in different ex vivo assays. Finally, our observations were corroborated by primary melanoma patient data analyses showing that reduced TYW2 expression was associated with increased response to ICB in patients.

Conclusion

Together, we demonstrate that defects in translation fidelity in cancer cells drive tumor immunogenicity. This study highlights the potential of tumor translational regulators as an attractive target for immunotherapy development, for enhancing the repertoire of tumor neoantigens.

EACR25-0960**16S rRNA sequencing based characterization of human gastric microbiome in patients with autoimmune atrophic gastritis and gastric neuroendocrine tumors**

H. Niedra¹, I. Konrade², V. Lisovska¹, R. Saksis¹, I. Mandrika¹, V. Rovite¹

¹Latvian Biomedical Research and Study Centre, Molecular and functional genomics, Riga, Latvia

²Riga East Clinical University Hospital, Riga, Latvia

Introduction

Autoimmune atrophic gastritis (AAG) is characterized by the development of anti-parietal cell antibodies. The continuous loss of parietal cells leads to oxytic atrophy, eventually resulting in the development of sites with metaplasia, an event highly associated with the development of gastric tumors. The exact mechanisms leading to the development of autoimmunity and AAG's transformation into gastric neuroendocrine tumors (G-NETs) remain to be elucidated. Furthermore, the chronic increase in gastric pH caused by hypochlorhydria is expected to result in noticeable changes within the composition of the gastric microbiota. There is a scarce number of studies that have explored the changes in the composition of the gastric microbiota in relation to AAG and G-NETs, an interesting aspect that may further contribute to the development of gastric tissue atrophy and the acquisition of malignant potential. In this study, we aimed to investigate the composition of gastric microbiota to elucidate potential microbial determinants that are involved in the development of AAG and G-NET.

Material and method

Gastric juice aspirates (GA) were collected during endoscopic visits. All participants provided signed informed consent before participating in the study. The study was approved by the Central Medical Ethics Committee of Latvia [1]. DNA from GA samples was extracted using the QIAamp PowerFecal Pro DNA kit, followed by 16S rRNA V3 and V4 region sequencing on the Illumina MiSeq system with 100k reads per sample. In bioinformatics analysis, the Host DNA contamination was detected and removed using Bowtie2 (v2.5.1) and GRCh38 (v44) GENCODE human genome reference. This was followed by read merging and concatenation using PANDAseq (v2.11). De-noising, chimera removal, and amplicon sequence variant (ASV) detection were performed using DADA2 as part of the QIIME2 wrapper (v2023.09). Only ASVs with a sequence frequency of 10 or more were retained. Remaining ASVs were classified using the naïve Bayes classifier available in QIIME2, with a V3-V4 region-filtered SILVA (v138.1) database as a reference.

Result and discussion

In our data, we observed that the number of identified species was uniform across the sample groups; however, significant changes were observed in the evenness score of the identified species: Benjamini-Hochberg (BH) adjusted P-values of 0.02 (controls vs. AAG) and 0.006 (controls vs. G-NET). Differential abundance analysis

revealed that both AAG and G-NET groups showed an increase in the abundance of the *Rothia* genus compared to healthy controls. Furthermore, a reduction in the abundance of the *Haemophilus* genus was observed in the AAG group, and a reduction in *Gemella* was observed in the G-NET group.

Conclusion

The changes in gastric microbiota in patients with AAG and G-NET can be observed in species evenness.

Moreover, patients with AAG and G-NET have an increased abundance of *Rothia* genera.

Infiltration of PD1+T cells after neoadjuvant FOLFIRINOX treatment associates with improved clinical outcomes in pancreatic cancer

R. Krog^{1,2}, M. IJsselsteijn¹, T. Brouwer², M. van Dam², R. van der Breggen¹, H. Morreau¹, B. Bonsing², S. Crobach¹, A. Vahrmeijer², N. de Miranda¹

¹Leiden University Medical Center (LUMC), Department of Pathology, Leiden, Netherlands

²Leiden University Medical Center (LUMC), Department of Surgery, Leiden, Netherlands

Introduction

Pancreatic ductal adenocarcinoma (PDAC) has limited therapeutic options and a dismal prognosis. In recent years, immunotherapies have revolutionized the treatment of various cancers, but, to this date, PDAC patients have not benefited from these breakthroughs. Modulation of the PDAC microenvironment with conventional therapies may break immunosuppressive barriers that thwart the success of immunotherapeutic approaches. Accordingly, we investigated the impact of neoadjuvant therapy regimens on the immune micro-environment of PDAC.

Material and method

We applied imaging mass cytometry (IMC) with 41 cellular markers to assess the immunological landscape of tissues derived from 32 PDAC patients, including patients that underwent neoadjuvant treatment with FOLFIRINOX or Gemcitabine combined with radiotherapy. We further examined the T cell compartment by analyzing an independent cohort of 133 PDAC patients by multiplex immunofluorescence (IF).

Result and discussion

We identified a clear impact of neoadjuvant therapy on several immune subsets, including a remarkable effect on the T cell compartment. CD4+ and CD8+ T cell infiltration within the tumor microenvironment (TME) was particularly pronounced in a subset of patients treated with FOLFIRINOX. In contrast, Gemcitabine-based chemoradiotherapy associated with reduced T cell infiltration, highlighting the distinct immunological consequences of these treatment regimens. Strikingly, tissues from FOLFIRINOX-treated patients also exhibited a higher frequency of PD-1-expressing T cells. Importantly, T cell infiltration was associated with an improved clinical outcome specifically in the FOLFIRINOX-treated group.

Conclusion

Our findings underscore the immunomodulatory capacity of standard-of-care therapies in PDAC. Importantly, our findings could inform the rational design of combinatorial strategies integrating chemotherapy (e.g., FOLFIRINOX) and immunotherapy. Furthermore, we demonstrated the need for patient stratification as the immunologic effects of neoadjuvant therapy appear to be restricted to a subset of patients.

EACR25-0994

Unraveling Tissue-Resident Memory to Combat Metastatic Breast Cancer

D. Amaral-Silva¹, R. L. Sequeira¹, K. van Gisbergen¹

¹Champalimaud Foundation, Physiology and Cancer, Lisbon, Portugal

Introduction

Primary breast cancer is the most frequently diagnosed cancer in women, with prognosis worsening once metastases form. Despite advances in immunotherapy that enhance CD8 T cell responses, these treatments often fail against metastatic disease. CD8 T cells can suppress metastases, but the tumor microenvironment drives exhaustion, limiting their effectiveness. Exhausted T cells produce fewer pro-inflammatory cytokines and express inhibitory receptors that restrain anti-tumor activity. A key challenge in cancer therapy is reinvigorating tumor-specific T cells that sustain function after metastases progress. However, it remains unclear which T cell subsets are essential for maintaining immune responses against metastatic tumors. We investigated the recruitment, origin, and effectiveness of CD8 T cells in combating disseminated tumor cells.

Material and method

We utilized the EO771 breast carcinoma model, an aggressive tumor line that metastasizes in mice. EO771 cells were genetically modified to express ovalbumin, allowing tracking of OVA-specific CD8+ T cells from OT-I mice. Tumor cells were orthotopically engrafted, leading to primary tumors that spontaneously metastasized to the lungs. This model enabled us to study tumor-specific CD8+ T cell recruitment, phenotype, and function at primary and metastatic sites. We used spectral flow cytometry to analyze CD8+ T cells in tumors and lymph nodes. Exhaustion markers PD-1 and Tim-3 identified terminally exhausted T cells, while precursor exhausted T cells were defined by CD62L expression in tumor-draining lymph nodes. Migration and localization of CD8+ T cells in lung metastases and lung-draining lymph nodes were examined to assess their role in anti-tumor immunity.

Result and discussion

At the primary tumor, tumor-specific CD8 T cells exhibited robust responses but were mostly terminally exhausted, co-expressing PD-1 and Tim-3. These cells were maintained by precursor exhausted T cells in tumor-draining lymph nodes expressing CD62L. After metastases developed, tumor-specific CD8 T cells were recruited to the lungs and lung-draining lymph nodes, displaying a similar exhausted phenotype. These results suggest that CD8 T cells respond to metastases by colonizing local lymph nodes, from which they establish immune responses against disseminated tumor cells.

Conclusion

Our findings highlight tumor-specific T cell precursors in metastatic site lymph nodes as critical players in immune responses against metastatic breast cancer. Targeting these precursors may enhance immunotherapy efficacy in advanced disease.

EACR25-0995

Reprogramming of Pro-tumoral Monocyte-derived Macrophages: A Novel Strategy Targeting Cathepsin B and Non-Apoptotic Caspases

E. Kerreneur¹, P. Chaintreuil¹, S. Boulakirba², C. Delaby¹, N. Droin³, G. Robert¹, P. Auberger¹, A. Jacquel¹

¹C3M INSERM U1065, Nice, France

³Gustave Roussy INSERM U1187, Paris, France

Introduction

Monocyte-derived macrophages (MDMs) are key innate immune cells involved in essential biological processes such as tissue repair, host defense and anti-tumor immunity. However, tumor or leukemia-associated anti-inflammatory macrophages (TAMs, LAMs) promote cancer growth by stimulating angiogenesis, inhibiting anti-tumor immunity and contributing to treatment resistance. Recently, several strategies have been developed to target these macrophages, by blocking their recruitment, reducing their population, activating them or reprogramming them. Therefore, a better understanding of the underlying mechanisms involved in the generation and polarization of anti-inflammatory MDMs is crucial for the development of new therapeutic avenues.

Material and method

Our team used an ex vivo model to generate and polarize human MDMs from the peripheral blood of healthy donors. After purification, primary human monocytes are differentiated into immature macrophages (M0) in response to CSF-1. These M0 macrophages are then polarized into a pro-inflammatory phenotype (M1) with LPS + IFN- γ , or an anti-inflammatory phenotype (M2) with IL-4. Flow cytometry, RT-qPCR, RNA sequencing, ELISA and various functional assays were used to characterize these different types of macrophages.

Result and discussion

Using this model, we demonstrated the crucial role of non-apoptotic caspase-8 in both monocyte-to-macrophage differentiation and their M2 polarization and identified a novel non-canonical activation of caspase-8 (CASP8) by cathepsin B (CTSB). Specific activation of caspase-8 by cathepsin B leads to the non-canonical cleavage and activation of caspases 3 and 7 and the cleavage of several substrate proteins at sites distinct from those observed during apoptosis. Finally, we evidenced that targeting the CTSB / CASP8 axis with pharmacological agents (CA-074, Emricasan or our own original and specific non-apoptotic caspase inhibitors) or with genetic approaches (siRNA) not only inhibits the generation of anti-inflammatory macrophages but also reprograms them towards a pro-inflammatory profile. We are currently working on characterizing and targeting of LAM populations via the CTSB / CASP8 axis in bone

marrow samples from patients with acute myeloid leukaemia.

Conclusion

Our work identifies a novel CTSB / CASP8 axis as a key regulator of monocyte-to-macrophages differentiation and M2 polarization. By targeting this pathway, we have successfully reprogrammed anti-inflammatory macrophages to a pro-inflammatory state, providing novel therapeutic strategies to counteract immuno-suppressive macrophages, reshape the tumor micro-environment and enhance anti-tumor immunity.

EACR25-1017

Deciphering the cellular and molecular mechanisms leading to immune exclusion and Tertiary Lymphoid Structure organization in Non-Small Cell Lung Cancer

P. Da Costa¹, N. Josseaume¹, M. Prieto¹, M. Alifano¹, A. Mansuet-Lupo¹, D. Damotte¹, I. Cremer¹

¹Centre de Recherche des Cordeliers, Inflammation, complement and cancer team, Paris, France

Introduction

The Tumor MicroEnvironment (TME) of Non-Small-Cell Lung Cancer (NSCLC) is a highly complex and heterogeneous ecosystem, consisting of tumor cells, immune cells, cancer-associated fibroblasts (CAF), and endothelial cells. Among immune cells, B and T lymphocytes can be organized into Tertiary Lymphoid Structures (TLS), associated with improved prognosis and response to immunotherapy. Conversely, low immune infiltration and absence of TLS have been linked to poor clinical outcomes. However, the mechanisms underlying immune cell infiltration and TLS formation within the TME are not fully elucidated. We hypothesize that tumor cell phenotype, blood/lymphatic vessels, CAF subsets, and extracellular matrix composition collectively influence immune cell infiltration and TLS organization. This study therefore aims to identify, using a multiomics approach, the molecular mechanisms involved in immune cell infiltration and TLS formation.

Material and method

We are analyzing a retrospective cohort of 211 NSCLC patients who underwent surgery. Immune cell infiltration in the TME is characterized using multiplex immunofluorescence, to quantify B and T cell densities, TLS presence and maturity, high endothelial venules and tumor cell densities. Additionally, we are quantifying stromal components, including CAF subsets and blood/lymphatic vessels. These features are analyzed using HALO software, followed by bioinformatics analyses to classify the cohort based on immune cell density and TLS characteristics. We have initiated spatial transcriptomics analysis using Visium HD on 18 patients and are conducting bulk transcriptomics on the entire cohort.

Result and discussion

Preliminary results indicate that 204 out of 211 patients exhibit at least one mature TLS, with 81% of these showing secondary follicle-like TLS (SFL-TLS), the highest stage of maturity. As expected, high density of SFL-TLS correlates with better overall survival. Based

on this classification, we have selected two patient groups for Visium HD analysis: one with low and one with high TLS density (9 patients in each group).

Conclusion

This study will provide valuable insights into the relationships between various TME components, and immune cell infiltration and TLS formation.

Additionally, it will provide transcriptomic profiles of distinct TME subtypes, contributing to a deeper understanding of the NSCLC immune landscape and supporting the identification of potential new therapeutic strategies.

HDAC6 inhibition alters T cell function and metabolism in non-small cell lung cancer

S. Tan¹, E. Kearney¹, S. Flanagan^{1,2}, J. Dunne^{1,3}, D. O'Reilly⁴, J. Naidoo^{3,4}, K. Wong⁵, C. Dowling^{1,3}

¹Royal College of Surgeons in Ireland, Dublin, Ireland

²University of Limerick, Limerick, Ireland

³Beaumont RCSI Cancer Centre, Dublin, Ireland

⁴Beaumont Hospital, Dublin, Ireland

⁵NYU Langone Health, New York, United States

Introduction

Non-small cell lung cancer (NSCLC) accounts for nearly 85% of lung cancer cases and is the leading cause of cancer-related deaths worldwide. Histone deacetylase 6 (HDAC6) has been described to drive cancer development through multiple pathways, such as oncogenic tumorigenesis, cell motility and proliferation. Recently, HDAC6 has also been shown to play a role in cancer cell metabolism. While HDAC6 appears to be a promising cancer drug target, the regulatory and metabolic role of HDAC6 on T cell activity remains largely unknown. This study aims to investigate the metabolic influence of HDAC6 inhibition in mediating T cell function in NSCLC.

Material and method

Whole blood samples were obtained from patients recruited for the PLAN clinical trial (NCT05542485) and GAMBIT clinical trial. Peripheral blood mononuclear cells were isolated from the blood samples to study CD8+ T cell activation/function following HDAC6 inhibitor (HDAC6i) treatment ex vivo. In addition, we used Single Cell ENergetIc metabolism by profiling Translation inHibition (SCENITH), a flow cytometry-based method that functionally profiles single cell metabolism ex vivo to examine metabolic alterations caused by HDAC6i in NSCLC. Metabolic changes within CD8+ T cells following HDAC6i treatment in NSCLC were also assessed using the Seahorse analyser.

Result and discussion

Interestingly, CD8+ T cell activation was augmented following treatment with HDAC6i. This was accompanied by changes in metabolism of CD8+ T cells. Furthermore, CD8+ T cells treated with HDAC6i demonstrated enhanced activity, consolidating the regulatory role of HDAC6 on CD8+ T cell function.

Conclusion

In short, the findings from this research elucidated the potential of HDAC6i as an anticancer agent in NSCLC by strengthening tumour killing ability of CD8+ T cells via metabolic modulation.

⁵University of Colorado, Department of Biochemistry and Molecular Genetics, Denver, USA

Introduction

Head and neck squamous cell carcinoma (HNSCC) is the seventh most common cancer worldwide characterized by a high mortality rate and resistance to chemotherapy. In recent years immune-checkpoint inhibitors (ICIs), have been approved for recurrent or metastatic HNSCC. However, the highly immunosuppressive micro-environment of HNSCC limits the efficacy of immunotherapy. The ABC transporter, ABCC1, has been widely studied for its role in promoting the extracellular efflux of chemotherapeutic agents contributing to the multidrug resistance phenotype observed in many tumors, including HNSCC. ABCC1 also regulates the efflux of various endogenous metabolites, such as leukotriene C4, GSH and sphingosine, which may affect key cancer-related processes, like inflammation

Material and method

The role of ABCC1 was analyzed by siRNA and CRISPR/Cas9-mediated KO in SCC cells. Metabolomic profiling and RNA-seq were performed on ABCC1 KO cells to investigate metabolic and transcriptional changes. To assess the in vivo impact of ABCC1, ABCC1 KO murine cells were inoculated into immunocompetent mice. After three weeks, tumors were excised and analyzed for immunophenotype

Result and discussion

We found that ABCC1 is highly expressed in the classical subtype of HNSCC, which is typically characterized by a gene expression profile related to detoxification. By integrating mass spectrometry (MS)-based metabolomic analysis and transcriptomic profiling, we found that HNSCC ABCC1KO cells exhibits dysregulation of methylglyoxal detoxification pathway and decrease of a gene signature associated with TNF- α signaling and purine metabolism genes. In detail, ABCC1 deletion leads to a significant reduction of the expression a class of cytokines (CXCLs), which are key mediators of the recruitment of tumor-associated neutrophils. Consistent with this, syngeneic transplantation studies revealed that SCC tumors lacking ABCC1 exhibit a significant reduction in neutrophil populations. Along the same line, we found that ABCC1 expression is positively

correlated with neutrophil levels in human HNSCC patients. Remarkably, high neutrophil infiltration and elevated neutrophil-to-lymphocyte ratio (NLR) have been linked to poor prognosis and reduced response to immunotherapy in HNSCC patients. In addition to regulating inflammatory chemokines, ABCC1 genetic deletion also affects the expression of a group of genes (CD39, CD73 and ENPP1) playing a crucial role in the production of extracellular adenosine (eADO), a key mediator of immune escape. Taken together, our findings suggest that ABCC1 is embedded in signaling cascades linking the detoxification pathway to immune regulation in HNSCC.

Conclusion

Our findings uncover the interconnected mechanisms through which ABCC1 shapes the immunophenotype and the inflammatory status of HNSCC, providing the proof of principle to exploit an ABCC1-based targeting approach to improve the immunotherapy efficacy in HNSCC.

EACR25-1061

Trem2+ Macrophages as a Novel Therapeutic Target for Metastatic Prostate Cancer

J. Auzmendi-Iriarte¹, V. Cid-i-Centelles¹, S. García-Longarte¹, L. Perez-Gutierrez¹, I. Mendizabal¹, A. Palazon¹, A. Carracedo¹, M. Piva¹

¹CIC bioGUNE, Derio, Spain

Introduction

Prostate cancer (PCa) is the most prevalent cancer in men, where metastasis is the leading cause death. Metastatic hormone naïve PCa (mHNPC) is determined at the time of first diagnosis, with limited therapeutic options available. Clinical trials testing immunotherapy, even in combination with standard of care, has showed limited clinical benefits. Among this resistant micro-environment, tumor-associated macrophages (TAM) have emerged as major mediators of immunosuppression that promote progression of various tumor types.

Material and method

In our group we generated novel conditional mouse models with different degree of aggressiveness of PCa. Pten and Lkb1 loss (Ptenpc-/-Lkb1pc-/-) in the prostate epithelium works as a model of mHNPC, as it results in very aggressive and fast-growing prostate cancer, developing metastasis in lumbar lymph nodes and lung. As a control model, the heterozygous loss of Lkb1 generated PCa, but with no signs of metastasis. Single RNAseq was performed in these two models, and also in localized and metastatic PCa human patients from Basurto Hospital. For preclinical studies, T051 cells derived from Ptenpc-/-Lkb1pc-/- model were injected subcutaneously and treatments were administered. Immunophenotyping studies were performed in BD FACSymphony and Attune NxT cytometers. Human monocytes from healthy donors were purified by Robosep from peripheral blood mononuclear cells and differentiated into macrophages for 7 days with M-CSF.

Result and discussion

In this work, we firstly demonstrated that macrophage function is crucial for tumour growth in Ptenpc-/-

Lkb1pc-/- subcutaneous model, as CSF1R blockage reduces ~ 50% tumour growth as a single agent, and ~ 85% when combining with PD1 blocking agent. Cytometry analysis confirmed macrophage depletion, accompanied by an increase in Ly6C+CD11b+ monocytic myeloid-derived suppressor cells (MDSC), suggesting a compensatory mechanism. Notably, CSF1R blockage increased CD8+CD3+ lymphocytes, which was exacerbated even more when combining with PD1 blockage. For the discovery of TAM-specific targets in this model, single cell RNAseq highlighted Trem2 as one of the key players in the metastatic mouse model, further validated in human metastatic patients. Cytometry analysis confirmed the increased expression of TREM2 in F4/80+CD11b+ TAMs, compared to CD11C+ dendritic cells, or Ly6G+CD11b+ granulocytic and Ly6C+CD11b+ monocytic MDSCs. In fact, PDL1+ TAMs presented enriched TREM2 levels, which may support its role in aggressiveness. In human healthy macrophages, the association between TREM2 and pro- or anti-inflammatory stimuli presents a different behaviour, suggesting the specificity of TREM2 towards TAMs.

Conclusion

In conclusion, we identified TREM2 as TAM marker in a novel mouse model of mTNPC, suggesting that its blockage might be a promising therapeutic strategy in combination with conventional immunotherapy.

EACR25-1070

Analysis of intratumor immune heterogeneity reveals spatial organization of immunosuppression in breast cancer

⁵Institut Curie, Division of Diagnostic and Theranostic Medicine, Paris, France

⁶Institut Curie, Laboratoire d'immunologie clinique, Paris, France

⁷Institut Curie, Department of Medical Oncology, Paris, France

Introduction

Recent advances in single-cell transcriptomics have shed light on breast cancer intratumoral heterogeneity (ITH). However, the spatial distribution of immune cell populations and the associate T-cell repertoire (TCR) in the breast tumor-microenvironment (TME) remain still poorly understood.

Material and method

Here, we performed paired single-cell RNA/TCR sequencing on 60,000 cells isolated from three distinct tumor regions (central- proximal to the tumor core, peripheral- proximal to the invasive margins, and intermediate- between the first two regions), in five

patients with early stage, untreated, luminal breast cancer.

Result and discussion

Our analysis revealed a distinct spatial organization of immune cells within the TME. The tumor periphery was enriched in monocytes and dendritic cells, as well as naïve CD4+ and memory-like CD8+ T cells, including both bystander and pre-dysfunctional populations. In contrast, the tumor core contained higher numbers of M2-like macrophages, clonally expanded Tregs, and late-dysfunctional CD8+ T cells with tumor-reactive properties. Peripheral regions exhibited increased expression of tertiary lymphoid structure (TLS) signatures, while the tumor core showed higher glycolysis activity. Multiplex IHC further confirmed key findings, including the enrichment of TCF1+ pre-dysfunctional CD8+ T cells in the periphery, highlighting a progressive accumulation of immunosuppressive cell populations toward the tumor core.

Conclusion

Our study reveals a region-specific immune organization in luminal breast cancer, with a progressive accumulation of macrophages, Tregs, and tumor-reactive late-dysfunctional CD8 T cells toward the core. These findings offer new insights into TME heterogeneity, with potential implications for personalized immunotherapy strategies.

Glutamine scarcity modulates innate immunity in lung cancer

W. Wang¹, W. Shen², Y. Chen¹

¹*China Medical University, Department of Biological Science and Technology, Taichung, Taiwan*

²*China Medical University, Taichung, Taiwan*

Introduction

KRAS mutations are common in non-small cell lung cancer (NSCLC), often diagnosed late, making it hard to treat and deadly. Chemotherapy and targeted therapies frequently fail. Immunotherapy, like Immune Checkpoint Blockade (ICB), is a breakthrough, yet 70% of advanced NSCLC patients don't respond due to poor T-cell activation. The cGAS/TBK1 pathway, key in innate immunity, senses threats and aids anti-tumor immunity via T-cells. In the tumor microenvironment (TME), glucose and glutamine are vital for tumor growth, but scarcity, especially of glutamine, alters cancer and immune behavior. We studied how glutamine lack affects immunity in NSCLC.

Material and method

We tested glutamine restriction's impact on the cGAS/TBK1 pathway in KRAS-mutant NSCLC cell lines. Cells were grown in low-glutamine media mimicking TME stress. Phospho-TBK1 levels were measured to assess pathway activity, and interferon-gamma (IFN- γ) expression was quantified for T-cell effects. We compared glutamine-rich and -poor conditions to simulate TME nutrient shifts.

Result and discussion

In this study, we found that glutamine restriction in the TME blocks the cGAS/phospho-TBK1 axis in lung cancer cells. Low glutamine reduced phospho-TBK1 activation, cutting IFN- γ levels and weakening immune surveillance. It also shifted cancer cell metabolism and

innate signaling, likely boosting immune evasion. This shows glutamine controls the cGAS/TBK1 pathway, tying nutrient stress to poor T-cell activation in NSCLC. This metabolic-immune link may explain ICB resistance.

Conclusion

Glutamine scarcity in the TME inhibits cGAS/TBK1 signaling, impairing T-cell activation and aiding immune evasion in NSCLC. This metabolic-immune interplay reveals why immunotherapy fails in many cases. Targeting glutamine metabolism could improve ICB success, offering new hope for NSCLC treatment.

Introduction

Malignant peripheral nerve sheath tumors (MPNSTs) are aggressive sarcomas developing either sporadically or in the context of Neurofibromatosis type 1 (NF1) against which there are no current treatment options. Despite being highly infiltrated by macrophages endowed with an anti-inflammatory M2-like phenotype, the potential role of these immune cells in MPNST growth has been elusive. Accumulating evidence shows that factors released in the tumor microenvironment (TME) skew tumor associated macrophages (TAMs) toward a protumoral phenotype sustained by specific metabolic adaptations. Here, we evaluated the phenotypic, transcriptional and functional properties of macrophages associated to MPNSTs identifying the role of the mitochondrial chaperone TRAP1 in sustaining several protumoral TAM actions.

Material and method

We exposed bone marrow derived macrophages isolated from WT and TRAP1 KO mice to MPNST cell medium and studied the phenotypic and transcriptional traits of resulting TAM-like cells. In addition, we performed functional characterizations of TAMs employing Boyden chamber and Matrigel assays of tumor/endothelial cells co-cultured with macrophages to investigate the ability of MPNST-conditioned macrophages to tune MPNST cell invasion/migration and endothelial cell angiogenesis.

Result and discussion

We have found that the conditioned media from MPNST cells drives the up-regulation of a set of conventional M2-like TAM markers, and of the metabolic enzymes glutamine synthetase (GLUL) and Arginase 1 (ARG1) in naïve and M2 anti-inflammatory macrophages. Such TAM-like cells sustain MPNST migration and exert proangiogenic properties both in vitro and in vivo through succinate accumulation and HIF-1 α stabilization. By ablating the mitochondrial chaperone TRAP1, these protumoral TAM functions are impaired, along with a reduced succinate accumulation and HIF-1 α expression.

Conclusion

Our data provide proofs of macrophage pro-tumoral polarization following exposure to MPNST cell released factors that remain to be identified. TRAP1 expression sustains the transition of macrophages toward the TAM-like state whereby TRAP1-dependent succinate accumulation leads to HIF-1 α stabilization and a pseudo-hypoxic response following MPNST conditioning. This work provides the first insight into TRAP1 role in pro-neoplastic TAMs, thus identifying this mitochondrial chaperone as novel therapeutic target in the macrophage cell compartment.

Tumor miRNAs in small-extracellular vesicles dampen the CD8+T cell response against tumor and predict response to immunotherapy in NSCLC

M. Chang¹, V. Dehame¹, P. Hulo², J. Chen²,

E. Pons-Tostivint², D. Fradin¹

¹*INSERM U1307 CRCI2NA, Nantes university, NANTES, France*

²*Centre Hospitalier Universitaire Nantes, Medical oncology, Nantes University, NANTES, France*

Introduction

Despite the development of immune checkpoint inhibitors therapy (ICI) in non-small cell lung cancer (NSCLC) patients, most of them eventually experience relapse. Resistance mechanisms to ICI are associated with low immune response. Antitumoral immune response is mainly promoted by CD8+ T lymphocyte (CD8 T cells). However malignant cells can escape this immune surveillance due to microRNA (miRNA) loaded into small extracellular vesicles (sEV) secreted by malignant cells. sEV are currently emerging as promising biomarkers. They are released by all cell types, participate at the cell-cell communication and can be found in all body fluids, reflecting at distance the state of the tumor. Here, we investigated i) the immunosuppressive role of sEV derived from patient's NSCLC (NSCLC-sEV) on antitumoral CD8+ T cells and ii) their use as biomarkers of response to ICI in the BREATHE (Biocollect for REseArch in THoracic cancer) biocollection.

Material and method

NSCLC-sEV were purified by ultracentrifugation from NSCLC patient-derived cell lines, from tumor resection or from plasma (ethics agreement DC-2011-1399, DC-2017-2987). Their immunosuppressive effects were studied by exposing CD8+ T cells to NSCLC-sEV, where their activation, proliferation, and viability were assessed. Their use as biomarker was investigating by NGS sequencing of their miRNA cargo. Using bioinformatic analysis, we identified potential immunosuppressive microRNAs loaded into sEV that were tested by direct transfection in CD8+ T cells.

Result and discussion

CD8+ T cells exposed to NSCLC-sEV showed reduced expression of their activation markers CD25, CD45 and CD226, and decreased secretion of antitumoral TNF α , granzyme B, and perforin-1, suggesting that they are unable to conduct an efficient anti-tumoral response.

NSCLC-sEV also upregulated the CD8+ immune checkpoint markers, such as PD-1, TIGIT, and TIM-3, and decreased the viability and proliferation of exposed CD8+ T cells. By bioinformatic prediction, we selected miRNAs loaded into NSCLC-sEV that could promote an immunosuppressive effect. Transfection of our candidate miR-29c-3p and miR-181a/b-5p, into CD8+ T cells induced an inhibition similar to that induced by native NSCLC-sEV. NSCLC-sEV and their miRNA cargo, at diagnosis, are also promising biomarkers of response to ICI since we identified 17 miRNAs which discriminate efficiently non-responders (patient having a disease progression by RECIST criteria on first CT evaluation) and long-term responders (patients free-from-progression at 18 months after the beginning of treatment).

Conclusion

To conclude, NSCLC-sEV can impair antitumoral CD8+ T cell response. We demonstrated that miRNAs included into sEV derived from tumor cells can impair CD8+ T cell response against cancer and are promising biomarkers of response to immunotherapy in NSCLC.

Distinct gut microbiota in breast cancer patients and its dynamics during endocrine treatment

Y. Tsodyks¹, N. Godneva², C. Fogel¹, D. Morzaev-Sulzbach¹, M. Bakalenik-Gavry¹, Y. Vachnish¹, A. Weinberger², E. Segal², E. Nili Gal-Yam³, M. Dadiani¹

¹*Sheba Medical Center, Cancer Research Center, Ramat Gan, Israel*

²*Weizmann Institute of Science, Department of Computer Science, Rehovot, Israel*

³*Sheba Medical Center, Institute of Breast Oncology, Ramat Gan, Israel*

Introduction

The effects of gut microbiota on cancer progression and treatment are increasingly recognized, with associations reported across various diseases and cancer types. However, its modulation in breast cancer remains under-explored. In this study we examined the gut microbiome of breast cancer patients compared to healthy controls and analyzed longitudinal changes in microbiome composition and clinical parameters during endocrine treatment.

Material and method

Newly diagnosed hormone receptor-positive (HR+) breast cancer patients (n=92) treated at the Sheba Breast Oncology Institute were recruited. Fecal and blood samples, along with extensive clinical data and detailed questionnaire, were collected at diagnosis and at multiple time points during endocrine treatment. Fecal samples underwent full shotgun metagenomic sequencing. The microbiomes of breast cancer patients were compared to those of a large control group (n = 920) of healthy age- and BMI-matched women collected at the Weizmann Institute. A machine learning algorithm was employed to differentiate between breast cancer and healthy microbiomes. Longitudinal changes in clinical parameters were correlated with gut microbiome alterations during treatment.

Result and discussion

Breast cancer patients exhibited a distinct microbiome composition with specific microbial signatures. Alpha diversity, a measure of microbial richness, was significantly lower in breast cancer patients compared to the healthy control group. The relative abundance of several microbial species differed significantly between breast cancer patients and controls. A predictive model successfully distinguished microbiome profiles of breast cancer patients from those of healthy women.

Longitudinal analysis revealed that certain species enriched in breast cancer samples, particularly from the *Bifidobacterium* family, decreased in abundance during endocrine therapy, shifting toward levels observed in healthy women. Additionally, changes in clinical parameters, such as decreases in LDL cholesterol and increases in HbA1c levels, were correlated with microbiome alterations. Functional analysis of these microbial species suggests a potential link between gut microbiota and the host's response to endocrine treatment.

Conclusion

The gut microbiome of women with breast cancer exhibits distinct characteristics with potential predictive value, warranting further investigation for future use in early detection and prevention strategies. The microbiome also appears to play a role in the physiological response to endocrine treatment, opening new avenues for personalized treatment approaches.

Indisulam evokes T cell dependent cytotoxicity through mis-splicing in neuroblastoma

N. Zourdoumis¹, Y. Ma¹, N. Mohan², C. Wickremesinghe¹, A. Melcher², L. Chesler², H. Keun¹, A. Nijhuis¹

¹Imperial College London, London, United Kingdom

²Division of Clinical Studies, The Institute of Cancer Research, London, UK, London, United Kingdom

Introduction

Neuroblastoma is a highly lethal pediatric tumour of the sympathetic nervous system. Multimodal therapy has had limited success, while development of immunotherapies has proven challenging, owing to the low surface human leucocyte antigen type I expression and negative thymic selection of T cells. However, high-risk MYCN amplified neuroblastoma is sensitive to splicing inhibitors. Indisulam, a molecular glue, degrades RNA binding motif 39 (RBM39), an RNA splicing co-factor, leading to aberrant splicing. This mis-splicing leads to the generation of neopeptides, some of which have been shown to be immunogenic in mouse melanoma. Here we assessed the presence of mis-spliced transcripts, coding for immunogenic neopeptides, generated from RBM39 degradation across cancer cell lines, and validated their presence in neuroblastoma *in vitro*. Additionally, we confirmed the ability of indisulam-treated neuroblastoma cells to trigger proliferation and activation of CD8+ T cells.

Material and method

We performed an in-silico analysis, matching events producing immunogenic neopeptides, to corresponding events identified in a literature search of studies with RNA splicing data on cell lines treated with RBM39 degraders. The presence of events identified in multiple

cell lines was confirmed through PCR using custom primers. The immunogenicity of indisulam treated cells was established through a Dendritic cell (DC) assay. DCs were isolated from human Peripheral Blood Mononuclear Cells (PBMCs) and cocultured with indisulam treated KELLY cells. The DCs were isolated and cocultured with syngeneic naïve T cells. The primed T cells were then cocultured with indisulam-treated KELLY cells. Flow cytometry was used to assess their proliferation and activation.

Result and discussion

Our in-silico analysis revealed that RBM39 degradation generates a robust profile of transcripts derived from mis-splicing, common across several cancer cell lines. The presence of two of these events was identified in two neuroblastoma cell lines, IMR-32 and KELLY. Interestingly, KELLY was not one of the cell lines included in our in-silico analysis, indicating that some of these events may be present across many neuroblastoma cell lines. Lastly, our DC assay revealed a significant increase in proliferation and activation of naïve human T cells exposed to KELLY cells treated with indisulam compared to the control.

Conclusion

Our findings indicate that splicing inhibitors can induce production of transcripts common across neuroblastoma and other cancer cell lines. We aim to identify the presence of the immunogenic neopeptides, these mis-spliced transcripts code for, through immunopeptidomics. Our findings show that combination of splicing inhibitors with immunotherapies, such as vaccines, could leverage these immunogenic neoantigens, paving the way towards the development of highly efficacious and specific immunotherapies against solid pediatric tumours.

Analysis of the spatial characteristics of the DLBCL tumor microenvironment utilizing the SignalStar® multiplex immunohistochemistry assay

T. Oliveira¹, J. Ziello², S. Zhang³, S. Klein², A. Ruiz⁴, G. Inghirami⁴

¹Cell Signaling Technology, Leiden, Netherlands

²Cell Signaling Technology, Boston, United States

³Visiopharm A/S, Horsholm, Denmark

⁴Weill Cornell Medical College, New York, United States

Introduction

Diffuse Large B-Cell Lymphoma (DLBCL) is the most prevalent form of non-Hodgkin lymphoma, with over 18,000 cases diagnosed annually in the United States. While approximately 60% of DLBCL patients achieve long-term remission through standard chemotherapy, those with refractory DLBCL face a poor prognosis. The immune landscape of DLBCL is highly complex, requiring a deeper understanding of the dynamic interplay between T cell activation and immuno-suppression within the tumor microenvironment (TME) to improve patient stratification and predict therapeutic outcomes. Given this complexity and the importance of spatial relationships among various cell types in the TME, it is essential to employ multiplex immunohistochemical

(mIHC) assays for simultaneous visualization of biomarkers and phenotypic markers.

Material and method

In this study, we developed a 12-plex SignalStar mIHC panel incorporating T cell phenotypic, activation, and suppression markers to characterize the TME in FFPE DLBCL cores. Immuno-oncology markers were visualized within the tumor and in the context of myeloid cells, distinguished by CD68 expression. The assay involved a single primary incubation of all 12 antibodies, followed by the application of fluorescently labeled oligonucleotide networks to amplify the signals of four antibody-oligo conjugates across three imaging rounds. After imaging the first four conjugates, the fluorescent signal was enzymatically removed, and the process was repeated for two additional rounds. The three resulting images were aligned using Visiopharm's Tissuealign™ platform. Quantitative analysis, including positive cell counts and marker co-localization, was performed using Visiopharm's Phenoplex™. Additionally, biomarker expression patterns were assessed with Phenoplex™, and the data were correlated with patient demographics, disease progression, and treatment responses.

Result and discussion

Our findings highlight the SignalStar mIHC assay as a valuable tool for unraveling the complexities of the immunosuppressive TME.

Conclusion

This assay is able to provide researchers with deeper insights into responses to immunotherapy and chemotherapy combination strategies.

IL1RAP targeting is a new therapeutic strategy for advanced triple negative breast cancer

M. Garzón-Tituaña¹, P. Petit¹, P. Azcoaga¹, F. Soler¹, A. Romo¹, Z. Telletxea¹, S. Manzano¹, I. Garmendia¹, M. Muñoz Caffarel¹

¹Biogipuzkoa Health Research Institute, Breast cancer group, San Sebastián, Spain

Introduction

The interleukin-1 (IL-1) family, with IL-1 α and IL-1 β as key members, plays a critical role in shaping the inflammatory tumor microenvironment in cancers, including breast cancer (BC). IL-1 signaling supports tumor growth and therapy resistance, requiring IL-1 receptor 1 (IL1R1) to dimerize with the IL-1 receptor accessory protein (IL1RAP). IL1RAP is overexpressed in several cancers, including triple-negative breast cancer (TNBC), but its role in TNBC progression remains unclear.

Material and method

Here, we investigate IL1RAP activation in TNBC using patient data, cell lines, and in vivo models. Analysis of TCGA and METABRIC databases with CANCERTOOL and TIMER 2.0 revealed elevated IL1RAP mRNA expression in estrogen receptor-negative (ER-) BC and TNBC, correlating with reduced disease-free survival. IL1RAP expression also associates with cancer-associated fibroblasts (CAFs), inflammatory mediators

(IL-1 α , IL-1 β , IL-6, IL-8), and the Oncostatin M receptor (OSMR), a key BC progression factor.

Result and discussion

In TNBC cell lines, RT-qPCR and western blot confirmed high IL1RAP expression, while Olink Target 48 Cytokine panel analysis showed increased pro-inflammatory cytokine production. IL-1 α /IL-1 β stimulation further upregulated IL-1 α , IL-1 β , IL-6, and IL-8 expression. Functionally, IL-1 β treatment of the MDA-MB-231 cell line enhanced cell migration in Transwell assays, whereas IL1RAP inhibition, using siRNA knockdown, significantly impaired this effect. Furthermore, in an *in ovo* tumor growth model, where TNBC cells were seeded onto the chorioallantoic membrane (CAM) of fertilized chicken embryos, IL1RAP inhibition reduced tumor growth *in vivo*. These results further validate the importance of IL1RAP in TNBC and highlight the relevance of the *in ovo* model in rapidly assessing tumor progression. This model allows us to explore IL1RAP-driven mechanisms in a complex microenvironment and provides a solid foundation for refining and guiding future studies in murine models with greater precision. Additionally, we identified a compelling interaction between IL-1 and Oncostatin M (OSM), a cytokine implicated in BC progression and metastasis. OSM promoted the expression of IL1RAP, IL1R1, IL-1 α , and IL-1 β in cultured TNBC cells and tumor xenografts, as shown by RT-qPCR and western blot analysis, further reinforcing the role of IL-1 signaling in BC-associated inflammation.

Conclusion

This study demonstrates that IL1RAP is overexpressed in TNBC and highlights the central role of IL-1 signaling in tumor-promoting inflammation within the tumor microenvironment. Overall, our findings suggest that IL1RAP represents a promising therapeutic target in TNBC and that its inhibition could serve as a potential treatment strategy for TNBC patients.

EACR25-1408

LIF promotes immunosuppression through C1q+TAMs in GBM

M. López Vázquez¹, A. Neva Alejo¹, L. Cuesta Casanovas¹, L. Carrillo Bosh¹, R. Iurlaro¹, S. Espinosa Gil¹, A. Arias¹, I. Cuartas¹, J. Seoane¹

¹VHIO, Barcelona, Spain

Introduction

Glioblastoma (GBM), the most common brain cancer in adults, has a mean survival of 14.6 months, which reflects its unmet therapeutic needs. Leukemia-inhibitory factor (LIF) is a pleiotropic cytokine part of the IL-6 family of cytokine that is expressed in GBM. Previously, it has been shown that LIF can act as an oncogenic factor and promote immunosuppression in the GBM tumor microenvironment. In recent years, a population of tumor-associated macrophages (TAMs) characterized by the expression of C1q has gained attention due to their immunosuppressive properties and correlation with poor prognosis. Moreover, Dexamethasone (DEX), which is widely used as a symptomatic treatment for GBM, has also been linked to immunosuppression.

Material and method

We studied the effect of LIF alone or in combination with DEX on bone-marrow derived macrophages (BMDMs) and GBM animal models. We then analyzed the immunosuppressive effect of C1q on T-cells using both isolated T-cells and mouse-derived tumor tissue cultures (MDTTCs) from tumors derived from wild-type and C1qa-/ mice co-cultured with T-cells. Finally, we studied the effect of LIF blockade in vivo alone or in combination with αPD1, comparing wild-type and C1qa-/ mice and assessing the anti-tumoral effect by measuring tumor growth and analyzing T-cell activation.

Result and discussion

LIF induced the expression of C1q both by RNA and protein in BMDMs. Neutralization of LIF in GBM animal models led to a decrease in the expression of C1q in CD11b+ cells and tumor growth. DEX synergized with LIF and increased the expression of C1q and M2-markers by BMDMs in vitro, as well as the C1q+TAM population in vivo. Moreover, C1q repressed the activation of T-cells in vitro, and blockade of LIF in MDTTCs showed an increased activation of co-cultured T-cells which was higher in the wild-type tumors compared to the C1qa-/ ones. In vivo, tumors were significantly smaller in C1qa-/ mice compared to wild type, and blockade of LIF led to an increased T-cell activation in wild-type, but not in C1qa-. Combination with αPD1 led to an increased anti-tumoral response both by tumor growth and T-cell activation.

Conclusion

Our results indicate that LIF promotes an immunosuppressive C1q+ TAMs population, that is involved in T-cell dysfunction. Treatment with DEX increases this population and the sensitivity of macrophages to LIF. Blocking LIF through neutralizing antibodies results in a decrease of the C1q+ TAM population, as well as in an anti-tumoral response and increased activation of T-cells. In the absence of C1q, tumor growth is delayed and the effect of αLIF is decreased, supporting both the role of C1q in tumor progression and that the antitumoral effects of αLIF can be partially attributed to the decrease in C1q+ TAMs. Therefore, targeting this population via LIF antagonists may contribute to improve immunotherapies in GBM.

EACR25-1442

Decoding Immune Evasion in Mismatch-repair Deficient Colorectal Cancer Organoid-Immune Co-culture Models

M. Madrova¹, Y. Jiang¹, L. McKenzie¹, C. Oddy¹, P. Vlckova¹, R. Vendramin¹, K. Shiu², C. Tape², M. Jansen²

¹*University College London Cancer Institute, London, United Kingdom*

²*University College London Hospitals NHS Foundation Trust, London, United Kingdom*

Introduction

Mismatch repair deficient (MMRd) colorectal cancer (CRC) accounts for 15% of all CRC cases. MMR status carries both prognostic and predictive value as patients with MMRd tumours, compared to MMR proficient CRC, display better outcomes and are sensitive to immune checkpoint inhibitors (ICIs). However, questions regarding optimal ICI duration and regimen, in particular

single or doublet ICI, remain unresolved. There is now an urgent need for predictive biomarkers that allow rational stratification.

Material and method

To understand ICI immune biology and immune escape in MMRd tumours in granular molecular detail, we set out to functionally study cancer and immune system interactions using mass cytometry profiling. We leverage a unique patient cohort with locally advanced MMRd CRC from the NEOPRISM-CRC trial (NCT05197322). Eligible patients are offered three cycles of neoadjuvant pembrolizumab before surgical tumour resection. Peripheral blood mononuclear cells (PBMCs) are collected and patient-derived organoids (PDOs) are isolated from pre- and post-treatment tumour samples. Patient-matched PDOs and tumour-stimulated PBMCs are co-cultured with and without pembrolizumab to recapitulate the immune micro-environmental niche in vitro. We carry out TOBis (Thiol-reactive Organoid Barcoding *in situ*) Mass Cytometry to characterise immune cell phenotypes and functional states of immune evasion and resistance to ICIs. These experiments are replicated in bulk and single cell cloned organoids to investigate the impact of (sub)clonal neoantigen complexity on immune response and pembrolizumab efficacy. We employ high-depth sequencing to map the neoantigen landscape of patient tumours and organoids.

Result and discussion

We have successfully established a collection pipeline and created a cohort of pre- and post-treatment matched PDOs alongside patient-matched PBMCs. We have generated a library of single cell cloned daughter organoids, >20 monoclonal organoid lines per parent bulk PDO. This approach allows in-depth dissection of the (sub)clonal neoantigen complexity and its impact on the anti-tumour immune response. Pilot co-culture experiments of PDOs and healthy donor PBMCs confirm the suitability of this platform to study tumour-immune cell interactions. TOBis Mass Cytometry will be used to capture shifts in cell cycle phases, immune cell phenotypes and cytotoxicity in the presence or absence of pembrolizumab. Corresponding fresh tumour samples were sequenced to interrogate the predictive value of neoantigen profiles of MMRd colorectal tumours. Data analysis is currently underway and results will be correlated with clinical outcomes and ICI response.

Conclusion

Our integrative approach provides a powerful framework to dissect immune evasion and ICI resistance in MMRd CRC, with potential implications for biomarker discovery and treatment optimisation.

EACR25-1473

TREM1 neutrophils drive multi-organ metastasis

M. Munarriz¹, A. Aroca², M. Gómez¹, D. Cáceres¹, S. Forisch³, S. Wcuker³, L. Álvarez-Vallina¹, R. Caballero⁴, M. Casanova-Acebes¹

¹*CNIO, Madrid, Spain*

²*CNIC, Madrid, Spain*

³*IRB, Barcelona, Spain*

⁴*GEICAM Spanish Breast Cancer Group, Madrid, Spain*

Introduction

Metastasis remains incurable, and there is an urgent need to identify biomarkers that can predict metastasis across different organs. Among metastatic lesions, neutrophils are one of the major immune infiltrates, and their presence is associated with poor prognosis and therapy resistance. Recently, there has been increasing recognition of neutrophil heterogeneity in solid tumors. However, the specific organs in which neutrophils are reprogrammed and the factors responsible for this reprogramming to promote metastasis remain poorly understood. In our lab, we identified that breast cancer (BC) patients with lung metastasis exhibited increased expression of Triggering Receptor Expressed on Myeloid Cells 1 (TREM1). TREM1 is primarily expressed in neutrophils in both humans and mice, and its bi-modal expression in tumors led us to investigate the functional heterogeneity of TREM1+ neutrophils.

Material and method

To explore this, we used well-established pre-clinical models of metastatic BC (E0771 orthotopic tumors and MMTV-PyMT GEMM, which closely mimic human breast cancer progression).

Result and discussion

We found that both experimental and spontaneous models of lung and liver metastasis triggered TREM1 expression in neutrophils. In contrast, full-body or neutrophil-specific deficiency of TREM1 inhibited metastasis growth in these organs. Next, to determine if tumor-derived factors are responsible for TREM1 upregulation, we co-cultured bone marrow neutrophils with conditioned media from BC metastatic cell lines. Tumor-derived factors induced TREM1 expression in vitro. We are currently screening for potential TREM1 ligands in vivo by analyzing the secretome of TREM1-deficient tumors and comparing it to wild-type (WT) tumors. TREM1 signaling is activated when its ligand binds to the receptor, amplifying inflammation. Thus, we hypothesize that TREM1-driven inflammation could be pro-metastatic. Indeed, TREM1 depletion impaired pro-interleukin-1 β (pro-IL-1 β) production in neutrophils. Interestingly, when using β -glucan to reprogram neutrophil progenitors, we observed that "trained" neutrophils exhibited reduced expression of TREM1+IL-1 β + pro-tumoral neutrophils. Since trained immunity reprograms the metabolism of hematopoietic progeny, we investigated the metabolic state of TREM1-deficient neutrophils. We found that TREM1-deficient neutrophils were fully mature, displayed increased OXPHOS metabolism and ROS production, but showed no differences in mitochondrial membrane potential compared to TREM1-sufficient neutrophils.

Conclusion

Taken together, our results suggest that TREM1 could serve as a potential biomarker for metastasis. We propose that TREM1 functions as a metabolic "rheostat" for neutrophils at metastatic sites, and that its activity may explain the heightened metastatic sensitivity of the lung through a TREM1-controlled regulatory axis involving glycolysis and IL-1 signaling.

The single cell landscape of intrahepatic NK cells in colorectal cancer metastasis: diversity and candidate therapeutic targets

D. Supino¹, J. Mikulak¹, S. Terzoli¹, R. Carrieri¹, V. Cazzetta¹, P. Marzano¹, P. Kunderfranco¹, A. Mantovani¹, D. Mavilio¹, C. Garlanda¹

¹IRCCS Humanitas Research Hospital, Rozzano, Italy

Introduction

Colorectal cancer is the third most frequent human malignancy characterized by high rates of hepatic metastasis and still lacks a curative approach. Patients with colorectal cancer liver metastases (CRLMs) have a 5-year overall survival between 20 and 45%, a recurrence of 60% and poor clinical benefits from immunotherapies. The liver is a preferential tissue for Natural Killer (NK) cells that are classified into two main subsets, namely CD56Bright/CD16- (CD56Bright) and CD56Dim/CD16+ (CD56Dim). Exploring the heterogeneity of intrahepatic NK cells beyond this dichotomy is key to identify specific immune checkpoints (ICs) and to unveil novel therapeutic targets.

Material and method

We conducted in depth single cell RNA-sequencing combined with multiparametric flow cytometry analysis of NK cells and total CD45+ immune cells. In addition, functional studies were performed to assess the relevance of immune-surveillance by NK cells and to leverage their anti-tumor potential against CRLMs.

Result and discussion

We demonstrated that tissue-resident CD56Bright NK cells in CRLMs are mature and potent anti-tumor effectors, showing minimal developmental relationship with intrahepatic CD56Dim and circulating NK cell subsets. In particular, unique transcriptional profile and peculiar expression of ICs were observed in CD56Bright and CD56Dim liver NK cell clusters, in line with their specific end-terminal differentiation programs in the metastatic niche. Among ICs, CXCR4 emerged as targetable inhibitory receptor involved in CXCL12-dependent mitigation of intrahepatic NK cells. CXCR4 negatively correlated with Interferon- γ (IFN γ) and increased production of this anti-tumor molecule was reported after CXCR4 blockade with the antagonist plerixafor. In addition, we identified IL-1R8 as an IC ubiquitously expressed by NK cells in CRLMs, demonstrating that its pharmacological inhibition with an original monoclonal antibody significantly improved NK cell anti-tumor effector functions.

Conclusion

In summary, the present study discloses the origin, heterogeneity and effector potential of matched circulating and intrahepatic NK cells from CRLM patients by using unbiased analytic approaches. It sheds light on an abundant tissue-resident IFN γ + CD56Bright NK cell population with an anti-tumor signature, and provides two possible therapeutic targets (i.e., IL-1R8 and CXCR4) to complement current CRLM immunotherapy.

EACR25-1513**POSTER IN THE SPOTLIGHT****Depleting tumour-infiltrating Tregs to enhance the efficacy of KRAS-mutant targeted therapies in lung cancer**

A. de Castro¹, M. Cole¹, P. Anastasiou¹, C. Moore¹, A. Alonso¹, E. Lieschke¹, F. van Maldegem², M. Zagorulya¹, M. Molina-Arcas¹, J. Downward¹

¹Francis Crick Institute, London, United Kingdom

²Amsterdam UMC, Amsterdam, Netherlands

Introduction

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related deaths, and around 15% of NSCLC patients present with a KRAS-G12C mutation. Recently, drugs selective against the KRAS-G12C mutant protein have been approved for clinical use. However, resistance development to these KRAS-G12C inhibitors (G12Ci) remains a prevalent and unresolved issue. Interestingly, although G12Ci only target mutant cancer cells, pre-clinical data show that they profoundly remodel the tumour microenvironment, diminishing the immunosuppressive myeloid compartment and increasing effector cytotoxic cells. However, this G12Ci-driven remodelling seems insufficient to drive durable responses in non-immune hot models, even when combined with anti-PD1.

Material and method

In this study, we make use of an immune-excluded orthotopic murine model of KRAS-G12C NSCLC and immunophenotyping approaches to explore potential mechanisms restraining the immunostimulatory potential of G12Ci.

Result and discussion

Here, we identify regulatory T cells (Tregs) as restrictors of an effective G12Ci-driven anti-tumour immune response. We show that treatment with G12Ci results in the rapid increase of tumour-infiltrating Tregs. Furthermore, we show that, in the proximity of Tregs, CD8 T cells lose their interactions with both dendritic cells and tumour cells, suggesting a disruption of the local cancer-immunity subcycle. Mechanistically, the elevation in Tregs was driven by an increase in CXCR3/CXCL9-11 signalling upon G12Ci treatment and was at least partially independent of external recruitment. Finally, we show that depleting tumour-infiltrating Tregs in combination with G12Ci was enough to re-invigorate the CD8 T cell response and drive long-term responses.

Conclusion

Overall, these results provide a strong rationale and showcase the potential for using Treg depleting strategies to improve the efficacy of G12Ci for the treatment of NSCLC.

EACR25-1534**Immune surveillance is actively impaired by the secretome of mismatch repair proficient colorectal cancers**

C. Cattaneo¹, S. Scardellato², G. Mauri², Z. Magnani¹, V. Matafora², W. Schepet³, S. Siena⁴, E. Voest³, C. Bonini¹, A. Bardelli²

⁴Niguarda Cancer Center, Milano, Italy

Introduction

Patients affected by colorectal cancer (CRC) with DNA mismatch repair deficiency (MMRd), often respond to immunotherapies based on immune checkpoint inhibitors (ICI), while mismatch repair proficient (MMRp) tumors do not. It is widely accepted that the high mutational burden and the elevated neoantigen levels associated with MMR deficiencies are the main determinants of sensitivity to immune-based therapies. Here, we asked whether factors beyond the neoantigenic landscape could account for the lack of response of MMRp CRC to immune checkpoint blockade.

Material and method

We developed a model in which MMRd and MMRp CRC cells express equal levels of a given antigen recognized by engineered T cells. This system allowed us to functionally dissect whether the lack of T cell-mediated recognition in MMRp tumors stems from an intrinsic resistance to T-cell attack rather than solely from a low mutational burden. We evaluated immune activation, cytotoxic capacity, and the impact of tumor-derived soluble factors on antigen-specific immune responses.

Result and discussion

MMRp tumors consistently displayed reduced immune recognition and resistance to T-cell-mediated killing. Impaired immune activation correlated with a distinct biological profile, characterized by reduced expression of key effector molecules. Functional assessments showed that while MMRd tumors were efficiently eliminated by engineered T cells, MMRp tumors remained unaffected, highlighting an intrinsic resistance mechanism. Further analysis revealed that soluble factors secreted by MMRp cells actively impaired neoantigen-mediated recognition in MMRd CRC cells. Our data suggest that the MMRp-derived secretome interferes with T-cell binding to tumor cells, disrupting the formation of productive immunological synapses and thereby preventing effective tumor recognition and killing.

Conclusion

The presence of an immunogenic antigen is per se not sufficient to overcome the intrinsic resistance of MMRp tumors to immune checkpoint blockade. Our study demonstrates that MMRp tumors exhibit both intrinsic resistance to T-cell attack and active suppression of immune activation through secretome-mediated mechanisms. These findings reveal a previously unrecognized role of the tumor secretome in shaping immune evasion, highlighting potential therapeutic targets to restore T-cell function in MMRp CRC.

EACR25-1540**Integrative molecular and spatial analysis of intratumoral tertiary lymphoid structures: insights into immunotherapy response**

B. Tunkova^{1,2}, L. Kasikova¹, V. Niederlova³, J. Tomankova¹, M. Hensler¹, J. Laco⁴, F. Jacob⁵, R. Spisek^{1,2}, O. Stepanek³, J. Palich Fucikova^{1,2}

⁴Faculty of Medicine in Hradec Kralove and University Hospital Hradec Kralove, Charles University, The Fingerland Department of Pathology, Hradec Kralove, Czech Republic

⁵University Hospital Basel and University of Basel, Ovarian Cancer Research, Department of Biomedicine, Basel, Switzerland

Introduction

Intratumoral tertiary lymphoid structures (TLS) have been associated with improved outcome and response to immunotherapy in various cohorts of patients with cancer. Predominantly, mature TLSs (mTLSs) developing germinal centers represent privileged sites for local antigen presentation by dendritic cells, contributing to the generation of tumor-targeting CD8+ effector memory T cells. In line with this notion, further understanding of key quantitative and qualitative differences between mTLSs formation and progression in immune checkpoint inhibitor (ICI)-responsive vs ICI-resistant neoplasms may guide the development of alternative therapies in poorly responsive carcinomas, such as metastatic high-grade serous ovarian cancer (mHGSOC).

Material and method

We harnessed spatial transcriptomics Xenium *in situ* platform and 35-plex immunofluorescence PhenoCycler Fusion technology alongside with advanced digital pathology to characterize spatial interplay between immune components within early and mTLS structures within mHGSOC and NSCLC tumor samples.

Result and discussion

Specifically, mTLSs of mHGSOC are associated with an enriched population of naïve (IgD+MUM-CD38-CD20+) and PDL1+CD20+ B cells, suggesting impaired level of antigen presentation. Regarding this notion, the majority of CD8+ T cells within mTLSs of mHGSOC are associated with TIM3+PD1+, terminally exhausted and ICI-resistant T cell phenotype. The active immuno-suppression might be further amplified by the presence of tumor associated macrophages within invasive zone of mTLS of mHGSOC, which might negatively contribute to TLS propagation leading to cancer evasion.

Conversely, spatial B-cell profiling identifies patterns of *in situ* maturation and differentiation, characterized by abundance of mature CD79a+CD20+ B cells and CD138+CD19+ plasma cells signatures in mTLS of NSCLC. As such, mTLSs of NSCLC preserve and ICI-responsive TCF1+PD1+CD8+ T cells phenotype, suggesting a robust anti-tumor immune response within these aggregates with subsequent propagation within the tumor.

Conclusion

Integration of high-dimensional multiplex immuno-fluorescence technology with spatial transcriptomics provides a unique tool for characterization of TLS cellular composition and functional relevance in shaping anti-tumor immunity. Further understanding of cancer

driven differences in mTLS composition can lead to the development of immunotherapeutic interventions tailored to unique immune landscapes of particular malignancies.

EACR25-1578

Develop feeder-free differentiation of human hypoimmunogenic iPSCs into natural killer (NK) cells with cytotoxic potential for advanced hepatocellular carcinoma (HCC) treatment

C. Yen¹, Y. Su², C. Luo², Y. Liu², S. Wang², J. Chen², C. Yen²

¹Taipei Medical University, Faculty of Medicine, Taipei, Taiwan

²National Cheng Kung University Hospital, Department of Oncology, Tainan, Taiwan

Introduction

Immunotherapy, particularly T cell-based therapies, has revolutionized cancer treatment, but faces challenges like severe adverse effects and high costs. NK cell-based therapy offers advantages such as safety and off-the-shelf feasibility. NK cells can identify and eliminate tumor cells without HLAs matching, reducing GvHD risk. Clinical-grade methods are producing large numbers of NK cells from various sources, with iPSC-derived NK cells showing promise due to their self-renewal ability and potential for gene editing. Hepatocellular carcinoma (HCC) is a common and deadly cancer with poor prognosis despite advanced treatments. HCC is immunologically cold, with lower NK cell numbers and function. Enhancing NK cell activity improves survival rates in HCC patients, and tumor-infiltrating NK cells predict better responses to sorafenib therapy.

Material and method

We developed a scalable NK cell production protocol from hypoimmunogenic iPSCs without feeder cells stimulation for clinical use. Hypoimmunogenic iPSCs formed embryoid bodies (EBs) and then differentiated into CD34+CD43+ hematopoietic progenitor cells (HPCs), followed by differentiated into CD56+CD3- NK cells (named iNK), using a combination of cytokines. Furthermore, we screened out specific nanobodies (Nbs) against B7-H3 (also known as CD276) from camelid gene library to equip iNK cells for targeting HCC cells.

Result and discussion

During the iNK differentiation period, we observed 2 to 10-fold cell increase in the number of iNK cells compared with iPSCs. After expansion, iNK cells became more homogenous and the purity of iNK cells can be up to 80%. More than 95% of cells expressed both CD45 and CD43. Expression of NKG2D and NKp44 was also high in iNK cells. Although the expression of CD16 was about 20%, iNK cells exhibited good cytotoxicity effect against HCC cell lines, HepG2. *In vitro* cytolytic ability of iNK cells was comparable to that of NK-92, an immortalized cell line exhibiting high activity of blood NK cells. On the other hand, we observed CD276 expressed higher lever in HCC compared to normal liver cells via western blot. And anti-CD276 Nbs can recognized the native CD276 epitope through flow cytometry method.

Conclusion

We established a feeder-free and scalable iNK differentiation platform from human hypoimmunogenic iPSCs for clinical use. In addition, we identified the anti-CD276 Nbs for enhancing the targeting of iNK cells. Using CD276-equipped iPSC-derived NK cells may hold significant potential for developing effective and accessible immunotherapies for HCC.

Introduction

Sarcomas are rare and heterogeneous neoplasms originating from diverse mesenchymal tissues. Standard therapies often fail to cure advanced diseases, underscoring the need for novel, biologically informed treatment options. Sarcoma tumor cells form a complex ecosystem with non-cancerous cells in their micro-environment, which may create unique dependencies and potential therapeutic vulnerabilities. In particular, tumor-infiltrating T cells have emerged as potent immunotherapeutic targets through immune checkpoint inhibition. Additionally, chimeric antigen receptor T cell therapy is effective in certain sarcomas. However, response rates to these treatments vary greatly within and across sarcoma subtypes and the roles of T cells in sarcoma ecosystems remain poorly understood. An informed selection of sarcoma patients for immunotherapies remains challenging due to a lack of predictive biomarkers.

Material and method

Viable sarcoma tissue, non-cancerous tumor-adjacent tissue, and peripheral mononuclear cells from patients' blood were collected under written consent and ethics approval and dissociated into single-cell suspensions. Sarcoma-infiltrating T cell states were analyzed using high parametric spectral flow cytometry and a panel of 36 antibodies. Transcriptional profiling of T cells and T

cell receptor sequencing were performed using single-cell transcriptomics with simultaneous surface protein detection (CITE-Seq).

Result and discussion

We used a combination of spectral flow cytometry and CITE-Seq to generate a comprehensive single cell map of sarcoma infiltrating T cells. T cell profiling using spectral flow cytometry revealed phenotypically diverse T cell states in 118 sarcomas spanning 28 sarcoma entities. We identified activated and potentially tumor-reactive T cells, as well as PD-1+ exhaustion-like T cells. Single cell transcriptomics of selected sarcomas uncovered additional heterogeneity within T cell populations, suggesting differences in their functionality that may influence immune surveillance and therapeutic outcomes. T cell receptor sequencing demonstrated clonal expansion of distinct T cell clones, underpinning an active role in sarcoma ecosystems.

Conclusion

Our findings shed new light on the complexity of T cell states in sarcoma ecosystems and will be used to advance T cell-directed precision-medicine approaches for sarcoma therapy.

EACR25-1637

Exploiting Tumour Ablation to Augment Anti-cancer Immunotherapy in Hepatocellular Carcinoma

*T. Humphries¹, A. Samson¹, E. West¹, K. Scott¹,
R. Brownlie¹*

¹*University of Leeds, Leeds Institute for Medical Research, Leeds, United Kingdom*

Introduction

Hepatocellular carcinoma is responsible for 75–85% of primary liver cancers and arises from chronic liver disease. Many patients with chronic liver disease often do not qualify for surgery due to liver fragility and instead undergo ablative therapy. Examples of ablative therapies include stereotactic ablative radiotherapy, cryoablation, oncolytic virus treatment and histotripsy. These therapies can enhance the anti-tumour immune response, via the release of damage-associated molecular patterns (DAMPs) from ablated tumour cells, however the underlying mechanisms remain unclear. Despite the growing use of these techniques, there is limited understanding of the immune-stimulatory effect and limited guidance for clinicians. The aim of this project is to characterise tumour immunology post-ablation directly comparing each therapy.

Material and method

To assess the immune-stimulatory effects of each ablative therapy we used flow cytometry, ELISAs, and immune assays to quantify key DAMPs from ablated tumour cells and assess immune activation. Mature dendritic cells were incubated with tumour supernatants to evaluate activation and immune checkpoint markers. Next, we will experiment on primary tissue and conduct immunophenotyping of PBMCs from patients undergoing ablative therapies in clinical trials.

Result and discussion

Our findings reveal significant increases in key DAMPs, particularly DNA and heat shock protein 70, in the supernatant of ablated tumour cells. This increase correlates

with enhanced expression of the early activation marker CD69 on PBMCs. Furthermore, dendritic cells exposed to supernatants from cryoablated tumour cells displayed elevated expression of multiple activation and immune checkpoint markers, including CD80, CD86 and PD-L1, suggesting a role in modulating the anti-tumour immune response.

Conclusion

This project has shown a significant increase in DAMP release from cell lines, triggering effective immune cell activation. Next, primary patient tissue will be treated to assess DAMP release and immune cell stimulation. Alongside this, PBMC immunophenotyping from treated patients will highlight a potential immune response at the systemic level. Future comparisons of in vitro and patient-derived data will help define the molecular mechanisms of ablative therapies at the cellular, tissue, and systemic levels. This will help aid the design of early-phase clinical trials combining immunotherapy with ablative treatment for HCC treatment.

⁶University Hospital Basel, Ovarian Cancer Research, Department of Biomedicine, Basel, Switzerland

Introduction

Immune checkpoint inhibitors (ICIs) have demonstrated remarkable activity in a subset of patients with solid malignancies, especially in the context of abundant tumor infiltration by CD8+ cytotoxic T lymphocytes (CTLs) – and consequent expression of PD-L1 by neoplastic and myeloid cells – at baseline. While natural killer (NK) cells have also been shown to control oncogenesis and tumor progression, at least in some oncological settings, their phenotypic and functional heterogeneity and its impact on ICI sensitivity remains incompletely understood.

Material and method

Here, we harnessed a variety of transcriptomic, spatial and functional assays to characterize the phenotypic and functional properties of NK cells in ICI-sensitive and ICI-resistant solid carcinomas.

Result and discussion

We demonstrate that advanced non-small cell lung carcinoma (NSCLC), which is generally considered an immunologically “hot” tumor – contains elevated levels of intratumoral cytotoxic CD56dim NK cells that (1)

express high levels of NKp46 and CD57, (2) exhibit patterns of in situ activation associated with mature tertiary lymphoid structures (mTLSs), and (3) correlate with favorable prognosis. Conversely, the NK cell compartment of immunological “cold” tumors such as high-grade serous ovarian carcinoma (HGSOC) – which generally contains immature TLSs and ICI-resistant TCF1-TIM3+CD8+ CTLs – is enriched in functionally exhausted CD56bright NK cells expressing high levels of TIM3 and NKG2A. In this latter context, while PD1 blockers fail to restore anticancer immunity, targeting NKG2A results in improved NK cells cytotoxicity coupled with the (at least partial) recovery of CD8+ CTL functions. Consistent with this notion, an NKG2A blocker positively interacted with a PD1 inhibitor in a syngeneic model of ovarian cancer.

Conclusion

Collectively, our findings delineate key phenotypic and functional differences in the NK cell compartment of ICI-responsive vs ICI-resistant tumors that may be harnessed therapeutically to restore anticancer immunity in the context of a functional interaction between NK cells and CD8+ CTLs.

PARP inhibitors as immune modulators in metastatic ovarian cancer therapy

P. Holicek¹, I. Moserova¹, S. Vosahlikova¹, M. Hensler¹, R. Mikyskova², L. Kasikova¹, S. Orsulic³, M. Reinis², R. Spisek¹, J. Fucikova¹

¹Sotio Biotech, Prague, Czech Republic

²Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic

³UCLA, LA, United States

Introduction

Epithelial ovarian carcinoma (EOC) is one of the top five causes of cancer-related death in women. Most patients with EOC achieve initial remission after primary or interval cytoreductive surgery combined with platinum-taxane chemotherapy. However, mutations in BRCA1 or BRCA2 genes, which lead to homologous recombination (HR) defects, play a crucial role in platinum sensitivity and justify the use of poly (ADP-ribose) polymerase (PARP) inhibitors as maintenance therapy, commonly linked to extended progression-free survival in EOC. Besides their direct cytotoxic and cytostatic effects, PARP inhibitors (PARPi) have shown significant immunostimulatory properties by disrupting DNA repair in cancer cells, and opening possibilities for synergy with immune checkpoint inhibitors (ICIs).

Material and method

We harnessed a variety of transcriptomic, spatial and functional assays to characterize the immunomodulatory effects of PARPi on immunological configuration of experimental BR5BRCA1/- syngeneic mouse model of ovarian cancer and human EOC tumor samples.

Result and discussion

Our finding demonstrates, that PARPi increase the mutational burden in EOCs due to unresolved DNA damage and releases of damage-associated molecular patterns (DAMPs), thereby increasing T cell infiltration within tumor microenvironment. In addition, PARPi

appear to promote potent type I interferon (IFN) secretion through the activation of cGAMP synthase and the stimulator of the interferon genes (STING) pathway. In combination with ICIs, PARPi showed a beneficial effect on the balance between adaptive anti-tumor immunity and innate myeloid components, leading to an improved cytotoxic T-cell response, as observed in mouse models and HGSOC tumor samples.

Conclusion

These observations emphasize the role of strategically designed combinations of PARPi and immunotherapeutic agents, which could be the key to overcoming immunosuppression in the EOC microenvironment, thereby improving clinical outcomes.

⁴*Acibadem University, Department of Biostatistics and Medical Informatics, Istanbul, Turkey*

⁵*Ege University, Department of Pulmonary Medicine, Izmir, Turkey*

Introduction

Microbiota-targeted biomarkers are emerging as promising non-invasive tools for the early detection of cancers. Increasing evidence suggests that alterations in microbiota can lead to significant disruptions in lipid metabolism. This study aims to investigate the oral and intestinal microbiome, lipidome, and their interactions, which hold substantial potential for providing clinical guidance.

Material and method

To achieve this, lipid profiles, as well as prokaryotic and eukaryotic microorganisms, were determined by collecting consecutive stool and saliva samples from lung cancer (LC) patients and healthy controls (HC) at three time points: pre-treatment, and at 6- and 12-months post-treatment. In all these samples, the 16S rRNA and 18S rRNA genes for bacteria and eukaryotes, respectively, were sequenced with an oxford nanopore platform. Lipid profile was investigated using nanoflow ultra-high performance liquid chromatography-electrospray ionization-tandem mass spectrometry. All data were evaluated and integrated by bioinformatics analysis.

Result and discussion

18S rRNA analyses indicated that stool samples from LC patients had significantly higher evenness and diversity, with comparable OTU counts to HC. Saliva samples from LC patients showed a higher OTU count but similar evenness and diversity. In contrast, 16S rRNA analysis

revealed lower OTU counts in both stool and saliva samples from LC patients compared to HC; however, OTU counts increased over time in consecutive samples from LC patients. Beta-diversity analysis showed no significant differences in microbiota composition between HC and LC patients, although initial and second samples from LC patients exhibited similar clustering patterns. 18S rRNA analyses revealed that Ascomycota was less abundant, while Mucoromycota was more abundant in the saliva of LC patients compared to HC; the opposite was true for stool samples. Pichia kudriavzevii was less abundant, while Carcinomyces was more abundant in saliva samples from LC patients. 16S rRNA analyses showed that Firmicutes were significantly more abundant in both samples from LC patients, while Euryarchaeota were less abundant in saliva. Streptococcus and Blautia were more abundant in both samples of LC patients, respectively, while Levilactobacillus was more abundant in stool from HC. Lipidomic analysis revealed increased diacylglycerol levels in saliva, potentially due to bacterial stimulation. Ceramide in LC patients correlated positively with Firmicutes, a correlation not seen in HC. Phosphatidylserine, found in saliva, may serve as a biomarker for LC, with significantly reduced levels in LC patients and a correlation with gram-negative bacteria.

Conclusion

This study demonstrates that microbiota may play critical roles in cancer development through their impact on lipid metabolism; however, further research is needed to explore this relationship in greater depth.

Supported by TUBITAK-120N924.

⁵*SciLifeLab, Karolinska Institutet, Department of Oncology-Pathology, Solna, Sweden*

⁶*University of Rome "Tor Vergata", Department of Biomedicine and Prevention, Rome, Italy*

Introduction

Although immune checkpoint blockade (ICB)-based immunotherapy has led to remarkable clinical results across various cancer types, its efficacy remains limited to a subset of patients. This underscores the urgent need to explore novel strategies to enhance therapeutic responses and expand the pool of responders. In this context, we investigated the modulation of ERAP1, a key enzyme in the antigen processing and presentation pathway. While loss of this enzyme activity is frequently correlated with reduced in MHC-I surface expression, which could contribute to tumor immune evasion,

impairment of ERAP1 expression in tumor cells has recently been shown to improve ICB efficacy in a murine neuroblastoma model. Therefore, ERAP1 represents an intriguing target for enhancing antitumor immune responses. Here, we examined how ERAP1 influences the tumor microenvironment (TME) in both ‘cold’ or immune excluded and ‘hot’ or immune inflamed murine melanoma models.

Material and method

Two murine melanoma cell lines expressing ERAP1 were genetically engineered using the CRISPR/Cas9 machinery targeting the ERAP1 gene to knock-out the enzyme. The efficacy of the gene editing was confirmed by Sanger sequencing and the loss of ERAP1 at the protein level by western blot. To understand to which extent ERAP1 inhibition impacts antigen presentation and immune responses, we performed peptide-dependent stability assays, immunopeptidomics, bulk RNA-seq analyses, ex vivo co-culture assays and in vivo studies. The tumors derived from the in vivo studies were further analyzed by flow cytometry and spatial proteomics to characterize the immune compartment of the tumor microenvironment.

Result and discussion

Our findings reveal that ERAP1 inhibition increases the susceptibility of melanoma cells to immune-mediated killing by altering the stability of peptide-MHC-I complexes and reshaping the tumor immunopeptidome. This, in turn, enhances the activation of T cells and NK cells. In ‘hot’ melanoma tumors, ERAP1 inhibition leads to tumor growth reduction by recruiting activated NK cells. In contrast, while ERAP1 inhibition alone is not sufficient to control tumor growth in ‘cold’ melanoma, it significantly reshapes the immune landscape by increasing immune cell infiltration and enhancing the recruitment of cytotoxic T cells into the tumor core.

Conclusion

These results support ERAP1 inhibition as a promising strategy for converting ‘cold’ tumors into ‘hot’ tumors, reinforcing its potential as a safe and effective approach for combination with immunotherapies. Additionally, they highlight the importance of identifying predictive biomarkers of response to ERAP1 inhibition.

EACR25-1759

A Nanopore Based Approach for Detection of *Fusobacterium nucleatum* Subspecies in Colorectal Cancer Tissue

W. Rosenbaum¹, A. Löfgren-Burström¹, M. Rubio García¹, S. Edin¹, V. Bronnec¹, R. Palmqvist¹
¹*Umeå University, Medical biosciences, Umeå, Sweden*

Introduction

The common oral bacteria *Fusobacterium nucleatum*, has long been associated with colorectal cancer – a leading cause of cancer death worldwide. Traditionally, *F. nucleatum* has been divided into four subspecies, namely *F. nucleatum* subspecies *animalis*, *F. nucleatum* subspecies *polymorphum*, *F. nucleatum* subspecies *vincentii* and *F. nucleatum* subspecies *nucleatum*. Recently, suggestions have been made to reclassify the four into separate species. However, accurately distinguishing between them remains challenging, especially utilizing

partial 16S regions. To address this problem, we have developed a Nanopore full length 16S sequencing workflow, which enables reliable classification of the four subspecies.

Material and method

Our method allows multiplexing of 192 samples on one flow-cell. Further, we have refined the initial PCR step using a high-fidelity polymerase. We also developed a novel demultiplexing tool which allows reuse of forward and reverse barcodes. For species classification, we provide a custom bioinformatic pipeline, using a comprehensive and curated 16S database.

Result and discussion

Our method successfully differentiates the four subspecies of *F. nucleatum* with a high sensitivity. To confirm the reproducibility of our method, we used a positive control consisting of a known microbial community mixed with human cells, which shows consistent results across sequencing runs. Given the strong association between *F. nucleatum* subspecies *animalis* and colorectal cancer, our method is well suited for detecting bacteria in clinical samples with low bacterial content and high presence of host DNA, e.g. patient fresh frozen colorectal tissue.

Conclusion

We present a full length Nanopore 16S sequencing workflow, from wet to dry lab, offering a cost effective and sensitive approach for detecting *Fusobacterium* subspecies, as well as other species. Given *F. nucleatum*'s link to colorectal cancer, our method enables studying its role and clinical implications. Given that the method is eligible for samples with low microbial content, it is well suited for examining bacteria in tissue samples from patients.

Teneurin-4 as a key player in cancer progression and target for gene-based vaccines to halt tumor growth and progression in preclinical models

G. Peppino¹, Z. Arshad¹, F. Riccardo¹, D. Loggia¹, L. Cherubin¹, C. Vit¹, A. Lamolinara², I. Castellano³, G. Barutello¹, E. Quaglino¹
¹*Università degli studi di Torino, Department of Molecular Biotechnology and Health Sciences, Torino, Italy*

²Università di Chieti-Pescara, Department of Neuroscience, Chieti, Italy

³Università degli studi di Torino, Department of medical sciences, Torino, Italy

Introduction

Cancer Stem Cells (CSC) play a crucial role in sustaining tumor growth and progression, highlighting the urgent need to identify novel functional targets expressed on CSC. By comparing the transcriptomes of differentiated Triple Negative Breast Cancer (TNBC) cells and CSC, we identified upregulated transmembrane proteins as promising candidates for cell- and antibody-based therapies. Among these, Teneurin-4 (TENM4), emerged as a compelling target due to its elevated expression in TNBC patients with poorer prognosis. This study aims to

unveil new molecular mechanisms in cancer biology and validate TENM4 as a therapeutic target across different tumor types.

Material and method

TNBC, Colorectal Cancer (CRC) and Neuroblastoma (NB) cells were silenced using RNAi and CRISPR/Cas9 technology. The role of TENM4 in self-renewal and migration was assessed in vitro through tumorsphere-forming ability assay and transwell invasion assay. Tumor growth and lung metastasis were evaluated following the subcutaneous injection of TENM4-proficient and deficient cells. Moreover, a retrospective analysis (n=59) evaluated the correlation between TENM4 expression and patient prognosis. Finally, the immunogenicity of a DNA-based vaccine against TENM4 was tested by Flow cytometry and ELISPOT assay.

Result and discussion

Our results demonstrate that TENM4 plays a crucial role in CSC self-renewal, migration, and invasion in TNBC, CRC, and NB. Moreover, we demonstrated TENM4 role in vivo in CRC growth and in TNBC metastasis, associated with fewer circulating tumor cells in mice injected with TENM4-deficient cells compared to controls. Additionally, we also demonstrated a decreased phosphorylation of FAK, AKT, ERK and a reduced expression of MMP9, suggesting an involvement of TENM4 in Extracellular Matrix (ECM) remodeling, potentially explaining the involvement of TENM4 in metastasis. Further data also suggest a role of TENM4 in TNBC chemoresistance, potentially involving endoplasmic reticulum stress and autophagy pathways. The clinical relevance of TENM4 in TNBC is underscored by the increase recurrence rates in TNBC patients with tumors with a higher TENM4 expression. Furthermore, TENM4 targeting via gene- and virus-based vaccination resulted safe and effective in eliciting anti-TENM4 response. Different experiments are ongoing to evaluate the efficacy of TENM4 targeting.

Conclusion

Overall, these data identify TENM4 as pro-tumorigenic in TNBC, CRC and NB, playing a role in stemness, migration, chemotherapy and metastasis. Moreover, the immunogenicity of the vaccination against TENM4 point out the possibility to use TENM4 as a valuable immune-target in different tumor subtypes.

EACR25-1862

Eosinophil deactivation by the breast tumor microenvironment can be reversed by interferons

Z. Varyova¹, M. Pohin¹, J. Webber¹, V. de Costa Escaron¹, G. Orend², A. Schwenzer¹, A. Harris³, A. Gérard¹, K. Midwood¹

¹University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom

²University of Strasbourg, Fédération de Médecine Translationnelle de Strasbourg, Strasbourg, France

³University of Oxford, Department of Oncology, Oxford, United Kingdom

Introduction

Eosinophils, granulocytes mainly studied in the context of allergy and helminth infection, were recently

recognized as important players in the response to immune checkpoint blockade (ICB) in breast cancer. However, in contrast to colorectal or lung tumors, depletion of eosinophils or induction of eosinophilia in murine models of breast cancer does not impact tumor progression. These data indicate that the breast tumor microenvironment (TME) can evade eosinophil-mediated cytotoxicity, although the underlying mechanisms remain poorly understood.

Material and method

Using NT193, E0771 and 4T1 murine syngeneic models of breast cancer, we explored phenotypical and functional heterogeneity of eosinophils in TME by spectral flow cytometry and bulkRNA sequencing of sorted subpopulations. Subset-specific signatures from transcriptomic analysis were a) validated on protein level and b) recapitulated in vitro, through development tracking of bone-marrow derived eosinophils and cytokine stimulation. Furthermore, predicted cell killing abilities were tested ex vivo and in vitro. Finally, we examined the impact of ICB on eosinophil subset regulation in NT193 treatment-responsive tumors.

Result and discussion

We identified two novel subsets of tumor-associated eosinophils. In the bone marrow and blood eosinophils express relatively high levels of Ly6C receptor, however they gradually lose the expression in TME during tumor progression, resulting in Ly6C+ and Ly6C- eosinophil populations. This phenotypic change correlates with higher tumor volumes and reduced tumor cell killing ability. Moreover, Ly6C+ eosinophils are more responsive to interferons and upregulate pathways involved in activation of adaptive immunity. We show that Ly6C+ eosinophils represent a long-lived population that naturally differentiates into Ly6C- deactivated state. This transition can be prevented and partially reversed in presence of interferons. Mice bearing NT193 tumours were treated with anti-PD-L1 to induce an interferon-rich TME, and whilst the proportion of Ly6C+ eosinophils was unchanged, these cells overexpressed Ly6C and shifted towards higher expression of MHC-I.

Conclusion

Our data provides new evidence that eosinophils are a highly plastic population that are shaped into a less active state by the progressing breast TME. We present an interferon-guided mechanism by which eosinophils escape differentiation and restore a more active Ly6C+ phenotype. This model could explain why depleting eosinophils in treatment-naïve breast cancer does not result in tumor regression, while re-activated eosinophils play an important role in responses to ICB.

⁵*Royal Prince Alfred Hospital, Department of Tissue Pathology and Diagnostic Oncology, Sydney, Australia*

⁶*Royal Prince Alfred Hospital, A.W. Morrow Gastroenterology and Liver Centre, Sydney, Australia*

Introduction

In 2020, Hepatocellular carcinoma (HCC) was the sixth most frequent cancer and third leading cause of cancer-related deaths worldwide. Many factors contribute to the development of HCC, including viral infection, alcohol intake, metabolic-associated disease, autoimmunity and genetic liver disorders. Despite the differences in these underlying causes, HCC develops in the context of chronic inflammation resulting in non-haematopoietic cell and tissue alterations. This opposing role of the immune system in both the development and control of chronic liver disease and HCC is not fully understood. A better understanding of this intricate network of cell interactions and tissue regions is required to enhance the efficacy of current therapeutic options.

Material and method

We evaluated the tumour microenvironment (TME) using Imaging Mass Cytometry (IMC) on tumour and non-tumour tissue specimens from 16 advanced HCC patients and single-cell RNA sequencing on cells from tumour and non-tumour tissue as well as paired peripheral blood mononuclear cells from 10 HCC patients

Result and discussion

Single-cell RNA sequencing identified a CD34+ cancer-associated fibroblast (CAF) cell population that was present in higher proportions in HCC tumour tissue when compared to non-tumour tissue. Using IMC, we quantified and spatially mapped CD34+ inflammatory CAF cell-interactions in both non-tumour and tumour tissue from HCC patients to determine its potential role in HCC development.

Conclusion

The development and progression of liver disease is underpinned by an inflammatory cascade that results in aggressive CAFs. Specific cell signatures in the liver tissue (non-tumour and tumour), unique to this cascade can be used to identify patients at risk of disease progression to HCC.

Transcripts containing Retrotransposable Elements play a regulatory role in modulating the functions of Tumor Infiltrating Lymphocytes

F. Panariello¹, R. Vadala², V. Ranzani¹, A. Stamboliu³, B. Polimenti², M. Panepuccia³, M. Federica¹, A. Sergio², B. Beatrice²

¹*National Institute of Molecular Medicine (INGM), Milan, Italy*

²*University of Milan, Department of Clinical Science and Community, Milan, Italy*

³*European School of Molecular Medicine (SEMM), Milan, Italy*

Introduction

Unravelling Tumor Infiltrating Lymphocytes (TIL) heterogeneity is essential to develop more effective immunotherapies. We have recently highlighted the role of LINE1, the predominant class of Retrotransposable Elements (RE), in regulating TIL exhaustion by integrating transcripts related to T cell activation and downregulating their canonical isoforms. Nevertheless, the role of RE expression as a determinant of TIL diversity and function remains poorly explored.

Material and method

We have isolated CD3+ and CD45+ T cells from tumor resections and normal adjacent tissues of Non-Small Cell Lung Cancer (NSCLC), Colorectal Cancer (CRC) and Esophageal Adenocarcinoma (EAC) patients. Due to the challenging task of studying transcripts containing RE with current single-cell technologies, we performed both long- and short-read scRNA-seq. We have developed a custom pipeline to analyze long-read data to generate a pan-cancer Atlas of RE-transcripts that we quantified at isoform level using full-length short-read data.

Recognizing that TIL phenotypes are plastic and dynamic, we have introduced a novel strategy of integrating dimensionality reduction performed on novel RE-transcripts with trajectory inference tools.

Result and discussion

We described approximately 50,000 novel transcripts that are specific to NSCLC, CRC and EAC, with some shared instances. Almost 46% of them included REs, resembling their genomic distribution. Trajectory inference analysis confirmed the positive correlation between LINE1 and exhausted TILs, but it also revealed an enrichment of Alu-containing transcripts in active T cells, while regulatory T cells (Treg) and follicular T helper cells (Tfh) mostly expressed transcripts containing the LTR class. Our results point into the direction of a strong connection between immune phenotypes and RE-transcripts expression. To elucidate the relevance and function of RE-transcripts in TIL identity, we will leverage CRISPR-Cas13 system to specifically modulate specific RE-transcripts and identify potential non-coding regulators.

Conclusion

Long-read sequencing technologies are revolutionary for the evaluation of RE-containing transcripts, that are often understudied because of the repetitive and interspersed nature of retrotransposons. By the integration of cutting-edge sequencing technologies and computational workflows, this project unveil the biological relevance of RE-transcripts in TILs identity. In doing so, it also introduces the innovative concept that RE-transcripts may serve as novel immunological checkpoints and a promising avenue for cancer therapy.

EACR25-1895

b2-microglobulin interaction with HLA class I influences the antigenic landscape and the presentation of cancer associated peptides

A. Barajas Molina¹, Y. Horokhovskyi², N. Acuti¹, M. Phanichkrivalkosil¹, H. Afrache¹, H. Urlaub², J. Liepe², M. Mishto¹

¹The Francis Crick Institute, London, United Kingdom

²Max Plank Institute, Göttingen, Germany

Introduction

B2-microglobulin (B2m) is the light chain of the human leukocyte antigen I, and despite being a well-known molecule of the peptide loading complex (PLC), the granularity of its impact on the antigenic landscape of human cells is not well known. Different attempts have been carried out to understand the role of B2m, mainly regarding its modulatory affinity to the heavy chain (HC) and its importance in stabilising the peptide HLA-I complex, promoting HLA-I recycling and preventing degradation of the heavy chain. Here, we aim to investigate how the interaction of B2m with the HLA-HC changes the quality of the peptide repertoire and the HLA-I ability to present endogenous and exogenous cancer-related epitopes.

Material and method

We transduced K562 and C1R cell lines with two different constructs of the HLA-A*02:01 allele, either coding for the HLA-HC only, in which case the HLA-I assembly relies on the endogenous expression of B2m, or HLA-HC fused to B2m by a linker. We then analysed the characteristics and features of the entire peptide repertoire presented by the HLA-I molecules. We also investigated the efficiency of these cell lines to present exogenous synthetic peptides pulsed, peptides derived from the proteasomal degradation of endogenous antigens, and peptides derived from the cross-presentation of exogenous antigens. For this, we used an indirect system of detection consisting in GFP-reporter Jurkat cells transduced with TCRs that recognise 4 epitopes of interest derived from cancer-related antigens, NRAS, KRAS and PMEL.

Result and discussion

Results and discussion: When we analysed the entire peptide repertoire by eluting the HLA-I immunopeptidomes, we found that the antigenic landscape of cell lines with B2m-HC fusion had been greatly impacted. We then computed the distribution of the predicted binding affinity of the identified peptides and found that these cell lines presented an overall weaker peptide repertoire, as the median of the predicted binding affinity of all the immunopeptidome was significantly higher compared to cell lines without the B2m-HC fusion. We observed how this system hindered the presentation of strong peptide binders derived from the proteasomal degradation of endogenous antigens by co-transducing monoallelic cell lines (4 different alleles) with minigene sequences that expressed known epitopes and observing higher presentation of these epitopes in cell lines without B2m-HC fusion. Finally, we confirmed this effect in a cross-presentation experimental setting where cell lines with and without the B2m fusion differentially presented known epitopes.

Conclusion

Overall, results suggested that fusing B2m to the HLA-HC appears to be enough to escape the ER quality control mechanisms and present poorly loaded HLA-I molecules, which impinges upon the presentation of strong peptide

binders that could potentially be therapeutic immunogenic targets.

EACR25-1898

Exploring the dual role of Toll-like receptor 2 in tumor cell autonomous and microbiota-driven chemoresistance in breast cancer

C. Cossu¹, A. Di Lorenzo¹, M. Adamo¹, M. Arigoni¹, L. Alessandri¹, R. Calogero¹, J. Cumbo², A. Ala², I. Castellano³, L. Conti¹

¹University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy

²A.O.U. City of Health and Science of Turin, S. Anna Hospital, Department of Surgery, Turin, Italy

³University of Turin, Department of Medical Sciences, Pathology Unit, Turin, Italy

Introduction

Besides immune cells, Toll-Like Receptor (TLR)2 is also expressed on breast cancer (BC) cells, correlating with poor prognosis and chemoresistance in patients. Indeed, chemotherapy (CT) induces DAMPs release by damaged cells, including TLR2 ligands. In addition, CT induce dysbiosis, increasing PAMPs release that may activate immune receptors like TLR2. We investigated the TLR2-mediated mechanisms in BC progression and chemoresistance and whether the breast microbiota composition influences CT response via TLR2 activation.

Material and method

Combination of TLR2 inhibitor CU-CPT22 and CT were tested both in vitro and in vivo in a 4T1 BC model.

Mammary dysbiosis was induced in BALB/c mice via antibiotics local administration. WT or TLR2-silenced 4T1 cells were injected into the dysbiotic mammary gland, and mice were treated with doxorubicin. Tumor growth was monitored, and tumor samples were analyzed for microbial composition by 16S rRNA sequencing. BC patients undergoing or not neoadjuvant CT were recruited, to collect both pre-operative biopsies and surgical resection samples for intra-tumoral microbiome analysis by 16S rRNA sequencing.

Result and discussion

TLR2 blockade increased tumor cell sensitivity to doxorubicin in vitro and in vivo, indicating that TLR2 targeting could enhance CT efficacy. Mammary dysbiosis exacerbated tumor progression and chemoresistance in 4T1 tumor-bearing mice, suggesting a potential role for dysbiosis in these mechanisms. Silencing TLR2 within the tumor abolished this effect, indicating that TLR2 expression by tumor cells may drive dysbiosis-dependent chemoresistance. Preliminary analysis of patient tumor samples revealed that CT can drastically alter intra-tumoral microbial composition. Notably, Sphingobacteriales and Lactobacillales were enriched in CT-treated patients compared to patients that did not receive CT.

Conclusion

TLR2 promotes BC progression and chemoresistance, and its inhibition restores BC sensitivity to chemotherapy. Furthermore, antibiotic-induced mammary dysbiosis promotes tumor progression and enhances chemoresistance in 4T1 tumor-bearing mice. However,

silencing TLR2 in tumor cells reverses these effects, suggesting that altered PAMPs release within the dysbiotic mammary gland binds to TLR2, exacerbating tumor growth and chemoresistance. Moreover, CT can reshape the intra-tumoral microbiome toward a more tumor-promoting composition, as suggested by the enrichment of Lactobacillales, linked to tumor growth in gastric cancer, and Sphingobacteriales, which secrete atypical lipopolysaccharides capable of activating TLR2. Further RNA sequencing will provide insights into chemoresistance mechanisms and TLR2-related pathway activation in relation to altered microbiome composition. These findings pave the way for therapeutic strategies combining microbiome modulators with TLR2-targeting approaches to enhance BC treatment efficacy.

Deciphering the complex relationship between diet, the gut microbiota and anti-tumour immunity

R. Simpson¹, J. Conway¹, C. Tseng², M. Okada³, O. Fuller³, S. Masson³, R. Scolyer¹, J. Tiffen², G. Long¹, E. Shanahan³

¹*Melanoma Institute Australia, The University of Sydney, Sydney, Australia*

²*Centenary Institute, Sydney, Australia*

³*The University of Sydney, School of Life and Environmental Sciences, Sydney, Australia*

Introduction

Diet and the gut microbiota are key factors that regulate systemic immune homeostasis. Diet is therefore closely linked to the capacity of the microbiota to regulate anti-tumour immunity during immune checkpoint inhibitor (ICI) immunotherapy. We therefore sought to use differing dietary contexts to assess the impact of long-term pre-established immune homeostasis on anti-tumour immunity.

Material and method

To model a healthy balanced diet versus a poor unbalanced diet, C57BL/6 mice were fed either a standard chow (CD) or high fat (HF)/high sugar (HS) diet for 6–8 weeks prior to inoculation with a syngeneic cancer cell line and the impact on tumour growth and responsiveness to ICI immunotherapy assessed. Microbiome samples were analysed using 16S rRNA gene sequencing. Immune populations across the mesenteric lymph nodes (MLN), blood (PBMC), spleen, tumour draining LN and tumour were profiled using mass/spectral flow cytometry. Oral glucose tolerance tests were also performed.

Result and discussion

Prior to tumour inoculation, mice on CD versus HF/HS long term have distinct gut microbial communities and immune repertoires across all sites. CD mice were enriched in fibre-utilisers/SCFA producers and associated with greater frequencies of ROR γ T+ Tregs in the MLN. In contrast, HF/HS mice were enriched with intestinal mucin degraders and bile tolerant microbes and had higher overall B cell frequencies and increased PD-1 and Ki67 expression across the B and T cell compartments. Surprisingly despite these differences, no differences in tumour growth or responsiveness to ICIs were observed

across 5 different melanoma cell lines of varying genetics and immunogenicity (YUMM1.7, YUMMER1.7, YUMM3.3, YUMM3.3-UVR, B16-F10). We postulated that the metabolic impacts of diet components, such as fat source and fatty acid composition, may be one aspect that plays an important role. We thus sought to compare the impact of differing high fat sources (coppa vs lard) on systemic metabolism and tumour growth. After only 2 weeks on diet, HF-Lard mice exhibited impaired glucose tolerance and reduced insulin sensitivity compared to CD and HF-Coppa mice. Notably, HF-Lard significantly accelerated the growth of YUMM3.3-UVR tumours. In contrast, both HF diets accelerated the growth of MC38 colorectal adenocarcinomas, and no differences were observed between diets for B16-F10 tumours in this short-term dietary context. This suggests that dietary fat source and its impact on metabolism, as well as tumour type/genetics are important factors in how the diet-gut axis influences tumour growth.

Conclusion

Together this highlights the complex relationship between diet, the gut microbiota and anti-tumour immunity. Ongoing work will provide valuable insight into the impact of different fat sources and diet durations on metabolism, the gut microbiota and anti-tumour immunity during ICI treatment and ultimately inform the design of more specific dietary interventions.

EACR25-1924

In-silico functional profiles of anaerobic bacteria in prostate cancer

S. Subramanian¹, A. Gihawi¹, R. Hurst¹, C. Cooper¹, D. Brewer¹

¹*University of East Anglia, Norwich Medical School, Norwich, United Kingdom*

Introduction

Prostate cancer is among the most common cancers globally (1 in 8 men in the UK will be diagnosed in their lifetime). Major risk factors include age, ethnicity, and family history. Microbial infections contribute to many cancers, and the prostate microbiome influences prostate cancer. Identifying the Anaerobic Bacterial Biomarker Set (ABBS) bacteria – *Fenollarria*, *Ezakiella*, *Peptophilus*, *Anaerococcus*, *Porphyromonas*, and *Fusobacterium* – may help predict aggressive prostate cancer at diagnosis. ABBS-positive samples are linked to more aggressive disease, and the mechanisms of actions of these bacteria are important to investigate.

Material and method

Whole genome sequencing data from 650 tumour samples in the Pan-Prostate Cancer Group (PPCG) were analysed for microbial content. Unmapped reads were quality-trimmed, human-depleted, and classified using Kraken. The metabolic profiles of ABBS-positive and negative samples were assessed using HUMAnN (v3.7). Gene families and pathways were analysed with Maaslin2 (v1.12.0) in R (v4.2.0).

Result and discussion

ABBS-positive tumours had 888 significantly enriched gene families and 336 metabolic pathways, including genes for tRNA synthetases for all 20 amino acids and methionine synthesis/salvage pathways. This was

significantly higher than the 75 gene families and 17 pathways found in ABBS-negative tumours. Key ABBS-associated pathways include methionine salvage/synthesis and tRNA charging. Cancer cells rely heavily on external methionine (Hoffman effect) and arrest in the S/G2 cell cycle phase under methionine restriction. Methionine metabolism may be a core feature of cancer development. tRNA charging, facilitated by aminoacyl-tRNA synthetases (ARSs), enables peptide bond formation. Aberrant ARS expression is linked to the transformation from benign to malignant cells, with ARS-encoding genes exhibiting expression profiles similar to Cancer-Associated Genes (CAGs) in 10 cancers.

Conclusion

These findings suggest microbial metabolism may contribute to prostate cancer progression when ABBS bacteria are present. Future work will look at mutational profiles in the PPCG that are associated with ABBS positive tumours, identifying additional bacteria with a similar metabolic profile and investigating the relationship of enzymes and pathways affected in ABBS positive tumours with long term survival in ABBS positive patients.

EACR25-1926

Unlocking Immune Resistance: The Role of PIRB Deletion in Pancreatic Cancer Therapy

A. Scagliotti¹, G. Tiberi², I. Depetro², S. Brugia paglia², P. Diez², S. Basile², C. Curcio², F. Novelli², P. Cappello²

¹*University of Turin, Department of Molecular and Health Sciences, Turin, Italy*

²*University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy*

Introduction

Paired Immunoglobulin-like Receptor B (PIRB) is the murine ortholog of the human Leukocyte Immunoglobulin-like Receptor B (LILRB) 2 and 3, immunological receptors with diverse tissue-specific functions. These receptors are physiologically expressed by hematopoietic cells, such as macrophages, granulocytes, dendritic cells, and B lymphocytes. Thanks to their intracellular Immunoreceptor Tyrosine-based Inhibitory Motives (ITIM), these molecules act as negative receptors, physiologically preventing premature activation and exaggerated responses. In addition, they have been associated with an immunosuppressive behavior of various cell types. Recently, these receptors have also been reported to be highly expressed by cancer cells, where they directly support their aggressive behavior, aerobic glycolytic metabolism, and metastatic spread.

Material and method

To better characterize its role in modulating the anti-tumoral immune response in models of pancreatic ductal adenocarcinoma (PDA) and to assess the capacity to elicit immunological memory, non-proliferating ovalbumin (OVA)-expressing PDA cells were inoculated subcutaneously into C57/BL6 WT and Pirb^{-/-} mice. After three weeks, mice were challenged with live cells, and tumor growth was measured biweekly. At time of sacrifice, ELISPOT, cytotoxicity, and ELISA assays

were performed to investigate both cellular and humoral responses. The intrinsic pro-tumoral role of PIRB when expressed by PDA cancer cells was investigated through the generation of a Pirb^{-/-} murine PDA cell line (K-PIRB) and the assessment of its proliferative and invasive behavior with a MTT, wound healing, and soft agar clonogenic assay. Pirb^{-/-} cells' sensitivity to both pro-tumoral Transforming Growth Factor (TGF) β and anti-tumoral Interferon (IFN) γ was assessed with RT-PCR and FACS analyses.

Result and discussion

The absence of PIRB significantly improved immunization against the well-known experimental antigen OVA. Indeed, immunized Pirb^{-/-} mice showed a reduced growth of subcutaneous living tumor cells, together with an enhanced number of IFN γ -secreting T cells and higher levels of OVA-specific IgG. In addition, K-PIRB cells displayed a significantly slower growth, proliferation, and migration properties in comparison to wild-type counterpart. In line with this, K-PIRB cells grew significantly less when injected orthotopically into both wild-type and Pirb^{-/-} mice. Furthermore, K-PIRB cells were less responsive to the pro-metastatic TGF β , while increasing their FAS and MHC-I levels upon stimulation with IFN γ .

Conclusion

Overall, PIRB represents a promising target not only to enhance the anti-tumor immune response, but also to directly impact on PDA growth and aggressive behavior. Further analyses will assess its clinical transferability and its potential synergistic effect when combined with approved therapies.

EACR25-1953

Harnessing Mitophagy in Tumor-Associated Macrophages to Enhance Anti-Tumor Immunity

P. Liu¹

¹*National Cheng Kung University (NCKU), Department of Biochemistry and Molecular Biology, Tainan, Taiwan*

Introduction

Tumor-associated macrophages (TAMs) and tumor cells are crucial in creating an immunosuppressive tumor microenvironment (TME) through metabolic programming. Understanding the metabolic changes within the TME and the impact of tumor-derived metabolites on the functional phenotypes of TAMs is essential for the development of effective cancer therapies. Recent studies highlight enhanced lipid metabolism in TAMs, which is linked to their protumorigenic functions. However, the mechanisms by which lipid metabolism shapes TAM phenotypes and functions during tumor progression remain inadequately understood.

Material and method

In our study, we found that tumor-derived lipids lead to increased lipid content and enhanced oxidative phosphorylation in TAMs. Simultaneously, we observed elevated levels of mitochondrial reactive oxygen species (ROS) and signs of mitochondrial dysfunction in these cells. Notably, TAMs displayed increased mitophagy activity, a selective autophagic process that removes damaged mitochondria.

Result and discussion

We hypothesize that excessive lipid accumulation or impaired fatty acid oxidation results in mitochondrial stress in TAMs. The upregulation of mitophagy appears to be a mechanism through which TAMs ensure their survival and maintain pro-tumorigenic functions despite mitochondrial dysfunction. Moreover, inhibiting X-mediated mitophagy may disrupt mitochondrial fitness, subsequently affecting the pro-tumorigenic phenotype of TAMs and potentially leading to reduced tumor progression.

Conclusion

These findings suggest that targeting mitophagy in TAMs could be a promising strategy to overcome immune suppression and metabolic barriers in the TME, ultimately enhancing anti-tumor immunity.

EACR25-1977

Bacterial Colonization in Breast Cancer: Exploring *Fusobacterium nucleatum* and Hypoxic Niches

C. Burke¹, C. Jahangir¹, C. Murphy¹, H. Dussmann², B. Maguire², J. Prehn², N. Buckley³, M. Tangney⁴, A. Rahman⁵, W. Gallagher¹

¹*University College Dublin, UCD School of Biomolecular and Biomedical Science, UCD Conway Institute, Dublin, Ireland*

²*Royal College Dublin, Dublin, Ireland, Center of Systems Medicine, Dept. of Physiology and Medical Physics, Dublin, Ireland*

³*School of Pharmacy, Queen's University Belfast, Belfast, United Kingdom*

⁴*University College Cork, Cancer Research@UCC, Cork, Ireland*

⁵*University College Dublin, UCD School of Medicine, Dublin, Ireland*

Introduction

Standard clinical parameters such as tumour size, age, lymph node status, and molecular markers are used to predict progression risk and treatment response. However, exploring additional markers could offer a more comprehensive understanding of the tumour microenvironment (TME). The TME influences tumour development, progression, disease severity, and survival, with tumour-associated bacteria playing significant roles. Studies on tumour-associated microbiota have focused on high bacterial-load sites such as the gut, oral cavity, and stomach, but interest is growing in non-gastrointestinal (GI) solid tumours, such as breast. Species present have been shown to contribute to DNA damage, immuno-suppression, and treatment resistance. *Fusobacterium nucleatum* is an opportunistic anaerobe, enriched in periodontal lesions, oral cancer, colorectal cancer, and has been shown to promote treatment resistance and metastatic progression. Also found in breast cancer, *F. nucleatum* potentially plays a role in immune evasion by inhibiting immune cell populations. Hypoxia, a common hallmark of solid tumours, poses a hospitable habitat for such anaerobic bacteria. Furthermore, tumour necrosis releases nutrients that further support bacterial colonisation. While *F. nucleatum* has been associated with immune suppression and treatment resistance in

colorectal cancer, its role in breast cancer remains unclear. This study aims to establish robust detection methods to enable further exploration of its impact in the breast TME.

Material and method

Due to the discrete nature of bacterial presence in breast cancer, we established robust cell line controls for *F. nucleatum* (ATCC 25586) and *F. animalis*, formerly *F. nucleatum* subsp. *animalis* (ATCC 51191) positivity, confirmed via qPCR. Cell lines were then used to optimise staining and digital image analysis techniques.

Result and discussion

We optimised immunofluorescence (IF) staining protocols and investigated the utility of both proprietary (provided by Professor Daniel Slade, Virginia Tech, USA) and commercially available (Diatheva, Italy) antibodies for *Fusobacterium* staining, with the former being deemed suitable to progress to tissue staining due to its capacity to detect both *F. nucleatum* and *F. animalis*. Multiplex-IF (mIF) and multiplex fluorescent in situ hybridization (mFISH) protocols were also developed for the co-detection of *F. nucleatum* and Carbonic Anhydrase-IX (CA-IX), a marker for hypoxia. We implemented digital pathology workflows to quantify bacteria-positive cells, CA-IX, and double-positive populations.

Conclusion

By establishing robust methods to target and quantify bacterial presence and hypoxia in the tumour micro-environment, we can begin to investigate the impact bacterial species have on the immune landscape in the TME. This work provides a foundation for future research into microbial influence on breast cancer its impact on treatment efficacy.

⁵*Instituto CUF de Oncologia, Oncologia, Lisbon, Portugal*

⁶*NIMSB - NOVA Institute for Medical Systems Biology, Universidade NOVA de Lisboa, Lisbon, Portugal*

Introduction

Metastatic breast cancer (mBC) remains a leading cause of cancer-related deaths among women globally. Despite therapeutic advances, many treatments fail to improve

patient outcomes, emphasizing the need for innovative approaches and reliable biomarkers to better predict treatment response. Recent studies highlight the critical role of neutrophils in cancer, with low-density neutrophils (LDN) acting as key modulators in the tumor microenvironment. Indeed, LDN are associated with tumor growth and metastasis, contributing to an immunosuppressive environment that supports cancer progression. Here, we further investigated the clinical significance of LDN in mBC by assessing their association with disease progression and patient outcomes.

Material and method

Blood samples from 72 metastatic BC patients were analysed, following LDN isolation via density gradient centrifugation. Flow cytometry was used to quantify and characterize these populations. The obtained results were associated with patients' clinical data.

Result and discussion

Our results demonstrated a significant accumulation of LDN in the blood of metastatic BC patients, particularly those with faster disease progression. Notably, elevated LDN levels were linked to reduced life expectancy independent of metastatic sites (bone, lung, or liver). Longitudinal analysis of LDN fluctuations in patients' blood regarding their clinical data further revealed that increased LDN frequency is often associated with adverse clinical events, disease progression, and non-response to treatment.

Conclusion

This study underscores the prognostic value of LDN in BC, with elevated levels of these cells indicating advanced disease and poorer outcomes. These findings suggest that LDN could serve as valuable biomarkers for monitoring disease progression and treatment response. Ultimately, integrating LDN assessment into the clinical practice could help better identify patients at higher risk of faster progression and may help guide therapeutic strategies toward a more personalized approach in BC management, potentially improving patient therapeutic outcomes.

EACR25-2026

Investigate the effect of alcohol-altered proteins from extracellular vesicles on the immune response and initiation of oral cancer

R. Cruz¹, A. Paes Leme¹

¹*CNPEM, Campinas, Brazil*

Introduction

The processes involved in carcinogenesis depend on changes in tumor cells and the dynamic communication in the microenvironment. Studies report smoking and alcohol consumption as risk factors for oral squamous cell carcinoma (OSCC). Still, the mechanism of alcohol on the OSCC initiation needs to be elucidated.

Material and method

Peripheral blood mononuclear cells (PBMC) from healthy donor buffy coats were treated with immunopeptides selected from a protein identified to be more present in the extracellular vesicles isolated from biopsy tissue from oral cancer patients and primary fibroblasts

treated with alcohol. TCD4 and TCD8 modulation of activation (CD25 and CD69), exhaustion (PD-1, LAG-3 and Tim-3), senescence (CD57) and differentiation (FOXP3) were analyzed by flow cytometry. Cytokines (IL-2, IL-4, IL-6, IL-10, IL-17, TNFα and IFNγ) present in the supernatant of PBMC treated with immunopeptides were measured by Cytometric Bead Array (CBA).

Result and discussion

PBMC treated for 72 hours with 10 μmol/L of immunopeptides showed a reduction in the percentage of TCD4+ cells expressing Granzyme B and decrease in the mean fluorescence intensity of Tim-3 in TCD4+ cells (treated vs. control; p≤0.05; paired Student's t-test). Moreover, a reduction in the percentage of TCD8+ cells expressing Granzyme B and increase in the percentage of TCD8+ CD25+FOXP3+ cells were noted (treated vs. control; p≤0.05; paired Student's t-test). Treatment of PBMC with immunopeptides also resulted in significant lower detection of IL-10, TNFα and IFNγ (treated vs. control; p≤0.05; paired Student's t-test) in the supernatant. These results are in line with other findings from our group that showed PBMC co-cultured for 72 hours with EtOH-treated fibroblasts or EVs showed lower mRNA expression of CD25 and CD69 (treated vs. control; p≤0.05; paired Student's t-test) and a decrease in the percentage of TCD3+ and TCD4+ cells expressing CD25 (treated vs. control; p≤0.05; Wilcoxon test) and TCD4+ cells expressing CD69 (treated vs. control; p≤0.05; paired Student's t-test).

Conclusion

The results indicate that immunopeptides can modulate the activation of T cells and might be related to initiation of tumorigenesis in oral cancer, and in future may be used as a therapeutic target for prevention and treatment of OSCC.

EACR25-2054

Tissue Microenvironment Shapes PMN-MDSC Function, Maturation, and NETosis Capacity

M. Bilotta¹, S. Forcelloni¹, P. Fiore¹, L. Moretta², P. Vacca¹, N. Tumino¹

¹*Pediatric Hospital Bambino Gesù, Innate Lymphoid Cells Units, Rome, Italy*

²*Pediatric Hospital Bambino Gesù, Tumor Immunology, Rome, Italy*

Introduction

PMN-MDSCs are a heterogeneous population of immature myeloid cells that suppress immune responses in various pathological conditions, including cancer. These cells exhibit significant heterogeneity and plasticity, with functional diversity dependent on their tissue origin and the signals they receive from the surrounding microenvironment. The study examines the heterogeneity and dynamic differentiation patterns of PMN-MDSCs in different tissue microenvironments, including bone marrow (BM), apheresis (AF), and peripheral blood (PB).

Material and method

PMN-MDSCs were identified by flow cytometry and isolated using magnetic beads separation or cell-sorting. Cells were obtained from BM, AF, and PB of tumor patients. Functional tests were performed using NK cells

as effector cells and tumor cell lines as target cells. scRNA-seq analysis was employed to identify distinct cell clusters within each tissue source, taking into consideration differentially expressed genes (DEGs). Pseudotime analysis was performed to predict the developmental trajectory of cells from the least differentiated to the most differentiated state. To simulate the tumor microenvironment, PMN-MDSCs derived from BM and AF were conditioned with pleural fluid (PF)

Result and discussion

ScRNA-seq analysis revealed that each PMN-MDSC subpopulation was segregated separately based on tissue origin, highlighting significant heterogeneity and functional diversity. Notably, conditioning with PF induced maturation of PMN-MDSCs and significantly increased their immunosuppressive activity. The identified factors were shown to promote PMN-MDSC maturation. A key result is that cytokines involved in the maturation of PMN-MDSC induce the expression of CD88a, a receptor involved in the formation of NETs (Neutrophil Extracellular Traps), and increases their NETosis capacity. PMN-MDSCs conditioned with PF showed gene expression patterns similar to those of PMN-MDSCs derived from peripheral blood (PB), suggesting the activation of immunosuppressive pathways.

Conclusion

PMN-MDSCs do not represent a monolithic population but rather a diverse collection of cells with distinct functional capabilities, which are influenced by their location and the surrounding tissue microenvironment. The results obtained highlight that modulating cytokines present in TME or CD88a signaling could represent a promising therapeutic approach to potentiate anti-tumor immunity. The study provides a detailed overview of the heterogeneity and dynamism of PMN-MDSCs, with a focus on the impact of the tissue microenvironment on their function, maturation, and ability to form NETs, suggesting new therapeutic strategies targeting these cells in pathological settings.

EACR25-2058

Chemotherapy Modulates the Immune Microenvironment and Epigenetic Landscape in MLL-AF9-Driven Acute Myeloid Leukemia

A. Santoro¹, A. Zangari¹, N. Gualandi¹, E. Carsana¹, T. Volpari², S. Fusco¹, K. Giannetti¹, A. Anselmo³, C. Lo Celso⁴, R. Di Micco⁵

⁵*University School for Advanced Studies IUSS, Pavia,*

Italy, San Raffaele Telethon Institute for Gene Therapy, Pavia, Italy

Introduction

Acute Myeloid Leukemia (AML) is an aggressive blood cancer characterized by the expansion of immature myeloid cells in the bone marrow (BM), leading to hematopoietic failure. AML remains associated with poor prognosis, due to early treatment failure and high relapse rates following intensive chemotherapy. Here, we investigated how chemotherapy reshapes the immune microenvironment in a murine model of AML to identify tumor vulnerabilities and enhance immune responses and treatment outcomes.

Material and method

MLL-AF9-transformed murine AML cells were transplanted into immunocompetent mice without myeloablation, followed by a standard chemotherapy regimen (5+3 days of Daunorubicin and Cytarabine). BM and spleen (SPL) were analyzed two days post-treatment for immune cell composition using flow cytometry. Single-cell RNA sequencing (scRNA-seq) examined transcriptional changes, and histone modifications were assessed via western blot.

Result and discussion

scRNA-seq identified five leukemic clusters: one monocytic non-cycling and four granulocyte-monocyte progenitor (GMP)-like clusters with distinct cell cycle and inflammatory states. While chemotherapy reduced overall leukemic burden, all clusters were maintained but cycling and inflammatory GMP-like clusters were slightly increased. However, none of the tumor clusters upregulated senescence signatures, and instead down-regulated inflammatory and interferon (IFN) pathways, indicating weak immune activation. In the non-leukemic compartment, T and NK cells showed no significant IFN activation post-chemotherapy, while inflammatory pathways were upregulated in monocyte/macrophage subpopulations. Quantitative Flow cytometry revealed a decrease in macrophages and an increase in monocytes in the BM. To investigate potential immune suppression mechanisms, we analyzed the epigenetic remodeling in leukemic cells. Expression of EZH2, the functional enzymatic component of the Polycomb Repressive Complex 2 (PRC2), was heterogeneous but upregulated in most GMP-like tumor clusters post-chemotherapy. Additionally, genes associated with H3K27me3 histone modification were downregulated, suggesting increased H3K27me3 levels, further confirmed via western blot analyses, highlighting EZH2 as a potential immunotherapeutic target.

Conclusion

Our findings indicate that chemotherapy reshapes the immune microenvironment in MLL-AF9 AML by modulating myeloid populations but fails to induce a strong IFN response or robust immune activation. The weak senescence signature in BM-derived leukemic cells suggests that chemotherapy alone is insufficient to trigger immunogenic senescence. Additionally, the upregulation of EZH2 and increased H3K27me3 levels suggest an epigenetic mechanism contributing to immune evasion and leukemia persistence. Targeting EZH2 may enhance immune activation, offering a potential therapeutic strategy to improve AML clearance.

⁴Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisboa, Portugal

⁵Instituto CUF de Oncologia, Lisboa, Portugal

Introduction

Neoadjuvant chemotherapy remains the standard of care for high-risk or inoperable breast cancer (BC) tumors, yet its success rate falls below 50%, highlighting the need for better strategies. T cell-based therapies, involving ex vivo expansion of patients' T lymphocytes, have emerged as a promising alternative, particularly for chemotherapy-resistant tumors, but their efficacy is often limited. Building on our previous findings that the antigen-presenting molecule, HLA-DR, is crucial in tumor infiltrating cytotoxic T lymphocytes (CTLs) for a favorable response to neoadjuvant chemotherapy, we further investigated the role of HLA-DR-expressing CTLs in anti-tumor responses and evaluated strategies to amplify these cells.

Material and method

To elucidate the role of HLA-DR in improving CTL-mediated tumor elimination, we conducted in vitro and in vivo experiments using zebrafish xenograft models. Then, aiming at increasing the population of HLA-DR-expressing CTLs, we optimized an ex vivo stimulation protocol using cells isolated from peripheral blood. Additionally, we tested the potential of different immune agents to boost their cytotoxicity against BC cells. This study included 209 BC patients, from whom both blood and tumor biopsy samples were collected, and 32 healthy donors who provided blood samples. These samples were used across all in vitro assays, including CTLs expansion, functional evaluation, and screening experiments.

Result and discussion

Our findings revealed that only CTLs expressing HLA-DR effectively eliminate tumor cells. Moreover, CD4⁺ T cells were identified as essential drivers of CTLs activation and cytotoxicity. Indeed, blocking HLA-DR or depleting CD4⁺ T cells impaired CTLs function, underscoring the importance of this interaction for therapeutic success. Notably, our study revealed that short-term stimulation increased HLA-DR expression while preserving CTLs functionality, whereas prolonged expansion diminished their effectiveness, underscoring the importance of prioritizing cell quality over quantity. Furthermore, we demonstrated that PD-1 blockade with

nivolumab further upregulated HLA-DR levels, amplifying CTL-mediated tumor cell killing.

Conclusion

Overall, our results emphasize the critical role of HLA-DR in T cell-based therapies and highlight the synergistic benefits of ex-vivo PD-1 treatment along with short-term stimulation in enhancing CTLs efficacy. These insights pave the way for improved immunotherapeutic strategies for chemotherapy-resistant BC.

EACR25-2069

Profiling the tumor-resident intracellular microbiota in small cell lung cancer and its influence on chemotherapy sensitivity

W. Zhang¹, Y. Li¹, X. Liu¹, J. Nie¹, Z. Chen¹, L. Ye¹, Q. Zhang¹, Y. He¹

¹Shanghai Pulmonary Hospital, Shanghai, China

Introduction

Small cell lung cancer (SCLC) is an aggressive subtype of lung cancer with a poor prognosis, often characterized by rapid relapse and resistance to chemotherapy. At present, the mechanism of chemoresistance in small cell lung cancer has not been fully elucidated. Notably, increasing evidence suggests that tumors harbor diverse microbiomes. Similar to the gut microbiome, the intratumoral microbiota has recently garnered attention for its capacity to modulate metabolism and the tumor microenvironment, thereby influencing the biological characteristics of tumor development. However, the role of the intratumoral microbiota in SCLC remains far less understood.

Material and method

Tumor samples were collected from 71 patients with SCLC at Shanghai Pulmonary Hospital between 2020 and 2022. A comprehensive analysis of the tumor-resident intracellular microbiota in SCLC was conducted using 16S rRNA gene sequencing. The intracellular bacterial communities were profiled, and their correlation with clinical outcomes was assessed.

Result and discussion

Our analysis revealed a diverse intracellular microbiota within SCLC tumors, with significant variations in bacterial composition among patients. Smoking significantly alters the intratumoral microbiota in SCLC, with LDA Effect Size analysis indicating higher abundance of Lactobacillales and Rothia in smoking patients. The presence of certain bacterial taxa, particularly Clostridium species, was associated with increased chemotherapy sensitivity. Additionally, survival analysis showed that patients with a higher abundance of Clostridium had longer progression-free survival. As Clostridium is primarily involved in short-chain fatty acid metabolism, we speculate that it may influence chemotherapy sensitivity by modulating tumor cell metabolism through the production of metabolites such as butyrate and propionate.

Conclusion

In conclusion, the tumor-resident intracellular microbiota in small cell lung cancer SCLC is associated with chemotherapy sensitivity and clinical outcomes, with certain Clostridium species linked to enhanced chemotherapy response. Our findings suggest that tumor-resident microbiota, albeit at low biomass, play an important role

in chemotherapy response, intervention of which might therefore be worth exploring for advancing oncology care.

EACR25-2090

Targeting CAIX in tumor microenvironment stimulates anti-tumor immune response

L. Škvarkova¹, M. Baratova¹, M. Bartošova¹, K. Ščasna¹, J. Hantabal², M. Zaťovičová^{2,4}, J. Pastorek⁴, L. Csaderová¹, E. Eruslanov⁵, E. Svastová¹

⁴MABPRO, a.s., Bratislava, Slovakia

⁵University of Pennsylvania, Department of Surgery, Perelman School of Medicine, Philadelphia, United States

Introduction

In solid tumors, the tumor microenvironment (TME) is often characterized by inflammation, hypoxia, and acidosis, which significantly impact cancer progression. These attributes of the TME substantially contribute to forming an immunosuppressive environment and influence cytokine production, immune cell recruitment, and their function. Carbonic anhydrase IX (CAIX), a hypoxia-induced enzyme, plays a crucial role in tumor cell adaptation to low oxygen conditions and generating an acidic tumor microenvironment. However, the role of CAIX in regulating anti-tumor immune responses has not been extensively investigated, and thus, it was a goal of this study.

Material and method

Spheroids of pancreatic ductal adenocarcinoma cells (PDAC) were established and treated with anti-CAIX combinatorial therapy using an inhibitor of CAIX enzymatic activity, SLC0111, and CAIX-specific antibody, M75. The infiltration of spheroids with immune cells and spheroid cell viability were evaluated using a Cytation instrument. RNA samples of PDAC cells were analyzed for cytokine expression by RT2 Profiler Array. RNA samples of CAIX+ and CAIX-silenced fibrosarcoma cells were analyzed by Clariom followed by unsupervised clustering. Gene Set Enrichment Analysis (GSEA) was used to analyze gene expression. The relationship between CAIX levels and gene sets identified by GSEA was also analyzed in TCGA sarcoma samples and pancreatic cancer. Human T cell responses were evaluated in the presence of culture media collected from CAIX+ and CAIX- cells by flow cytometry.

Result and discussion

We found that combination therapy against CAIX, or silencing CAIX expression, led to enhanced infiltration of immune cells into spheroids. CAIX-suppressed spheroids exhibited a higher degree of cancer cell death. Differential gene expression analysis of PDAC cells treated with combinatorial therapy and CAIX-silenced fibrosarcoma cells revealed the upregulation of genes involved in anti-tumor immune responses. T cell activation assays showed that conditioned media from

CAIX+ tumor cells dramatically inhibited T cell responses, while conditioned media from CAIX-silenced cells increased activation of CD8 T cells. Furthermore, GSEA analysis identified that attenuation of CAIX expression is associated with the upregulation of genes involved in IFN-γ, IFN-α, and inflammatory responses. A negative correlation between CAIX levels and these immune pathways, which predicted better overall survival, was confirmed by *in silico* analysis of cancer patient samples.

Conclusion

We found that besides the known effects of CAIX on the survival of tumor cells in hypoxia, the activity of this enzyme plays an important role in the suppression of anti-tumor immune responses. Thus, targeting CAIX may represent a new opportunity to create a favorable milieu for anti-tumor immune responses in the TME.

Rapid and Ficoll-free Magnetic Isolation of Human Monocytes from Whole Blood in High Purity and Yield

I. Gessner¹, C. Zimmer¹, C. Langer¹, U. Bissa¹, A. Baranska¹, G. Winkels¹, J. Bödder², J. de Vries², J. Fauerbach¹, C. Dose¹

¹Miltenyi Biotec, R&D Reagents, Bergisch Gladbach, Germany

²Radboud Institute for Molecular Life Sciences (RIMLS), Department of Medical Biosciences, Nijmegen, Netherlands

Introduction

Monocytes and their derived differentiated cell types, such as monocyte-derived dendritic cells (moDCs), myeloid-derived suppressor cells (MDSCs), macrophages, and tumor-associated macrophages (TAMs) play a crucial role in cancer research and cell-derived therapies. Thus, ensuring robust, reliable and efficient procedures for their process generation is fundamental. Herein, we present a magnetic separation procedure based on new technology for a rapid, scalable and efficient isolation of human monocytes from whole blood in a ficoll-free process. This method enables the isolation of pan-monocytes (CD14+/CD16+) from human whole blood within 35 minutes. It offers a significantly shorter processing time compared to other magnetic cell separation techniques, which involve labor- and time-consuming steps to obtain peripheral blood mononuclear cells (PBMCs).

Material and method

The isolated monocytes were analyzed via flow cytometry for cell count and purity and tested for unspecific cell activation. Moreover, the differentiation potential of the isolated monocytes was evaluated by *in vitro* cell differentiation assays to yield moDCs, classically activated macrophages (M1) and alternatively activated (M2) type macrophages, as well as MDSCs. Additionally, co-culture experiments of moDCs with autologous T-cells were performed to investigate the stimulation performance of moDCs.

Result and discussion

Our isolation method resulted in a highly pure (>90%) untouched CD14+ monocyte population, with no unspecific cell activation, demonstrating their suitability for downstream applications. Moreover, isolated monocytes could be successfully differentiated into moDCs, M1 and M2 type macrophages, as well as MDSCs. Co-culture experiments of moDCs with autologous T cells demonstrated their successful ability to stimulate antigen specific T cells proliferation.

Conclusion

Based on these results, we introduce a new and highly efficient magnetic cell separation protocol that enables the rapid, scalable and ficoll-free isolation of human monocytes from whole blood. This will facilitate downstream applications including immunotherapy and cancer research.

EACR25-2120

Two-in-One: New Opportunities for Autologous Co-Isolation of T and B Cells from Small Blood Samples

R. Königsmark¹, H. Ahmed¹, S. Höher-Peters¹, M. Lang¹, S. Vergani¹, G. Winkels¹, J. Fauerbach¹, C. Dose¹

¹Miltenyi Biotec B.V. & Co. KG, Research & Development, Bergisch Gladbach, Germany

Introduction

Immunomagnetic cell isolation plays a key role in studying specific cell populations, enabling their respective contributions driving immunological reactions. Current separation methods are restricted to isolate one target population at a time, necessitating sample splitting or sample relabeling. Thus, these conventional approaches compromise on cell yield and limiting studies on autologous derived cells. With the MACSprep™ CD3 and CD19 Selection Kit, Miltenyi Biotec offers a new cell separation workflow to generate T and B cells from limited human blood samples in manual and automated processes. This newly developed workflow was established on the autoMACS® NEO as a fully automated cell separation device therefore also enabling simultaneous multi-cell separations as shown here.

Material and method

Expanding the previously developed StraightFrom® REAlease® approaches, the described innovative cell separation technology of the selection kit combines orthogonal release mechanisms that allow simultaneous labeling and sequential elution of target cells from a single MACS column. In this study, we demonstrate the efficacy of the cell separation process by co-isolating CD3+ T cells and CD19+ B cells from human whole blood with high purities and the comparability between manual and automated processes via the autoMACS NEO device. Furthermore, isolated cells were dissociated from separation labels using the benefits of the REAlease technology and taken into cell culture, to verify their naïve expression of activation markers and maintenance of full functionality upon stimulation.

Result and discussion

The results showcase high purities and recoveries achieved through the co-isolation of CD3+ T cells and CD19+ B cells from human whole blood by the MACSprep™ CD3 and CD19 Selection Kit even down

to small starting volumes of 0.5 mL. The fully automated separation via the autoMACS NEO device allows comparable results to manual separation with minimal hands-on-time. Upon cell culture, no expression of specific surface activation markers in absence of stimuli for either CD3+ T cells or CD19+ B cells was observed.

Conclusion

This novel cell separation technology represents a significant advancement in immunomagnetic cell isolation, offering a smart workflow solution for classical multi-cell isolation from single complex and quantity-limited blood samples accompanied with walk-away, standardized automation processes. Therefore, it holds promise for accelerating research in cancer immunology, investigation of autologous derived cell populations and vaccines dealing with limited starting materials requiring precise cell isolation techniques.

EACR25-2125

In vitro investigation of *Parvimonas micra*'s role in colorectal cancer progression

M. Rubio Garcia¹, W. Rosenbaum¹, A. Löfgren Burström¹, S. Edin¹, S. Nyunt Wai², R. Palmqvist¹, V. Bronnec¹

¹Umeå University, Medical Biosciences, Pathology, Umeå, Sweden

²Umeå University, Molecular Biology, Umeå, Sweden

Introduction

Colorectal cancer (CRC) is the second-leading cause of cancer related deaths. Several risk factors contribute to CRC development, some of which can be non-modifiable (e.g. age, genetic predisposition, inflammatory bowel), while others can be modifiable (e.g. smoking, alcohol consumption, western-style diet, low fiber intake, physical inactivity). Recent studies have shown an association between gut microbiota and CRC progression. Those risk factors can disrupt the bacterial symbiotic relationship in the human gut, leading to imbalances in microbial composition called dysbiosis. Dysregulation in the gut microbiota has been linked to CRC development. Recent studies have highlighted some onco-pathogens, such as *Fusobacterium nucleatum*, *Parvimonas micra*, and *Peptostreptococcus stomatis*, as being associated with CRC, but their exact role in tumor progression remains unclear.

Material and method

Full-length 16S sequencing alongside qPCR analysis has been used to identify and quantify the relative abundance of *P. micra* in clinical samples. The presence of *P. micra* was also correlated with other CRC-associated bacteria. To further investigate these microbial interactions and their potential role in CRC progression, multiple clinical strains of *P. micra* were evaluated for their ability to form biofilms, as well as their interactions with other CRC-related bacteria in biofilm formation. To assess the impact of *P. micra* on CRC progression, cell proliferation and migration assays were conducted using different CRC cell lines. Western blot analysis was performed on protein extracts from CRC cell lines infected with *P. micra* to evaluate the activated pathway.

Result and discussion

Results from qPCR analyses and 16S rDNA sequencing confirmed the association of *P. micra* with CRC, in line with our previous findings. Biofilm analysis showed an increase in biomass when *P. micra* was co-cultured with *F. nucleatum* and *P. stomatis*, suggesting a possible synergistic microbial interaction. Factors secreted by *P. micra* were found to enhance CRC cell proliferation and migration, indicating that the bacterium may promote tumorigenic process. Preliminary protein expression analysis showed upregulation of autophagy-related markers (P21, LC3B), suggesting activation of autophagy pathways. Additionally, a high concentration of *P. micra* heat shock protein HSP60 (also known as GroEL) was detected in the bacterial supernatant, suggesting a potential role in host-pathogen interactions.

Conclusion

Our findings support a role for *P. micra* in CRC progression and suggest a possible link to other onco-pathogen through the biofilm synergy. Moreover, *P. micra* might induce autophagy as a survival mechanism via the release of bacterial HSP60. These findings highlight a potential crosstalk between microbial biofilm formation, autophagy induction, and CRC progression positioning *P. micra* as an important factor within the tumor microenvironment.

EACR25-2127

Targeting TLR2 improves the efficacy of breast cancer therapies

A. Di Lorenzo¹, C. Cossu¹, E. Bolli¹, E. Di Gregorio¹, C. Romiti¹, N. Solari¹, G. Donofrio², F. Cavallo¹, G. Ferrauto¹, L. Conti¹

¹*University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy*

²*University of Parma, Department of Medical-Veterinary Science, Parma, Italy*

Introduction

Despite significant progress in its treatment, breast cancer (BC) remains the leading cause of cancer death in women. Therefore, the development of combination therapies able to target key cancer-inducing or cell-sustaining pathways is needed. We have previously demonstrated that Toll-like receptor 2 (TLR2) promotes CSC self-renewal, breast cancer progression and resistance to chemotherapy due to DAMPs binding. TLR2 inhibition restores and potentiates doxorubicin anti-tumor effect in vitro and in vivo. In addition, TLR2 seems to regulate the expression of the cystine/glutamate antiporter xCT, which controls redox balance and mediates several pro-tumoral mechanisms. The role of xCT in breast cancer is largely studied by our group and different vaccines have been developed to target this antigen with promising results in pre-clinical models. In this study, TLR2 targeting is exploited to improve the efficacy of both chemo- and immunotherapy as a new strategy for breast cancer treatment.

Material and method

We analyzed the effects of TLR2 inhibitors in combination with chemotherapies or inhibitors of the cystine-glutamate antiporter xCT, a promising BC target. 4T1 tumor-bearing mice were treated with nanosystems

delivering TLR2 inhibitors in combination with chemotherapy and xCT immunotargeting.

Result and discussion

TLR2 conferred resistance to immunogenic cell death inducers such as some chemotherapies or xCT inhibitors in BC cells. Treatment with TLR2 inhibitors induced apoptosis of BC cells, and a synergistic effect was observed with chemotherapy or xCT inhibitors. Nanoparticle-mediated delivery of TLR2 inhibitors significantly impaired tumor progression in vivo, and their combination with chemotherapy or xCT immunotargeting further improved these effects.

Conclusion

In conclusion, TLR2 mediates several pro-tumoral mechanisms including chemoresistance. TLR2 inhibition improves the efficacy of chemo- and immunotherapies opening new perspectives for the treatment of breast cancer.

¹¹*Eberhard Karls University, Cluster of Excellence iFIT (EXC 2180), Tübingen, Germany*

Introduction

Intratumoral bacteria are increasingly recognized as influential within the tumor microenvironment (TME). However, their role remains poorly unexplored in hepatocellular carcinoma (HCC), the third most common cause of cancer-related death worldwide. We recently reported two distinct HCC TME subtypes in patients

treated with atezolizumab+bevacizumab (atezo+bev): ImmunePos, enriched with CD8+ T effector cells and CXCL10+ macrophages and associated with atezo+bev responses, and ImmuneNeg, lacking immune cell infiltration. Here, we aimed to explore the clinical relevance of tumor resident bacteria in response to atezo+bev in HCC.

Material and method

We characterized the intratumoral microbiome in 290 HCC samples from patients treated with atezo+bev (n=247) and atezo alone (n=43) from the IMbrave150 and GO30140 clinical trials. RNAseq was used to profile the HCC resident microbiome at the genus level.

Microbial content was identified by screening transcriptomic reads using the PathSeq pipeline within the Genome Analysis Toolkit. Reads aligning to the human GRCh38 genome were removed, and the remaining reads were mapped to microbial reference genomes. To filter out contaminants and adjust for batch effects, we retained only genera with a relative abundance of $\geq 10\%$. The association between bacterial prevalence (relative abundance present in > 10% of samples) and abundance with progression-free survival (PFS), overall survival (OS), and our TME classification was evaluated.

Result and discussion

Here we show that the prevalence of *Bacillus* in HCCs of atezo+bev treated patients, was associated with a significantly longer PFS ($p = 0.006$) and a trend toward prolonged OS ($p = 0.075$) compared to those without *Bacillus*. In addition, *Bacillus* prevalence and abundance were significantly higher in atezo+bev responders (prevalence: $p = 0.0029$, abundance: $p = 0.0032$ vs non-responders) but not in responders to atezo alone. Especially, ImmunePos responders to atezo+bev, were significantly enriched with *Bacillus* (prevalence: $p = 0.0009$ vs non-responders; abundance: $p = 0.01$ vs ImmuneNeg responders; $p = 0.0002$ vs non-responders).

Conclusion

We identified *Bacillus* specifically associated with a significantly longer PFS and a trend towards longer OS in atezo+bev-treated HCC patients. Moreover, responders to atezo+bev, particularly those with ImmunoPos characteristics, showed significantly higher abundance and prevalence of *Bacillus*, which suggests that TME has a role in determining the bacterial landscape.

⁵*University Hospital Miguel Servet, Department of Paediatric Oncology and Hematology, Zaragoza, Spain*

⁶*University Hospital Lozano Blesa, Aragon Health Research Institute (IISA); CIBERESP; ARAID, Cancer Heterogeneity and Immunomics, Zaragoza, Spain*

Introduction

Immunotherapy has revolutionized treatment of adult cancers in the last decades. Nevertheless, it is not as effective for paediatric cancers, probably due to differences in their immune system and intrinsic characteristics of tumours. Indeed, tumour microenvironment of paediatric tumours has not been fully studied, and little is known about neoantigenicity of mutations. The main aim of this work was to characterize the tumour microenvironment of paediatric neuroblastoma using spatial transcriptomics. The final goal was to identify putative tumour neoantigens in paediatric neuroblastoma patients to study their role as biomarkers or therapeutic strategy.

Material and method

We analysed four FFPE samples of paediatric neuroblastoma patients from Hospital Miguel Servet (Zaragoza, Spain). Spatial transcriptomics was conducted using Visium Spatial Gene Expression kit (10x Genomics) and sequenced using NovaSeq (Illumina). Resulting data were analysed using Space Ranger (10X genomics), Loupe Browser (10x Genomics), and the R package Seurat. To identify potential neoantigens, we used a training cohort ($n = 1089$) and a validation cohort ($n = 225$) from cBioPortal and bioinformatic tools such as NetMHCpan.

Result and discussion

Preliminary results from spatial transcriptomics allowed identification of different transcriptomic clusters, confirming the heterogeneity and complexity of the tumour microenvironment. In some samples, the antigen presentation pathway mediated crosstalk between two adjacent tumour regions, one of them showing a greater infiltration of immune cells. We are currently evaluating differential gene expression among the different types of cells of the tumour microenvironment. We found that patients with a higher number of neoantigens had worse overall survival. To evaluate the feasibility of neoantigens as potential therapeutic strategies, we studied the recurrence of neoantigens among patients. Despite most neoantigens were private, two immunogenic mutations were recurrent. Interestingly, these mutations associated with worse patient prognosis. We then confirmed neoantigenicity of these mutations using other prediction tools focused on different steps of antigen presentation.

Conclusion

Altogether, studying the tumour immune microenvironment could be useful to identify patients that will benefit from immunotherapy. Furthermore, targeting neoantigens could be a therapeutic strategy for paediatric solid tumours.

This study was supported by Asociación de Padres de Niños con Cáncer de Aragón (ASPAHOA).

EACR25-2151

Paracrine and Neoplastic Effects of D-2HG

C. Slater^{1,2,3}, A. Tron³

¹Gustave Roussy, Paris, France

²Harvard University, Boston, United States

³Servier Pharmaceuticals, Boston, United States

Introduction

In intrahepatic cholangiocarcinoma (iCCA), 13% of patients exhibit Isocitrate Dehydrogenase 1 (IDH1) mutations, resulting in the production of the onco-metabolite R-2-hydroxyglutarate (2-HG). Ivosidenib (Tibsovo®) targets this mutation and lowers 2-HG levels, yet often only achieves partial clinical responses. Here we hypothesize that despite potent reduction of 2-HG by ivosidenib, remaining residual levels of 2-HG inhibiting sensitive enzymes result in suboptimal efficacy. This research examines 2-HG's targets and its effects on neoplastic and immune cells.

Material and method

Neoplastic Effects: We will compare the effect of genetic versus pharmacological (ivosidenib) depletion of 2-HG in genetically modified iCCA mouse cell lines expressing mutant IDH1 (mIDH1). The role of 2-HG gene targets will be investigated using sub-targeted screens, transcriptomics, epigenetic profiling, and in-vivo studies.

Paracrine Effects: Clinical findings suggest that the immunosuppressive tumor microenvironment of mIDH1 tumors is due in part by the inhibitory effect of 2-HG on T-cells. We will explore T-cell immunity in mIDH1 tumor-harboring mice and engineer T-cells to prevent intrinsic 2-HG accumulation. Using genetic screens in T-cells, we aim to identify mechanisms to overcome 2-HG-induced immunosuppression that could enhance T-cell infiltration and function.

Result and discussion

Anticipated findings include identifying genes inhibited by 2-HG despite ivosidenib treatment, clarifying their roles in mIDH1 biology and treatment outcomes. We also expect to reveal the effects of 2-HG's influence on immune evasion and immunological mechanisms impacting treatment efficacy.

Conclusion

This study aims to elucidate 2-HG's targets, proposing strategies to enhance clinical outcomes by minimizing 2-HG levels and uncover new pathways that, when inhibited, could increase ivosidenib efficacy.

Differential Impact of *Staphylococcus aureus* Infection on Lung Cancer and Normal Bronchial Cells

D. Ece¹, G. Mukhtarova¹, U. Mert¹, A. Caner^{1,2}, T. Göksel³, G. Gökmén⁴

¹Ege University, Basic Oncology, Izmir, Turkey

²Ege University, Parasitology, Izmir, Turkey

³Ege University, Pulmonary Medicine, Izmir, Turkey

⁴Ege University, Food Engineering, Izmir, Turkey

Introduction

Staphylococcus aureus (*S. aureus*) infection is a frequent complication in lung cancer patients, accounting for up to 70% of infectious issues. Traditionally seen as an

extracellular pathogen, *S. aureus* is now recognized for its ability to survive and replicate intracellularly within tumor tissues. This intratumor invasion can trigger inflammatory pneumonia, obstructive pulmonary diseases, and secondary infections, potentially leading to organ dysfunction. Despite advances in cancer treatments, these infections remain a major cause of mortality, emphasizing the urgent need for improved strategies to manage bacterial complications in lung cancer patients. This study aims to elucidate the molecular and cellular effects of *S. aureus* infection on lung cancer and normal bronchial epithelial cells.

Material and method

The effects of *S. aureus* infection at 1:25, 1:50, and 1:100 ratios on A549 lung cancer and BEAS-2B bronchial epithelial cell lines were established. Intracellular infection was visualized using Giemsa staining. The intracellular *S. aureus* burden was quantified through CFU analysis, and the infection index was subsequently calculated. Cell cycle and apoptosis assay using flow cytometry. Immunofluorescence staining was conducted to detect DNA damage induced by the infection. To assess metastatic potential, colony formation assays, invasion and migration assays were performed. CD44/133 staining was utilized to explore stem cell-like properties. The expression levels of key genes involved in cancer progression, apoptosis, and migration were examined using RT-PCR.

Result and discussion

The findings of this study highlight the significant effects of *S. aureus* infection at varying rates on both the A549 and the BEAS-2B cell lines. The results demonstrated that *S. aureus* infection significantly impacted various cellular processes, including apoptosis, cell cycle, DNA damage, and metastatic / stemness potential in A549 cells than BEAS-2B cells. Additionally, alterations in gene expression related to cancer progression, apoptosis, and migration were detected, providing valuable insights into the molecular mechanisms underlying the interaction between *S. aureus* and both lung cancer and normal bronchial epithelial cells. These findings contribute to a deeper understanding of the role of bacterial infection in cancer biology and its potential implications for cancer progression and treatment.

Conclusion

This study revealed that *S. aureus* infects both lung cancer and normal bronchial epithelial cells, but lung cancer cells are more vulnerable to intracellular invasion and dysfunction. These differential effects underscore the need for further research into the underlying molecular mechanisms to develop targeted therapies that address both cancer progression and associated bacterial infections, ultimately improving outcomes for lung cancer patients.

Glucocorticoid Receptor: An Oncosuppressor 'Immune-dependent' in EGFR-driven Lung Adenocarcinoma

S. Trouvilliez¹, L. Czeloth¹, M. Homolya¹, M. Beres¹, C. Trenk¹, E. Casanova¹, H. Moll¹

¹Institute of Pharmacology, Medical University of Vienna, Vienna, Austria

Introduction

Lung cancer is the leading cause of cancer-related deaths worldwide due to its aggressive nature, with oncogenic mutations in EGFR being one of the most common genetic drivers of this disease. In particular, lung adenocarcinoma (LUAD), the most common subtype of lung cancer, often forces patients to endure significant physiological stress, leading to the production of cortisol. However, the consequences of physiological glucocorticoid receptor (GR) mediated signaling in LUAD is not well described. Interestingly, GR expression is downregulated in tumors in comparison to healthy parenchyma with lower GR expression correlating with poorer patient survival outcome.

Material and method

We use autochthonous mouse models of lung tumorigenesis to study the impact of tumor cell intrinsic GR signaling in EGFR driven lung tumors, supplemented by *in vitro* experiments.

Result and discussion

GR deletion in EGFR driven lung tumor cells promotes tumor initiation and progression, resulting in drastically reduced survival, in immunocompetent mice. *In vitro*, however, GR deficient tumor cells proliferate slower, and also following transplantation into immunodeficient mice. This discrepancy suggests a pivotal role of the tumor microenvironment in GR's tumor-suppressive effects. Indeed, loss of GR results in an immuno-suppressive microenvironment characterized by lower cytotoxic and helper T cells and increased myeloid derived cells and tumor associated macrophages. To stronger emphasize the impact of the immune microenvironment, we then implemented more immunogenic mouse models where cancer cells express the neoantigen ovalbumin. Intriguingly, mice harboring GR deficient, OVA expressing tumors exhibited increased tumor burden not only compared to GR and OVA expressing controls, but also compared to the non-OVA, GR deficient group. This suggests that GR deficient tumor cells hijack infiltrating T cells to boost tumorigenesis. In addition, by multiplex cytokine assay, we discovered that bronchoalveolar lavage derived from tumor intrinsic deficient GR mice present an higher level in TGF β and CXCL12 which might promote the tumor immunosuppressive microenvironment and the tumor growth.

Conclusion

We identified tumor intrinsic GR signaling as a powerful tumor suppressor in EGFR driven LUAD, with its loss resulting in a tumor promoting tumor microenvironment. These findings may have major impact on current treatment strategies, including the outcome of osimertinib therapy.

BAP1 deletion disrupts IFN- γ signaling and sensitizes ASXL1 mutated myeloid leukemia cells to NK cell cytotoxicity

C. Badami¹, L. Kristenson¹, F. Svensson¹, T. Kathirkamanathan², F. Bergh Thorén¹

¹TIMM Laboratory at Sahlgrenska Center for Cancer Research, University of Gothenburg, Department of Medical Biochemistry and Cell Biology, Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

²TIMM Laboratory at Sahlgrenska Center for Cancer Research, University of Gothenburg, Gothenburg, Sweden

Introduction

Natural Killer (NK) cell recognition and killing of malignant cells involve multiple structures expressed by NK cells and target cells. Here, we analyzed multiple genome wide CRISPR screens to identify genes of importance for K562 cell susceptibility and resistance to NK cell cytotoxicity. A recurrent hit in multiple screens was the BRCA1-associated protein 1 (BAP1) gene that was found to protect K562 cells from NK cell cytotoxicity. BAP1 is a tumor suppressor gene that encodes a deubiquitinating enzyme that modulates multiple cellular processes. Germline BAP1 mutations are associated with tumor predisposition syndrome and somatic loss of function mutations have been frequently associated with various tumors. BAP1 is rarely mutated in leukemia, but it is reportedly implicated in the presence of Additional sex combs-like 1 (ASXL1) mutations.

Material and method

To determine how BAP1 affected cell susceptibility to NK cells, we generated BAP1 knock-out (KO) in K562 cells and exposed them to NK cells in functional assays. We also characterized BAP1 deficient cells with immunostaining and proteomic analysis. Moreover, we performed BAP1 knock-down (KD) in a series of ASXL1 wild-type and mutated myeloid leukemia cell lines.

Result and discussion

In the absence of interferon gamma (IFN- γ), BAP1 KO cells did not present with enhanced sensitivity to NK cells as suggested by the screen. However, IFN- γ -treated BAP1 KO cells triggered increased NK cell degranulation and were more sensitive towards NK cell killing than corresponding wild-type cells. Interestingly, in the presence of IFN- γ , BAP1-deficient cells failed to upregulate HLA class I expression that otherwise inhibited NK cell cytotoxicity. Further experiments revealed that these cells displayed reduced expression of the IFN- γ receptor 1. Interestingly, BAP1 knockdown in a series of myeloid leukemia cell lines selectively decreased HLA-E and IFN- γ receptor 1 expression in cell lines harboring ASXL1 mutations.

Conclusion

This study proposes a new role of BAP1 and provides further insight into biological consequences of targeting BAP1 in ASXL1-mutated myeloid leukemia suggesting a rationale for combining BAP1 inhibition and NK cell-based immunotherapy.

EACR25-2190

Notch3-Regulated miRNAs Target CXCR4 to Enhance Leukemic Cell Dissemination in T-ALL

C. Varricchio¹, F. Squillante², I. Sergio², S. Indraccolo³, S. Coni¹, M. Toribio⁴, S. González García⁴, M. Felli²

¹Sapienza University of Rome, Department of Molecular Medicine, Rome, Italy

²Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy

³University of Padua, Department of Surgery Oncology and Gastroenterology, Padua, Italy

⁴Centro de Biología Molecular Severo Ochoa, Consejo Superior de Investigaciones Científicas (CSIC), Universidad Autónoma de Madrid (UAM), Immune System Development and Function Unit, Madrid, Spain

Introduction

T-cell Acute Lymphoblastic Leukemia (T-ALL) is an aggressive malignancy driven by Notch-activating mutation, leading to thymocyte maturation arrest and uncontrolled proliferation. A key feature of T-ALL progression is the trafficking of leukemic cells between the thymus and bone marrow, where a protective microenvironment may support their expansion. We hypothesize that miRNA-mediated regulation of CXCR4 plays a crucial role in thymocyte escape and engraftment in the BM. In a Notch3-transgenic (N3-ICtg) mouse model, we observed an aberrant expansion of DNCD3 ϵ^+ CXCR4 $^-$ cells, suggesting a potential link between CXCR4 downregulation and Notch3 hyperactivation, along with a panel of upregulated miRNAs.

Material and method

To validate our mouse model findings in human T-ALL, we transfected TALL1 cells with miR150-5p mimics (100nM-200nM) and analyzed CXCR4 expression using qRT-PCR and FACS analysis. In Molt3 cells we silenced Notch3 and quantified miR139-5p and miR150-5p levels by qRT-PCR. ChIP assay was performed to assess the binding of RBPJK to the miR139-5p promoter in both TALL1 and Molt3 cells. To further investigate the Notch/CXCR4/miRNAs crosstalk, experiments were conducted using SupT1 cells stably expressing specific miRNAs via lentiviral transduction, along with T-ALL patient-derived xenograft and human T-ALL primary samples.

Result and discussion

We assessed the combined effect of the two miRNAs in transfected N3-dependent TALL1 cells, characterized by high miR139-5p and low miR150-5p, showing down-regulation of CXCR4. N3-knockdown in Molt3 cells resulted in decreased expression of both miRNAs, indicating a functional connection between Notch3 signaling and miRNA expression. ChIP assay revealed that RBPJK (Notch transcriptional effector) is efficiently recruited in both TALL1 and Molt3 cells, confirming its direct regulation by Notch signaling. To extend our results to human T-ALL patients, we analyzed and detected the inverse correlation between CXCR4 expression and miR150-5p and miR139-5p expression in a panel of PDX and patients' samples.

Conclusion

Our results confirm that miR139-5p and miR150-5p regulate CXCR4 in human T-ALL. Future studies will be conducted on human SupT1 cell line, possibly to explore miRNA release via extracellular vesicles (EVs) in the thymic microenvironment. In conclusion, these results suggest that Notch-induced miRNA deregulation may play a crucial role in the advanced stages of T-ALL by promoting leukemic cell dissemination and thymic dysfunction, ultimately identifying potential biomarkers for targeted new therapeutic strategies.

Macrophage-Mediated Fibrosis Drives Immunotherapy Resistance in Melanoma

M. Pandini¹, G. Meregalli¹, D. Mishra², G. Basso², G. De Simone², D. Di Mitr³

¹Humanitas University, Pieve Emanuele, Italy

²Humanitas Clinical and Research Center, Rozzano, Italy

³Humanitas University, Italy

Introduction

Macrophages represent the primary infiltrating immune subset in most cancer types and tumor-associated macrophages (TAMs) sustain tumor growth, promote invasion and mediate immune suppression. Cellular metabolism is implicated in the education of macrophages and dictates their phenotype. Interestingly, macrophages engulfed with lipids have been recently described in various cancers, including prostate, gastric cancer and melanoma. However, the mechanisms that drive lipid accumulation in macrophages and the consequences of such metabolic phenotype on cancer therapy remain uncovered.

Material and method

In this study, we applied high-throughput techniques, including single cell RNA sequencing and proteomic analysis to unravel the mechanisms responsible for lipid loading in macrophages and to explore the implications of lipid accumulation on functional activity of TAMs in melanoma.

Result and discussion

Our investigation confirmed that lipid accumulation is a distinct feature of tumor-infiltrating macrophages in melanoma. Notably, we observed that lipid-accumulation in TAMs correlates with tumor size and with the expression, by macrophages, of markers associated with immunosuppression, including Arginase-1 and PD-L1. Bulk RNA sequencing revealed that the CLEAR signaling pathway is deregulated in lipid-loaded macrophages compared to the lipid-deprived counterpart. Accordingly, we observed that the transcription factor EB (TFEB), master regulator of the CLEAR network, is dysfunctional in tumor-conditioned macrophages. In addition, autophagic flux is impaired in macrophages exposed to tumor cells, thus indicating a potential role of TFEB in promoting autophagy deficiency and lipid accumulation in TAMs. In the second part of the project, we explored the mechanisms triggered by lipid accumulation in TAMs. Notably, we discovered that lipid loaded macrophages can sustain a pro-fibrotic program and directly contribute to fibrosis, producing collagen and extracellular matrix (ECM)-related proteins. Importantly, inhibition of this pro-fibrotic program effectively prevented expression of genes related to ECM in macrophages and improved response to immunotherapy in melanoma models.

Conclusion

In conclusion, this project sheds light on mechanisms that contribute to lipid accumulation in TAMs and introduces innovative approaches to target lipid-loaded macrophages in melanoma. Based on our findings, we propose to target lipid accumulation in TAMs as a strategy to improve efficacy of current available immunotherapies, thus

representing an opportunity for advancing cancer therapy.

The ILC compartment in mismatch repair-deficient colorectal cancers is dominated by CD127-negative ILC1-like cells with cytotoxic activity

Z. Li¹, N. de Vries¹, J. Roeland¹, M. van den Ploeg¹, R. van der Breggen¹, M. IJsselsteijn¹, F. Koning¹, N. de Miranda¹

¹Leiden University Medical Center, Leiden, Netherlands

Introduction

The immune microenvironment of colorectal cancer (CRC) plays a critical role in patient prognosis. Our previous study identified an unconventional innate lymphoid cell (ILC) population ($\text{Lin}^- \text{CD7}^+ \text{CD127}^- \text{CD103}^+ \text{CD45RO}^+$) enriched in mismatch repair (MMR)-deficient CRCs, exhibiting hallmarks of cytotoxic activity. However, the specific role of this ILC subset in anti-tumor immunity remains poorly defined.

Material and method

To further characterize this subset, we employed single-cell RNA sequencing (scRNA-seq), single-cell mass cytometry, and imaging mass cytometry to define the phenotypic hallmarks of CD127⁻ ILCs in CRC. Additionally, we flow-sorted ILCs from colon tumors to assess their tumor-killing capacity in relation to Human Leukocyte Antigen (HLA) Class I expression on target cells.

Result and discussion

The predominant ILC population in MMR-deficient CRCs consists of CD127⁻CD103⁺ ILC1-like cells, followed by CD127⁻CD103⁻ NK-like cells and a minor subset of CD127⁺CD103⁻ conventional ILCs. These cells express the transcription factor TBX21 (T-bet) but lack Eomes expression. Furthermore, CD127⁻CD103⁺ ILCs exhibit a distinct molecular profile, expressing Killer-Immunoglobulin-like Receptors (KIRs), various co-inhibitory and co-stimulatory molecules, NKG2A, and HLA class II molecules. Functionally, CD127⁻CD103⁺ ILCs demonstrate cytotoxic activity against colorectal cancer cells.

Conclusion

Our findings reveal that CD127⁻CD103⁺ ILC1-like cells, distinct from NK cells and conventional ILCs, are enriched in MMR-deficient CRC. Their high NKG2A/CD94 expression suggests a potential mechanism for recognizing HLA Class I-deficient tumor cells. These results highlight the active role of ILCs in anti-tumor immunity and suggest their potential as targets for cancer immunotherapy.

Comprehensive Profiling of Transgenic Mouse Antibody Repertoires with High-Throughput Single Cell BCR and Whole Transcriptome Sequencing

A. Sapre¹, A. Salvino¹, G. Gallareta-Olivares¹, E. Papalex¹, J. Jacob¹, A. Kumar¹, K. Fedder-Semmes¹, N. Juiz¹, C. Roco¹, A. Rosenberg¹

¹Parse Biosciences, Seattle, United States

Introduction

Transgenic mouse models are excellent tools to model human antibody response against antigens or disease of choice, given their ability to undergo diversification, in vivo affinity maturation, clonal selection and clonal expansion in their natural immune environment. Current antibody discovery methods lack the scale required to fully screen the antibody repertoire of transgenic mouse models to uncover maximum desirable antibody hits per discovery campaign.

Material and method

Here, we demonstrate our novel combinatorial barcoding approach to enable high-throughput single cell BCR and whole transcriptome profiling of transgenic mouse samples with unprecedented sensitivity, scalability, and flexibility. As a proof of concept, we profiled over 1 million cells from multiple transgenic mice that were either naive or immunized with antigens of interest to obtain hundreds of thousands of paired BCR clonotypes.

Result and discussion

Using the whole transcriptome data, we detected all B cell subpopulations including plasma cells at single cell resolution. We then used the paired heavy and light chain BCR data to detect productive chains in the majority of B cells revealing both unique and expanded clonotypes. In the expanded clonotype pool we found specific patterns of VDJ utilization and amino acid motifs compared to the naive pool.

Conclusion

This method paves the way for high throughput screening of antibody repertoires from transgenic mice to allow for deep mining of repertoires for antibody discovery and therapeutic outcomes.

EACR25-2230

The lipid droplet metabolic hub regulates human NK cell function

S. NG¹, P. Strobl¹, N. Pietrosemoli², C. Chica², J. Di Santo², L. Surace¹

¹University of Bonn, Bonn, Germany

²Institut Pasteur, Paris, France

Introduction

Metabolic perturbations, including aberrant lipid metabolism, are characteristics of the tumor microenvironment and promote immune cell dysfunction. Natural killer (NK) cells can infiltrate tumors and play an integral role in tumor immunosurveillance. Metabolic dysregulation has been associated with impaired NK cell activity, resulting in enhanced tumor growth and an increased rate of metastasis. The effects of metabolically challenging environments on NK cell metabolism and pro-inflammatory and cytotoxic functions remain poorly understood.

Material and method

Blood samples from HDs were obtained from the Establisement Francais du Sang (Paris, France). Peripheral blood mononuclear cells (PBMCs) were isolated with Ficoll-Paque (GE Healthcare). Metabolomics: FACS-sorted fresh or cytokine activated NK cells (250,000 cells) were washed in ammonium carbonate (75 mM). Preheated (70 °C) 70% ethanol extraction solvent was added to extract metabolites. The

analysis was performed by General Metabolics as previously reported (Surace, *Nature Imm*, 2021). FACS: Cells were stained with surface antibodies and Viability Dye eFluor 506 (eBioscience) in phosphate-buffered saline/2% fetal calf serum for 30 minutes on ice. For intracellular staining, cells were stimulated for 18 hours, and Golgi Plug/Golgi Stop (BD) were added for the last 3 hours. Cells were fixed/permeabilized using Cytofix/Cytoperm (BD) and then stained. Samples were acquired using the LSRFortessa (BD) and analyzed by FlowJ10 software (Tree Star). Bodipy dyes (493 and FLC16 or 12) were used to assess fatty acid uptake and lipid droplet content.

Result and discussion

We profiled the metabolome of the two main circulating human NK cell subsets, the highly cytotoxic CD56Dim CD16+ and the cytokine-producers CD56Bright CD16-NK cells, by mass spectrometry. We found that both NK cell subsets are equipped with distinct diet- and host-derived metabolites at steady-state. Neutral lipids appeared to be enriched in CD56Dim NK cells compared with the CD56Bright NK cells and are stored in lipid droplets. Upon activation, both subsets showed a loss of metabolites and increased lactate production, consistent with previously reported high glycolytic rates in proliferating cells. However, only activated CD56Bright NK cells intensified lipid uptake and lipid-droplet biogenesis. Inhibition of fatty acid oxidation affected only cytokine production in CD56Bright NK cells, while Diacyl-glycerol O-acyltransferase 1 (DGAT1)-mediated lipid storage was crucial in orchestrating cytotoxicity and cytokine production in both subsets. Altogether, our data suggest lipid droplets are an essential organelle regulating NK cell biology.

Conclusion

Understanding how NK cell function is regulated and reprogrammed by lipid metabolism is beneficial for developing strategies to reverse NK cell dysfunction in tumors and inflammatory settings characterized by aberrant metabolism.

EACR25-2269

Immunomodulatory effects of HuR inhibition in EGFR-TKI resistant NSCLC cells

M. Casciello¹, A. Nigro², A. Cascone², V. Pagliara³, A. Napoli⁴, M. Bevilacqua⁴, F. Sabbatino³, V. Casolaro⁴, C. Stellato⁴, J. Dal Col⁴

³University of Salerno, Oncology Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana, Baronissi, Italy"

⁴University of Salerno, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana, Baronissi, Italy"

Introduction

Immunotherapy has produced positive results in patients with advanced non-small cell lung cancer (NSCLC),

except for those bearing a mutant epidermal growth factor receptor (EGFR). In particular, once resistance to EGFR-tyrosine kinase inhibitors (TKIs) is established, EGFR-mutant NSCLC patients do not benefit from therapy with immune checkpoint inhibitors (ICIs) despite PD-L1 expression. Acquired resistance to EGFR-TKI is associated with an immune suppressive phenotype, involving downregulation of class I HLA antigens expression and increased secretion of interleukin(IL)-6, IL-8 and transforming growth factor-(TGF) β . These factors are all targets of the RNA-binding protein (RBP) HuR, which regulates mRNA stability/translation of bound transcripts. Given the mounting role of HuR in cancer immune evasion, we investigated its function in modulating two mechanisms contributing to the poor response to ICIs in EGFR-TKI resistant cells: cytokine secretion and class I HLA expression.

Material and method

EGFR-TKI-resistant cell lines (HCC827GR/PC9GR/H1975OR) were generated by treating HCC827/PC9/H1975 cells with Gefitinib or Osimertinib. PC9- and H1975-HuR-KO were generated by CRISPR/Cas9 technology. KH-3 and SRI-42127 commercially available HuR inhibitors were used. Protein expression was analyzed by immunoblotting, confocal microscopy, flow cytometry. Cytokine secretion on cell supernatants was analyzed by ELISA assay and flow cytometry-based multiplex immunoassays.

Result and discussion

Confocal microscopy analysis identified increased cytoplasmic HuR, a feature of functional activation, in EGFR-TKI-resistant cells compared to parental cells. Levels of HuR targets IL-6 and IL-8 were significantly increased in EGFR-TKI-resistant cells respect to parental cells ($p < 0.01$), while their levels were reduced in PC9- and H1975-HuR-KO cells ($p < 0.05$). Furthermore, the loss of HuR impaired in vitro acquisition of resistance to both gefitinib and osimertinib in PC9 and H1975 cells, together with a selective decrease (>80%; $p < 0.01$) of IL-8 secretion. HuR inhibitor SRI-42127 (2.5 μ M, 24 hours) reduced only IL-8 release from both PC9GR and H1975OR, whereas the inhibitor KH-3 significantly reduced, in a dose-dependent manner, the levels of both IL-6 and IL-8 in H1975OR cells. In addition, flow cytometric analysis showed PD-L1 upregulation and class I HLA antigens downregulation in H1975OR compared to H1975 cells. Intriguingly, pharmacological HuR inhibition induced a 2 fold increase of class I HLA antigens in both cell lines suggesting an improvement in antigen presentation.

Conclusion

Our results indicate that HuR contributes to EGFR-TKIs resistance acquisition and modulates IL-8 and class I HLA expression, which are determinants of poor response to ICIs. These studies support the evaluation of HuR inhibitors to restore the EGFR-TKI responsiveness to immunotherapy.

EACR25-2286**Divergent Metabolic States of Circulating vs. Tumor-Infiltrating Lymphocytes in Cancer***P. Ritter^{1,2,3}, S. Oliveto^{1,3}, S. Biffo^{1,3}*¹*National Institute of Molecular Genetics, fondazione "Romeo ed Enrica Invernizzi", Milano, Italy*²*Politecnico di Milano, Department of Chemistry, Materials and Chemical Engineering "Giulio Natta", Milano, Italy*³*University of Milan, Department of Biosciences, Milano, Italy***Introduction**

Understanding the metabolic differences between tumor-infiltrating lymphocytes (TILs) and peripheral blood lymphocytes (PBLs) is crucial for characterizing immune cell functionality in the tumor microenvironment. TILs often exhibit distinct metabolic profiles compared to their circulating counterparts due to the hypoxic and nutrient-deprived conditions within the tumor. To investigate these metabolic adaptations, we employed a microfluidic droplet-based single-cell analysis platform, enabling real-time assessment of metabolic activity at a single-cell resolution. This approach allows for direct comparison of lymphocyte populations in physiologically relevant conditions, providing insights into how the tumor microenvironment influences immune cell metabolism.

Material and method

Single-cell metabolic activity was analyzed using a microfluidic droplet-based system (Lighthouse Biotech, Italy). Lymphocytes were resuspended in a working mix containing a pH sensitive fluorescent dye and encapsulated into 20–30 pL droplets within a microfluidic chip. After incubation, the droplets passed through a fluorescence-based detection zone, where metabolic activity was assessed in real time based on extracellular acidification dynamics. Fluorescence signals were recorded at the single-cell level, allowing for quantitative comparisons across lymphocyte populations. Statistical analysis confirmed a significant difference in extracellular acidification between TILs and PBLs, supporting the metabolic divergence induced by the tumor microenvironment. Based on these measurements, metabolically active cells were identified and sorted into distinct subpopulations, enabling further downstream analyses of their functional and phenotypic characteristics.

Result and discussion

Single-cell metabolic profiling revealed higher extracellular acidification in TILs compared to circulating PBLs, suggesting a metabolic shift associated with the tumor microenvironment. Statistical analysis confirmed that TILs exhibited a significantly greater acidification rate, likely reflecting adaptation to hypoxic and nutrient-deprived conditions. Additionally, the assay detected metabolic heterogeneity within both populations, indicating the presence of distinct subpopulations with varying acidification rates. Sorting these cells based on metabolic activity enables further functional studies, providing valuable insights into immune adaptation in cancer and the potential for therapeutic targeting of metabolically reprogrammed lymphocytes.

Conclusion

Our findings highlight a metabolic shift in TILs, emphasizing the role of metabolic adaptation in tumor immunity. By enabling quantitative assessment of metabolic activity at a single cell level, this approach provides a valuable tool to identify immune subpopulations with therapeutic potential, offering insights for refining immune-based cancer therapies.

EACR25-2294**Enhancing immunotherapy in KRAS G12C-driven lung cancer through B cell responses and Tertiary Lymphoid Structure formation.***A. Alonso de la Vega¹, J. Boumelha¹, K. Ng¹, P. Anastasiou¹, C. Moore², M. Molina Arcas¹, G. Kassiotis¹, J. Downward¹*¹*Francis Crick Institute, London, United Kingdom*²*Francis Crick Institute, United Kingdom***Introduction**

Lung cancer remains the leading cause of cancer-related mortality worldwide, with mutations in the KRAS oncogene accounting for 20–30% of lung adenocarcinoma (LUAD) cases. The development of targeted therapies and the use of immune checkpoint blockade (ICB) inhibitors has dramatically improved the clinical benefit and outcome of KRAS mutant lung cancer patients. Unfortunately, most patients do not respond to immunotherapy highlighting the importance of identifying predictive markers for patient response. Recent studies have identified tertiary lymphoid structures (TLS) to be good prognostic markers for ICB response. However, cause-and-effect relationships of the associations between TLS, KRAS inhibitors and immunotherapy have not yet been established.

Material and method

To investigate the mechanistic basis behind these associations, we have established a novel immunogenic mouse model for KRAS-driven lung adenocarcinoma that expresses antigens derived from endogenous retroviruses (ERV) and stimulates TLS formation *in vivo*. Using multiplexed imaging and genetically engineered models, we evaluate the contribution of TLS, B cells and anti-tumour antibodies to immune protection and how this is enhanced by KRAS-G12C inhibitor (G12Ci) treatment in KRAS-mutant lung cancer.

Result and discussion

We found that these tumours elicit a potent humoral response through the formation of germinal center structures and the generation of specific anti-ERV envelope protein antibodies. This antibody-mediated response is pivotal in establishing immunological memory, ensuring sustained protection against tumour relapse. Notably, Cas9-mediated deletion of specific proviruses confirmed that TLS formation and B cell responses are triggered by ERV expression. Furthermore, forced expression of ERV in an immune-cold model was sufficient to generate specific antibodies against ERV tumour antigens. Additionally, we explored the therapeutic potential of KRAS inhibition, which has been shown to elicit potent antitumor immune responses and synergize with anti-PD-1 therapy. We demonstrated that G12Ci treatment promotes anti-tumour B cell responses.

and the formation of mature and functional TLS structures.

Conclusion

Overall, our findings shed light on the potential of ERVs and G12Ci in enhancing the efficacy of immunotherapeutic approaches for KRAS mutant lung cancer. Exploring effective methods to induce ERV-derived antigens and understanding the mechanisms by which G12Ci influences B cell responses and TLS formation holds promise for predicting and improving patient response.

Study on sex-based myeloid cell differences in a clinically relevant glioblastoma mouse model

A. Sironi¹, C. Saulle¹, M. Bizzotto¹, M. Tamborini¹, M. Pizzocri¹, D. Supino¹, C. Garlanda¹, L. Politi¹, E. Stanzani², M. Matteoli¹

¹IRCCS Humanitas Research Hospital, Rozzano, Italy

²National Research Council (CNR) - Neuroscience Institute, Monza, Italy

Introduction

Glioblastoma (GBM) is the most common malignant primary tumor of the central nervous system with an extremely poor prognosis. Sex differences in GBM incidence, outcome and clinical data are well recognized, however the biological mechanisms which drive these discrepancies are not fully understood. The impact of gender on GBM immunosuppressive tumor microenvironment, is still among the unmet clinical needs.

Material and method

To investigate sex differences in GBM progression and its implication on the innate and adaptive immune landscape we exploited the preclinical GBM model obtained injecting orthotopically the syngeneic SB28 glioma cells in the striatum of C57BL/6J mice. Male/Female differences in terms of engraftment rate and tumor growth were analyzed in-vivo by bioluminescence intensity analysis at different time-point. By immunofluorescence analysis we were able to define this model in terms of tumor infiltrative capacity and progressive myeloid cell recruitment. High-dimensional flow cytometry detection of 18 parameters allow to better investigate innate/adaptive immune compartments.

Result and discussion

We observed that in a timeframe of 14-days SB28 murine model recapitulates the infiltrative features, the modest immune visibility, the proportion of immune cell populations and the spatially progressive myeloid recruitment of human GBM. We then stratified mice according to sex, and we were able to identify differences in tumor growth in the early phase of tumor progression which were maintained throughout the duration of tumor growth assessment (Two-way ANOVA Bonferroni's multiple comparison test, *p < 0.05). Preliminary data at early time-point showed higher infiltration of myeloid population in the tumor core and border of male mice, while lymphoid populations showed higher frequencies in females.

Conclusion

Investigating the sex-specific phenotype of myeloid and lymphoid cells longitudinally across the tumor growth'

timeline and their interaction with glioma cells in this clinically relevant GBM model will permit to better understand the sex-based differences in human GBM, paving the way for sex-personalized approaches that may lead to improve therapeutic efficacy.

EACR25-2309

Primary human M1 and M2 macrophage to evaluate inflammatory and pro-resolving mediators and their role in tumor growth

G. Chene¹, E. Wanecq¹, M. Bellio¹, M. Dubourdeau¹

¹AMBIOTIS, France

Introduction

Introduction: Tumor-associated macrophages (TAMs) play a crucial role in the tumor microenvironment (TME) and are predominantly associated with an M2-like phenotype, which supports tumor growth, immune suppression, and metastasis. Macrophages exhibit remarkable plasticity and can polarize into M1 (pro-inflammatory, anti-tumor) or M2 (immunosuppressive, pro-tumor) subtypes. M1 macrophages secrete pro-inflammatory cytokines, engage in tumor cell destruction, and sustain inflammation, whereas M2 macrophages contribute to tissue repair, immune suppression, and tumor progression. Given the resemblance of TAMs to M2 macrophages, understanding their functional properties is critical for developing therapeutic strategies targeting the TME. The aim of this study was to develop a primary human macrophage model mimicking M1 and M2 characteristics and to evaluate their functional and secretory profiles, with a focus on their role in tumor progression.

Material and method

Monocytes from human donors were differentiated into M1 macrophages using GM-CSF and IFN- γ , while M2 macrophages were obtained through M-CSF, IL-10, and dexamethasone treatment. The expression of M1- and M2-specific markers was analyzed to confirm polarization. Morphological and functional characterizations were performed, including NADPH oxidase activity (superoxide anion production), phago-cytosis assays, and tumor cell growth modulation. Additionally, bioactive lipid secretion from arachidonic acid metabolism was assessed using liquid chromatography-tandem mass spectrometry (LC-MS/MS) following cell stimulation.

Result and discussion

M1 macrophages exhibited higher secretion of IL-12p70 and superoxide anion compared to M2 macrophages. M1 cells also expressed elevated levels of SLAM and HLA-DR, whereas M2 macrophages showed increased CD14 expression. Functionally, M2 macrophages demonstrated enhanced phagocytic activity against *Candida albicans* yeast, while co-culture experiments with the HCT116 tumor cell line revealed that tumor cell proliferation was greater in the presence of M2 macrophages than M1. Furthermore, M1 macrophages were found to produce higher levels of TXB2, PGE2, PGD2, and 15-HETE.

Conclusion

These findings confirm that primary human macrophages differentiated in vitro exhibit functional M1 and M2 characteristics consistent with their physiological roles. Notably, M1 macrophages display tumoricidal activity, whereas M2 macrophages support tumor growth, reinforcing their resemblance to TAMs. This model provides a valuable tool for investigating macrophage plasticity in the TME and for screening strategies aimed at reprogramming TAMs toward a pro-inflammatory, anti-tumor phenotype.

²Fondazione Istituto Italiano di Tecnologia (IIT), Center for Life Nano- and Neuro-Science, Rome, Italy

Introduction

Notch receptor family members regulate essential steps of T cell development and their aberrant activation inside this subset represents the main causative event for 'T-Cell Acute Lymphoblastic Leukemia' (T-ALL). The features of juvenile T-ALL are recapitulated in the Notch3 transgenic (N3tg) mice, in which tumoral T-cells drive the accumulation of Myeloid-Derived Suppressor Cells (MDSCs), that in a cancer context can inhibit anti-tumor immune response, thus promoting disease progression. Programmed cell death 1 (PD-1) is an inhibitory receptor that suppress T-cell activation, upon binding to its ligand, PD-L1. MDSCs contribute to tumor progression through different mechanisms, including expression of PD-L1 which suppresses PD-1+ immune cells, such as T- and NK-cells (NKs). Targeting the PD1/PD-L1 axis with immune checkpoint inhibitors (ICIs), such as anti-PD-L1 antibodies, represents a promising approach to enhance immune response against tumor, that however, is poorly studied in T-cell leukemia. Thus, our aim is to explore the role of MDSCs as possible target of immunotherapy in T-ALL.

Material and method

We administrated both a single anti-PD-L1 antibody and a combined anti-Gr-1/anti-PD-L1 antibody therapy to N3tg mice by intraperitoneal injections. At the end of the treatment, N3tg mice and relative controls, were sacrificed and appropriate spleen subsets were isolated to evaluate suppressive function of MDSCs and NK cytotoxic activity. To extend results to humans we also performed co-culture experiments between human NK-92 and Notch3-dependent T-ALL cell line, TALL-1, to assess the effects of tumor cells on PD-1 expression on NKs.

Result and discussion

We demonstrate an inverse correlation between MDSC suppressive function and NK activity during T-ALL progression, that correlates with significant accumulation of PD-L1+ MDSCs and PD-1+ NK cells. Treatment with anti-PD-L1 antibodies leads to a reduction in the absolute

number of both tumor T-cells and MDSCs, while increasing NK cytotoxic function. Further, preliminary data indicate that combined therapy with anti-Gr-1 and anti-PD-L1 antibodies, targeting MDSC differentiation and suppressive function respectively, may further enhance disease control. Additionally, in humans we observed that T-ALL cells induce PD-1 expression on NK-92 cell line, suggesting that, as in murine model, MDSCs can inhibit NK cell function through the PD-1/PD-L1 interaction.

Conclusion

Our findings suggest that targeting the PD-1/PD-L1 axis on MDSCs may modulate NK antitumor immune response, resulting in the inhibition of T-ALL progression. Further studies are required to better define therapeutic efficacy of MDSC-targeted combined therapy and to assess their influence on ICI-side effects.

³Ege University, Dermatology, Izmir, Turkey

Introduction

Skin cancer is a major public health concern, with melanoma being one of the most aggressive and deadly forms. Ultraviolet (UV) radiation is recognized as a primary environmental risk factor for melanoma, inducing DNA damage, oxidative stress, and immune suppression. In addition to UV exposure, recent studies suggest that the skin microbiota, particularly *Staphylococcus epidermidis*, may play a role in cancer progression and modulation. While some strains of *S. epidermidis* exhibit protective effects against skin neoplasia, others have been associated with cancer-related mechanisms. This study aims to investigate the effects of *S. epidermidis* infection and UV radiation on keratinocytes and melanoma cells, focusing on cellular responses and potential carcinogenic interactions.

Material and method

In this research, human keratinocyte (HaCaT) and melanoma (SK-MEL-30) cell lines were cultured under standard conditions and infected with *S. epidermidis*. Following bacterial infection, the cells were exposed to controlled doses of UV radiation to assess their response to photodamage. Then, total RNA isolation, cDNA synthesis, and qPCR were done. Depending on these methods, the determination of gene expression level of major genes which play roles in the cancer mechanism was provided. Various cellular analyses, including profiling, migration assays, and cell cycle analysis, were conducted to evaluate the impact of *S. epidermidis* and UV exposure on cancer-related pathways.

Result and discussion

The results of this study provide insights into the interplay between skin microbiota and environmental carcinogens, contributing to a better understanding of microbial involvement in melanoma pathophysiology.

Conclusion

Findings from this research may have implications for the development of novel therapeutic strategies targeting microbial interactions in skin cancer prevention and treatment.

Exploring the potential of common spliceosome mutations as biomarkers for directing immune checkpoint blockade therapies in myeloid malignancies

R. Briggs¹, H. McMillan¹, L. Roets², K. Savage¹, K. Lappin¹

¹*Queen's University Belfast, Patrick G Johnston Centre for Cancer Research, Belfast, United Kingdom*

²*Queen's University Belfast, Patrick G Johnston Centre for Cancer Research, Belfast, United States*

Introduction

DNA damage repair deficiencies (DDRD) can elicit an innate immune response via activation of the cytosolic dsDNA-sensing cGAS-STING pathway. However, activation of this pathway can induce the up regulation of immunosuppressive checkpoint proteins, promoting an inflamed but immunosuppressed state. This provides a rationale for the use of immune checkpoint inhibitors (ICIs) for DDRD-positive tumours. Interestingly, mutations in the spliceosome, a premature-mRNA splicing complex, are commonly found in myeloid malignancies. Previously, we described how mutations in a key spliceosome component, SF3B1, conferred a DDRD. Therefore, this study aims to explore how common spliceosome mutations in SRSF2 and SF3B1 can be exploited to guide the use of ICIs in myeloid malignancies.

Material and method

Using CRISPR/Cas9-generated isogenic models harbouring the SRSF2P95H and SF3B1K700E mutations, DNA damage repair kinetics, micronuclei induction and cytosolic dsDNA/dsRNA accumulation were assessed using immunofluorescent labelling. qRT-PCR and ELISA analysis were used to assess expression and secretion of inflammatory cytokines, respectively, following treatment with daunorubicin, a topoisomerase II inhibitor. The immune competent embryonic chick chorioallantoic membrane (CAM) model was used for in vivo validation of the benefit of ICIs in spliceosome-mutant models.

Result and discussion

Similar to previous findings in our SF3B1K700E model, the SRSF2P95H mutation conferred a reduced ability to repair DNA damage, indicating a potential DDRD. DNA damaging agents have been shown to boost cGAS-STING activation, particularly in DDRD tumours. DNA damage induction by daunorubicin induced significant increases in micronuclei and cytosolic dsDNA in SRSF2P95H and SF3B1K700E models compared to WT controls. Significant increases in expression and secretion of inflammatory cytokines, CCL5 and CXCL10, were observed in both our SRSF2 and SF3B1-mutant models, compared to WT counterparts post-daunorubicin. Interestingly, no significant reductions in CCL5 transcription or secretion were observed following

STING-depletion in the SRSF2P95H model but were significantly reduced following depletion of MAVS, an adaptor protein involved in cytosolic dsRNA sensing. Indeed, cytosolic dsRNA accumulation was significantly increased in SRSF2P95H cells post-daunorubicin.

Furthermore, ICI with nivolumab resulted in SF3B1K700E tumour control, but interestingly induced more aggressive SRSF2P95H tumours in the immune competent CAM model.

Conclusion

To date, our data suggests that the SRSF2P95H and SF3B1K700E mutations confer an increased capacity to induce an innate immune response compared to their WT counterparts. However, this response may be reliant on the dsRNA-sensing MAVS pathway rather than the STING-dependent pathway. Together, this data is paving the way for use of SRSF2 and SF3B1 mutational status as a biomarker for the use of ICIs.

Introduction

Dendritic cells (DCs) play a pivotal role in antitumor immune responses by acting as key antigen-presenting cells that initiate T-cell activation and immune surveillance. DC vaccines are being investigated in cancer immunotherapy due to their ability to stimulate antigen-specific T-cell responses. However, tumor cells can evade immune surveillance by modulating tumor microenvironment, which impairs effectiveness of DC-based therapies. In breast cancer, DC function is compromised, and monocyte-derived DCs (MoDCs) from patients also exhibit tolerogenic phenotype. Tumor extracellular vesicles (TEVs) have emerged as key mediators of intercellular communication, but their role in modulating MoDC function remains incompletely understood. This study aimed to evaluate the impact of TEVs isolated from MCF-7 (luminal A) and MDA-MB-231 (MDA) (triple-negative) breast cancer cell lines on MoDC differentiation in vitro. MDA cells are highly invasive and serve as a model for metastasis and therapy resistance.

Material and method

TEVs were isolated using the ExoQuick-TC kit and characterized by Western blotting, Nanosight, and Transmission Electron Microscopy. MoDCs derived from

healthy donors were cultured with IL-4, GM-CSF, and LPS, with or without TEVs (30 µg/mL). MoDCs cultured without or with HEK-293 EVs were used as controls. Phenotypic markers (CD11c, HLA-DR, CD80, CD86, and PD-L1) were analyzed by flow cytometry. miRNAs expressed in MDA EVs were quantified by qPCR.

Result and discussion

The results showed that TEVs from both cell lines differentially modulated the phenotype of mature dendritic cells. MDA EVs significantly reduced HLA-DR, CD11c, CD80, and CD86 expression, while increasing PD-L1 levels, suggesting a shift toward an immunosuppressive phenotype. MCF-7 EVs only decreased CD80 expression. Both types of TEVs upregulated PD-L1, indicating potential immune evasion. MoDCs treated with MDA EVs exhibited impaired ability to induce CD4+ and CD8+ T cell proliferation but induced the differentiation of Treg lymphocytes in mixed lymphocyte reaction. qPCR analysis revealed an up-regulation of let-7i, miR-10a, miR-10b, miR-126, miR-155, miR-21, miR-29b, and miR-34a. Bioinformatics analysis, using miRTarBase, the GSE22886 dataset in GEO2R, Python and GSEAPY package, identified pathways associated with interferon signaling, interleukin-6 and co-stimulatory molecule expression as potential targets of upregulated miRNAs.

Conclusion

This study underscores the role of TEVs in modulating MoDC phenotype and function, suggesting that these nanovesicles contribute to establishment of an immunosuppressive tumor microenvironment and evasion. The miRNAs identified in these vesicles may represent a potential mechanism through which they induce a tolerogenic DC profile. The ability of TEVs to modulate DC function highlights their potential as critical regulators of immune responses in cancer and opens new therapeutic avenues

The role of TRAIL/TRAIL-receptor bidirectional signaling for NK-cell cytotoxicity against neuroblastoma cells

E. Islamagic¹, C. Badami¹, N. Leijon¹, T. Gustafsson¹, L. Kristenson¹, F. Bergh Thorén¹

¹*University of Gothenburg, Sahlgrenska Center for Cancer Research, Gothenburg, Sweden*

Introduction

Neuroblastoma (NB) is the most common pediatric extracranial solid malignancy, described as a cold tumor due to low MHC class I expression and therefore an ideal target for natural killer (NK) cell-based therapies. NK cells kill cancer cells using two different mechanisms, by release of cytotoxic granules and by ligating death receptors using ligands, such as Fas and TRAIL. Recent reports suggest that TRAIL ligation may result in bi-directional signaling. Here we investigated the role of TRAIL/TRAIL-receptor interplay and reverse signaling for NK cell responses towards neuroblastoma cells with the long-term goal of developing novel NK-based immunotherapeutic strategies in neuroblastoma.

Material and method

We performed degranulation and cytotoxicity assays using neuroblastoma cells (SK-N-AS or KELLY)

incubated with NK cells isolated from the buffy coats of de-identified healthy donors and pre-activated IL-2 and IL-15 to maximize TRAIL expression. To pinpoint the involvement of TRAIL-Rs in the NK degranulation process, we either disabled the binding to TRAIL with TRAIL-R1/R2-blocking antibodies or knocked down the receptors. To estimate the significance of death receptors for the degranulation process, we independently blocked signaling from NK cell receptors, such as NKG2D, NKp46, or DNAM-1, and compared the results.

Result and discussion

We found that neuroblastoma cell lines SK-N-AS and KELLY express TRAIL-R2 and that they trigger substantial NK cell degranulation and cytotoxicity. TRAIL-R1/R2 blockade reduced NK cell degranulation more than blockade of the major activating receptors NKG2D and DNAM-1, and to a similar extent as NKp46 blockade. Additionally, combined blockade of TRAIL-Rs and activating receptors, almost completely rescued neuroblastoma cells from NK cell killing. Furthermore, the knock-down of TRAIL-R1/R2 molecules reduced neuroblastoma cell death killing and significantly reduced the NK cell degranulation towards neuroblastoma cells. All data point towards a notable role of the TRAIL-TRAIL-R1/R2 complex in NK-cell activation.

Conclusion

Our findings suggest bidirectional TRAIL signaling upon NK cell interaction with neuroblastoma cells. Blockade/knock-down of TRAIL-R1/R2 did not only reduce NK cell killing of SK-N-AS and KELLY but also strongly reduced granule-mediated cytotoxicity of NK cells, highlighting the importance of TRAIL in NK cell signaling.

Combination therapy with EPHA3 monoclonal antibody and anti-CD47 antibody reprograms tumor-associated macrophages to inhibit recurrent head and neck cancer

M. Kim¹, S. Kim¹, J. Kim¹, M. Han¹

¹*University of Ulsan College of Medicine, ULSAN, Korea (Republic of)*

Introduction

This study investigates the combination efficacy of EPHA3 monoclonal antibody and anti-CD47 antibody treatments in recurrent head and neck cancer through the reprogramming of TAMs (tumor-associated macrophages).

Material and method

We utilized various cancer cell lines to assess the expression of EPHA3, CD47, and markers for M1 and M2 macrophage subtypes through western blotting, FACS, and FISH in both parent and radioresistant cell lines. The effects of EPHA3 and CD47 treatments were evaluated both in vitro and in vivo on human and mouse cell lines, with a focus on tumor growth, phagocytosis, and changes in immune cell infiltration

Result and discussion

Our results indicated that overexpression of EPHA3 and CD47 is associated with decreased phagocytosis in radioresistant cancer cells, particularly within the M2

macrophage subset. However, combined treatment with EPHA3 and CD47 antibodies significantly reduced tumor growth and enhanced phagocytosis both in vitro and in vivo. This was accompanied by an increase in M1 macrophage markers (iNOS, TNF- α , IL-6) and a decrease in M2 markers (arginase 1, CD206, IL-10, P-STAT1), as demonstrated by flow cytometry. Additionally, EPHA3 antibody treatment was found to potentiate CD47-mediated repolarization towards the M1 phenotype. In conclusion, our findings suggest that treatment with EPHA3 and anti-CD47 antibodies promotes tumor cell phagocytosis and inhibits tumor growth by shifting TAMs from a tumor-promoting (M2) state to a tumor-inhibiting (M1) state in vivo.

Conclusion

This highlights the potential therapeutic value of targeting TAM polarization in the treatment of recurrent head and neck cancer.

CD4 T cells in mediating direct anti-tumor activity and MHC class II loss in melanoma patients

F. Zhao¹, S. Stupka¹, S. Kwapik¹, A. Heinold², P. Crivello³, K. Fleischhauer³, P. Horn², D. Schadendorf¹, A. Sucker¹, A. Paschen¹

¹University Hospital Essen, Dermatology, Essen, Germany

²University Hospital Essen, Institute for Transfusion Medicine, Essen, Germany

³University Hospital Essen, Institute of Experimental Cellular Therapy, Essen, Germany

Introduction

CD4 T cells, recognizing antigens presented by MHC-II molecules, are well-defined for their role as helpers or regulators in cancer immunity. However, single cell sequencing studies found intratumoral CD4 T cells with cytolytic markers present in various cancers, suggesting also their direct anti-tumor activity, similar to cytotoxic CD8 T cells. Strikingly, a subset of melanomas shows strong constitutive expression of MHC-II molecules, despite of the general restriction to professional antigen presenting cells.

Material and method

Using autologous human tumor-T cell systems, we expanded tumor-reactive CD4 T cells from patients with advanced metastatic melanoma and analyzed their cytokine production via flow cytometry. Additionally, we performed FACS staining and targeted next-generation DNA sequencing to examine the expression of MHC-II genes in short-term cultured melanoma cell lines derived from consecutive patient samples.

Result and discussion

We demonstrate that CD4 T cells with tumor antigen specificity are present in patient blood and among tumor-infiltrating lymphocytes (TILs). These T cells directly kill autologous melanoma cells that constitutively express MHC-II molecules. Longitudinal sample analyses reveal the genetic loss of tumor antigen-presenting MHC-II molecules over the course of the disease, suggesting that melanoma immune evasion occurs due to strong selective pressure from CD4 T cells. Strikingly, MHC-II molecule

expression exhibits both intra- and inter-metastasis heterogeneity in the absence of genetic alterations, suggesting that non-genetic mechanisms may regulate MHC-II loss in tumor cells to evade CD4 T cell surveillance.

Conclusion

Overall, our study highlights the importance of tumor-reactive CD4 T cells as direct anti-tumor effectors and emphasizes the need for deeper analyses of CD4 T cells and MHC-II regulation in melanoma.
